INTERNATIONAL PROGRAMME ON CHEMICAL SAFETY

The preparatory work for the toxicological evaluation of pesticide residues carried out by the WHO Expert Group on Pesticide Residues for consideration by the FAO/WHO Joint Meeting on Pesticide Residues in Food and the Environment is actively supported by the International Programme on Chemical Safety (IPCS).
IPCS is a joint venture of the United Nations Environment Programme, The International Labour Organization and the World Health Organization. One of the main objectives of IPCS is to carry out and disseminate evaluations of the effects of chemicals on human health and the quality of the environment.

LIST OF PARTICIPANTS

2013 Joint FAO/WHO Meeting on Pesticide Residues

GENEVA, 17–26 SEPTEMBER 2013

FAO Members

Dr Ursula Banasiak, Delegate of the Federal Institute for Risk Assessment, Max-Dohrn-Strasse 8-10, 10589 Berlin, Germany

Professor Eloisa Dutra Caldas, Pharmaceutical Sciences Department, College of Health Sciences, University of Brasilia, Campus Universitário Darci Ribeiro, 70910-900 Brasília/DF, Brazil (*FAO Rapporteur*)

Mr David Lunn, Principal Adviser (Residues), Plant Exports. Plants, Food & Environment Directorate, New Zealand Food Safety Authority, PO Box 2835, Wellington, New Zealand

Dr Dugald MacLachlan, Australian Government Department of Agriculture, Fisheries and Forestry, GPO Box 858, Canberra, ACT 2601, Australia (*FAO Chairman*)

Mr Christian Sieke, Unit Residue Assessment of Pesticides and Biocides, Department of Chemicals Safety, Federal Institute for Risk Assessment, Max-Dohrn-Strasse 8-10, 10589 Berlin, Germany

Dr Yukiko Yamada, Advisor to Vice Minister / Chief Scientific Advisor, Ministry of Agriculture, Forestry and Fisheries, 1-2-1 Kasumigaseki, Chiyoda-ku, Tokyo 100-8950, Japan

Secretariat

Dr Árpád Ambrus, Hungarian Food Safety Office, 1143 Budapest Tábornok u 2, Hungary (FAO Temporary Adviser)

Mr Kevin Bodnaruk, 26/12 Phillip Mall, West Pymble, NSW 2073, Australia (FAO Editor)

Ms Gracia Brisco, Food Standards Officer, Joint FAO/WHO Food Standards Programme, Food and Agriculture Organization of the United Nations (FAO), Viale delle Terme di Caracalla, 00153 Rome, Italy (Codex Secretariat)

Dr Michael Doherty, Office of Pesticide Programs, Health Effects Division, Risk Assessment Branch II, United States Environmental Protection Agency, MS 7509C, Washington, DC 20460, USA (FAO Temporary Adviser)

Dr Yi Bing He, Department of Science and Education, Ministry of Agriculture, No. 11 Nong Zhan Guan Nanli, Chaoyang District, Beijing 100125, China (FAO Temporary Adviser)

Dr Paul Humphrey, Pesticides Program, Australian Pesticides and Veterinary Medicines Authority (APVMA), PO Box 6182, Kingston, ACT 2604, Australia (FAO Temporary Adviser)

Mr Makoto Irie, Plant Product Safety Division, Food Safety and Consumer Affairs Bureau, Ministry of Agriculture, Forestry and Fisheries, 1-2-1 Kasumigaseki, Chiyoda-ku, Tokyo 100-8950, Japan (FAO Temporary Adviser)

Dr Mi-Gyung Lee, Department of Food Science and Biotechnology, College of Natural Science, Andong National University, #388 Songcheon-dong, Andong-si, Gyeongbuk, 760-749, Republic of Korea (FAO Temporary Adviser)

Dr Xiongwu Qiao, Shanxi Academy of Agricultural Sciences, 2 Changfeng Street, Taiyuan, Shanxi 030006, China (CCPR Chairman)

Ms Monique Thomas, Pest Management Regulatory Agency, Health Canada, 2720 Riverside Drive, Ottawa, ON, Canada K1A 0K9 (FAO Temporary Adviser)

Ms Trijntje van der Velde-Koerts, Centre for Nutrition, Prevention and Health Services, National Institute for Public Health and the Environment (RIVM), Antonie van Leeuwenhoeklaan 9, PO Box 1, 3720 BA Bilthoven, the Netherlands (FAO Temporary Adviser)

Ms Yong Zhen Yang, Plant Production and Protection Division, Food and Agriculture Organization of the United Nations (FAO), Viale delle Terme di Caracalla, 00153 Rome, Italy (FAO JMPR Secretariat)

Dr Guibiao Ye, Director of Pesticide Residue Evaluation, Institute for the Control of Agrochemicals, Ministry of Agriculture, Maizidian 22, Chaoyang District, Beijing 100125, China (FAO Temporary Adviser)

Abbreviations

(Well-known abbreviations in general use are not included. Specific abbreviations for pesticide degradation products, etc., may be used in the monographs and these are either identified where first used or in a table within the monograph. Two-letter codes for pesticide formulations are given in the Manual on development and use of FAO and WHO specifications for pesticides, 1st Ed., FAO Plant Production and Protection Paper 173, FAO, Rome, 2002.)

ACN	Acetonitrile
ADI	acceptable daily intake
ai	active ingredient
AR	applied radioactivity
ARfD	acute reference dose
asp gr fn	aspirated grain fraction
AU	Australia
BBCH	B iologischen Bundesanstalt, B undessortenamt und C hemische Industrie
bw	body weight
CAC	Codex Alimentarius Commission

WP	wettable powder

Use of JMPR Reports and Evaluations by registration authorities

Most of the summaries and evaluations contained in this report are based on unpublished proprietary data submitted for use by JMPR in making its assessments. A registration authority should not grant a registration on the basis of an evaluation unless it has first received authorization for such use from the owner of the data submitted for the JMPR review or has received the data on which the summaries are based, either from the owner of the data or from a second party that has obtained permission from the owner of the data for this purpose.

1. INTRODUCTION

A Joint Meeting of the FAO Panel of Experts on Pesticide Residues in Food and the Environment and the WHO Core Assessment Group on Pesticide Residues (JMPR) was held at World Health Organization (WHO) Headquarters, Geneva (Switzerland), from 17 to 26 September 2013. The Panel Members of the Food and Agriculture Organization of the United Nations (FAO) met in preparatory sessions on 12–16 September.

The Meeting was opened by Dr Kazuaki Miyagishima, Director, Department of Food Safety and Zoonoses, WHO. On behalf of FAO and WHO, Dr Miyagishima welcomed and thanked the participants for providing their expertise and for the significant time and effort put into such an important activity. He also expressed gratitude to the respective national authorities, institutes and organizations that have allowed their experts to contribute to this important work on pesticide residues. Dr Miyagishima said that whereas the assessment of new compounds is very important and represents the major part of the work of JMPR, it is also crucial to continue our efforts on the periodic re-evaluation of old pesticides still in use. This should allow developing countries to use old, inexpensive pesticides so that they can access international markets for their food commodities; it also should allow the removal of those compounds that are most persistent in the environment and pose the greatest risk to public health. Dr Miyagishima also noted that in order to continue using the best available science in a transparent manner, the WHO Core Assessment Group will meet during an additional day this year to update the guidance documents for experts and sponsors. Finally, JMPR is celebrating in 2013 the 50th anniversary of the first joint FAO/WHO evaluation of pesticide residues in food, and Dr Miyagishima addressed his best wishes to the Meeting on behalf of the two parent organizations.

During the meeting, the FAO Panel of Experts was responsible for reviewing residue and analytical aspects of the pesticides under consideration, including data on their metabolism, fate in the environment and use patterns, and for estimating the maximum levels of residues that might occur as a result of use of the pesticides according to good agricultural practice (GAP). Maximum residue levels and supervised trials median residue (STMR) values were estimated for commodities of animal origin. The WHO Core Assessment Group was responsible for reviewing toxicological and related data in order to establish acceptable daily intakes (ADIs) and acute reference doses (ARfDs), where necessary.

The Meeting evaluated 36 pesticides, including 11 new compounds and 3 compounds that were re-evaluated within the periodic review programme of the Codex Committee on Pesticide Residues (CCPR), for toxicity or residues, or both.

The Meeting allocated ADIs and ARfDs, estimated maximum residue levels and recommended them for use by CCPR, and estimated STMR and highest residue (HR) levels as a basis for estimating dietary intake.

The Meeting also estimated the dietary intakes (both short-term and long-term) of the pesticides reviewed and, on this basis, performed dietary risk assessments in relation to their ADIs or ARfDs. Cases in which ADIs or ARfDs may be exceeded were clearly indicated in order to facilitate the decision-making process of CCPR. The rationale for methodologies for long- and short-term dietary risk assessment are described in detail in the FAO manual on the submission and evaluation of pesticide residue data for the estimation of maximum residue levels in food and feed (2009).

The Meeting considered a number of current issues related to the risk assessment of chemicals, the evaluation of pesticide residues and the procedures used to recommend maximum residue levels.

AZOXYSTROBIN (229)

First draft was prepared by Dr Ursula Banasiak, Delegate of the Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

Azoxystrobin (methyl (E)-2-[2-[6-(2-cyanophenoxy)pyrimidin-4-yloxy]phenyl]-3-methoxyacrylate) was first evaluated for toxicology and residues by the JMPR in 2008. The Meeting derived an ADI of 0.2 mg/kg bw per day and decided that an ARfD is unnecessary. The 2008 JMPR concluded that the residue definition for plant commodities for compliance with MRL values and for consumer risk assessments was parent azoxystrobin. Maximum residue levels, STMRs and STMR-Ps for 82 commodities or commodity groups were estimated. The compound was re-evaluated for residues by the JMPR in 2011 and 2012.

Azoxystrobin was listed by the Forty-fourth Session of the CCPR (2012) for the review of additional MRLs. The 2013 JMPR received GAP information and residue data in coffee beans, pulses, potatoes, barley, oats and sorghum.

RESIDUE ANALYSIS*Analytical methods*

The Meeting received information on analytical methods for azoxystrobin residues in coffee beans (POPIT Met.029, PLARA 082 v.07), potatoes (RAM 305), pulses (RAM 305, RAM 243), cereal grain, straw and forage (RAM 305/03). The methods RAM 305, RAM 305/03 and RAM 243 were previously reported by the JMPR in 2008 and method POPIT MET.029 by JMPR in 2011. Method PLARA 082 v.07 is briefly described below and the recoveries are summarized in Table 1.

Method: PLARA 082 v.07
Reference: PLMV 027 039/2010
Commodity: Coffee bean
Analyte: Azoxystrobin, R230310
Determination: LC-MS/MS
LOQ: 0.01 mg/kg
Accuracy: The mean recovery in coffee was between 91–105 % at each fortification level.
Repeatability: The relative standard deviations (RSDs) of azoxystrobin recoveries at each fortification level and overall during method validation were all below 20 %.
Linearity: The linearity of detector response was confirmed by analysis of nine concentrations of standard solutions in the range 0.01 to 2.0 ng/mL of azoxystrobin with three injections for each concentration. Linearity of response was demonstrated with a correlation coefficient (R^2) of 0.9995.
Specificity: No interfering peaks were detected in control samples above the LOD.
Description: A sample of ground coffee beans (1 g) is extracted by shaking for 15 minutes with ethyl acetate (20 mL), ultrasonicing for 15 minutes and centrifuging. The extract is removed and the extraction repeated. The extracts from the two extractions are combined, an aliquot (3 mL) taken, evaporated to dryness and resuspended in 3 mL methanol/water (1:1 v/v) using vortex mixing. An aliquot (1 mL) of the resulting extract is taken, and mixed with 4 mL methanol/water (1:1 v/v) using a vortex mixer and then ultrasonicing for 15 minutes. This extract is analysed directly by LC-MS/MS with quantification by external standardisation.

Table 1 Recovery data for azoxystrobin in coffee (PLMV 027 039/2010)

Commodity	Fortification level (mg/kg)	Recovery (%)	No. of analyses (n)	Mean recovery (%)	RSD (%)	Range (%)
Coffee bean	0.01	96, 91, 95, 96, 98, 99	6	96	3	91–99
	0.1	105, 95, 92, 97,	7	97	5	91–105

Commodity	Fortification level (mg/kg)	Recovery (%)	No. of analyses (n)	Mean recovery (%)	RSD (%)	Range (%)
		94, 91, 101				
	Overall		13	96	4	91–105

USE PATTERN

The information available to the 2013 JMPR on registered uses of azoxystrobin is summarized in Table 2. Copies of labels including an English translation if appropriate were made available to the Meeting.

Table 2 Registered uses of azoxystrobin

Crop	Country	Form	Application		Spray			PHI, days	Remarks
			Method	Rate, kg ai/ha	Volume, L/ha	No	Interval, days

^a A single early season application followed by a single application at 50% to full flag leaf emergence.

^b Use of an adjuvant at 0.5% of the spray application volume is recommended.

^c BBCH scale (<http://www.pub.jki.bund.de>)

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials for azoxystrobin uses that produced residues on the following commodities:

Commodity	Group	Table No
Beans, dry	VD Pulses	3
Peas, dry	VD Pulses	4
Potato	VR Root and tuber vegetables	5
Barley	GC Cereal grains	6
Oat	GC Cereal grains	7
Sorghum	GC Cereal grains	8
Coffee beans	SB Seed for beverages and sweets	9
Bean fodder	AL Legume animal feed	10
Pea fodder (dry)	AL Legume animal feed	11
Pea vines (green)	AL Legume animal feed	12
Barley straw	AF Straw, fodder and forage of cereals	13
Barley hay	AF Straw, fodder and forage of cereals	14
Oat straw	AF Straw, fodder and forage of cereals	15
Oat hay	AF Straw, fodder and forage of cereals	16
Oat forage (green)	AF Straw, fodder and forage of cereals	17
Sorghum stover	AF Straw, fodder and forage of cereals	18
Sorghum forage (green)	AF Straw, fodder and forage of cereals	19

Conditions of the supervised residue trials were generally well reported in detailed field reports. If two field samples were taken or results of two replicate plots were submitted, the mean value was calculated. From two trials carried out side-by-side the higher residues were chosen and not the average.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analysis or duration of residue sample storage were also provided. Residue data are recorded unadjusted for recovery. When residues were not quantifiable they are shown in the tables as below the LOQ (e.g. < 0.01 mg/kg). When residues were not detectable, they are shown as n/d.

Residues and application rates have generally been rounded to two significant figures. Residue values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. Those results included in the evaluation are underlined.

*Pulses**Beans, dry*

Eleven independent supervised trials were conducted on dry beans in the UK, Italy and France in 1998–2005. Azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of 0.20–0.25 kg ai/ha with a spray interval of 14 days. Applications were made between BBCH growth stages 61 and 87. Samples of dry bean seed were collected at normal commercial harvest at PHIs of 14–36 days. The analytical methods used were RAM 305/01, RAM 305/02 and RAM 305/03 with a validated limit of quantification of 0.01 mg/kg. Detailed trial summaries are presented in Table 3.

Table 3 Azoxystrobin residues in beans, dry

^a Sample harvested partially dried from the field, drying was completed indoors for a further 39 days.

Peas, dry

Twenty independent supervised trials were conducted on dry peas in the UK and France in 1996–2004. In each trial, azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of 0.20–0.25 kg ai/ha with a spray interval of 14 days. Applications were made between BBCH growth stages 61 and 77. Samples of dry pea seed were collected at normal commercial harvest at PHIs of 30–45 days. Several trials were conducted as decline trials. In these trials, peas are separated from the pods by hand, except where noted in the table. The analytical methods used were RAM 305/02, RAM 243/04 and RAM 243/05 with a validated limit of quantification of 0.01 mg/kg. Detailed trial summaries are presented in Table 4.

