

HPAI Control Measures and Household Incomes in Viet Nam

Joachim Otte, FAO Pro-Poor Livestock Policy Initiative (PPLPI)

1 Introduction

A broad array of HPAI control measures are being considered for the poultry sector in Viet Nam. Because the poor are highly represented in this country's poultry production, any national strategy for intervention in this sector needs to take careful account of their welfare. The following figure shows that income from poultry production has an important equity effect in the Vietnamese economy, as this source is much more equally distributed than total income.

Figure 1: Income Distribution in Viet Nam

Source: VHLSS (2002).¹

¹ The results reported here are based on data from the 2002 Viet Nam Household Living Standards Survey (VHLSS), a nationally representative sample of 65,000 households from around the country. For convenience, this sample has been aggregated to 600 representative households, classified by income quintile, rural and urban, in each of 30 provinces.

If serious adverse impacts on the poor are to be avoided, it is essential to develop and implement control strategies that are adapted to initial conditions and local institutions. Because of diversity in the former (both between as well as within countries) and complexity of the latter, economywide prescriptions and 'rules of thumb' are unlikely to achieve anything close to optimality. As the resource flow diagrams in Figures 2 and 3 indicate, in Thailand for example, small holders (light green background) are responsible for less than 25% of poultry production and marketing, while in Viet Nam they account for about two-thirds of production and half of direct marketing. For this reason, the poverty risk of market displacement (black diagonals) is much greater in Viet Nam, and simple macro approaches like moratoria on backyard production of a given scale could pose a serious hardship for the country's rural poor population majority.

2 Reducing HPAI risks while safeguarding livelihoods

If the policy makers want to reduce HPAI risks to larger animal and human populations, without undue adverse effects on the poor, they need more effective means for identifying local outbreaks and containing them. The information needed to accomplish exists, but it has until now been very difficult to obtain. Much evidence suggests that local communities are well aware of local outbreaks and infection patterns, but that reporting processes are plagued by inefficiency and incentive problems.

Based on its existing livestock sector research at the micro, meso, and macro level, PPLPI would like to contribute to the initiation of a new HPAI policy research agenda to devise socially more effective means of monitoring and control. This includes a systematic approach that combines rigorous epidemiological and economic analysis with risk management, an approach in the following referred to as Strategic Pathogen Assessment for Domesticated Animals (SPADA). Stochastic simulation models of disease transmission are being developed to identify control policies that might be beneficial in the reduction of the transmissibility of HPAI at the local, regional and national level. The results of these models are intended as inputs into the economic component, which is designed to assess the ramifications of the disease beyond the animal production systems themselves. A risk management component involves localized design and testing of monitoring, incentive, and penalty mechanisms for disease reporting combined with traceability schemes, the aim of which is to limit downstream disease risks and improve upstream product quality characteristics.

In this brief note a few initial examples of the economic risk assessment are presented. The approach recognizes the microeconomic realities of poultry production and livelihoods, including the diversity of household production systems and the complexity of market incentives they face. The approach is divided into three components, each with an essential role to play in a pro-poor approach to HPAI risk reduction.

1. **Surveillance:** The research examines alternative policy designs to facilitate early detection of outbreaks. These combine surveillance, incentives for collective responsibility and self-reporting, taking into account the resource constraints of different communities, for the development of mechanisms that allow for reduced health risk and economic survival of the producers.
2. **Control:** Effective decentralization of control capacity is essential to the long-term success of disease management. In the HPAI epicenter countries, this will require new incentive relationships between district and provincial authorities, the central government, and outside stakeholders (NGOs, aid agencies, etc.). Regional participation and coordination are essential for sustained risk reduction. This component of the research will also aim to extend IPALP tools for incidence analysis so that the costs and benefits of alternative control strategies can be more accurately anticipated.
3. **Traceability:** An important class of strategies that will have to be introduced in order to control the spread of agriculturally originated contagious diseases

are mechanisms to trace the movement of agricultural products generally and livestock in particular. At the same time, consumer concern in relation to food quality and safety, and the introduction of modern supply chain management systems are increasing the value of product identification throughout the food chain. Thus traceability has dual value to consumers and producers, increasing the effectiveness of demand targeting and raising value-added by origin. With appropriate policies, private and public investments in systems of traceability that address food safety concerns can also benefit smallholders by linking them into more integrated food chains. These chains can increase distribution efficiency, reduce marketing margins and risks, and stimulate upstream technology transfer and product quality improvements, all of which improve the likelihood of smallholder survival until alternative income sources emerge. This pro-poor benefit stands in sharp contrast to the displacement effects many current control strategies threaten to cause.

