THE VISION FOR IDAF PHASE III

INTRODUCTION

Development strategy during the 1960 and 1970s was based on the philosophy that developing countries lacked improved technology and capital for speeding up their development. Industrialization was promoted in order to capitalize on the abundant fish resources. However, the anticipated expansion of the economy did not happen and the development approach shifted towards an integrated rural strategy where emphasis is put on the community as a whole to upgrade incomes and the quality of life through technical assistance and the active participation of fisherfolk and the community.

In this context, emphasis was initially placed on the Community Fishery Centre (CFC) concept as a means of promoting artisanal fishery development. But it became apparent that the presence of a complex of facilities and services tailored to meet local needs was no guarantee that the structures/facilities would be used or that development would occur. The active participation of fisherfolk and the mobilisation of local and community resources was imperative in order to assure sustainability of initiatives undertaken by development projects and/or the community.

So far and in general terms, the IDAF Programme has worked under the context of abundant or seemingly adequate fishery resources with moderate population pressure. The scenario is however changing (and very fast for that matter) and we would soon face the triple constraints of reduced or depleting fish stocks, degrading environment and increasing population pressure. Like in other sectors, it must be anticipated that just to survive, parts of the population surplus in the fishing communities will enter the artisanal fisheries, which will increase the competition for the resources among the small scale fisherfolk in addition to the prevailing competition between the artisanal and industrial fisheries, with their attendant effect on the environment.

This scenario calls for a continuation of the integrated participatory strategy which remains relevant to the development of artisanal fisheries in West Africa. However, the emphasis needs to be placed on the elements and mechanisms that favour the sustainability of initiatives: responsible fishing, the empowerment processes that ensure the devolution of major resource management and development decisions to the local community, the strengthening of national human and institutional capacities at all levels for a sustainable and equitable fisheries resources management and development, as well as in the follow-up and consolidation of past achievements.

DEVELOPMENT OBJECTIVE

Thus the development objective of the Programme in the present phase III which started on 1 July 1994 is to ensure twenty coastal West African countries a sustainable development and management of their artisanal fisheries for maximum social and economic benefit of their fishing communities in terms of employment, proteins and earnings. This will be done through an integrated and participatory approach in which emphasis will be laid on equity, gender issues, the transfer of technology for development, environment protection, as well as the strengthening of human and institutional capacities.

1. INTRODUCTION

For several decades, attempts have been made to improve the hauling of artisanal canoes in developing countries, especially on beaches difficult to approach, where landing sites are traditionally occupied by fishing communities.

Despite the efforts, the problem of an easy landing and hauling of canoes on the heavy surfing beaches is yet to be solved, especially in small scale fisheries in which the working tool is mainly small and fragile open dugout or planked canoes.

Motorization of canoes started in West Africa about forty years ago. As a result, the length and therefore the weight of the canoes increased considerably. It is now common to see dugout canoes with 16 metres overall length, as well as planked canoes like the Senegalese type reaching 22 metres with a weight of 6 tons when empty. These big open canoes are propelled with 40 horsepower outboard motor.

Landing of canoes on these dangerous surfing beaches often results in capsizing when crossing the surf with an overloaded canoe which is not always easy to manoeuvre.

Furthermore, the swell often prevents quick hauling of the canoe. This results in significant damages to the hull because of repeated shocks due to bad grounding.

2. PREPARATION OF THE PRESENT MANUAL

Due to the curiosity and real interest shown for the hauling devices by the people trained as well as the users, the present publication was prepared to supply the potential builders who are the small welders and mechanics operating in the coastal villages of West Africa with a practical working document. Fisheries administrations, mainly extension services should also benefit from it.

In knowing that artisanal mechanics and welders concerned have limited knowledge on reading technical plans, and the sketches are not to scale, it was considered more convenient to directly mention on each drawing or sketch the maximum of quotations. The user will therefore directly observe the drawings and work immediately with the different elements used in the construction of a manual capstan or a transportable slipway.

