FAO has been monitoring the world’s forests at 5 to 10 year intervals since 1946. The Global Forest Resources Assessments (FRA) are now produced every five years in an attempt to provide a consistent approach to describing the world’s forests and how they are changing. The FRA is a country-driven process and the assessments are based on reports prepared by officially nominated National Correspondents. If a report is not available, the FRA Secretariat prepares a desk study using earlier reports, existing information and/or remote sensing based analysis.

This document was generated automatically using the report made available as a contribution to the FAO Global Forest Resources Assessment 2020, and submitted to FAO as an official government document. The content and the views expressed in this report are the responsibility of the entity submitting the report to FAO. FAO cannot be held responsible for any use made of the information contained in this document.

Introductory text

The Ministry of Physical Planning, Land and Forest Management (Min. of RGB) is the Ministry that is responsible for forest management in Suriname. Within this Ministry the Foundation for Forest Management and Production Control (SBB) is the institution which is responsible for sustainable forest management in the country. As a forestry institution, SBB has the responsibility to report to the Global Forest Resources Assessment (FRA) 2020. In order to complete this reporting it is necessary to consult other forestry related Ministries, Institutions and organizations that have the co-responsibility for good management of the forests in the country. It is very important to have insight in both, long- and short term national planning on macro level that can lead to deforestation and forest degradation.

With about 93% of the country still covered with natural tropical rainforest, Suriname is one of the most forested countries in the world. Suriname has a long history of sustainable forest management practices and forest protection. In this framework it can be noted that national efforts lead to adequate conservation and protection of the forest, and promotion of sustainable forest management in the country. The designation of 2.3 million ha of the country (14% of the total land area) as protected areas, and the development of the Celos Management System as a tool for the sustainable utilization of the 4 million ha forest designated for sustainable production of forest products, within the so called "Forest Belt" are evidence of the country’s effort to keep the natural forest intact. In Suriname the so called Reduced Impact Logging (RIL) system is practiced and promoted in the production forest, minimizing the damages to the forest as a result that the forest cover remains intact even after timber has been harvested by allowing a natural regeneration. Nevertheless, the increased timber production has its challenges to monitor the application of this RIL-guidelines as mentioned in the draft Code Of Practice for SFM, which might lead to unforeseen forest degradation. Developments in other sectors, than the forestry sector leads to deforestation, for instance due to mainly planned and unplanned mining, mainly gold mining, a man-made hydropower lake, agriculture, infrastructure construction etc.

Catalyzed by the National REDD+ Readiness program and the regional ACTO-project ‘Monitoring the forest cover of the Amazon region” the National Forest Monitoring System (NFMS) has been developed and further strengthened. This NFMS is composed of subcomponents: the Satellite Land Monitoring System (SLMS), the Near Real Time Monitoring System (NRTM), the National Forest Inventory (NFI), the Sustainable Forestry Information System Suriname (SFISS), a Community Based Monitoring component and a reporting component. First the Satellite Land Monitoring System (SLMS) has been developed. Within this system yearly data on deforestation, biannual data on land use/cover after deforestation and 5-yearly data on Land Use/ Land Cover is being produced using satellite images. The technology used, is based on the technology used by INPE in the PRODES program in Brazil. All data and maps produced within the SLMS are displayed on the geoportal www.gonini.org. Furthermore, a baseline study has been carried out in collaboration with the following Surinamese institutions: the SBB, the Center of Agricultural Research and Development Suriname (CELOS), the National Zoological Collection and an agricultural and forestry research institutions of Costa Rica; CATIE. Within this study a baseline of the best estimates of forest carbon stocks based on existing forest inventory plots was established. This study and the results of the SLMS are the basis for the calculation of the historical emissions caused by deforestation within the country’s first Forest Reference Emission Level (FREL) submitted to the UNFCCC in 2018. With Support of the Global Climate Change Alliance (GCCA), steps have been taken to establish a National Forest Inventory for the mangrove forest and also to do an in-depth assessment of the occurrence of mangrove forest in the country. In the coming years, the SBB will further work on the development of an efficient NFI-design. The NRTM encompasses the continuous detection of currently unplanned logging activities, where after teams of forest guards are sent to the field. This could be easily expanded, by including the detection of unplanned deforestation or unplanned activities within the protected areas. All plans related to the NFMS are recorded in the NFMS-roadmap. Active participation of all forest-related rightholders and institutions is strongly encouraged throughout this process.