3 Examples

We are fortunate in the case of Viet Nam to have very detailed data on the microeconomics of household production. With this we have been able to calibrate simulation models and evaluate the effects of policies toward livestock production generally and poultry in particular. Here we present two preliminary assessments of a backyard poultry ban, using as our reference the principle of eliminating chicken and duck production for all sector 3 and 4 enterprises.

Given the apparent links between human HPAI infection and small holder production, an obvious deterrent would be to simply separate domestic birds and humans by mandating universal confinement of 'commercial' poultry in larger scale production systems, restricting smallholders to subsistence production. In Viet Nam, this would affect the majority of individual poultry producers (i.e. the country's rural poor majority, see Figure 2), most of whom are poor rural households. This rather simplistic approach would obviously exacerbate poverty in an already poor country, although it should also be noted that rural production systems are diversified and could shift resources to partially offset the direct effects of such a policy. More effective policy analysis would seek to measure these adjustments and estimate the ultimate incidence, and then examine alternative measures and compensation schemes.

Figure 3 presents the effects on annual household income for the 600 representative households in our sample, ordered across the horizontal axis by share of total income (i.e. the poorest are on the left). Clearly, this control / eradication policy would disproportionately affect the poor. Most poor households could probably diversify production to limit losses to below 10 percent of annual income, but some would lose over 25 percent. The anti-poor effects of this policy are relatively transparent.

If rural households cannot raise poultry for sale, they might also not be permitted to raise birds for their own consumption as separation of these two uses could be very difficult to enforce. Figure 4 indicates the cost to Vietnamese households of giving up sale of poultry and buying poultry for their own consumption. In many cases, this more than doubles the household cost of the policy, with an average negative income effect for the lower quartile that is several percentage points higher.

4 Conclusion

This brief note discusses the importance of microeconomic analysis and localized design and implementation of policies to reduce HPAI risk such that it is most likely to achieve stakeholder acceptance, and therefore successful control. Despite the global momentum for rapid and intensive measures to control poultry stocks and restructure management practices, in the HPAI epicentre countries these policies must address the economic and institutional realities of poor rural majority populations. To reconcile such macro and micro perspectives effectively is a much greater challenge than simply allocating international resources to national governments. To promote a more comprehensive analysis of this situation, four salient insights need to be borne in mind:

1. Policies toward HPAI in epicentre countries necessarily implicate the rural poor majority. **These people need to be recognized as part of the solution to reducing disease risk, not the problem.** We can neither ignore nor exempt such a large group from risk reduction strategies, but the strategies must be designed with them in mind.
2. Because of diverse initial conditions and weak institutional linkage, national policies cannot be implemented effectively without close attention to local incentives. Despite international pressure to act quickly on control measures, **one size will not fit all or even a significant percentage of local conditions.**
3. It has been seen time and time again that prescriptive eradication measures fail to achieve their direct objective and can cause many adverse indirect effects. **By driving the problem 'under ground', disease risk actually increases** and rural markets/livelihoods are more seriously disrupted.
4. Well designed monitoring and traceability systems could improve the terms of market access for the rural poor, making many of them better off as a result of HPAI policies. **Risk reduction strategies must incorporate extension and marketing services** that transfer standards and technology upstream, product quality and diversity downstream, increasing value-added for small holders.

HPAI presents an unusual opportunity for international cooperation because millions of poor rural households can contribute significantly to the global commons of pandemic disease prevention. Their participation in this effort must be better understood and indeed rewarded if success is to be achieved.