Refer to Table 2 and 3 for the designation of the parts needed for the construction of a capstan or slipway. For example, if one needs the dimensions of Figure 10, the reference is in Table 2; giving information on the number of requested pieces, type of material used, dimensions in millimetre, unless otherwise specified, and the remarks.

3. IDAF ACTIVITIES ON HAULING DEVICES

Taking into account the difficulties in landing an artisanal canoe on these coastal areas with predominant heavy swell and the tidal waves phenomenon, IDAF, in collaboration with Departments of Fisheries of countries concerned, trained small artisanal mechanics and welders on the construction of manual capstans and transportable slipways for the quick hauling of artisanal fishing canoes.

The construction of manual capstans and transportable slipways and the training of mechanics and welders were carried out in four countries; The Gambia, Senegal, Ghana, and Benin.
In the Gambia where the first capstan was built in 1996, IDAF constructed the equipments, demonstrated and trained beneficiaries on the use of a wooden base frame capstan of the FAO/BOBP type. The reference model was conceived by G. Pajot, Senior Fishing Technologist of BOBP (Bay of Bengal Programme for Fisheries Development).

At least ten were introduced in several member countries of the Bay of Bengal Programme (BOBP/WP/71). These capstans were very much appreciated and are still in use after nearly ten years.

The steel base frame of the capstans and the slipways have been conceived and designed by the IDAF Programme in Cotonou, Benin.

In 1997, IDAF constructed a manual capstan (FAO/BOBP type) with a wooden frame in Kayar, Senegal. It also conducted demonstrations and trained the users.

It should be noted that the wood used, mahogany, which was more expensive than the steel frames, was replaced after a year because of its destruction by insects, despite of tar coating. This wooden frame was substituted by a steel frame made from angle iron 60 x 60 x 6, similar to the steel frames of the capstans built in Benin and Ghana.

In Kayar, which has one of the most important artisanal fishing fleet in Senegal, six transportable slipways were introduced in 1998.

In 1997/98, the programme built a manual capstan with steel frame and four transportable slipways at Cotonou-Port, Benin. The users were also trained through demonstrations.

The Programme also trained welders and constructed and demonstrated the use of a manual capstan at the Integrated Centre for Inland Fisheries at Yeji, Ghana.

4. CONSTRUCTION COSTS

The cost of these hauling devices varies according to the country, the year of construction and the price of the material. It should be noted that all the steel parts were purchased in scrap metal shops in order to decrease the construction costs. Indicative costs for the construction of the hauling devices are shown in table 1.

5. SPECIFICATIONS AND RECOMMENDATIONS

The weight of the capstan, with wooden frame or steel frame is almost the same, that is around 145 kg together with 100 metres of 14 mm steel wire coiled on drum.

Life span of the capstan is about ten years when maintained by greasing the drum’s pivot and all articulated parts twice a year. When constructing, the capstan should receive at least two coats of red oxide plus two coats of tar. One should repeat the tar application every year.

The drum capacity is 165 metres of manually coiled 14 mm steel cable type 6 x 7 (6/1). When coiling, a good greasing of the cable must be done.

Cleaning the cable of sand after each use is highly recommended. To get a steel cable life span of the steel cable of about four years is possible with a good maintenance and if steel cable is reversed from time to time.

If constructed according to the recommended dimensions and materials, the transportable slipway weighs 112 kg. When carried by 6 people, the distributed weight becomes 18.6 kg per person, which is lighter to transport on the beach.

The transportable slipways are also coated with two coats of red oxide after construction. To get a life span of about eight years, it is recommended to apply a coating of red oxide and a coat of tar once a year. These products are readily available in many shops along the fishing villages.

After every use of the slipways, the fishermen should clean the axles and axle holders of sand with a bucket of water.