Within a period of 10 years the national timber production in Suriname has increased from 200,000 m3 per annum to 860,000 m3 per annum. The current database in operation “the LogPro” is outdated because of the recent development, including the increased timber production and timber export. SBB is in a process with the technical assistance of CATIE and financial assistance of the IDB/GEF, the national REDD+ programme and the government of Suriname, to develop a new forest product registration database, the Sustainable Forestry Information System Suriname “the SFISS”. The SFISS will be an important tool to further improve the logtracking system, in the process of strengthening sustainable forest management in the country. To further strengthen the forest monitoring and service to the private sector, a reorganization process has been started to adjust the current organization structure of the SBB. This will result in an organization adequate to perform, based on the current national and international development within the forest sector. Also, on a regular basis capacity building on all levels, as well technical as administrative, including the crew of forest guards, takes place within the SBB. To guarantee the physical presence of the forest guards in the field, the necessary infrastructure including forest guard stations are in place on strategic locations in the forest. One of the objectives of the national forest policy is to increase the contribution of the timber sector to the national economy. In this context, efforts have been made and the national timber production and earnings from the timber export has been doubled compared with two years ago.

In the framework of institutional strengthening within the forest sector, recently an important process has been started. The Minister of RGB has installed a commission to startup and proceed with the process that was stopped due to several reasons, towards a forest management authority, the "BOSNAS". It can be noted that the SBB was established as a vehicle towards the establishment of a full fledged forest management authority “BOSNAS”. The commission is currently reviewing and updating the documents that were formulated in the previous process in this regard. When this process is finalized, a forest management authority will be in place, based on regulations ensuring that the operational cost of the
authority can be financed with earnings from the forest sector. Furthermore there will be no scattered forest and nature management in the country, all forest and nature institutions responsible for protection and management of the forest, including The Forest Service (LBB), The Nature Conservation Division of LBB, STINASU and SBB will be merged into this new authority “BOSNAS”.

### National classification and definitions

<table>
<thead>
<tr>
<th>National class</th>
<th>Definition</th>
<th>Source</th>
</tr>
</thead>
</table>
| Forest | Land covered primarily by trees, but also often containing shrubs, palms, bamboo, herbs, grass and climbers, with a minimum tree crown cover of 30% (or equivalent stocking level), with the potential to reach a minimum canopy height at maturity in situ of 5 meters, and a minimum area of 1.0 ha. The forest definition in Suriname excludes:  
1. Tree cover from trees, including palm trees, planted for agricultural purposes (such as coconut, citrus, oil palm etc);  
2. Tree cover in areas that are predominantly under urban or agricultural use.  
It should be noted that shifting cultivation (slash and burn agriculture) is included as forest, as long as it is done in a traditional way so that the forest gets the chance to regenerate after harvest. | Technical report: Forest cover monitoring in Suriname using remote sensing techniques. (SBB, 2017) |
| Shifting cultivation | Shifting cultivation is the traditional use of the forest by indigenous and tribal peoples (ITPs). It is composed of a mosaic of small deforested pieces of land combined with fallow land at different stages of regeneration of the forest. On the Landsat images it is recognizable as a combination of small deforested patches embedded in an area of secondary forest (light green on the image). Shifting cultivation is mainly found the surrounding of the villages of indigenous and tribal communities, in the vicinity of rivers and/or roads. The forest dependent communities clearly indicate that shifting cultivation is a traditional and sustainable use of the forest (Gomes-Poma, A. & Kaus A.., (1992).) Shifting cultivation (included in the definition of forest): The patches that are deforested are mostly smaller than the minimum area of forest and the Minimum Mapping Unit (1 hectare) of the deforestation maps. There is a remaining tree cover and the area will recover after it is left to regenerate. The conversion from natural forest to shifting cultivation is seen as forest degradation. | Forest reference emission level for Suriname’s REDD+ programme. (SBB, 2018) |
| Non-forest | Land areas not covered with forest in the reference year 2000 | |
| Deforestation | Deforestation is defined as the direct and/or induced conversion of forest cover to another type of land cover after the year 2000 in a given timeframe (DeFries et al., 2006; GOFC-GOLD, 2009). | Technical report: Forest cover monitoring in Suriname using remote sensing techniques. (SBB, 2017) |
In the context of this FREL submission, deforestation is defined as "the direct and/or induced conversion of forest cover to another type of land cover in a given timeframe".