Root and tuber vegetables

Potatoes

Trials have been conducted in the USA and Canada in 2009 to support the registered use pattern.

Five independent supervised trials were conducted. In each trial, azoxystrobin was applied once as an SC formulation containing 250 g ai/L at a rate of 0.44–0.50 g ai/100 kg tubers. In one trial, four different application methods were used, namely spray application to tubers falling from a conveyor belt, surface application, application inside a spray chamber and spray application on a brush table. All other trials used spray application to tubers falling from a conveyor belt or moving along a roller table. In one trial, a bulk sample was collected and processed to flakes, chips and wet peel. Potatoes from the residue trials were sampled after the test substance had dried (0 day). In three trials, additional treated samples were placed in typical potato storage conditions for up to 231 days to generate residue decline data. Samples were collected in duplicate.

Following collection, with the exception of the bulk sample for processing, the potato tubers were frozen and shipped to the laboratory for analysis. The bulk samples were stored at ambient temperature prior to shipment to the processing facility. Processed samples were frozen after collection. The analytical method used was RAM 305/03 with a validated limit of quantification of 0.01 mg/kg. The data are presented in Table 5.

*Cereal grains**Barley*

Trials have been conducted in the USA in 2009 and 2010 to support the registered use pattern. Seven independent supervised trials were conducted. In each trial, azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of 0.15 kg ai/ha. Grain samples were harvested at 16–54 days after the final application. The analytical method RAM 305/03 was used. The residue data are summarized in Table 6.

Sorghum

Twelve independent supervised trials were conducted in the US in 2004 to support the registered use pattern in the US. In each trial, azoxystrobin was applied three times as an SC formulation containing 250 g ai/L at a rate of 0.28 kg ai/ha with a 7 day application interval. Grain samples were harvested at 14 and 21 days after the last application. The analytical method RAM 305/03 was used. The results are summarized in Table 8.

Seed for beverages and sweets

Coffee beans

Azoxystrobin residues in coffee were evaluated by the 2011 JMPR. Nineteen trials were conducted in Brazil. In four trials (2006/2007) azoxystrobin was applied three times at a rate of 0.15 kg ai/ha with a 60 days application interval. Beans were harvested at PHIs of 14, 21 and 30 days. In three trials (2002/2003) azoxystrobin was applied three times to parallel plots, to one plot at a rate of 0.1 kg ai/ha and to the second plot at a rate of 0.2 kg ai/ha, both with an application interval of 60 days. In six trials (WG formulation, 2010/2011) azoxystrobin was applied two times pre-flowering at the rate 0.05 kg ai/ha with 30 days interval and three times at the rate 0.12 kg ai/ha with a 60 day application interval. Beans were harvested at PHIs 21, 28 and 35 days. Adjuvant was added to all applications. In six trials (EC formulation, 2010/2011) azoxystrobin was applied two times pre-flowering at the rate 0.05 kg ai/ha with 30 days interval and three times at the rate 0.1 kg ai/ha with a 60 day application interval. Beans were harvested at PHIs 21, 28 and 35 days. The residue data were reported by the 2011 JMPR and were not repeated in this document.

New trials on coffee Arabica have been conducted in Colombia in 2010/2011 and in Guatemala and Brazil in 2011 to support the registered use pattern in Colombia. Seven independent supervised trials were conducted in which azoxystrobin was applied three times as an SC formulation containing 200 g ai/L at a rate of 0.15 kg ai/ha. In two trials, a 30 day interval between applications was used, and samples of beans collected at PHIs of 0, 14, 28 and 42 days. In five trials, an application interval of 41–48 days was used, and beans were harvested at a PHI of 14–15 days, or at intervals of 5, 10, 15, 20 and 25 days from the decline trial.

Following harvest, the coffee cherries were processed according to normal local practices to give dry bean samples which were shipped to the laboratory for analysis. The analytical methods used were PLARA 082 v.07 and RAM 305/3, both with validated limits of quantification of 0.01 mg/kg. The residues are summarized in Table 9.

*Legume animal feeds**Bean fodder*

Seven independent supervised trials were conducted on dry beans in the UK and France in 2005. Azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of about 0.20 kg ai/ha with a spray interval of 14 days. Applications were made between BBCH growth stages 61 and 87. The analytical methods used were RAM 305/01, RAM 305/02 and RAM 305/03 with an LOQ of 0.01 mg/kg. Residue data are presented in Table 10.

Pea fodder (dry)

Twenty independent supervised trials were conducted in the UK and France in 1996–2004 on peas. In each trial, azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of 0.20–0.25 kg ai/ha with a spray interval of 14 days. Applications were made between BBCH growth stages 61 and 77. Samples of dry pea seed were collected at normal commercial harvest at PHIs of 30–45 days. The remaining plant can be used as fodder (dry). The results are shown in Table 11. The analytical methods used were RAM 305/02, RAM 243/04 and RAM 243/05 with a validated limit of quantification of 0.01 mg/kg.

Straw, fodder (dry) and forage of cereal grains

Barley straw and fodder, dry

Trials have been conducted on barley in the USA in 2009 and 2010 to support the registered use pattern. Seven independent supervised trials were conducted. In each trial, azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of 0.15 kg ai/ha. Straw samples were harvested at 16–54 days after the final application. Hay samples were harvested from separate plots at 0–21 days after the final application. The analytical method RAM 305/03 was used. The residue data are shown in Tables 13 (straw) and 14 (hay).

Oats forage (green)

Twelve independent supervised trials have been conducted in the USA in 2009 and 2010. In each trial, azoxystrobin was applied twice as an SC formulation containing 250 g ai/L at a rate of 0.15 kg ai/ha. Forage samples were harvested at 0–21 days after the final application. The analytical method RAM 305/03 was used. The residue data are summarized in Table 17.

FATES OF RESIDUES IN STORAGE AND PROCESSING

In processing-effect on the residue level

The Meeting received information on the fate of azoxystrobin residues during the processing of potatoes to flakes, chips and wet peel, sorghum to aspirated grain fractions and of green coffee to roasted and instant coffee. The information submitted on processing procedures is summarized below.

Potato

A processing study was carried out during 2009 on potatoes obtained from a trial conducted in Idaho, USA (Report No. TK0003297). One post-harvest application of azoxystrobin formulated as a 250 g ai/L SC was made to potato tubers at the rate of 0.45 g ai/100 kg. Potato tubers were sampled on day 0 after the applied spray had dried.

Potatoes were processed to flakes and wet peel as follows:

- Potatoes were washed and their specific gravity was determined. The potatoes were batch steam peeled, and then batch scrubbed. The potato peel was collected from the peeling and scrubbing process. The peeled potatoes were hand trimmed to remove additional peel, rot, green or damaged potatoes.
- The collected peel was hydraulically pressed, blended with the cut trim waste and a representative sample collected and frozen as the 'wet peel' sample.
- The peeled potatoes were cut into slabs and washed in cold tap water to remove free starch. The potato slabs were precooked at 70–77 °C for approximately 20 minutes, and then cooled to less than 32 °C for 20 minutes. The cooked potato slabs were steam-cooked at 94–100 °C for 40–42 minutes, mashed and then mixed with an emulsion of pre-weighed food additives. The cooked mash was fed into a drum dryer to dry the cooked mash into a thin sheet, and then broken into large flakes by hand. The flakes were uniformly milled into potato flakes in a hammer mill. The milled potato flakes were dried on a fluidized bed dryer before samples of 'potato flakes' were collected and frozen.

Potatoes were processed to chips (crisps) as follows:

- Washed potatoes were batch peeled and hand trimmed if necessary. The peeled potatoes were cut into thin slices (approximately 1.6 mm thick) and washed with hot water to remove free starch.
- The slices were drained and fried at approximately 163–191 °C in frying oil for approximately 120 seconds. The fried potato chips were drained and salted and samples of 'chips' then collected and frozen.

Samples of pre-processing potato tubers, wet peel, potato flakes and chips were analysed using method RAM 305/03. Samples were stored frozen for a maximum period of 7.3 months from sampling to analysis and residues in the processed products are deemed to be stable over the storage period. The results are summarized in Table 20.

Sorghum

A processing study was carried out in Texas, USA in 2004 (Report T002036-03, field test no SC-FR-04-534). Three applications with 0.27–0.28 kg ai/ha were made. Grain samples were taken 13 days after the last treatment. Samples were analysed by method RAM 305/3 (LOQ 0.01 mg/kg).

The aspirated grain fraction was generated as follows:

- After drying, the sample was placed in a dust generation room containing a holding bin, drag conveyors, and a bucket conveyor.
- As the sample was moved in the system, aspiration was used to remove light impurities (grain dust). The sample was moved for 120 minutes.

- The light impurities were classified by sieving. After classification of each sample, all material through the 2360 micron sieve was recombined to produce one aspirated grain fraction.

Coffee

A processing study was carried out during 2011 on coffee beans (Coffee Arabica, variety Bourbon) obtained from a trial conducted in Guatemala (Report TK0046957). Three applications of azoxystrobin formulated as a 200 g ai/L SC were applied to coffee plants at the rate of 750 g ai/ha (5 × rate). Applications were made at intervals of 42–44 days, and coffee cherries were harvested 14 days after the final application. Coffee cherries were pre-processed according to normal local practices to dry green beans (the raw agricultural commodity), and these were then processed to roasted coffee beans and instant coffee.

The coffee cherries were pre-processed to dry green coffee beans (RAC) as follows:

- The skin and some of the pulp of the coffee berry was removed by mechanically pressing the fruit through a screen in water batch, the remaining pulp was removed via a fermentation and washing process, and the bean then dried and the thin parchment layer remaining removed by hand.
- The process for producing dry green beans took 6–14 days.

Green coffee beans were processed to roasted and instant coffee as follows:

- Whole green coffee beans were aspirated to remove light impurities. The beans were roasted to a 'mild roast' using a modified table top roaster at a temperature of 199–216 °C for 10–30 minutes. Samples of dry roasted coffee beans were collected after cooling.
- Roasted coffee beans were ground using a disc mill and sifted using a sifter equipped with 18 and 36 mesh sieves. Material below the 18 mesh sieve but above the 36 mesh sieve was used for extraction. The ground coffee beans were extracted with water and steam in a pressurised extraction vessel. The exit temperature of the liquid extract was 129–163 °C. The extract was cooled to 13–24 °C in a heat exchanger. The extract was filtered through a 100 mesh screen, centrifuged and screened again using a 120 mesh screen. The resulting coffee extract was concentrated in a vacuum evaporator until the solids content was 15–30%, and then filtered through a 125 mesh screen. The resulting liquor extract was frozen dried and reduced to granules to form frozen dried (instant) coffee. Samples of instant coffee were collected for analysis.
- On completion of processing, samples of roasted coffee beans and instant coffee were frozen immediately and stored frozen before being shipped still frozen to the analytical laboratory.

Samples of dry green coffee beans, roasted coffee beans and instant coffee were analysed using method RAM 305/3. The validated limit of quantification was 0.01 mg/kg. Samples were stored frozen for a maximum period of 1.9 months from sampling to analysis and residues in the processed products are deemed to be stable over the storage period. The results are shown in Table 20. The processing factors are summarized in Table 21.

^a Calculation based on RAC with residues of 0.016 mg/kg

APPRAISAL

Azoxystrobin was first evaluated for toxicology and residues by the JMPR in 2008. The Meeting derived an ADI of 0–0.2 mg/kg bw per day, decided that an ARfD was unnecessary and concluded that the residue definition for plant and animal commodities for compliance with MRL values and for consumer risk assessment was parent azoxystrobin. The compound was re-evaluated for residues by the JMPR in 2011 and 2012.

Azoxystrobin was listed by the Forty-fourth Session of the CCPR for the review of additional MRLs by the JMPR in 2013. The Meeting received information on GAP and residue supervised trials data on pulses, potatoes, coffee beans, barley, oats and sorghum.

Methods of residue analysis

The Meeting received recovery data on analytical methods for coffee beans. After extraction with ethyl acetate, the residues were determined by LC-MS/MS with an LOQ of 0.01 mg/kg.

Results of supervised residue trials on crops

Most trial designs used replicate plots. If two field samples were taken or results of two replicate plots were submitted, the mean value was calculated. From two trials carried out side-by-side the higher residues was chosen.

Pulses

The 2008 JMPR estimated a maximum residue level for azoxystrobin in soya beans, dry of 0.5 mg/kg and an STMR of 0.06 mg/kg. The 2008 assessment based on the US GAP for soya beans at 6 × 0.28 kg ai/ha and a PHI of 14 days.

The use pattern in Germany for field peas, field beans and lupins is one to two applications at 0.25 kg ai/ha, with a spray interval of 14–28 days and a PHI of 35 days. The GAP in France is two foliar applications applied at 0.2–0.25 kg ai/ha with a spray interval of 14 days and a PHI of 35 days for dry peas (including chickpeas), 42 days for dry beans and lupins and 28 days for lentils.

Eight European trials (2 × UK, 4 × France, 2 × Italy) on dry beans were treated twice with 0.2–0.25 kg ai/ha. One additional French trial was treated with 0.13 + 0.2 kg ai/ha. The residues were in dry beans at PHIs of 26–36 days < 0.01 mg/kg (9).

Twenty trials were conducted on dry peas in the UK and in France matching the French and German GAPs. Azoxystrobin was applied twice at a rate of 0.2–0.25 kg ai/ha with a spray interval of 14 days. Samples of dry pea seed were collected at normal commercial harvest at PHIs of 30–45 days. If results of two replicate plots were submitted, the mean value was calculated. From two trials carried out side-by-side the higher residues were chosen for evaluation. The residues (n=20) were < 0.01 (8), 0.01 (5), 0.015, 0.015, 0.02, 0.025, 0.03, 0.03 and 0.065 mg/kg.

The Meeting estimated a maximum residue level of 0.07 mg/kg and an STMR 0.01 mg/kg for azoxystrobin residues in pulses, dry except soya beans.

Potato

The 2008 JMPR estimated a maximum residue level for azoxystrobin in root and tuber vegetables of 1 mg/kg, an STMR of 0.23 mg/kg and a highest residue of 0.45 mg/kg. The 2008 assessment based on the US GAP for root vegetables at 6×0.37 kg ai/ha.

Azoxystrobin is registered in the USA for one post-harvest application at 0.49 g ai/100 kg tubers. Six trials were submitted with one application of 0.44–0.50 g ai/100 kg tubers. Samples were taken directly after treatment. In three trials, stored tubers were analysed also (0–59; 0–61 and 0–231 days after treatment). The maximum residues from samples taken after treatment and after storage were 1.0, 1.5, 2.3, 2.3 and 3.8 mg/kg.

The current Meeting estimated for azoxystrobin residues in potato a maximum residue level of 7 mg/kg Po and an STMR of 2.3 mg/kg. The previous recommendation of 1 mg/kg azoxystrobin for root and tuber vegetables was withdrawn. For root and tuber vegetables, except potatoes, the Meeting confirmed the previous recommendation.

Barley and oats

The 2008 JMPR estimated a maximum residue level for azoxystrobin in barley and oats of 0.5 mg/kg and an STMR of 0.08 mg/kg based on the European GAP and residue data.

Azoxystrobin is registered in the USA in barley and oats as foliar spray with 2×0.15 kg ai/ha, a PHI in days for grain was not specified. The recommended use pattern is for a single early season application followed by a single application at 50% to full flag leaf emergence. New residue data were received for barley and oats.

On barley, seven independent supervised trials were conducted. In each trial, azoxystrobin was applied twice at a rate of 0.15 kg ai/ha. The residues in grains were 0.014, 0.019, 0.037, 0.05, 0.19, 0.31 and 0.99 mg/kg.

