THE THREE PRINCIPLES OF CONSERVATION AGRICULTURE

1) Minimum Soil Disturbance

- Direct planting involves growing crops with minimum soil disturbance since the harvest of the previous crop. Direct planting can be used with all annual and perennial crops and vegetables.
- Conservation agriculture can be done manually (e.g., likoti) or mechanically (e.g., animal or tractor drawn conservation agriculture planters).

Advantages of minimum soil disturbance:

- Protects the soil against erosion by water and wind.
- Improves infiltration and conserves soil moisture.
- Increases yield per unit of fertilizer or manure applied. In the long term decreases the amount of fertilizer per hectare.
- Cost savings: fuel, time and labour costs in the long term.
- Improves soil organic matter.

2) Permanent Soil Cover: crop residues and live mulches

- Mulch is any organic material (such as decaying leaves, bark, or compost) spread over the soil and around a crop to enrich and insulate the soil. Live mulches are crops intercropped for purposes of providing soil cover. Crop residue or live cover protect the soil from direct impact of erosive raindrops; conserves the soil by reducing evaporation and suppresses weed growth.

Advantages of permanent cover: residues and live mulches:

- Protects the soil from erosion by water or wind.
- Suppresses weed germination and growth.
- Improves recycling of nutrients.
- Improves organic matter accumulation & carbon sequestration.

3) Crop rotations and/or intercropping

- Crop rotation means that different crops are alternated in the same field, preferably cereals (maize and wheat) followed by legumes (beans).

Advantages of crop rotations & intercropping:

- Reduction of pests and diseases: different crops are susceptible to different diseases and pest agents. Therefore, growing such crops in rotation will reduce the incidence of diseases and pests at no cost.
- Improvement of water use: crops with different rooting systems also utilize soil water at different soil depths.
- Improve fertility and production: crops have different rooting patterns which take up nutrients at different soil depths. Rotations help to utilize soil nutrients more efficiently. In addition, legumes fix nitrogen in the soil for the benefit of successive cereal crops in a rotation.
- Protects the soil from erosion by water and wind.
- Suppresses weed germination and growth.
- Improves recycling of nutrients.
- Improves organic matter accumulation & carbon sequestration.