Explanatory notes:
This excludes areas that are in a status of a temporarily loss of the forest cover, such as:
- Shifting cultivation (included in the definition of forest): The patches that are deforested are mostly smaller than the minimum area of forest and the Minimum Mapping Unit of our deforestation maps. There is a remaining tree cover and the area will recover after it is left to regenerate. The conversion from natural forest to shifting cultivation is seen as forest degradation.
- Natural deforestation where the forest cover will recover naturally such as small areas where wind break or unplanned fires took place.

Source: Forest reference emission level for Suriname’s REDD+ programme. (SBB, 2018)

Original data
Within the framework of the ACTO project "Monitoring Deforestation, Land Use Change and Logging in the PanAmazon Forest", the Forest Cover Monitoring Unit (FCMU) was established within the Foundation for Forest Management and Production Control (SBB). One of the activities within the FCMU is creating deforestation maps of Suriname, as a part of teh Satellite Land Monitoring System (SLMS)-subsystem of the NFMS. Up to now the following maps has been produced: Basemap 2000 and Deforestation maps for the periods: 2000-2009, 2009-2013, 2013-2014, 2014-2015, 2015-2016. Recently the deforestation map for 2016-2017 was finalized. The method used for the production of these map is about the same as the one in Brazil, using Landsat images and TerraAmazon, a freeware distributed by the Brazilian Institute for Space Research (INPE). Furthermore, Quality Assessment/ Quality Control (QA/QC) were performed on the Deforestation map 2000-2015 and Deforestation map 2015-2016 based on the methodology developed by Olofsson (2014). The results of these assessment are shown in the table below.

Table. QA/QC results for the Deforestation map 2000-2015 and Deforestation map 2015-2016.

Analysis and processing of national data

Estimation and forecasting

Change of Forest area

Taking into consideration long term national planning, forested areas will be converted to other types of land use, with the possibility of forest loss and the decline of the forest cover as a result.

Main projects and project ideas that are expected, leading to forest loss in the longer term are:
Infrastructure: National Infrastructure Plan indicate that the existing road network will be expanded, with further integration and expansion of the east-west connection road and the north-south connection road. Also is planned, the construction of a railway from the Bakhuis area to Apura and from Apura further to Paranam, to facilitate the transportation of bauxite, gas, aluminum and timber. The estimated length of this railway is 300 km. The implementation of this project will most probably lead to forest loss.

Mining: According to the Multi-annual Development Plan, the government of Suriname has the intention to initiate more large scale mining projects in collaboration with multi-national companies. Two large scale gold mining projects are planned, one in the central part and another one in the eastern part of Suriname. A bauxite mining project together with a hydropower project is planned in the western part of the country. These projects will lead to deforestation. A lot of illegal gold mining is taking place within the forest that leads to small patches of forest loss.

Palm oil: In 2004 the government of Suriname signed an agreement with a Chinese investor to develop a palm oil project in the eastern part of the country with an area of 50,000 ha. Due to social reasons it was not possible to execute this project. At this moment some activities of this project is being implemented. The investor has logging agreement with members of the local community in parts of this project area. Furthermore it can be noted that an area of 32 ha is deforested for the setup of a nursery. There is no indication when deforestation will take place according to the presented business plan to plant the palm trees.

Non traditional agriculture: The National Agricultural Plan indicates that, a cacao plantation will be developed on a area of 3,000 ha. On an area of 2,000 ha grass will be cultivate for the generation of bio-energy and a coconut plantation will be developend on an area of 5,000 ha. Furthermore a project will be initiated for the cultivation of bamboo. For these projects a part of natural forest will be converted in to agriculture land.

1995

2000

2005

2010

2015

2020
The Forest areas of 1990, 2000, 2010 and 2015 does not match figures mentioned in FRA 2015. This because the maps have been updated recently. Based on previous analyses, Deforestation maps consist of the class Cloud (inclusive cloud shadow), which mean no data. This class has been filled in with other images before and after the period when deforestation were identified and classified. Also a conversion matrix was used in order to reclassify the Cloud polygon to another class. Thus, if a specific area, classified as cloud in year 2014, and is Forest in 2013 and 2015, then this Cloud polygon in 2014 was reclassified as forest. Based on these updates the forest areas reported in FRA 2020 could differ with the ones reported in FRA 2015.