On oats, twelve supervised trials were submitted treated at a rate of 0.15 kg ai/ha. The residues in grains were 0.013, 0.028, 0.028, 0.028, 0.048, 0.049, 0.053, 0.058, 0.06, 0.12, 0.12 and 0.63 mg/kg.

The Meeting noted that the populations of azoxystrobin residues in grains of barley and oats have similar distributions and can be combined (n=19): 0.013, 0.014, 0.019, 0.028, 0.028, 0.028, 0.037, 0.048, 0.049, 0.05, 0.053, 0.058, 0.06, 0.12, 0.12, 0.19, 0.31, 0.63 and 0.99 mg/kg.

The current Meeting estimated a maximum residue level of 1.5 mg/kg for azoxystrobin residues in barley and oats to replace the previous recommendation (0.5 mg/kg). An STMR value of 0.05 mg/kg for was estimated.

Sorghum

The US GAP for sorghum is 2×0.28 kg ai/ha with a PHI of 14 days. Twelve independent supervised trials were conducted. In each trial, azoxystrobin was applied three times at a rate of 0.28 kg ai/ha with a 7-day application interval. The residues in grains were 0.48, 1.3, 1.4, 1.4, 1.7, 1.8, 1.9, 2.2, 2.3, 2.8, 4.5 and 8.0 mg/kg.

The Meeting estimated a maximum residue level of 10 mg/kg and an STMR of 1.85 mg/kg for azoxystrobin residues in sorghum grain.

Coffee beans

The 2011 JMPR estimated for azoxystrobin residues in coffee beans a maximum residue level of 0.02 mg/kg and an STMR of 0.01 mg/kg based on the Brazilian residue data and Brazilian GAP of 2×0.15 kg ai/ha (interval 90 days) or 3×0.1 kg ai/ha (interval 60 days) and a PHI of 30 days.

The GAP in Columbia is registered as 3×0.15 kg ai/ha (interval 45 days) and a PHI of 15 days. Seven new trials have been conducted in Brazil, Colombia and Guatemala in 2010/2011 to support the registered use pattern in Colombia. Azoxystrobin was applied three times at a rate of 0.15 kg ai/ha. The residues in green coffee beans were < 0.01 (4), 0.01, 0.01 and 0.015 mg/kg at a PHI of 14–15 days.

Four further Brazilian trials conducted in 2006/2007 and matching the Colombian GAP were reported by the 2011 JMPR (trials M06024, Roncato, 2008). After application of 3×0.15 kg ai/ha and a 14 day PHI, the azoxystrobin residues were < 0.01 mg/kg (4).

In total, the residues of azoxystrobin in green coffee beans matching Colombian GAP were, in rank order (n=11): < 0.01 (8), 0.01, 0.01 and 0.015 mg/kg.

Based on residues data matching Colombian GAP, 0.02 mg/kg were calculated as maximum residue level using the OECD MRL calculator. The Meeting noted that the calculated value is very close to the highest level of 0.015 mg/kg (mean of < 0.01 and 0.02 mg/kg from 2 replicated plots) and proposed rounding up to 0.03 mg/kg.

The current Meeting estimated a maximum residue level of 0.03 mg/kg and an STMR of 0.01 mg/kg for azoxystrobin residues in coffee beans to replace the previous recommendation.

Legume animal feeds

The use pattern in Germany for field peas, field beans and lupins is one to two applications at 0.25 kg ai/ha with a spray interval of 14–28 days. The GAP in France is for dry peas (including chickpeas), dry beans, lentils and lupins two foliar applications at 0.2–0.25 kg ai/ha with an interval of 14 days.

Pea hay or pea fodder (dry)

Twenty trials were conducted on dry peas in the UK and France matching the GAP of France and Germany. Azoxystrobin was applied twice at a rate of 0.2–0.25 kg ai/ha with a spray interval of 14 days. Samples of pea fodder were collected at normal commercial harvest, PHIs of 30–45 days.

Residues found, on fresh weight basis, were (n=20): 0.34, 0.61, 0.62, 0.63, 1.0, 1.4, 1.6, 1.8, 1.8, 2.0, 2.1, 2.3, 3.6, 3.7, 3.8, 3.9, 4.0, 4.8, 7.2 and 18 mg/kg.

The residue values, on dry weight basis, were (88% dry matter): 0.39, 0.69, 0.70, 0.72, 1.1, 1.6, 1.8, 2.0, 2.0, 2.3, 2.4, 2.6, 4.1, 4.2, 4.3, 4.4, 4.5, 5.5, 8.2 and 20 mg/kg.

The Meeting estimated a maximum residue level of 20 mg/kg for azoxystrobin residues in pea hay or fodder (dry) on dry weight basis. The estimated median and highest residue values were 1.9 mg/kg and 18 mg/kg on fresh weight basis or 2.35 mg/kg and 20 mg/kg, respectively on dry weight basis.

Pea vines (green)

Pea vines (green) aren't in international trade and an MRL is not necessary. Nevertheless, the commodity is used as animal feed and the estimation of an STMR and a highest residue values is requested.

In 18 trials conducted on peas in the UK and France matching the GAP of France and Germany for peas (dry), pea vines were sampled. Azoxystrobin was applied twice at a rate of 0.2–0.25 kg ai/ha with a spray interval of 14 days. The highest residue values of pea vines samples

collected at PHIs of 2 to 30 days after treatment were selected for the evaluation. The residues were on fresh weight basis (n=18): 0.89, 1.3, 1.4, 1.5, 1.8, 2.6, 3.1, 3.1, 3.3, 3.4, 4.1, 4.5, 4.8, 4.8, 4.9, 5.6, 5.8 and 9.4 mg/kg.

The Meeting estimated a median and a highest residue of 3.35 and 9.4 mg/kg (fresh weight) equivalent to 13.4 and 37.6 mg/kg (25% dry weight basis) for azoxystrobin residues in pea vines.

Straw and fodder (dry) of cereal grains

Based on GAP and residue data for barley, oats, rice, rye, triticale and wheat straw, the 2008 JMPR estimated a maximum residue level for straw and fodder of cereal grains, except maize of 15 mg/kg, an STMR of 1.7 mg/kg and a highest residue value of 11 mg/kg on dry weight basis.

Azoxystrobin is registered in the USA in barley and oats as foliar spray with 2×0.15 kg ai/ha and a 7-days PHI for forage and hay. New trials are available for barley straw, oats straw, barley hay and oats hay matching the US GAP. The straw samples were taken at grain harvest 16 – 49 days after treatment. Samples of hay were taken 6 - 7 days after treatment.

The residues in barley straw on fresh weight basis (n=7) were 0.18, 0.28, 0.36, 0.70, 2.6, 3.3 and 3.5 mg/kg; this is equivalent to 0.20, 0.31, 0.40, 0.79, 2.9, 3.7 and 3.9 mg/kg (dry weight, based on 89% dry matter).

The residues in oats straw on fresh weight basis (n=12) were: 0.074, 0.075, 0.088, 0.15, 0.30, 0.31, 0.35, 0.62, 0.70, 0.73, 0.88 and 1.3 mg/kg; this is equivalent to 0.082, 0.083, 0.098, 0.17, 0.33, 0.34, 0.39, 0.69, 0.78, 0.81, 0.98 and 1.4 mg/kg (dry weight, based on 90% dry matter).

The residues in barley hay on fresh weight basis (n=7) were: 0.46, 0.69, 0.76, 0.84, 2.1, 3.2 and 3.7 mg/kg; this is equivalent to 0.52, 0.78, 0.86, 0.95, 2.4, 3.6 and 4.2 mg/kg (dry weight, based on 88% dry matter).

The residues in oats hay on fresh weight basis (n=12) were: 0.20, 0.27, 0.53, 0.66, 0.89, 1.1, 1.3, 2.2, 3.0, 3.1, 3.2 and 3.4 mg/kg; this is equivalent to 0.22, 0.30, 0.59, 0.73, 0.99, 1.2, 1.4, 2.4, 3.3, 3.4, 3.6 and 3.8 mg/kg (dry weight, based on 90% dry matter).

The Meeting noted that the residues in straw and fodder of barley and oats resulting of azoxystrobin treatment according to US GAP were covered by the MRL recommendation of the 2008 JMPR for straw and fodder of cereal grains, except maize of 15 mg/kg (90% dry matter). The estimated median residue value was 1.5 mg/kg (fresh weight) equiv. to 1.7 mg/kg (dry weight) and the highest value 9.9 mg/kg (fresh weight) equiv. to 11 mg/kg (dry weight). A new estimation of a maximum residue level, a median and a highest residue was not necessary. Because residue data on sorghum show higher residues, the commodity “straw and fodder of cereal grains, except maize” should be revised to “Straw and fodder (dry) of cereal grains, except maize and sorghum”. The previous recommendation for “Straw and fodder of cereal grains, except maize” should be withdrawn.

The US GAP for sorghum is 2×0.28 kg ai/ha with a PHI of 14 days. Twelve trials on sorghum stover, dry, matching the US GAP were submitted. The residues on fresh weight basis (n=12) were: 0.39, 0.53, 0.71, 2.4, 2.6, 3.7, 4.0, 4.5, 4.8, 5.3, 10.5 and 14.5 mg/kg; this is equivalent to 0.44, 0.60, 0.81, 2.7, 2.95, 4.2, 4.5, 5.1, 5.5, 6.0, 12 and 16 mg/kg (dry weight, based on 88% dry matter).

The Meeting estimated maximum residue level of 30 mg/kg for azoxystrobin residues in sorghum straw and fodder, dry on dry weight basis. The estimated median residue value was 3.85 mg/kg (fresh weight) equiv. to 4.35 mg/kg (dry weight) and the highest residue 14.5 mg/kg (fresh weight) equiv. to 16 mg/kg (dry weight).

Cereal forage (green)

Residue data were received for oat and sorghum forage (green). Because these aren't commodities in international trade, MRLs are not necessary. Nevertheless, the commodities are used as animal feed and the estimation of STMRs and highest residue values is requested.

Oats forage (green)

Azoxystrobin is registered in the USA in oats as foliar spray with 2×0.15 kg ai/ha and a 7-days PHI for forage and hay. Twelve trials are available for oats forage matching the US GAP. The residues on fresh weight basis (n=12) were: 0.11, 0.20, 0.26, 0.44, 0.52, 0.78, 0.86, 0.95, 1.0, 1.4, 1.6 and 2.0 mg/kg.

The 2008 JMPR estimated a median residue value of 1.7 mg/kg and a highest value of 4.0 mg/kg for oats forage (fresh weight). The current Meeting noted that the residues in oats forage resulting of azoxystrobin treatment according to US GAP are covered by the estimation of the 2008 JMPR.

Sorghum forage (green)

The US GAP for sorghum is 2×0.28 kg ai/ha with a PHI of 14 days for grain. Supervised residue trials conducted included residue data for forage from 3 to 21 days after treatment. The residues on fresh weight basis (n=14) were: 0.25, 0.27, 0.29, 0.32, 1.5, 1.5, 1.6, 1.6, 1.7, 1.9, 5.6, 7.2, 11 and 12 mg/kg.

The Meeting estimated a median and a highest residue value of 1.6 and 12 mg/kg (fresh weight) equivalent to 4.6 and 34 mg/kg (35% dry weight basis) for azoxystrobin residues in sorghum forage (green).

Fate of residues during processing

The Meeting received information on the fate of azoxystrobin residues during the processing of potatoes to flakes, chips and wet peel, sorghum to aspirated grain fractions and green coffee to roasted and instant coffee.

The processing factors obtained in the processing studies and estimated STMR-P values are summarized below.

Raw agricultural commodity (RAC)		Processed commodity		
Name	STMR, mg/kg	Name	Processing factor	STMR-P, mg/kg
Potato	2.3	Flakes	< 0.011	0.0253
		Chips	0.012	0.0276
		Wet peel	0.904	2.08
Barley	0.05	Barley malt	0.10 ^a	0.005
		Barley spent grain	0.15 ^a	0.0075
		Beer	0.03 ^a	0.0015
Sorghum	1.85	Aspirated grain fractions	50	92.5
Coffee beans, green	0.01	Roasted coffee beans	0.625	0.006
		Instant coffee	1.06	0.0106

^a Estimated by JMPR in 2008

Farm animal dietary burden

The 2013 JMPR evaluated residues of azoxystrobin in the following animal feed items: pulses, potato, cereal grains (barley, oats, sorghum), legume animal feeds as well as straw, fodder and forage of cereal grains which are listed in the OECD feeding table.

Estimated maximum and mean dietary burdens of farm animals

Dietary burden calculations based on the feed items evaluated by the JMPR in 2008 and 2013 for beef cattle, dairy cattle, broilers and laying poultry as presented in Annex 6. The calculations were made according to the livestock diets, in the OECD table, from Australia, the EU, Japan and US-Canada. The following table below shows the values calculated by the 2008 JMPR and by the current Meeting.

	Livestock dietary burden, azoxystrobin, ppm of dry matter diet (calculation 2008/2013)							
	Japan		US-Canada		EU		Australia	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	-/0.96	-/0.96	34/17	15/12	55/61	19/25	58/72	32/51 ^c
Dairy cattle	-/16.3	-/2.97	33/30	16/12	72 ^a /74	27 ^b /29	39/45.5	20/20
Poultry – broiler	-/1.4	-/1.4	0.44/1.7	0.44/1.7	0.62/2.2	0.40/1.9	0.59/1.7	0.59/1.7
Poultry – layer	-/1.4	-/1.4	0.44/1.7	0.44/1.7	23 ^d /21	9.1 ^e /9.5	0.59/1.7	0.59/1.7

^a Highest maximum beef or dairy cattle burden suitable for MRL estimates for mammalian meat, edible offal and milk

^b Highest mean dairy cattle burden suitable for STMR estimates for milk

^c Highest mean beef or dairy cattle burden suitable for STMR estimates for mammalian meat and edible offal

^d Highest maximum poultry broiler or layer burden suitable for MRL estimates for poultry meat and eggs

^e Highest mean poultry broiler or layer burden suitable for STMR estimates for poultry meat and eggs

Animal commodity residue levels

The Meeting noted that the new estimation did not result in a significant change of the dietary burdens of farm animals, except the mean burden for beef cattle what increased from 32 ppm in 2008 to 51 ppm in 2013 (factor 1.59).

The 2008 JMPR calculated for a dietary burden of 32 ppm mean residues of 0.013 mg/kg in liver, < 0.01 mg/kg in kidney and 0.01 mg/kg in fat. The estimated STMR values were 0.01 mg/kg for meat (fat) and edible offal from mammals other than marine mammals.

The table below shows the recalculation of the STMR values for meat (fat) and edible offal for mammals, other than marine mammals based on the results of the cattle feeding studies evaluated by the 2008 JMPR and the new dietary burden calculation.

	Mean estimated azoxystrobin concentrations (STMR, mg/kg)			
Beef cattle	Muscle	Liver	Kidney	Fat
Dietary burden (51 ppm)	< 0.01	0.02	< 0.01	0.015
Feeding level [25 ppm]	< 0.01	< 0.01	< 0.01	< 0.01
Feeding level [75 ppm]	< 0.01	0.03	0.01	0.02

The current Meeting calculated mean residues of 0.02 mg/kg in liver and < 0.01 mg/kg in kidney, < 0.01 mg/kg in muscle and 0.015 mg/kg in fat. The estimated STMR values were 0.02 mg/kg for edible offal (mammalian), 0.01 mg/kg for muscle and 0.015 mg/kg for fat.

