1. Summary

Carob (locust) bean gum is mainly consisting of the high molecular weight (approximately 50,000-3,000,000) polysaccharides composed of galactomannans and is obtained from the endosperm of the seed of the carob (locust) tree, Ceratonia siliqua (L.) Taub (Fam. Leguminosae). It is used as thickener, stabilizer, emulsifier and gelling agent, and approved in most areas of the world (e.g. European Union, United States of America, Japan and Australia).

Carob bean gum was evaluated and ADI “not specified” was allocated at 25th JECFA (1981). The specifications were prepared at 35th JECFA (1989) and published in FNP 49 (1989) and republished in FNP 52 “Compendium of food additive specifications”. They were discussed at 42nd, 44th, 51st and 53rd JECFA, and their revised specifications were published in FNP 52 Add 2, 3, 6 and 7, and republished in FAO JECFA Monographs “Combined compendium of food additive specifications”. At 67th JECFA the Committee reviewed the specifications of “Carob bean gum” and noted that they were covered two grades of product. The Committee decided to prepare two specifications monographs, “Carob bean gum” and “Carob bean gum (clarified)”. Both monographs were designated tentative and published in FAO JECFA Monographs 3 (2006). Further information on gum content, solubility in water and a test method for methanol and isopropanol as residual solvents using capillary gas chromatography were required before the end of 2007. The outstanding information was received prior to the 69th meeting of JECFA.

2. Description

Carob bean gum, also known as locust bean gum, carubin or algaroba, is obtained from the endosperm of seed of the carob (locust) tree, Ceratonia siliqua (L.) Taub (Fam. Leguminosae). The carob tree is a large evergreen tree and its fruit is a long brown pod containing very hard brown seeds, the kernels. The seeds are dehusked by treating the kernels with dilute sulfuric acid or with thermal mechanical treatment, elimination of the germ followed by milling and screening of the endosperm (native carob bean gum). The gum may be washed with ethanol or isopropanol to control the microbiological load (washed carob bean gum). It may also be further clarified (purified, extracted) by dispersing in hot water, recovery with isopropanol or ethanol, filtering, drying and milling, which is called as clarified (purified, extracted) carob bean gum. Clarified carob bean gum in the market is normally standardized with sugars for viscosity and/or reactivity.

Carob bean gum is mainly consisting of the high molecular weight (approximately 50,000-3,000,000) polysaccharides composed of galactomannans.

The clarified gum has higher galactomannans content and no longer contains the cell structure.

The gum is a white to yellowish white, nearly odourless powder.

Carob bean gum is insoluble in most organic solvents including ethanol. It is partially soluble in water at ambient temperature and soluble in hot water. Carob bean gum typically needs heating to above 85° for 10 minutes for complete solubility.

The gum may be precipitated from aqueous solution by some electrolytes, and, in particular, polyvalent ones such as lead acetate, phosphotungstic acid, and tannic acid. Solutions containing greater than 0.3% gum are gelled by the addition of borate at pH 7.5 or greater. The gel is reversed by decreasing the pH below 7.0, by heating, or addition of mannitol (a sequestrant for borate).
3. Manufacturing

3.1. Manufacturing principle

The endosperms are recovered after separation of the husk and the germ and milled. The clarified gum is obtained by dissolution in hot water and then recovery by precipitation in ethanol or isopropanol.

Carob bean gum processing flow chart

3.2. Detailed manufacturing

The carob kernels are difficult to process, since the seed coat is very tough and hard. By special processes, the kernels are peeled without damaging the endosperm and the germ. The following procedures are applied:

Acid peeling process: The kernels are treated with sulfuric acid at a certain temperature to carbonize the seed coat. The remaining fragments of the seed coat are removed from the clean endosperm in an efficient washing and brushing process. The peeled kernels are dried and cracked and the more friable germ gets crushed. The germ parts are sifted off from the unbroken endosperm halves. The carob bean gum produced by this process is “whitish” and has higher viscosity.

Thermal peeling process: Alternatively, the kernels may be roasted in a rotating furnace where the seed coat more or less pops off from the rest. The endosperm halves are recovered from the burned husk and the
crashed germs. This process yields a product of somewhat darker colour. The effect is that no sulfuric acid as processing aid is necessary, and, therefore, no effluent originates from the production process.

Afterward, the isolated endosperm is ground to fine particle size powder which represents the final product “Carob Bean Gum”.

*Clarified (Extracted, Purified) Carob Bean Gum*

Carob Bean Gum is dispersed in water and dissolved by heating. This solution is filtered (with a filter aid) to remove insoluble material. From this clear solution, the Carob Bean Gum is precipitated with isopropanol or ethanol, the precipitate is filtered off, dried and ground to fine particle size powder.

4. Chemical characterization

4.1. Composition and properties

Carob bean gum is comprised of a high molecular weight polysaccharides composed of galactomannans consisting of a linear chain of (1→4)-linked β-D-mannopyranosyl units with (1→6)-linked α-D-galactopyranosyl residues as side chains. Standard texts report the molecular weight as approximately 310,000. However the INEC Technical Committee reports that the standard method using the consumption of sodium chlorite is unsuitable and recommends a gel permeation chromatography method. This provides a molecular weight range of 50,000 to 300,000. The mannose:galactose ratio of carob bean gum is approximately 4:1. The mannose and galactose content has been reported as 73-86% and 27-14%, respectively.

4.2. Possible impurities

The commercial samples of carob bean gum contain approximately 5-12% moisture, 1.7-5% acid-soluble ash, 0.4-1.0% ash, and 3-7% protein. The samples of clarified carob bean gum contain approximately 3-10% moisture, 0.1-3% acid-soluble matter, 0.1-1% ash, and 0.1-0.7% protein.

The possible impurities are:

- Husk (reflected by the Acid-insoluble-matter criterion)
- The germ (adequately reflected by the Protein criterion)
- Residual amounts of ethanol or isopropanol for washing or extraction solvent (limited to 1%, singly or in combination)
- Microbiological contamination
5. Functional uses

5.1 Technological function

Carob bean gum is used as thickener, stabilizer, emulsifier, gelling agent. Carob bean gum is compatible with xanthan gum and forms gel. It affects the gelling properties of carrageenan and agar.

5.2 Food categories and use level

In the United States, carob bean gum is listed for use as a stabilizer and thickener in the following foods:

<table>
<thead>
<tr>
<th>Food Category</th>
<th>Maximum Use Level (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baked goods &amp; baking mixes</td>