Within the Forest Cover Monitoring Unit (FCMU), an Area of Interest (AOI) with a total surface of 16,367 x 1000 ha is used for forest cover monitoring in Suriname. While the country area presented by the FAO is 16,382 x1000 ha and the Land area presented on the platform is 15,600 x 1000 ha.

Based on the figures from FCMU and FAO stats the calculations for Table 1a were executed as followed:

1. A calibration factor was calculated based on the total country area used by FAO and the total AOI of FCMU. The areas of the National Classes were then multiplied with this factor in order to calibrate the areas of these mentioned classes with the FAO stats. (Equation: Calibration factor= Total country area of FAO / Total country area of FCMU)

2. The Land area was then calculated based on the calibrated National classes for the year 2015. Therefore the National classes: Forest+ Shifting cultivation + Non forest + Deforestation, were added up (16,059 x 1000 ha).

3. Forest areas for the following years 1990, 2000, 2010, 2015, 2020 were then calculated, by extracting the calibrated Non forest and Deforestation (Other Land), from the Land area (16,059 x 1000 ha). These figures of forest areas were then filled in Table 1a.

4. In table 1a from the platform, where already the FAO land area (15,600 x 1000ha) is pre-filled, the area of Other land is calculated by extracting the Forest area (of step 3) from the pre-filled land area of the platform (15,600 x 1000 ha).

It can be mentioned that the results of the Other land do not represent the exact figures of this category in Suriname (Non forest and Deforestation) (see Table in Original data). For future reporting (FRA 2025), the intention is to adjust the total land areas presented by the FAO stats.

### Original data

Besides the Deforestation maps, Post-deforestation Land Use Land Cover (LULC) maps are produced in close collaboration with different stakeholders such as Govermental institutions, University and National Planning office of Suriname. Three Post-Deforestation LULC maps were produced for the following periods: 2000-2009, 2000-2013, and 2000-2015. The Post-Deforestation LULC 2000-2017 is already finalized but still need to be validated in the field.

Recently, a National LULC map for 2015 was produced within the Cross Cutting Capacity Development (CCCD) project with the same platform of stakeholders from the Post-Deforestation LULC maps and support of an international consultant. See tables below.

Around 13,000 ha of forest plantations have been established in the period 1954-1977, with both pine (pinus caribaea) and broadleaf species (of which 7,000 ha pinus caribaea plantations). Source: Forest Service (LBB) plantation map.

The mining areas (gold and bauxite) are being rehabilitated by tree planting. About 1,150 ha of the mining areas has been rehabilitated. (Source: Country experts) An area of 1.5 ha of mangrove forest is planted in the coastal zone of the district of Coronie. This was done in the period 2010 and 2013.

Furthermore expansion of mangrove planted forest in the area of Weg naar Zee is being implemented, where an area of 1 ha is already finalized. Source: Professor Naipal of the Anton de Kom University of Suriname, 2018.

### Analysis and processing of national data

#### Estimation and forecasting

**Change of Forest area**

Taking into consideration long term national planning, forested areas will be converted to other types of land use, resulting in the decline of the forest cover.
Main projects and project ideas that are expected to lead to forest loss in the longer term are:

**Infrastructure:** National Infrastructure Plan indicate that the existing road network will be expand, with further integration and expantion of the east-west connection road and the north-south connection road. Also is planned, the construction of a railway from the Bakhuis area to Apura and from Apura further to Paranam, to facilitate the transport of bauxiet, gas, aluminum and timber. The estimated length of this railway is 300 km. The implementation of this project will lead to forest loss.

**Mining:** According to the Multi-annual Developent Plan the government of Suriname has the intention to initiate more large scale mining in collaboration with multi-national companies. Two large scale gold mining projects are planned, one in the central part of Suriname and another one in the eastern part of the country. A bauxite mining project together with a hydropower project is planned in the western part of the country. These projects will lead to deforestation. A lot of illegal gold mining is taking place within the forest that leads to small patches of forest loss.