The previous MRL recommendations for animal commodities and the STMRs for whole milk, milk fat, poultry meat (fat), poultry edible offal and eggs were maintained.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

*Definition of the residue (for compliance with the MRL and for estimation of dietary intake)
for plant and animal commodities: azoxystrobin.*

The residue is fat-soluble.

CCN	Commodity name	MRL, mg/kg		STMR or STMR-P mg/kg
		Proposed	Previous	
GC 0640	Barley	1.5	0.5	0.05
SB 0716	Coffee beans	0.03	0.02	0.01
GC 0647	Oats	1.5	0.5	0.05
AL 0072	Pea hay or fodder (dry) ^a	20 ^a		1.9 ^b
VR 0589	Potato	7 Po		2.3 Po
VD 0070	Pulses, dry, except soya beans	0.07		0.01
VR 0075	Root and tuber vegetables	W	1	0.23
VR 0075	Root and tuber vegetables, except potato	1		0.23
GC 0651	Sorghum	10		1.85
AS 0651	Sorghum straw and fodder, dry	30 ^a		3.85 ^b
AS 0081	Straw and fodder of cereal grains, except maize and sorghum	15 ^a		1.5 ^b
AS 0081	Straw and fodder of cereal grains, except maize	W

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of azoxystrobin were calculated for the 13 GEMS/Food cluster diets using STMRs and STMR-Ps estimated by the JMPR in 2008, 2011, 2012 and 2013. The results are shown in Annex 3 of the 2013 JMPR Report.

The ADI is 0–0.2 mg/kg bw and the calculated IEDIs were 2–10% of the maximum ADI. The Meeting concluded that the long-term intake of residues of azoxystrobin resulting from the uses considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The 2008 Meeting decided that an ARfD for azoxystrobin is unnecessary and concluded that the short-term intake of residues resulting from the use of azoxystrobin is unlikely to present a public health concern.

BENTAZONE (172)*First draft prepared by Dr Yibing He,**Department of Science and Education, Ministry of Agriculture, China***EXPLANATION**

Bentazone, a post-emergence herbicide, was originally evaluated by the JMPR in 1991 and re-evaluated for residues and toxicity several times up to 2004. It was reviewed as part of the periodic re-evaluation programme of CCPR on toxicity by the 2012 JMPR. Bentazone is a selective herbicide which is used at post emergence applications to control dicotyledonous weeds in agriculture, horticulture, ornamentals and amenity grasslands. The mode of action is based primarily on an irreversible blockage of the photosynthetic electron transport and in further consequence the inhibition of photosynthesis at photo system II. As a result of this reaction, CO₂ assimilation is suppressed and after a short period of growth stagnation, the plant dies.

At the 43rd Session of the CCPR (REP 12/PR, Appendix VIII), bentazone was scheduled for periodic residue review by the 2013 JMPR. The Meeting received information on physical and chemical properties, metabolism, environmental fate, analytical methods and freezer storage stability, national registered use patterns, as well as supervised trials, processing studies and livestock feeding studies.

IDENTITY

ISO Common name	bentazone
Chemical name	
IUPAC name	3-isopropyl-1H-2,1,3-benzothiadiazin-4(3H)-one 2,2-dioxide
CAS name	3-(1-methylethyl)-1H-2,1,3-benzothiadiazin-4(3H)-one 2,2-dioxide
CAS Registry Number	25057-89-0
CIPAC Number	366
Synonyms and trade names	
Manufacturer's codes	51929

Structural formula

Molecular formula	C ₁₀ H ₁₂ N ₂ O ₃ S
Molecular weight	240.3 g/mol
Minimum content of ai

Animal metabolism

The Meeting received animal metabolism studies with bentazone in lactating goats and laying hens.

Lactating goats

[¹⁴C] Bentazone

Three lactating goats were dosed orally with [¹⁴C] bentazone once daily for 5 or 8 consecutive days at the nominal equivalent rate of 3 (goat A) or 50 (goat B1 and B2) mg ai/kg bw, corresponding to residue levels in feed of 123 (goat A), 1420 (goat B1) and 1580 (goat B2) mg ai/kg animal feed respectively (Giese, U, 1990, 1992/10161; Großhans, F, 1991, 1991/11137). During the administration period blood, milk, urine and faeces were collected. 24 hours after the last administration the goat was sacrificed and liver, kidney, muscle, fat, bile and GIT were obtained. Two further goats were dosed for 8 days with 3 mCi per day corresponding to about 1.7 g of the test substance (nominally 50 mg/kg; 1.42–1.58 g bentazone/kg feed). The animals were sacrificed 4 hours after the last administration and liver, kidney, muscle, fat, bile and GIT of one goat were obtained for determination of radioactivity. Goat B2 was regarded as a reserve animal intended to be used for method development and adaptation work, but it was not included in this study. Samples were stored at -18 °C or below until analysis. Residues were analysed for radioactivity by LSC or combustion/LSC. The amount of the excreta, milk, and edible tissues, and after extraction and liquid-liquid partition they were analysed by TLC and PLC. Metabolites were identified by MS. The results are summarized in Table 1 and Table 2.

[^{14}C]-6-hydroxy-bentazone

Two lactating goats were orally dosed daily for 5 or 6 consecutive days with [^{14}C]-6-hydroxy-bentazone, which was uniformly labelled in the ring (specific activity, 1.439 mBq/mg; radiochemical purity, 97.2%) (Giese, U, 1991, 1991/10702; Hafemann, C, 1995, 1995/10011). A goat was administered orally about 1.5 mCi [^{14}C]-6-hydroxy-bentazone per day corresponding to about 84 mg 6-hydroxy-bentazone (nominally 2 mg/kg, 40.5 mg 6-hydroxy-bentazone/kg feed) for 5 consecutive days. During the administration period blood, milk, urine and faeces were collected. 24 hours after the last administration the goat was sacrificed and liver, kidney, muscle, fat, bile and GIT were obtained. Another goat was dosed for 6 days with 3 mCi per day corresponding to about 1.7 g of the test substance (nominally 40 mg/kg; 970 mg 6-hydroxy-bentazone/kg feed). The animal was sacrificed 4 hours after the last administration and liver, kidney, muscle, fat, bile and GIT were obtained for determination of radioactivity. The faeces, urine and milk samples were stored at -18 °C. Residues were analysed for radioactivity by LSC or combustion/LSC. The concentrations of 6-hydroxy-bentazone were too low in goat A to obtain significant radioactivity peaks by chromatography of the extracts. The isolated metabolites in goat B were chromatographically characterized. The results are summarized in Table 3 and Table 4.

[^{14}C]-8-hydroxy-bentazone

Two lactating goats were orally dosed daily for 5 or 6 consecutive days with [^{14}C]-8-hydroxy-bentazone, which was uniformly labelled in the ring (specific activity, 1.390 mBq/mg; radiochemical purity, 95.4%) (Giese, U, 1991, 1991/10703; Kohl, W, 1995, 1995/10062). A goat was administered orally about 1.5 mCi [^{14}C]-8-hydroxy-bentazone per day corresponding to about 69 mg 8-hydroxy-bentazone (nominally 2 mg/kg, 41.7 mg 8-hydroxy-bentazone/kg feed) for 5 consecutive days. During the administration period blood, milk, urine and faeces were collected. 24 hours after the last administration the goat was sacrificed and liver, kidney, muscle, fat, bile and GIT were obtained. Another goat was dosed for 6 days with 3 mCi per day corresponding to about 1.8 g of the test substance (nominally 40 mg/kg; 731.6 mg 8-hydroxy-bentazone/kg feed). The animal was sacrificed 4 hours after the last administration and liver, kidney, muscle, fat, bile and GIT were obtained for determination of radioactivity. The faeces, urine and milk samples were stored at $-18\text{ }^{\circ}\text{C}$ or below. Residues were analysed for radioactivity by LSC or combustion/LSC. The isolated metabolites in goat B were chromatographically characterized. The results are summarized in Table 5 and Table 6.

Laying hens

[^{14}C]-Bentazone, 6-OH-[^{14}C]-bentazone and 8-OH-[^{14}C]-bentazone were each administered orally by gelatine capsule to separate groups of 10 laying hens (*Gallus gallus domesticus*) once daily for 5 consecutive days at the nominal rate of 10 mg/bird/day (Hawkins, DR, 1988, 1988/0432). The test substance was uniformly labelled in the ring (bentazone: specific activity, 43.68 mCi/mg, radiochemical purity, 99%; 6-OH-bentazone: specific activity, 42.98 mCi/mg, radiochemical purity, 99%; 8-OH-bentazone: specific activity, 40.91 mCi/mg, radiochemical purity, > 99%). The treated hens were separated into six cages of five hens each. Four hens were used as a control group. All birds were sacrificed 6 hours after the final dose. All samples were stored at -15 °C or below until taken for analysis. Radioactivity was measured by liquid scintillation counting (LSC) and the nature of

radioactivity in excreta, eggs and tissues was investigated further. The levels of radioactivity in the tissues and eggs of hens from 6-OH-bentazone and 8-OH-bentazone groups were generally too low for analysis. The results are summarized in Table 7 and Table 8.

Plant metabolism

The Meeting received plant metabolism studies with bentazone on soya beans, rice, maize, green beans, potatoes and wheat.

Soya bean

The metabolism of [^{14}C]-bentazone (uniformly labelled with ^{14}C in the phenyl ring, specific activity, 42.4 $\mu\text{Ci}/\text{mg}$; chemical and radiochemical purity > 99%) was studied in soya bean (variety: Centenial) after single and double applications at 2.24 and 1.68 (1.12) kg/ha (Brown, M, *et al.*, 1987/5079). Forage (foliage) at early and late pre-harvest intervals (PHI), hay and seed samples were collected for metabolism investigations. Radioactivity was measured by liquid scintillation counting (LSC) and the nature of radioactivity in interim and harvest samples was investigated further with TLC and GLC. The results are summarized in Table 9 to Table 12.

Rice

A metabolism study in rice (variety: *Nihonbare*) was conducted with [^{14}C] bentazone (uniformly labelled with ^{14}C in the phenyl ring, specific activity, 43.68 $\mu\text{Ci/mg}$; radiochemical purity > 99%) at a rate of 1 kg ai/ha in a single treatment after development of the first rice shoots (Huber, R and Schepers, U, 1987, 1987/0420). Plant parts of the rice were sampled at 0 and 26 days after application of bentazone. In the final harvest samples, the grains, glumes, awns, straw and roots were divided for analysis. Radioactivity was measured by liquid scintillation counting (LSC) and the nature of radioactivity in interim and harvest samples was investigated further with radio-TLC, radio-HPLC and GC-MS. The results are summarized in Table 13 and Table 14.

^b Residue values were determined by HPLC analysis

^c None of these fractions accounted for > 6% of the TRR

^d Radioactive residues in the lignin pool were determined using three different lignin extraction procedures. Values for lignin and cellulose fractions are taken from the Honeycutt/Alder lignin extraction procedure.

*do not represent "bound residues", as by IUPAC-definition

Figure 2 Flow diagram of the metabolism of bentazone in rice

Maize

The metabolism of an aqueous solution of the sodium salt of [^{14}C] bentazone (uniformly labelled with ^{14}C in the phenyl ring, specific activity, 189.35 $\mu\text{Ci}/\text{mg}$; radiochemical purity > 98%) equivalent to 1.68 kg/ha of bentazone was investigated in maize (variety: *Michigan 407-2x*) (Clark, JR, Hoehne, C and Huber, R, 1976, 1976/5060). Whole plant samples (without roots) were removed from the plots at 0, 7, 14, 21, 42, 63 and 126 days (final harvest) after the application of bentazone. All plant samples were frozen soon after collection and shipped with dry ice to the metabolism laboratory for analysis. In the final harvest samples, the grain, cobs, husks and stover were separated before analysis. Radioactivity was measured by liquid scintillation counting (LSC) and the nature of radioactivity in interim and harvest samples was investigated further with GLC. The results were summarized in Table 15.

Green beans

The metabolism of [^{14}C]-bentazone (uniformly labelled with ^{14}C in the phenyl ring, specific activity, 9.885 mCi/mMole or 91.4 dpm/mg; radiochemical purity 99.7%, chemical purity 99.6%) was studied in green beans (variety: *Bluelake*) after single and double applications at 2.24 and 1.68 kg ai/ha (Clark, J, and Winkler, V, 1988, 1988/5543). Foliage, succulent beans, hay and seeds was collected or harvested at various PHIs. The samples were immediately placed in a cooler containing dry ice. After transport to the laboratory the samples were immediately put into -20 °C freezers. Radioactivity was measured by liquid scintillation counting (LSC). The results are summarized in Table 16.

Table 16 Percent of applied [^{14}C] bentazone remaining in plant parts after single and double applications

Potatoes

The metabolism of [¹⁴C]-bentazone (uniformly labelled with ¹⁴C in the phenyl ring, specific activity, 96967 dpm/μg; radiochemical purity 98.73%) was investigated in potatoes (variety: *Grata*) in 1989 (Hofmann, M, 1989, 1989/10248). Ten potato plants were each treated twice at 1.12 kg ai/ha. Samples of leaves were taken 4 hours after the first application as well as shortly before and 4 hours after the second application. The potatoes were harvested 41 days after the last application. All samples were stored in a freezer at -20 °C. Radioactivity was measured by liquid scintillation counting (LSC). At harvest time the total radioactive residues (TRR) of potatoes and potato tops were 0.156 mg eq/kg and 29.4 mg eq/kg, respectively.

The further metabolism study on potatoes (variety: *Grata*) was conducted with [14C] bentazone (uniformly labelled with ¹⁴C in the phenyl ring, specific activity, 96967 dpm/μg; both chemical and radiochemical purity > 99%) in 1994 (Ellenson, JL, 1994, 1994/5106). Foliar spray application of the parent compound was made at pre-harvest intervals of 62 and 41 days using two equal 1.12 kg ai/ha treatments. The samples were collected and stored in a freezer at -20 °C. Fractionation and residue analyses were carried out separately on peels and pulp. Separate peel and pulp freeze-dried samples were first extracted with methanol and then DCM. The residual slurries were partially hydrolysed with 3 N HCl and basified with NaOH. The slurries were partitioned with DCM, re-acidified with HCl and partitioned with ethyl acetate. The final slurry was neutralized, centrifuged, and separated into insoluble material, aqueous fraction, and ethyl acetate fraction which was combined with the previous ethyl acetate fraction. The aqueous fraction was further concentrated by evaporation and filtered, resulting in a final aqueous fraction and a filter residue which was combined with the marc fraction. Radioactivity was measured by liquid scintillation counting (LSC) and the nature of radioactivity in samples was investigated further with HPLC. The results were summarized in Table 17 and Table 18.

Wheat

The metabolism of [^{14}C] bentazone (uniformly labelled with ^{14}C in the phenyl ring, specific activity, 18.1 317400 dpm/ug; radiochemical purity 97.3%, chemical purity 95.2%) was investigated in wheat (Rabe, U, Kloeppner, U, 2011, BASF DocID 2010/1062115).

Wheat (variety: *Thassos*) was grown in plastic containers located in a phytotron and treated with one foliar application of [^{14}C] bentazone at BBCH growth stage 31–32. The active substance was applied once at an application rate of 1 kg ai/ha, representing the critical GAP. Samples of wheat forage and hay were collected at BBCH 39 (20 days after application) and samples of grain, chaff and straw were sampled at BBCH 89 (83 days after application). All samples were stored in a freezer at, or below, $-18\text{ }^{\circ}\text{C}$ immediately after they were collected until analysis.