Every month, the users should also lubricate the axles with black oil to maintain a good motion of the rollers, and prevent deterioration of the axle shape.
6. **List of tools needed for the construction of manual capstans and transportable slipways.**

A minimum of tools is required for the construction of hauling devices, whatever the device: either a capstan or a transportable slipway. They are:

1. tape measure
2. pencil
3. metallic try squares graduated up to 20 cm
4. spirit level
5. hacksaw
6. 20 hacksaw blades of good quality
7. wooden hand saw, in case of choosing a wooden frame for capstan
8. hammer (about 500 grams)
9. combination pliers (6 inches)
10. adjustable spanner (10 inches)
11. flat spanners for bolts of 12 mm
12. hand drill (better an electric drilling tool able to use drill bits of 13 mm as a minimum)
13. drill bit of 12 mm
14. electrical grinder
15. 2 cutting disks for the grinder
16. metal polishing disks for the grinder
17. arc welding machine with a minimum capacity of 30 amperes, able to use welding rods of Ø 3.2 mm
18. 2 packs of welding rods of Ø 3.2 mm (for one capstan).
(If a slipway is to be constructed, one should consider the use of 1.5 pack of welding rods of Ø 3.2 mm (for 1 slipway).
19. 4 paint brushes (2 inches wide)
20. 2 litres of thinner
21. 2 kg of grease for one capstan (greasing the hub of the drum and the fairled)
22. 1 kg of grease for two slipways (initial greasing of the rollers, shafts and inside the shafts' holders.

</table>
The idea is to decrease the effort exerted by fishermen when they return from sea. Even when exhausted, they should be able to contribute physically to the hauling of their canoe. To carry out this activity, the fishermen go through several difficulties which increase their strenuous effort. These include waves crushing the beach and quicksands that make the hauling of canoes tremendously difficult without rail planking or appropriate rollers. Sometimes the fishermen use branches or paddles as wooden railing on which to place rollers cut out from coconut or palm trees approximately 20 – 30 cm in diameter. This traditional hauling system for artisanal canoes is in use within the West African artisanal fisheries in several landing sites throughout the twenty member countries associated with IDAF (from Mauritania to Angola).

The introduction of capstans and the transportable slipways should decrease a great number of problems related to the pulling ashore of the big artisanal fishing canoes in West Africa.

Figure 16 - A COMPLETED AXLE HOLDER POSITIONED ON THE SLIPWAY'S FRAME

- Diameter 63/53
- Appr. 155 mm from the inferior part of the frame
- Weld on both sides
- Strongly weld the axle holders to the frame on all sides
- The longitudinal and transversal frames are made of I Beam 80 x 42 x 3.9
Detail of the axle fitting on a steel circular plate to be inserted at both edges of the roller.

Insert the circular steel plate in the edge of the tube on the whole thickness of the plate (=10mm) to keep the same roller's length.

Before welding, check the parallelism of the axles in relation to the outside of the tube, to get a correct motion of the rollers once fitted. (Use the device shown on figures 19 and 20).

A roller assembled, ready to be mounted on the axle holder.
Axle holder made of I Beam 250 mm long strongly welded on the whole base perimeter.

Transport handle (made of iron rod Ø 12 mm welded at 40 mm from the base of the frame).

Steel triangle plate to prevent the slipway from sinking into the sand. 300 x 300 x 340. Thickness: 4 mm.
Steel square used as an axle guide to keep the axle parallel to the outside of the tube. This square should be welded vertically and parallel to the axle's guiding tube.

IMPORTANT
The space between the outside of the roller and the sharp edge of the I Beam should be 1 mm as a maximum on the four contact points, as shown by the above arrow.

Edge of the roller on which the tool is put on.

Outside Ø 110 mm
Axle's guiding tube inside Ø 46 mm

Steel plate 5 mm thick

Figure 20 - ELEVATED VIEW OF THE POSITIONNING TOOL FOR THE SLIPWAYS ROLLER AXLES

The tool is put on the extremity of the roller to be able to maintain a correct position of the axle during welding.

Axle guiding tube Ø46 mm able to accept a Ø45 mm steel axle

1 mm maximum space between Beam and roller