**Palm oil:** In 2004 the government of Suriname signed an agreement with a Chinese investor to develop a palm oil project in the eastern part of the country with an area of 50000 ha. Due to social reasons it was not possible to execute this project. At this moment some activities of this project is being implemented. The investor has logging agreement with members of the local community in parts of this project area. Furthermore it can be noted that an area of 32 ha is deforested for the setup of a nursery. There is no indication when deforestation will take place according to the presented business plan, to plant the palm trees.

**Non traditional agriculture:** The National Agricultural Plan indicates that, a cacao plantation will be developed on a area of 3000 ha. On a area of 2000 ha grass will be cultivate for the generation of bio-energy and a coconut plantation will be developend on an area of 5000 ha. Furthermore a project will be initiated for the cultivation of bamboo. For these projects a part of natural forest will be converted in to agriculture land.

### Reclassification into FRA 2020 categories

The reclassification of the National classes to the FRA categories are shown in the table below.

</table>
**Comments**

The Naturally regenerated area is calculated by extracting, Planted forest from total forest area. This Naturally regenerated forest consists of regenerated abandoned agriculture plantation, shifting cultivation, logged over areas and undisturbed forest. (Equation: Naturally regenerated forest= Total forest area- Planted forest)

Original data

Within the framework of the Global Climate Change Alliance (GCCA+), a Mangrove project will be executed. Within this project a mangrove biodiversity monitoring system will be setup, resulting in a baseline mangrove map along with the execution of a National Forest Inventory (NFI) for the mangrove stratum of Suriname. At this moment the process of classification is being executed. An idication of the surface of the Mangrove area can already be estimated based on the first results. The first estimation shows that the mangrove area in Suriname has a surface of approximately 60,000 ha.

An old agriculture plantation map was overlaid with the forest cover data of 2000. The forest cover within this area can be seen as naturally regenerated forest, as these agriculture plantations were abandoned about 100 years ago. The forest had enough time to regenerate, but still signs of human activity is visible.

Original data

Monitoring of the forest changes in Suriname is done within the Forest Cover Monitoring Unit (FCMU) using Remote sensing techniques, Satellite imageries and free softwares such as Terra Amazon (software developed by the National Institute for Space Research (INPE) from Brazil) and QGIS. Untill now deforestation figures are available for the following periods: 2000-2009, 2009-2013, 2013-2014, 2014-2015, 2015-2016. Recently the deforestation figures for 2016-2017 are in a process to be finalized. The deforestation figures are shown in the tables below. The intention is to produce yearly deforestation maps in order to identify the trend of deforestation and make available on the National geoportal “Gonini” (www.gonini.org) for the general public and especially for the policymakers.

Besides National policy formulation, the deforestation figures are very important in the context of the REDD+ project which is in the preparation phase at this moment. These deforestation figures have been used as activity data in the development of the FREL for Suriname, and will also be used for the emission reduction reporting.

It can be noted that the National class “Deforestation 2000-2009” actually indicates deforested area from the year 2001 until the end of 2009. For the other classes it represent the period as mentioned in it. Furthermore, it can be mentioned that from the year 2014 yearly deforestation maps are produced.

After the production of every deforestation map, a Quality Control/ Quality Assessment (QA/QC) is executed using a stratified sampling method developed by UN REDD. From this assessment Stratified estimated areas and Confidence interval for each class are obtained. See Table below. For the reporting of FRA 2020 the Stratified estimated areas are used.
Beside the Deforestation monitoring, Post-deforestation Land Use Land Cover (LULC) monitoring is done within FCMU in close collaboration with National stakeholders. The first Post-deforestation LULC map covers the period 2000-2009. After this, Post-deforestation LULC maps were produced every two years (2000-2013, 2000-2015, and 2000-2017).

Analysis and processing of national data

Estimation and forecasting

At this moment Suriname is in the preparation phase of the REDD+ project. In this framework the following four components need to be in place:

1. National strategy (NS);
2. Safeguard Information System (SIS);
3. Forest Reference Emission Level (FREL);

It is worth mentioning that for the NS and FREL already Scenario modeling has been executed in order to support the development of documents regarding these components.