Prior to extraction and determination of the total radioactive residues (TRR), subsamples of wheat chaff and grain were homogenised. Frozen subsamples of all other matrices were mixed with dry ice and homogenised. The homogenised material was transferred into polycarbon boxes and stored at $-18\text{ }^{\circ}\text{C}$ or below. In order to determine the TRR values by combustion analysis, small aliquots of the homogenised subsamples were combusted to $^{14}\text{CO}_2$. Subsamples of homogenised plant material were extracted three times with a sufficient volume of methanol. After each extraction step, the liquid phase was separated from the solid, and the remaining plant material was subjected to the next extraction step. The methanol extracts of the three steps were combined, adjusted to a defined volume and measured by liquid scintillation counting (LSC). The residue was extracted two additional times in the same way with appropriate volumes of water. The aqueous extracts were also combined, adjusted to a defined volume with water, and aliquots of the combined aqueous extract were radio-assayed by LSC. Results of methanol and water extractions are referred to as extractable radioactive residues (ERR). The residue after solvent extraction (methanol and water) of each sample was deep frozen and freeze dried, and the weight of the remaining sample was determined. The samples were homogenised prior to combustion analysis of aliquots for the determination of the residual radioactive residues (RRR). The total radioactive residues (TRR) were the result of the combustion of aliquots or the sum of ERR and RRR values. Samples of forage, straw and grain were homogenized in liquid nitrogen, combusted and radio-assayed by liquid scintillation counting (LSC). The LOQ was 0.001 mg/kg, 0.002 mg/kg and 0.0003 mg/kg in wheat forage, straw and grain, respectively. The TRR in samples are summarized in Table 19. Identification and quantification of extractable residues in wheat matrices are summarized in Table 20. Characterisation of the residual radioactive residues after solvent extraction in wheat matrices are summarized in Table 21.

^a For wheat straw, chaff and grain additional solubilisation steps were performed. In all cases sodium hydroxide solution released the highest amount of radioactivity from the respective residual material. Therefore the radioactive residues after sodium hydroxide solubilisation are cited as the final residue for these matrices.

Based on the identified metabolites the proposed metabolic pathway of bentazone in wheat involves the hydroxylation of the benzothiadiazine ring. The hydroxyl groups were subsequently glycosylated generating the metabolites M351H013 and M351H017. In addition, the benzothiadiazine ring was conjugated with monosaccharide/disaccharide at the nitrogen atom at position one. Further metabolism lead to the degradation of the carbon skeleton of bentazone and re-assimilation into natural compounds like carbohydrates. The proposed metabolic pathway for bentazone in wheat is shown in Figure 3.

* Not detected as free metabolites in wheat matrices

Figure 3 Proposed metabolic pathway of bentazone in wheat

Environmental fate in soil

The Meeting received information on the environmental fate of bentazone in soil, including studies on soil metabolism, and crop rotational studies.

Soil metabolism (aerobic degradation)

The aerobic soil metabolism of bentazone was investigated in a sandy loam (pH 7.3, 1.23% OC) freshly collected from the field and passed through a 2 mm sieve before use (Staudenmaier, H and

Kuhnke, G, 2010, 2010/1057318). The soil was treated with [^{14}C -phenyl]-bentazone (5.15 MBq/mg, radiochemical purity 96.5%) at a nominal rate of 2.7 mg per kg dry soil which corresponds to a field application rate of 1000 g bentazone per hectare, calculated on the basis of an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g/cm³.

Soil aliquots of 100 g (dry weight basis) were weighed into test vessels and incubated in the dark under aerobic conditions at soil moisture of 40% of the maximum water holding capacity and a temperature of 20 °C. A closed incubation system with continuous aeration (moistened air) was used with an attached trapping system for the collection of volatile compounds. At two time points during incubation (57 and 126 DAT), the microbial biomass was determined by the substrate induced respiration method, verifying that the soil was viable throughout the incubation period. Samples were taken at 0, 1, 3, 7, 14, 30, 64, 91, 120 and 150 days after treatment. At sampling times 0, 30, 120 and 150 DAT, soil samples were worked up in duplicate.

The soil samples were extracted twice with methanol and twice with water/methanol (v:v, 1:1). The amount of radioactivity in the individual extracts was determined by liquid scintillation counting. The methanol and water/methanol extracts per soil sample were combined, respectively, and analysed by means of HPLC. The remaining soil was homogenized and combusted after extraction to determine the amount of non-extractable residues (NER) in soil. The NER were further characterized by NaOH extraction and subsequent fractionation into fulvic acids, humic acids and humins. The fulvic acid fraction was furthermore partitioned with ethyl acetate. A full material balance was provided for each sampling interval. The results showed that the amount of extractable radioactivity in soil continuously decreased from 102.2% of the total applied radioactivity (TAR) at 0 DAT to 6.9% TAR after 150 days of incubation. The amount of the test item bentazone decreased from 101.0% TAR at 0 DAT to 2.3% TAR at 150 DAT. Metabolites were formed only in minor amounts of which the most prominent metabolite (max. 2.8% TAR) was identified as N-methyl-bentazone (M351H009). All other metabolites were formed in even lower amounts and their sum in the total extracts never exceeded 2.2% TAR at any sampling time. Mineralization to ^{14}C -CO₂ reached a total of 9.0% TAR after 150 days of incubation. No other volatile compounds were detected.

Non-extractable radioactive residues were formed in considerable amounts during incubation. They increased from 3.3% TAR on day 0 to a maximum of 68.8% TAR after 150 days. After extraction with NaOH, still about half of the radioactivity (2.3–34.8% TAR) remained tightly bound to the soil matrix (humines). The NaOH extractable radioactivity was distributed between the humic acid (1.0–11.9% TAR) and the fulvic acid fraction (2.7–21.0% TAR) in a ratio of about 1:2. The fulvic acid fraction was further characterized by partitioning with ethyl acetate. Amounts of 1.6 to 7.3% TAR of the fulvic acid fraction were soluble in ethyl acetate, whereas 0.9 to 13.1% TAR remained in the water phase. The ethyl acetate soluble fractions from samples of 30 DAT to 120 DAT were investigated by HPLC. Parent compound was found to be the most prominent peak, accounting for 3.0 to 3.7% TAR. The material balance throughout the incubation period ranged from 92.6 to 105.5% TAR except for the 150 DAT sampling, for which a material balance of only 84.7% TAR was achieved. The average material balance for all soil samples was 98.0% TAR. Results are presented in Table 22 to Table 25.

120	7.3 (0.195)	3.0 (0.081)	4.3 (0.114)

The degradation rate of bentazone under aerobic conditions was investigated in four different soils (Bruch West: 1.37% OC, pH 7.8; Li 10: 0.97% OC, pH 6.8; LUFA 2.2: 0.15% OC, pH 6.2; LUFA 2.3: 0.98% OC, pH 7.4) at a temperature of 20 °C (Tornisielo, A, Sacchi, RR, 2011, 2011/1000621). The soils were typical agricultural soils from Germany, freshly collected from the field and passed through a 2 mm sieve before use. The soils were treated with a nominal rate of 2.0 mg ¹⁴C-labelled bentazone (5.29 MBq/mg, radiochemical purity: 97.3%) per kg dry soil which corresponds to a field application rate of 750 g bentazone/ha, assuming equal distribution in the upper 2.5 cm soil layer and a soil density of 1.5 g/cm³.

The incubations were carried out under dark conditions at soil moisture of 40% of the maximum water holding capacity. A closed incubation system with continuous aeration (moistened air) was used with an attached trapping system for the determination of volatile compounds. Samples were taken at 0, 3, 7, 14, 29, 62, 90, and 120 days after treatment. The soil samples were extracted twice with methanol and four times with methanol/water (1:1) and the extracts analysed by means of LSC and HPLC. The amount of non-extractable residues was determined by combustion and subsequent LSC measurements.

The mass balance throughout the study ranged from 91.8 to 113.2% TAR with average values of 98.3 to 100.3% TAR for each soil. The extractable radioactivity decreased from 93.8–100.9% TAR (total applied radioactivity) at day 0 to 6.9–19.4% after 120 days. The majority of radioactivity in the extracts was always unchanged test item. At the end of incubation, bentazone was detected in amounts of 4.8–18.8% TAR. Three metabolites appeared in the chromatograms. By comparison of retention times with the reference substance, one metabolite could be assigned to the known soil metabolite N-methyl-bentazone. It reached maximum amounts of about 5% TAR in soil LUFA 2.2. In all other soils, it never exceeded 2.3% TAR. The other two unknown compounds never exceeded 2.2% TAR at any sampling time. Formation of CO₂ was observed in all four soils reaching in total 9.1 to 21.2% TAR after 120 days. No other volatile compounds were detected. Non-extractable residues were formed in high amounts with a maximum of 63.8 to 92.5% TAR at the end of the study. The distribution of radioactive residues in the different soils treated with ¹⁴C-labelled bentazone at various time intervals from 0 DAT to 120 DAT is shown in Table 26 to Table 29.

Aerobic degradation of relevant metabolites in soils

The aerobic soil degradation of N-methyl-bentazone was investigated in a loamy sand (LUFA Speyer 2.2: 2.29% OC, pH 5.7), a loam (LUFA Speyer 3A: 2.2% OC, pH 7.1) and a clay loam (PTRL soil: 1.31% OC, pH 6.8) (Class, T, 2005, 2005/1026922). The soils were all freshly collected from the field, and sieved through a 2 mm screen. Before treatment, the soil moisture was adjusted to 40–50% of the maximum water holding capacity. The microbial biomass was determined (Anderson & Domsch) after acclimatization, during and at the end of the incubation.

Individual soil samples consisted of 50 g soil (dry weight equivalents) and placed in open incubation flasks covered only partially to allow air exchange, but to prevent excessive loss of soil humidity. The incubations were kept in the dark at 20 ± 2 °C. Non-labelled N-methyl-bentazone was dosed at 0.64 mg / kg or 32 µg per 50 g (dry-weight) soil incubation. This dose was calculated assuming a bentazone application rate of 1.5 kg/ha and a resulting metabolite formation of max. 0.32 kg/ha, corresponding to an initial concentration of 0.64 mg/kg dry soil.

Soil samples were taken and analysed for remaining N-methyl-bentazone after the following incubation periods: 0 (in duplicate), 1, 2, 3, 4, 6, 8, 15, 30, 37, 60 (duplicate), 90, 120 (duplicate), 150 (duplicate), and 181 (duplicate) days. All dosed and incubated soil specimens were extracted, cleaned-up using SPE and analysed right after the respective incubation period, using the ion trap LCQ LC/MS/MS. At the end of the 181-days incubation period, all stored raw soil extracts and the raw extracts obtained from the 21 concurrent recovery soil samples, were diluted 10-fold and analysed without any further SPE clean-up (thus eliminating any potential losses) using the more sensitive triple-quadrupole API 3000 LC/MS/MS instrument. The purpose of these re-analyses was to confirm the degradation data by eliminating day-to-day variations when using the LCQ instrument over the period of 6 months. The results of HPLC-MS analysis (API 3000 LC/MS/MS) are shown in Table 34.

Aerobic degradation in water/sediment

A degradation of [^{14}C] bentazone (43.7 $\mu\text{Ci/mg}$, radiochemical purity > 96%) was investigated in two different water/sediment system under aerobic conditions over a period of 100 days at 20 °C in the dark. Two sediments named “Krempe” (pH 6.9, 2.1% OC) and “Ohlau” (pH 6.4, 0.37% OC) were characterized as sandy and as sand. 0.34 mg test substance were applied per kg water, which is equivalent to an application rate of 1 kg ai/ha (Bieber, WD, 1994, 1994/11026).

Water and sediment samples were taken after the following incubation periods at 0, 0.25, 1, 2, 7, 14, 30, 60 and 100 days. Water samples were acidified and extracted with ethyl acetate. Wet sediment samples were extracted with methanol/water and methanol. The extracts were analysed with LSC, radio-TLC, radio- HPLC or GC-MS. The results are shown in Table 35 to Table 37.

Soil photolysis

The photolytic degradation of [¹⁴C] bentazone (5.15 MBq/mg, radiochemical purity 96.5%) was studied on a sandy clay loam soil (1.85% OC, pH 7.8) (Hassink, J, 2012, 2011/1276919; Hassink, J, 2012, 2012/1023466). [¹⁴C] bentazone was homogeneously applied on the surfaces of soil in 1 cm deep stainless steel dishes at a concentration of 7.207 mg/kg dry soil (equivalent to an application rate of 1081 g ai/ha). The incubation conditions were irradiation from a Xenon lamp (about 3 mW/cm²) at 22 °C for 15 days. Duplicate samples were taken 0, 1, 3, 7, 10 and 15 days after treatment. Dark control samples were analysed at the same sampling days. Volatiles were trapped in appropriate trapping solutions.

Soil samples were extracted with methanol and methanol/water and the extracts analysed by LSC and HPLC. Bound residues were quantified by combustion and subsequent LSC measuring. The bound residues were further characterised by NaOH-extraction and distribution of radioactivity between fulvic acids, humic acids and humines. The overall results for the material balances in the photolysis and the dark control samples were in the range of 95.3–100.3% TAR. Carbon dioxide was the only volatile degradation product trapped with 8.1% TAR detected after 15 days in the photolysis test and 1.8% TAR in the dark control.

The sample extractability for the photolysis test differed from the dark control. At the end of the study about 32% TAR were not extractable from the illuminated soil samples. About 20% TAR were non-extractable at the end of the incubation of the dark control samples. The alkali-soluble radioactivity amounted to about 12–24% in the period of 3 to 15 days after treatment in the soil photolysis and was further fractionated to distinguish between acid-insoluble humic acids and acid-soluble fulvic acids. The major part of the radioactivity could be assigned to the fulvic acid fraction (max. 18.7% TAR at 7 DAT). In the dark control samples the amount of non-extractable residues was less than under light. It was confirmed that the alkali-soluble fraction (max. 12.2% TAR at 15 DAT) consisted of radioactive material mainly assigned to the fulvic acid fraction (max. 6.3% TAR at 15 DAT). HPLC analysis of the fulvic acid fractions showed that the radioactivity is divided between several unspecific polar peaks in negligible amounts. The concentration of bentazone decreased to 48.7% TAR in the course of the photolysis study and to 77.0% in the dark control samples. No degradation products was present in more or equal to 1% TAR, respectively. 4% TAR occurred in the photolysis samples or in the dark controls. The results are shown in Table 38 to Table 45.

The results of the present study showed that sunlight may have an influence on the degradation rate of bentazone in soil. The incorporation into the humic substances was observed to be faster under irradiated than under dark conditions. However, no photo degradates were formed in significant amounts (all peaks < 4%).

Figure 4 Proposed pathway for the degradation of bentazone in soil

Crop rotation studies

Information on the fate of bentazone in follow-on crop studies was made available to the Meeting.

A confined rotational crop study was conducted with U-¹⁴C-phenyl-labelled bentazone (5.29 MBq/mg, radiochemical purity 97.3%) (Radzom, M. *et al.*, 2011, 2010/1143715). The active substance was applied to bare silty loamy sand soil in plastic containers at an application rate of 1 × 1000 g ai/ha using an automatic spray track system. The nature and the level of radioactive residues were investigated in lettuce (immature and mature; Variety: *Matildas*, *Giesela*), white radish (top and root; Variety: *April Cross*) and spring wheat (forage, hay, straw and grain; Variety: *Thasos*) after plant back intervals of 30, 120 and 365 days. Plant samples were harvested at maturity, and additional immature lettuce samples as well as spring wheat forage samples (in part dried to hay) were taken 27 to 40 days and 56 to 74 days after planting or sowing, respectively. Soil (1.86% OC; pH 7.5) samples were taken after ploughing and after harvest of the mature crops for each plant back interval. The sampled material was stored in a freezer. All plant samples were homogenised and the radioactive residues in these samples and in the soil samples were determined by combustion analysis.

Significant translocation of radioactive residues from soil into the plants was observed for the plant back interval of 30 DAT which declined rapidly for longer aging periods of 120 and 365 days. The residue concentration in the top soil layer after aging and ploughing slightly decreased with increasing plant back intervals. The total radioactive residues (TRR) in lettuce (immature and mature samples) did not exceed 0.128 mg/kg for all plant back intervals. The TRR in white radish top was 0.168 mg/kg at a plant back interval of 30 DAT, decreasing to 0.019 mg/kg after 120 DAT and to 0.003 mg/kg (TRR combusted) after 365 DAT. The total radioactive residues in roots of mature crop decreased from 0.128 mg/kg (30 DAT), to 0.012 mg/kg (120 DAT) and finally to 0.001 mg/kg (365 DAT, TRR combusted). In spring wheat, the highest residue levels were measured in hay (ranging from 0.070 to 1.591 mg/kg, for 30 DAT and 365 DAT, respectively) and straw (0.049 to 1.107 mg/kg, for 30 DAT and 365 DAT, respectively). Total radioactive residues in grain accounted for 0.041 to 0.711 mg/kg.

The extractability of the radioactive residues with methanol and water ranged from 43.7% to 71.3% TRR for lettuce and white radish. For spring wheat matrices, the extractability was relatively low with 8.5% to 30.0%, indicating incorporation of radioactivity in plant constituents. The major portions of the radioactive residues were generally extracted with methanol, except for spring wheat grain where similar portions were extracted with methanol and water.

In all the crop matrices analysed, considerable amounts of the radioactive residues were not extractable with methanol and water. The residual radioactive residues after solvent extraction of all matrices of the plant back intervals 30 DAT and 120 DAT were further characterised using a sequential solubilisation procedure including solubilisation with aqueous ammonia, macerozyme/cellulase and glucosidase/hesperidinase. These incubations were, where applicable, followed by treatments with amylase/amyloglucosidase, tyrosinase/laccase, microwave incubation, and treatments with hydrochloric acid and sodium hydroxide. The solubilised residues had possibly been associated with or embedded / incorporated in insoluble plant material (e.g. proteins, cell wall polymers and starch). Analysis of the extracts and solubilisates after solvent extraction using the HPLC resulted for all crops, matrices and DAT intervals in an early eluting peak or peak group. This peak or peak group represented the main component in all matrices and for all aging intervals and was identified as polar fraction. The composition of the polar fraction was further investigated using an HPLC method suitable for saccharide analysis. The main portion of the residues corresponded to glucose, fructose and sucrose (> 50% ROI), showing composition of the polar fraction of carbohydrates.

Bentazone and/or its soil metabolites were taken up by and transformed in the rotational crops primarily into sugars (glucose, fructose and sucrose and further components of similar polarity) which were without exception the most abundant components in all matrices examined (methanol/water extracts and solubilisates after solvent extraction). The unchanged parent molecule was found as minor component in samples of immature (30 DAT) and mature lettuce (30 and 120 DAT) in concentrations of < 0.0013 mg/kg and 1.2% TRR only. Additional medium polar degradation products were detected at even lower concentrations.

RRR residual radioactive residue

Figure 5 Metabolic pathway of [¹⁴C] bentazone in rotational crops

RESIDUE ANALYSIS

Analytical methods

The Meeting received descriptions and validation data for analytical methods for residues of bentazone and the conjugates of 6-OH- and 8-OH-bentazone in plant and animal matrices. Bentazone residues can be measured in most matrices to an LOQ of 0.01 to 0.05 mg/kg. The methods effectively measure 'total' bentazone.

Technical procedure-Method for the determination of Bentazon, 6-OH-Bentazon and 8-OH-Bentazon in plant matrices—Method 438/1. (Linder, G *et al.*, 2000, 2000/1000243)

Analyte:	bentazone, 6-OH-bentazone and 8-OH-bentazone	GC/MSD	Method No. 438/1
LOQ:	0.02 mg/kg		
Description	BASF Method No. 438/1 allows the determination of bentazone and all sugar conjugates which can be hydrolysed to 6-OH-bentazone and 8-OH-bentazone. It is a miniaturised version of the BASF Method No. 438/0 and was adapted to a number of additional crops. Bentazone and its metabolites are extracted from plant matrices with aqueous methanol. After purification of a 20% aliquot by an iso-octane liquid-liquid partition, the two relevant metabolites which are present as glucosides are hydrolysed using enzymatic cleavage to 6-OH-bentazone and 8-OH-bentazone. After a Ca(OH) ₂ -precipitation step to remove acidic plant constituents, a reversed phase C ₁₈ -column clean-up is performed. The analytes are then methylated with diazomethane and their derivatives are purified using a silica gel-column. The final determination of the residues of bentazone and its OH-metabolites is performed by GC-MS.		

Bentazone and its two OH-metabolites: Validation of residue method 438/2 for plant materials using LC/MS/MS. (Class T., 2007, 2007/1013924)

Analyte:	bentazone, 6-OH-bentazone and 8-OH-bentazone	LC-MS/MS	Method No. 438/2
LOQ:	0.01 mg/kg.		
Description	Extraction and enzymatic cleavage of residues of bentazone and its conjugated 6-OH- and 8-OH-metabolites from plant specimen was adopted from BASF Method No. 438/2 which uses GC-MS for the determination of the analytes in plant materials: bentazone and its hydroxy-metabolites present in plant as glucosides were extracted from plant material with aqueous methanol. After purification of an aliquot by liquid-liquid partition with iso-octane, glucosides were cleaved enzymatically to 6-OH-bentazone and 8-OH-bentazone. After $\text{Ca}(\text{OH})_2$ -precipitation of acidic plant constituents, a reversed phase C_{18} -SPE clean-up was performed. Final determination of bentazone and its OH-metabolites was performed by LC-MS/MS, monitoring two parent-daughter ion transitions for each compound.		

Determination of Bentazone, 6-OH-Bentazone and 8-OH-Bentazone in plant matrices—Independent laboratory validation of the analytical method No. 438/2. (Schulz, H., Meyer, M., 2007, 2007/1013926).

Analyte:	bentazone, 6-OH-bentazone and 8-OH-bentazone	LC-MS/MS	Method No. 438/2
LOQ:	0.01 mg/kg.		
Description	Bentazone and its metabolites are extracted from plant or animal matrices with aqueous methanol. After purification of an aliquot by an iso-octane liquid-liquid partition, the two relevant metabolites which are present as glucosides were hydrolysed using enzymatic cleavage to 6-OH-bentazone and 8-OH-bentazone. After a $\text{Ca}(\text{OH})_2$ -precipitation step to remove acidic matrix constituents, a reversed phase C_{18} -SPE clean-up is performed. The final determination of bentazone and its hydroxy-metabolites is performed by LC-MS/MS, monitoring two parent-daughter ion transitions for each compound.		

Method for determination of Bentazon and its metabolites residues in rice grain and bran, soya bean seed, hulls, forage and refined oil, corn grain, and dry peas. (Abdel-Baky, S, 1995, 1996/5278)

Analyte:	bentazone, 6-OH-bentazone and 8-OH-bentazone	GC-TSD GC-MSD	Method No. D9310
LOQ:	0.05 mg/kg.		
Description	Residues are extracted from all matrices with methanol. The extracts are concentrated and hydrolysed with MeOH/HCl to release the 6-OH-bentazon and 8-OH-bentazone metabolites. The samples are made basic with 50% KOH (pH 14) and extracted with dichloromethane (DCM) to remove neutral and basic matrix impurities. The sample solutions are acidified with concentrated HCl (pH < 1), and then extracted with ethyl acetate. The final extracts are evaporated and the residues are derivatised with diazomethane. The methylated products, N-methylbentazon (BH 351-NMB), 8-methoxy-N-methylbentazon (BH 351-8OMNM), and 6-methoxy-N-methylbentazon (BH 351-6OMNM), are purified on a mini-silica column (1 gram) by elution with DCM/hexane. Final quantitation has been done on two analytical instruments: a capillary gas chromatograph with a thermionic specific detector (GC-TSD) and a capillary gas chromatograph with a mass selective detector (GC-MSD).		

Method for peppermint and lemon balm: Analysis of residues after treatment with Basagran: Active ingredient: bentazone. (Class, T and Bacher, R, 1998, 1998/11399)

Analyte:	bentazone and 8-OH-bentazone	(GC-MS/MS).
LOQ:	0.05 mg/kg.	
Description	Residues are extracted from all matrices with methanol. The extracts were methylated with diazomethane and detected with gas chromatography with a mass selective detector (GC-	

MS/MS).

Bentazone and its two OH-metabolites: Validation of residue method 438/2 for animal materials using LC/MS-MS. (Bacher, R, 2007, 2007/1013925)

Analyte: bentazone, 6-OH-bentazone and 8-OH-bentazone LC-MS/MS Method 438/2

LOQ: 0.01 mg/kg.

Description Extraction and enzymatic cleavage of residues of bentazone and its conjugated 6-OH- and 8-OH-metabolites from plant specimen was adopted from BASF Method No. 438/2 which uses GC-MS for the determination of the analytes in plant materials: bentazone and its OH-metabolites present in animal matrices as glucuronides or sulphates were extracted with aqueous methanol. After purification of an aliquot by liquid-liquid partition with iso-octane, glucuronides and sulphates were cleaved enzymatically to 6-OH-bentazone and 8-OH-bentazone. After $\text{Ca}(\text{OH})_2$ -precipitation of acidic matrix constituents, a reversed phase C_{18} -SPE clean-up was performed. The final determination of bentazone and its hydroxy-metabolites was performed by LC-MS/MS, monitoring two parent-daughter ion transitions for each compound.

Determination of Bentazone, 6-OH-Bentazone and 8-OH-Bentazone in animal matrices—Independent laboratory validation of the analytical method. No. 438/2. (Schulz, H and Meyer, M, 2007, 2007/1013927)

Analyte: bentazone, 6-OH-bentazone and 8-OH-bentazone LC-MS/MS Method. No. 438/2

LOQ: 0.01 mg/kg.

Description Bentazone and its metabolites are extracted from animal matrices with aqueous methanol. After purification of an aliquot by an iso-octane liquid-liquid partition, the two relevant metabolites which are present as glucosides were hydrolysed using enzymatic cleavage to 6-OH-bentazone and 8-OH-bentazone. After a $\text{Ca}(\text{OH})_2$ -precipitation step to remove acidic matrix constituents, a reversed phase C_{18} -SPE clean-up is performed. The final determination of bentazone and its OH-metabolites is performed by LC-MS/MS, monitoring two parent-daughter ion transitions for each compound.

A summary of analytical method and procedural recoveries are presented in Table 56.

Table 56 Recoveries of bentazone, 6-OH-bentazone and 8-OH-bentazone in-plant matrices spiked with 0.02, 0.2 and 2.0 mg/kg (Linder, G *et al.*, 2000, 2000/1000243)

Stability of residues in stored analytical samples

The Meeting received information on the stability of residues of bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone residues in maize (green plant, grain and straw), pea (seed), flax (seed) and potato (tuber) over a period of two years. In addition to these individual studies, storage stability determinations, together with procedural recovery analyses, were also carried out concurrently with the field trials samples and are reported in the residue trials reports.

The deep frozen storage stability of bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone, determined as glucoside derivatives, were investigated over a period of two years in different plant matrices such as maize (green plant, grain and straw), pea (seed), flax (seed) and potato (tuber) (Sasturain, J *et al.*, 2002, 2002/1008779). The glucoside derivatives of 6-OH-bentazone and 8-OH-bentazone were produced in wheat cell suspension cultures and rape cell suspension cultures, respectively. Untreated matrix samples were fortified with 0.5 mg/kg of the test substances and stored at -20 °C in the dark. The storage conditions correspond to the usual storage conditions for field samples. Samples were analysed after 0, 27, 97, 180, 355, 539 and 713 days.

Bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone are extracted from plant matrices with aqueous methanol. After purification of a 4% aliquot by an iso-octane liquid-liquid partition, the two relevant metabolites which are present as glucosides are hydrolysed using enzymatic cleavage to 6-OH-bentazone and 8-OH-bentazone. After a Ca(OH)₂-precipitation step to remove acidic plant constituents, a reversed phase C₁₈-column clean-up is performed. The analytes are then methylated with diazomethane and their derivatives are purified using a silica gel-column. The final determination of the residues of bentazone and its hydroxy metabolites is performed by GC-MS. The limit of quantitation (LOQ) of the method for bentazone, 6-OH-bentazone and 8-OH-bentazone is 0.02 mg/kg each.

Procedural recoveries for bentazone averaged at about 90% for maize plant, at 94% for grain, at 97% for straw, at 87% for potato tuber, at 98% for flax seed and at 88% for pea. The mean recoveries for 6-OH-bentazone were about 77% in maize plant, 81% in grain, 83% in straw, 76% in potato tuber, 79% in flax seed and 74% in pea. Recoveries for 8-OH-bentazone averaged at about 72% in maize plant, at 73% in grain, at 80% in straw, at 72% in potato tuber, at 76% in flax seed and at 75% in pea.

Recoveries in stored samples for bentazone showed stability (> 70%) for 713 and 722 days in maize plant, grain, straw, in flax seed and in pea. Only in potato the recovery dropped to 66% but this was correlating with a low procedural recovery. The recoveries in stored samples for 6-OH-bentazone and 8-OH-bentazone were well above 70% in maize plant, grain, straw, potato tuber, flax seed and in pea after 713–722 days of storage.

Table 63 Recoveries for bentazone, 6-OH-bentazone and 8-OH-bentazone in stored and freshly spiked plant matrix samples (Sasturain, J *et al.*, 2002, 2002/1008779)

USE PATTERNS

Labels and English translations were available for all the uses. Bentazone is applied either as a solo product or in combinations with other active substances and controls broad leaf weeds and is used in many crops in pre-emergence and post emergence. A summary of the current approved label rates are provided in Table 64.

Table 64 Summary of registered uses of bentazone

Crop Code No.	Crop	Country	F/G/P ^a	Application			Application rate per treatment			PHI [days] min ^c

	Maize forage and fodder	France, Germany, Italy, Netherlands, Spain, UK	Table 95
	Rice straw	China, Japan	Table 96
	Wheat straw	Germany, Italy, Spain	Table 97
	Grass	Denmark, Netherlands, USA	Table 98

In addition to the description and details of the field trials, each report includes a summary of the analytical method(s) used, together with the corresponding procedural recoveries, and in most cases, concurrent recoveries in stored frozen samples. In the field trials where multiple analyses are conducted on a single sample or where multiple samples were taken from a single plot, the average residue value is reported. Where results from separate plots with distinguishing characteristics, such

Results have not been corrected for concurrent method recoveries unless indicated. Residues and application rates have generally been rounded to 2 significant figures or, for residues near the LOQ, to 1 significant figure. The actual application rates were within $\pm 10\%$ of the nominal dosage rate. Residue values from the trials conducted according to the maximum GAP have been used for the estimation of maximum residue levels. Those results included in the tables are single underlined. If higher residue values were detected at longer PHI than specified in the cGAP, those values were used for the calculations.

For purposes of MRL estimation and risk assessment in this report, ND values in the reports were considered as < LOQ. For total bentazone, metabolites were calculated as parent equivalent; the conversion factor for both metabolites is 0.938; for calculation purposes, residues were treated as follows: 0.01 + 0.01 + 0.01 = 0.03; 0.01 + < 0.01 + < 0.01 = 0.03; < 0.01 + < 0.01 + < 0.01 = < 0.03; < 0.02 + < 0.02 + < 0.02 = < 0.06.