The Scenario modeling was done for the period 2016-2035 based on the historical deforestation figures of the Deforestation maps from 2000-2015. Three scenarios were executed among which:

1. Business as Usual (same deforestation rate as the rate of 2015);
2. Development scenario (highest historical deforestation rate was used and all projects mentioned in the Development Plan (OP) 2017-2021 were taken into consideration);
3. REDD+ scenario (mean historical deforestation rate was used and also the projects mentioned in OP 2017-2021 were taken into consideration but with some restriction. For example: No deforestation is assumed to occur in the protected areas (existing & proposed) and in the mangrove forest.

In table below the results of the different scenarios are shown.

Table. Scenario modeling results for the different periods

<table>
<thead>
<tr>
<th>Scenario (Area ha/year)</th>
<th>2015-2020</th>
<th>2020-2025</th>
<th>2025-2030</th>
<th>2030-2035</th>
</tr>
</thead>
<tbody>

Analysis and processing of national data

Estimation and forecasting

It can be noted that abandoned agriculture areas in the coastal zone are not being utilized for more than 10 years. There is no indication of the further development of these areas. A great part of these areas has vegetation that meets the criteria of the forest definition.

Comments

**Category** | **Comments related to data definitions etc.** | **Comments on reported trends**
---|---|---
Palms | | In parts of the district of Coronie coconut palms are the dominated vegetation. Unfortunately the exact data of the surface is not available.
Abandoned areas | Description: Land that was still used in 2000 for human activities, but which have been abandoned and is already in an advanced state of regeneration in 2015, covered primarily by trees, with a minimum tree crown cover of 30% (or equivalent stocking level), with the potential to reach a minimum canopy height at maturity in situ of 5 meters, and a minimum area of 1.0 ha. These areas may also have some rectangle structures, indicating the presence of previous agriculture plantations and can possibly be located near swampy areas. | No National definition is yet in place. This is a discription of the class defined in collaboration with national stakeholders during the CCCD project where a National Land Use Land Cover map for 2015 was produced.
2 Forest growing stock, biomass and carbon

Original data

The Growing stock calculation was based on data from the Technical report State-of-the-art study: Best estimates for emission factors and carbon stocks for Suriname (SBB, 2017). This study was carried out harmonizing data from 11 forest inventories executed in Suriname. And it was also an update of an earlier study done by Arets et al. (2011), completed with the data collected in 12 field transects established during the Forest Carbon Assessment and Monitoring project (SBB, 2012) and the data collected in 31 sampling units (SU) throughout the pilot NFI project in 2013-2014. For more information regarding harmonization of the databases, it is refer to the Forest Reference Emission Level for Suriname’s REDD+ Programme document (SBB, 2018).

In the table below, the Above ground biomass for living and dead organic material and Below ground biomass is shown for each forest stratum.

Table. Carbon stock (t C ha-1) by pool per strata (Cont’d)
### Analysis and processing of national data

**Estimation and forecasting**

The total Carbon stock was calculated based on the Above Ground Biomass (AGB) of trees mentioned in the table in chapter Original data. This was then converted to total Biomass. In order to get the total Growing stock, the total Biomass was then divided by 0.95, the BCEF for humid tropical natural forest.

To calculate the trend of the total Growing stock among the different years, Growing stock of 371.89 m³ per ha and the Forest areas mentioned in Table 1a were used.

Analysis and processing of national data

Estimation and forecasting
To calculate the Growing stock for the ten most dominant tree species in Suriname, the harmonized database consisting of all the executed forest inventories was used (Technical report State-of-the-art study: Best estimates for emission factors and carbon stocks for Suriname, 2017). Only trees with a dbh size equal and above 10 cm were used for this assessment.

Original data

On the National Geoportal (www.gonini.org) several layers are available related to the forest cover in Suriname, amongst other the Protected Areas, the Multiple Use Management Areas (MUMA’s), and Timber cutting license areas. Based on these layers an indication of the forest surface within the before mentioned categories can be assessed. It is possible that in some areas human activities can take place leading to decrease in forest cover i.e. MUMA’s.

The MUMA’s are important tools for the stabilization of the coastal zones (these have been established as a buffer zone against the dynamics of the ocean to protect the land area). The MUMA’s are composed of water and land (forest and non-forest). Therefore the extend of the MUMA’s was overlaid on the Deforestation maps, which allowed to calculate the forest area within their extend.

The table below provides information of the year when each MUMA was established.