Green beans

A total of 16 trials in green beans were conducted in different representative growing areas in Northern and Southern Europe in 2008 and 2009 to determine the residue level of bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone. (Schulz, H, 2009, 2009/1024806; Schroth, E, Martin, T, 2010, 2009/1123296). The results are shown in Table 70.

Sugar beet

A field trial on sugar beet was performed in the United States in order to determine the magnitude of the residue of bentazone and its metabolites in sugar beet raw agricultural commodities (RACs) in 1973 (Cannizzaro, R, 1974, 1974/5055). The results are shown in Table 75.

^b Plant parts were taken without roots

A total of 10 field trials were conducted in representative fresh pea growing areas and the United Kingdom (fresh peas) and USA to determine the residue level of bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone in or on raw agricultural commodities (RAC) in 1993, 1994 and 2007 (Versoi, PL *et al.*, 1995, 1995/5159). The results of green pea vine are shown in Table 88.

^a At application*Grass*

A total of 25 field trials of grass were conducted in Europe to determine the residue level of bentazone in or on raw agricultural commodities (RAC) from 1979 to 1984 (Bassler, R, 1994, 1994/10678; Fuchs, A, 1985, 1984/10469; Fuchs, A, 1985, 1984/10468; Fuchs, A, 1985, 1984/10467; Fuchs, A, 1985, 1984/10466; Fuchs, A, 1985, 1984/10465; Fuchs, A, 1985, 1984/10464; Fuchs, A, 1985, 1984/10463; Anonymous, 1981, 1981/10438). The results are shown in Table 98.

FATE OF RESIDUES IN STORAGE AND PROCESSING

Information and Data from Trials on Stored Products

Bentazone is not used in stored products.

Information and Data from Residues in Processed Commodities

The Meeting received five processing studies on soya beans, maize, rice, linseed and peanuts.

During the 1991 growing season, two field trials in soya beans were conducted in representative growing areas in the USA (Iowa and Illinois) (Stewart, J 1992, 1992/5169). Bentazone

was applied at an exaggerated rate of five times 2.25 kg ai/ha and the spray volume used was approximately 190 L/ha. The application was done at growth stage BBCH 12–89. Specimens of soya bean samples (RAC seeds) as well as processed fractions thereof were collected at harvest (BBCH 89). The soya bean samples were processed according commercial standards into hulls, meal, crude oil, refined oil and soapstock. The specimens were analysed for bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone with BASF Method No. 19A which quantifies the relevant residues with a limit of quantitation (LOQ) of 0.05 mg/kg. The results are summarized in Table 99.

Table 99 Summary of total residues in process fractions and processing factors

^a Trial 1: RCN 91016, Trial 2: RCN 91017

During the 1991 growing season, two field trials were conducted in representative maize growing areas in the United States to determine the residue level of bentazone in or on raw agricultural commodities (RAC) and processing products (Stewart, J, 1992, 1992/5168). Bentazone was foliar applied an exaggerated five times at rates of 2.24 kg ai/ha to maize. Maize grain specimens were harvested at maturity (BBCH 89), 69–70 days after the last application (DALA). The samples were processed using a small-scale wet-milling procedure according to commercial standards into starch, crude oil and refined oil. Maize grain samples were also processed using a small-scale dry-milling procedure into grits, meal, flour, crude oil and refined oil according to commercial standards. The results are summarized in Table 100.

^b Trial 1: RCN 91014, Trial 2: RCN 91015

^c Average of two analyses

During the 1989 growing season, one field trial was conducted in representative linseed growing area in the United States (Minnesota) to determine the residue level of bentazone in or on raw agricultural commodities (RAC) and processing products (Single, Y, 1992, 1992/5124). Bentazone was applied by ground equipment an exaggerated three times at rates of 1.69 kg ai/ha to linseed. Linseed specimens were harvested at maturity (BBCH 89), 30 days after the last application (DALA) and processed in a manner designed to simulate the commercial procedure. The results are summarized in Table 102.

Table 102 Summary of total residues in process fractions and transfer factors

Portion Analysed	Residue Bentazone, Parent (mg/kg)		Residue Bentazone, Total (mg/kg)		Processing Factor ^a Bentazone, Parent			Processing Factor ^a Bentazone, Total		
	1	2	1	2	1	2	Mean	3	4	Mean
seed (RAC)	0.49		1.24		—	—	—	—	—	—
meal	0.31		0.84		0.63			0.68		

^a Transfer factor = residue in processed fraction / residue in RAC

During the 1975 growing season, a field trial was conducted in the United States to determine the residue level of bentazone in or on raw agricultural commodities (RAC) and processing products (Horton, WE, 1973, 1975/5056). Bentazone was applied once at a rate of either 2.24 or 4.48 kg ai/ha to peanuts at the four-leaf stage (BBCH 14) at 10 inch plant height. Peanut specimens were harvested 65 days after the last application. Samples were processed into crude oil, refined oil, meal and soapstock. None of them contained detectable residues. Since the residues in peanut were not determined processing factors cannot be calculated.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Dairy goats

A lactating goat feeding study was conducted to determine the magnitude of residues of bentazone and its metabolites 6-hydroxy bentazone in milk and animal tissues (Keller, W, 1981, 1981/10068). Seven crossbred lactating female goats, 3 to 6 years of age, were orally dosed for 21 consecutive days with the diets containing test compound. Observations were continued for a further 14 days. The dose levels in the dry food were for bentazone 15 mg/kg and 75 mg/kg and for 6-hydroxybentazone 75 mg/kg and 150 mg/kg on the basis of an individual feed intake of 3 kg of feed per animal per day and incorporating an allowance for the difference in dry matter percentage between the type of diet offered (cereal/protein concentrate feed and hay) and fresh herbage, respectively. Milk samples from day 1, 7, 14, 21, 28 and 35 were analysed. The results are shown in the tables 103 and 104. Tissues

such as loin muscle, leg muscle, back fat, omental fat, liver and kidney were not analysed. The results are shown in Table 105 and Table 106.

APPRAISAL

Bentazone, a post-emergence herbicide, was originally evaluated by the JMPR in 1991 and re-evaluated for residues and toxicity several times up to 2004. It was reviewed as part of the periodic re-evaluation programme of CCPR on toxicity in 2012 JMPR. Bentazone is a selective herbicide applied as a post emergence treatment to control dicotyledonous weeds in agriculture, horticulture, ornamentals and amenity grasslands. The mode of action is based primarily on an irreversible blockage of photosynthetic electron transport and in further consequence the inhibition of photosynthesis at photosystem II. As a result of this reaction, CO₂ assimilation is suppressed and after a short period of growth stagnation, the plant dies.

At the 43rd Session of the CCPR (REP 12/PR, Appendix VIII), bentazone was scheduled for periodic review of residues by the 2013 JMPR. The Meeting received information on physical and chemical properties, metabolism, environmental fate, analytical methods and freezer storage stability, national registered use patterns, as well as supervised trials, processing studies and livestock feeding studies.

The 2012 JMPR established an ADI for bentazone of 0–0.09 mg/kg bw/day and reaffirmed its previous conclusion that no ARfD is necessary.

Bentazone is 3-isopropyl-1H-2,1,3-benzothiadiazine-4(3H)-one 2,2-dioxide.

The chemical structures and names of metabolites discussed in this appraisal are:

6-OH-bentazone (M351H001) 3-Isopropyl-1H-2,1,3-benzothiadiazine-4(3H)-one-6-hydroxy-2,2-dioxide	
8-OH-bentazone (M351H002) 3-Isopropyl-1H-2,1,3-benzothiadiazine-4(3H)-one-8-hydroxy-2,2-dioxide	
Bentazone-6-O-glucoside (M351H013)	
Bentazone-8-O-glucoside (M351H017)	
Bentazone-N-glucuronide (Metabolite A, M351H004) 3-isopropyl-1-methyl-2,2-dioxo-2,1,3-benzothiadiazin-4-one	
M351H014 and isomers: M351H015-016, -018-019, -022	

Animal metabolism

Information was available on metabolism of bentazone in lactating goats and laying hens.

Laboratory animals

Metabolism in laboratory animals was summarized and evaluated by JMPR in 2012. Studies on toxicokinetics showed that elimination was almost exclusively via the urine (approximately 91% within 24 hours). Five days after dosing, less than 2% was found in faeces and less than 0.02% in expired air. Biliary excretion of radioactivity was minimal. No significant differences were found in absorption and elimination among the different species investigated (rat, rabbit and mouse). Bentazone is minimally metabolized in vivo, with the parent compound being the predominant excretion product. Only small amounts of 6-hydroxybentazone (up to approximately 6% of the dose) and minimal amounts of 8-hydroxybentazone (less than approximately 0.2% of the dose) were detected in urine.

Lactating goats

Lactating goats were administered orally with uniformly ring-labelled [^{14}C]-bentazone for 5 or 8 consecutive days at 3 and 50 mg/kg bw, 97.3% and 99.1% TAR was recovered respectively. Most of the administered dose was eliminated in the urine (91.4% and 80.6% TAR). TRR levels in tissues ranged from 0.017 mg eq/kg for muscle to 0.91 mg eq/kg in fat for the low dosed goat and from 1.2 mg eq/kg in muscle to 54 mg eq/kg in kidney for the high dosed goat. The parent bentazone was the major residue component and constituted about 71–96% (0.034 mg/kg and 0.39 mg/kg) of TRR in milk, 71–97% (0.010 mg/kg and 1.2 mg/kg) in muscle, 94–98% (1.6 mg/kg and 2.8 mg/kg) in fat, 91–98% (0.55 mg/kg and 49 mg/kg) in kidney, 83–84% (0.033 mg/kg and 3.1 mg/kg) in liver. The liver in high dosed goat contained bentazone-N-glucuronide (11.1% TRR, 0.40 mg/kg) in addition to the parent compound. Two unidentified minor metabolites at a concentration of 0.002 mg/kg bentazone equivalents were found in milk from the goat dosed at 3 mg/kg bw.

The metabolism studies with [^{14}C]-6-hydroxy-bentazone and [^{14}C]-8-hydroxy-bentazone were conducted separately at two dose levels of 2 mg/kg bw and 40 mg/kg bw for 5 or 6 consecutive days, respectively. Residue were rapidly excreted 70–86% TAR for 6-hydroxy-bentazone and 83–91% TAR for 8-hydroxy-bentazone. The major residue component in edible tissues was unchanged 6-hydroxy-bentazone constituted >43% TRR and main metabolite was sulphate conjugate of 6-hydroxybentazone (43% of the TRR) in milk. The unchanged 8-hydroxybentazone (29–95% TRR) was the major residue component in the milk and edible tissues. In all three studies unidentified metabolites in milk or edible tissues amounted less than 10% of the TRR.

Laying hens

[^{14}C]-bentazone, [^{14}C]-6-hydroxybentazone and [^{14}C]-8-hydroxybentazone were each administered orally to separate groups of 10 laying hens once daily for 5 days. The doses were 10 mg/hen/day, equivalent to feed containing about 100 ppm. The excretion of radioactivity was rapid. The mean proportions of the total cumulative dose recovered 6 hours after the final dose were 94% from the bentazone group, 90% from the 6-hydroxybentazone group and 93% from the 8-hydroxybentazone group. The mean concentrations of radioactivity were highest in the kidneys in all groups (3.9, 0.66, 1.6 mg eq/kg), followed by muscle (0.39, 0.32, 0.23 mg eq/kg), and liver (1.1, 0.13, 0.23 mg eq/kg). After the administration of bentazone, the parent compound was the major radioactive component in extracts of liver (0.91 mg/kg, 84% TRR) and was exclusively found in muscle (0.29 mg/kg, 100% TRR), fat (0.056 mg/kg, 100% TRR) and eggs (0.13 mg/kg, 100% TRR).

In summary, bentazone is the major residue in the animals tissues, milk and eggs (> 70% TRR).

Plant metabolism

The Meeting received plant metabolism studies with bentazone on soya bean, rice, maize, green beans, potatoes and wheat.

Soya beans

Soya beans were treated with [^{14}C] bentazone once at 2.24 kg ai/ha or twice at 1.68 and 1.12 kg ai/ha. Forage at long and short pre-harvest intervals, hay and bean samples were collected. The residues from single treated forage were 19 mg eq/kg and 7.0 mg eq/kg at 9 DAT and 36 DAT and from the double treated forage were 17 mg eq/kg and 24 mg eq/kg at 9 days after the first treatment and 11 days after the second treatment. In hay, residues for the single treated forage were 21 mg eq/kg at 93 days after treatment and for the double treatment 80 mg eq/kg at 48 days after the second treatment. The residues of bentazone, 6-hydroxy and 8-hydroxy bentazone in the double treated forage, 11 days after the second treatment, were 5.0 mg/kg (21% TRR), 1.8 mg/kg (3.3% TRR) and 2.3 mg/kg (9.6% TRR), respectively. The residues in seed were too low for further analysis.

Rice

Rice plants were treated by foliar application with 1 kg ai/ha of [^{14}C] bentazone and radioactive residues were determined in whole plants, grain and straw. At day 0, only bentazone (72% TRR) and 6-hydroxy-bentazone (6.5% TRR) were detected. At day 26 bentazone decreased to 24% of the TRR and 6-hydroxy-bentazone in free form increased to 17% of the TRR. At 63 days, 15% bentazone (7.8 mg/kg) and 4.0% 6-hydroxy-bentazone (2.1 mg/kg) were found in straw. In grain samples 63 days after treatment only 6.6% of the TRR was extracted and 93% remained in the insoluble fraction. It was shown that the terminal ^{14}C residue consisted predominantly of recycled fragments of bentazone and 6-hydroxy-bentazone taken up into glucose, polysaccharides and lignin. Minor residues of bentazone were observed in rice grains (1.5% TRR, 0.007 mg/kg) and were below the limit of detection (0.02 mg/kg).

Maize

The metabolism of bentazone was investigated in maize grown in outdoor plots and sprayed with an aqueous solution of the sodium salt of [^{14}C] bentazone at a rate equivalent of 1.68 kg ai/ha. In forage only bentazone and 6-hydroxy-bentazone were found in the methanol extract. The levels were 0.12 mg eq/kg and 1.2 mg eq/kg after one week and declined to < 0.05 mg eq/kg and 0.09 mg eq/kg after 9 weeks, respectively. Analysis of the final harvested grain, cobs, husk and stover showed no residues of bentazone or 6-hydroxy- or 8-hydroxy-bentazone (< 0.05 mg/kg).

Green beans

The magnitude of the residues in green beans were determined after one application of [^{14}C] bentazone at 2.24 kg ai/ha or two at 1.68 and 1.12 kg ai/ha. The total radioactive residues in forage (4.1–22% TAR, 5.0–45 mg eq/kg), succulent bean (0.1–0.6% TAR, 0.13–1.9 mg eq/kg) and seed (0.02–0.04% TAR, 0.61–1.3 mg eq/kg) were not further identified.

Potatoes

The metabolism in potato plants was studied after two foliar spray applications of 1.12 kg ai/ha [^{14}C] bentazone. Potato tubers were harvested 41 days after the final treatment. TRR levels found in the whole tuber (0.14 mg eq/kg) were mainly located in the pulp (0.1 mg eq/kg), while the peel contained lower residues (0.037 mg eq/kg). The identified extractable residues were bentazone (3.7% TRR, 0.005 mg/kg) and conjugates of 6-hydroxy-bentazone (about 25% TRR, 0.034 mg/kg). Most of the radioactivity (56% of the TRR) was incorporated into starch.