**Table. Year of establishment of the different MUMA’s**

Analysis and processing of national data

Estimation and forecasting

Production (a), includes the area on which the valid concession licenses are obtained for commercial timber exploitation. The data of these areas are based on the old timber cutting maps of LBB and the timber cutting licenses database of SBB.

Important is to mentioned that the area of the valid concession license are issued within the production forest where already infrastructure is developed. The expectation is that in the near future the extent of this category will not increase significantly, due to the fact that there is no indication of forest accessibility infrastructure projects within the production forest.

### Comments

Refering to the first table it can be noted that:

Production (a), includes the area on which the valid concession licences are obtained for commercial timber exploitation. The data of these areas are based on the old timber cutting licenses maps of LBB and the timber cutting licenses database of SBB.

Protection of soil and water (b), includes all the areas of the MUMA’s.

Conservation of Biodiversity (c), includes all protected areas.

Multiple use (e), includes the areas of the MUMA’s and also the areas on which communal cutting licenses (HKV) and community forest are issued to indigenous and tribal forest communities. It is allowed to utilize the HKV and community forests for timber production as well for subsistence use and commercial utilization. Furthermore, it is also allowed to utilize theme for the gathering of NWFP and agroforestry.
Other (f), are the special protected forest, which are established for scientific research.

Referring to the second table it can be noted that:

The category Production includes the indicated production forest within the forest belt. Due to lack of sufficient Land Use Plan, different types of license overlap in the same areas. A consequence of the lack of sufficient Land Use Plan is, that within the indicated production forest mining licenses are also issued, leading to decrease of the forest.

Original data

It is possible that in the past decades the total area of the land tenure: Private ownership, Allodial property, Lease hold, Land lease, and Others, is increased but no data are available. Forests on private land do not cover more than a total area of 50,000 ha. Within the Constitution of Suriname the tribal rights for the utilization of land is not yet settled clearly, however these tribal rights are being recognized by the Government. It can be noted that there are initiatives and ongoing processes to guarantee the legal rights of the tribal communities, within the surrounding areas of their villages. A recent development is that the National Assembly of Suriname has approved the “wet Beschermde Dorpsgebieden”, this is a law to protect the surrounding areas of the villages. With this, another step has been taken to solve the tribal rights issue.

Table. Estimated forest area of Suriname by type of tenure as of 1985

<table>
<thead>
<tr>
<th>National classification</th>
<th>Area (x 1000 ha)</th>
</tr>
</thead>
</table>

47
Analysis and processing of national data

**Estimation and forecasting**

Because of the lack of sufficient Land Use plan, it is possible to issue other rights besides timber cutting rights within the production forest. There is a possibility that within the production forest, licenses for Lease hold and Land lease are issued. The reported figures of these licenses could be an underestimation (the updated figures are not available).

|                     | - MUMA's  |
| Individuals         | Incidental cutting licenses and concessions issued to natural persons |
| Private business entities and institutions | Incidental cutting licenses, exploration licenses and concessions issued to legal persons (companies). |
| Communities         | Communal cutting license and community forest |
| Other               | A holder of a land lease or lease hold rights can, if there is no overlapping with actual forest management rights, dispose of the wood within the boundaries of their terrain. |
Comments

Based on the Timber Act of 1947, communal cutting licenses (HKV) were issued to forest based communities. With the approval of the Forest Management Act of 1992, which is the successor of the Timber Act of 1947, the community forest has been introduced to facilitate the forest based communities. However, until now there are still 60 communal cutting licenses with a total surface of 423,529 ha. The intention is to convert all the communal cutting licenses into community forests. In collaboration with the Ministry of Regional Development (Min. of RO), the Ministry of RGB is in process to convert all communal cutting licenses into community forest. The intention is also to facilitate villages which until now do not have community forest. Taking these factors into consideration, the expectation is that the total surface of the community forests will increase.

National classification and definitions

<table>
<thead>
<tr>
<th>National class</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Burned Area</td>
<td>Areas that have recently been burned.</td>
</tr>
</tbody>
</table>

Original data

For the category “Total land area affected by fire” (Table 5b), the Post-deforestation LULC maps produced by FCMU in close collaboration with National stakeholders, were used. The surface of the Post-deforestation LULC class “Burned areas” are shown in the table below. It is noticable that these burned areas are most often near the open savannas. Is it not clear if the burned areas are caused by human activities or natural causes.

Mentioning worth is that in the interior the forest communities practice the “slash and burned” method to do agricultural activities (Shifting cultivation). In this case also forest areas are burned, but it is not reported as the category “Area affected by fire”. The Shifting cultivation is mainly found close to the villages of indigenous and tribal communities, in the vicinity of rivers and/or roads. The forest dependent communities clearly indicate that shifting cultivation is a traditional and sustainable use of the forest. Based on this the area of Shifting cultivation is reported as Forest.

Table. Map areas of the Post-Deforestation LULC class “Burned areas” for the following periods: 2000-2009, 2000-2013, 2000-2015

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>Burned areas</td>
<td>243</td>
<td>2052</td>
<td>2502</td>
<td>2972</td>
</tr>
</tbody>
</table>

The figures of the Burned areas in the period 2000-2009, 2000-2013, 2000-2015, and 2000-2017, represent the accumulated figures of the previous periods. Futhermore, it can be clarified that areas which are regenerated are excluded from these figures. It is not clear yet for what Land Use these areas were burned in case were human activities took place.

Analysis and processing of national data

Estimation and forecasting

Forest fires occur in small scales in Suriname and does not have big impact on the forest. There is a mechanism in place in cases forest fires occur, to take action (Nationaal Coördinatie Centrum voor Rampenbeheersing (NCCR)).

<td></td>
</tr>
</tbody>
</table>

Comments
Suriname does not have yet, an active monitoring system of forest degradation in place. However the FREL of Suriname was developed based on Forest degradation due to logging activities and Deforestation. The definition for forest degradation used within the FREL is defined as follows: “human-induced or natural loss of the goods and services, provided by the forest land, in particular the forest carbon stocks, not qualifying as deforestation, over a determined period of time”. Within the framework of the development of the FREL, a study has been conducted to assess the emission factor due to logging activities. Based on the Timber production and the emission factor, the emission due to logging activities is determined.

It can be mentioned that in the near future the monitoring of Forest degradation will be set up, focussing on the surrounding areas of mining activities and shifting cultivation.

Original data
Comments

Forest policy formulation in Suriname is based on a participatory process. There is a platform with representatives of the Foundation for Forest Management and Production Control (SBB), the private sector organizations, forest community organizations and other relevant stakeholders. When necessary meetings are organized regarding policy making issues these platform is invited to participate.

Regarding the Traceability system for wood products, it can be noted that currently the existing Log tracking system is being updated. The focus is to have an adequate Log tracking system for log production. The intentioned is to finalize this process mid 2019.

</tbody>
</table>

### National classification and definitions

- **Original data**
  
The area of permanent forest estate includes, the production forest, the nature reserves, MUMA’s and the temporary maintained forest, excluded by the greenstone belt, non forest areas, hydrography and the deforestation within the mentioned areas. The greenstone belt represents the area where gold occurrences are present. Within this area the most gold mining licences are issued.
Comments
The forest within the area of permanent forest estate shows a decreasing trend, due to the fact that within this area deforestation takes place. Because of the lack of sufficient Land Use Plan, other types of licenses are issued within this area resulting in loss of forest.

#### Original data

On regular basis, the SBB, register the employment in the total Forestry sector, including logging, timber transport and timber processing.
### Comments

The total employment within the forest sector in Suriname is 6,650. Of this 3,500 are employed in logging activities and 800 in the transport of logs. Furthermore, 50 persons can be categorized as a support service to forestry. The forest management institutions employs 300 persons. Also it can be mentioned that the employment within the timber processing industry is 2,000. There are no silviculture activities within the forest sector of Suriname.

Employment data regarding the gathering of non wood forest products is not available.

#### Comments

The University of Suriname (ADEKUS) has a 2 year programme for Sustainable Management of Natural Resources (SMNR) on master level, this programme also includes sustainable forest management.

The Technological Faculty of the University of Suriname (ADEKUS) has a 3 year education programme for forestry on bachelor level.

The NATIN is a mid-level technical education institution with a 4 year programme for forestry.
7c Non wood forest products removals and value 2015

</thead>
</table>

### Comments

There is no data available of the production and local trade of non wood forest products. The Nature Conservation Division of the Forest Service (LBB) registers export data of the non wood forest products. The reported figures only represents the export of non wood forest products. The actual production figures is most probably higher than the reported figures.