Wheat

A wheat metabolism study was performed with [^{14}C] bentazone. The active substance was applied once at a rate of 1 kg ai/ha. Samples of wheat forage and hay were collected at BBCH 39 (20 days after application) and samples of grain, chaff and straw were sampled at BBCH 89 (83 days after application). The total radioactive residues (TRR) for wheat forage accounted for 4.46 mg eq/kg. Wheat hay showed the highest residue level of all matrices at 31 mg eq/kg, followed by wheat straw with residue levels of 17 mg eq/kg. In wheat chaff the residues amounted to 1.6 mg eq/kg while

lowest residue levels were found in wheat grain at 1.1 mg eq/kg. The parent compound was found to be moderately metabolized until harvest. Portions between approximately 39% and 56% of the TRR were still present as unchanged bentazone in forage, hay and straw. The major metabolite in quantitative terms was an O-monosaccharide conjugate of a 6-hydroxylated derivative of parent compound. Other metabolites identified represented less than 4.7% of the TRR each. In the grain the major part of the radioactivity was characterized as carbohydrates (58% of the TRR).

In summary, the metabolism of bentazone in six different crops was similar and considered comparable. The main residue components were parent bentazone and 6-hydroxy-bentazone in soya bean forage and hay, rice hay and straw and grain, maize forage, potato tuber and wheat hay and straw. However, the parent compound was quite low in grains or seeds and confirmed by the supervised trials.

Environmental fate in soil

The Meeting received information on the environmental fate of bentazone in soil, including studies on aerobic soil metabolism, degradation in water/sediment system soil photolysis and crop rotational studies.

Aerobic soil metabolism

The aerobic soil metabolism of bentazone was investigated with [^{14}C -phenyl]-bentazone at a nominal rate of 2.0 and 2.7 mg per kg dry soil. The majority of radioactivity in the extracts was always unchanged compound. At the end of incubation, bentazone was detected in amounts of 2.3–19% TAR. None of metabolites exceeded 5% TAR. Metabolites were formed only in minor amounts of which the most prominent metabolite (max. 2.8% TAR) was identified as N-methyl-bentazone. The half-lives were calculated to be 31 to 45 days. Mineralization to ^{14}C - CO_2 reached a total of 9.0% to 21% TAR. No other volatile compounds were detected. In summary, bentazone was not persistent in soil.

Water/sediment dissipation

The degradation of [^{14}C] bentazone was investigated in two different water/sediment systems (sandy loam/sand) under aerobic conditions over a period of 100 days at 0.34 mg/kg in water. The major residue component was parent bentazone which accounted for more than 60% of the TAR after 100 days. Methyl-bentazone was observed only in the water phase with the maximum concentration less than 13% of the TAR after 100 days. The half-lives in the total system were calculated to be greater than 500 days. Bentazone is stable in the water/sediment system.

Soil Photolysis

The photolytic degradation of ^{14}C -labelled bentazone was investigated on a sandy clay loam soil. The overall results for the material balances in the photolysis and the dark control samples were in the range of 95–100% TAR. Carbon dioxide was the only volatile degradation product trapped (8.1% TAR) after 15 days in the photolysis test and 1.8% TAR in the dark control. The concentration of bentazone decreased to 49% TAR in the course of the photolysis study and to 77% in the dark control samples. No degradation products of $\geq 4\%$ TAR occurred in the photolysis samples or in the dark controls. The half-lives for bentazone in the test systems were calculated to be 13 days under continuous irradiation and 42 days in the dark.

Confined rotational crop

The metabolism of bentazone in succeeding crops was investigated in wheat, radish and lettuce cultivated at three different replant intervals for all crops (30, 120 and 365 DAT). Significant translocation of radioactive residues from soil into the plants was observed for the plant back interval of 30 DAT which decreased rapidly after longer aging periods of 120 and 365 days. The residue concentration in the top soil layer after aging and ploughing decreased slightly with increasing plant

back intervals. The total radioactive residues (TRR) in lettuce (immature and mature samples) did not exceed 0.13 mg eq/kg for all plant back intervals. The TRR in white radish tops was 0.17 mg/kg at a plant back interval of 30 DAT, 0.019 mg eq/kg after 120 DAT and to 0.003 mg eq/kg (TRR combusted) after 365 DAT. The total radioactive residues in radish roots of mature crop decreased from 0.13 mg eq/kg (30 DAT), to 0.012 mg eq/kg (120 DAT) and finally to 0.001 mg eq/kg (365 DAT, TRR combusted). In spring wheat, the highest residue levels were measured in hay (declining from 1.6 to 0.07 mg eq/kg, for 30 DAT and 365 DAT, respectively) and straw (declining from 1.1 to 0.049 mg eq/kg, for 30 DAT and 365 DAT, respectively). The total radioactive residues in grain accounted 0.71 to 0.041 mg eq/kg after 30 to 365 days.

Bentazone and/or its soil metabolites were taken up and transformed in the rotational crops primarily into sugars (glucose, fructose and sucrose and further components of similar polarity) which were without exception the most abundant components in all matrices examined. The unchanged parent molecule was found as minor component in samples of immature (30 DAT) and mature lettuce (30 and 120 DAT) in concentrations of < 0.0013 mg/kg and 1.2% TRR only. Additional medium polar degradation products were detected in minor concentrations. The results of this study indicated that potential for uptake of parent bentazone residues from the soil by the succeeding crops is low.

Methods of analysis

The Meeting received descriptions and validation data for analytical methods for residues of bentazone in raw agricultural commodities, feed commodities and animal commodities.

The methods for crop and animal matrices typically use an initial extraction and hydrolysis step, either with acid, base or enzymatic treatment to hydrolyse any sugar conjugates in plant or animal matrices. After a $\text{Ca}(\text{OH})_2$ -precipitation step to remove acidic plant constituents, a reversed phase C_{18} -column clean-up is performed. The analytes are then methylated with diazomethane and their derivatives are purified using a silica gel-column. The final determination of the residues of bentazone and its OH-metabolites is performed by GC-MS or LC-MS/MS. Bentazone residues can be measured in most matrices to an LOQ of 0.01 mg/kg. All methods are considered sufficiently validated for the determination of bentazone, 6-OH-bentazone and 8-OH-bentazone including conjugates thereof. No multi-residue method was provided.

Stability of residues in stored analytical samples

The Meeting received information on the freezer storage stability of residues of bentazone in plant and animal commodities.

Storage stability studies indicated that the residues are stable over a period of two years maize (green plant, grain and straw), pea (seed), flax (seed) and potato (tuber). Analytical results demonstrated that bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone as glucoside derivatives, were stable in the different plant matrices over the test period of two years.

No storage stability study on bentazone in animal matrices was provided to the Meeting.

Definition of the residue

The composition of the residue in the metabolism studies, the available residue data in the supervised trials, the toxicological significance of metabolites, the capabilities of enforcement analytical methods and the national residue definitions already operating all influence the decision on residue definitions.

Animal metabolism studies showed that the parent bentazone was a major component of the residue, representing 84–100% of the TRR in poultry matrices and 71–98% of the TRR in goats. No 6-hydroxy and 8-hydroxy bentazone were found in milk and tissues in goat metabolism studies. Analytical methods are suitable for the determination of bentazone. The Meeting decided that for animal commodities, parent bentazone is the appropriate residue of concern for MRL enforcement and for dietary risk assessment.

The maximum octanol-water partition coefficient of bentazone ($\log K_{ow} = -0.94$ at pH 7) implied that bentazone may not be fat-soluble. Noting that bentazone residues in goat fat were

artificial and TRRs in poultry fat were much less than those in muscle the Meeting agreed that bentazone residue is not fat-soluble.

Metabolism studies on plants and supervised trials showed that the main residues in food or feed of plant origin were bentazone and one or both of its conjugated metabolites, 6-hydroxy- and 8-hydroxy-bentazone. However, the two hydroxy-bentazones were less toxic compared with parent bentazone and only existed in feed commodities. Therefore the Meeting decided that for plant commodities, parent bentazone is the appropriate residue of concern for MRL enforcement and for dietary risk assessment.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake for animal and plant commodities): *bentazone*.

The residue is considered to be not fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised trials data in bulb onions, cucumbers, sweet corn, green peas, green beans, dried beans, soya beans, potatoes, barley, oats, maize, rice, sorghum, wheat, linseed, peanuts, herbs, alfalfa, clover, sugar beet and grass.

Onion, bulb

The critical GAP for bentazone on bulb onions was from Turkey (one foliar application at 0.96 kg ai/ha with a PHI of 30 days). Eight trials were available from southern Europe on bulb onions matching Turkish GAP from which residues were < 0.01 (7) and 0.02 mg/kg.

The Meeting estimated an STMR of 0.01 mg/kg and a maximum residue level of 0.04 mg/kg for bulb onion to replace the previous recommendation of 0.1 mg/kg.

Spring onion

The critical GAP for bentazone on spring onions was from the Netherlands (one spray application of 0.72 kg ai/ha, at least 10 cm height). Two trials were available from the Northern Europe on spring onion matching Dutch GAP with residues of < 0.01 and 0.04 mg/kg. Two trials from the Southern Europe were reported at a rate of 0.96 kg ai/ha treated at later growth stage. The residues of bentazone in spring onion from these trials were < 0.01(2) mg/kg.

Noting that the residues from the Northern and Southern Europe's trials were similar, the Meeting agreed to combine Northern and Southern Europe dataset to estimate an STMR 0.01 mg/kg, and a maximum residue level of 0.08 mg/kg for spring onion.

Cucumber

The critical GAP for bentazone on cucumber is from Sweden (one spray application of 1.0 kg ai/ha with a PHI of 42 days). Four trials were available from Canada on cucumber matching Swedish GAP from which residues were < 0.02(4) mg/kg.

Four trials from Canada on cucumber were not considered sufficient for the estimation of a maximum residue level.

Sweet corn (corn-on-the-cob)

The critical GAP for bentazone on sweet corn is from Canada (one spray application of 1.08 kg ai/ha, at 1 to 5-leaf stage) and in France (one spray application of 1.2 kg ai/ha with a PHI of 28 days). Two trials were available from Canada on sweet corn complying with Canadian GAP with residues of < 0.02 (2) mg/kg and one 2× trial treated at a later growth stage with a residue of < 0.02 mg/kg. Two trials were available from France on sweet corn matching French GAP with residues of < 0.01(2) mg/kg. Ten trials were available from Europe on maize cobs w/o husks against French GAP with residues in immature corn of < 0.01(10) mg/kg.

As the residues from the European trials were considered similar, the Meeting decided to combine them and estimated an STMR 0.01 mg/kg, and maximum residue level of 0.01* mg/kg for sweet corn (corn-on-the-cob) respectively.

Peas (pods and succulent = immature seeds)

The critical GAP for bentazone on peas is from the USA (two applications of 1.12 kg ai/ha with a PHI of 10 days). Ten trials were available from the USA on peas matching US GAP, residues found in peas (pods and succulent immature seeds) were < 0.05(6), 0.05, 0.06, 0.46 and 0.74 mg/kg.

The Meeting estimated an STMR 0.05 mg/kg, and maximum residue level of 1.5 mg/kg for peas (pods and succulent immature seeds) and agreed to withdraw the previous recommendation of 0.2 mg/kg for garden pea (young pods) (= succulent, immature seeds).

Beans, except broad bean and soya bean

The critical GAP for bentazone on beans, except broad beans and soya beans was from France (one application at 1.22 kg ai/ha with a PHI of 42 days). From eight trials in Northern Europe and six trials in Southern Europe on green beans with pods matching French GAP at a shorter PHI (35days) residues were < 0.01 (14) mg/kg.

The Meeting estimated an STMR 0.01 mg/kg, and maximum residue level of 0.01* mg/kg for beans, except broad bean and soya bean (green pods and/or immature seeds) and agreed to withdraw the previous recommendations of 0.2 mg/kg for common bean (pods and /or immature seeds) and 0.05 mg/kg for lima bean (pods and /or immature seeds).

Beans, shelled

Five trials from the Northern Europe and seven trials from the Southern Europe on green beans (immature seeds) (green beans without pods) matching French GAP at a shorter PHI (35 days) gave residues of < 0.01 (11) and 0.02 mg/kg.

The Meeting estimated an STMR 0 mg/kg, and maximum residue level of 0.01* mg/kg for beans, shelled (succulent = immature seeds), respectively.

Peas (dry)

The critical GAP for bentazone on peas in the USA, is two applications at 1.12 kg ai/ha with a PHI of 30 days. Three trials were available from the USA on peas matching US GAP resulting in residues of < 0.05(2) mg/kg.

Three trials on peas (dry) were not considered sufficient for the estimation of a maximum residue level. The Meeting agreed to withdraw the previous recommendation of 1 mg/kg for field pea (dry).

Beans (dry)

The critical GAP for bentazone on beans (dry) in Poland, is one application at 1.44 kg ai/ha, at 6–12 cm plant height. From seven southern European trials on beans matching Polish GAP residues were < 0.02(6) and 0.021 mg/kg. Two trials were available from northern Europe on beans matching the GAP of Poland with residues of < 0.02(2) mg/kg.

As residues from the Southern and Northern European trials were similar, the Meeting decided to combine the two datasets and estimated an STMR 0.02 mg/kg, and maximum residue level of 0.04 mg/kg for beans (dry) to replace the previous recommendation of 0.05 mg/kg.

Soya beans (dry)

The critical GAP for bentazone on soya beans (dry) is from Spain (one application of 1.0 kg ai/ha, 1st and 3rd trifoliolate leaf); The GAP in Germany is for one application of 0.96 kg ai/ha, emergence to 10 cm height; and the GAP in the USA, two applications of 1.12 kg ai/ha with no PHI. Twelve trials

were available from southern Europe on soya bean matching Spanish GAP with some trials treated at later growth stage. Residues found were < 0.01(12) mg/kg. Two trials were available from northern Europe on soya beans matching German GAP with one trial treated at a later growth stage with residues of < 0.01(2) mg/kg. Six trials were available from the USA on soya beans matching US GAP with residues of < 0.05(6) mg/kg. Two exaggerated rate trials from the US resulted in residues of < 0.05(2) mg/kg.

The Meeting estimated an STMR 0.01 mg/kg, and maximum residue level of 0.01* mg/kg for soya bean (dry) on the basis of European dataset replacing its previous recommendation of 0.1 mg/kg.

Potatoes

The GAP for bentazone on potatoes in Ireland is for one application of 1.44 kg ai/ha, before shoots exceed 15 cm in height. The GAP in Spain is for one application of 1.0 kg ai/ha, from post-emergence to the fourth leaf growth stage. Eight trials were available from southern Europe on potato matching Spanish GAP from which residues found were < 0.01(4), 0.01, 0.02(2) and 0.06 mg/kg. Twenty five trials were available from northern Europe on potato matching Irish GAP from which residues found were < 0.02(24) and 0.04 mg/kg.

Noting that Southern European trials resulted in higher residue, the Meeting estimated an STMR 0.01 mg/kg, and a maximum residue level of 0.1 mg/kg for potato confirming the previous recommendations.

Cereals grains

Barley, oats and wheat

The GAP for bentazone on cereal grains in Finland is for one application of 1.48 kg ai/ha, 2–3 leaf stage (BBCH 12–13). Five trials were available from southern Europe on barley matching the Finnish application rate but treated at later growth stage. Residues found were < 0.02(5) mg/kg. One trial was available from Canada on barley matching the Finnish application rate and treated at later growth stage with a residue of < 0.02 mg/kg.

The residue found from one trial on oats from Germany, at higher application rate than that of the Finnish GAP and treated at later growth stage, was below the LOQ (0.05 mg/kg).

Three trials were available from southern Europe on wheat matching the Finnish application rate and treated at later growth stage with residues of < 0.02 (3) mg/kg.

Maize

The GAP for bentazone on cereal grains in Italy is one application of 1.48 kg ai/ha with no PHI; the GAP in the Netherlands is for one application of 1.44 kg/ha, at 5-leaf stage. Thirteen trials were available from southern Europe on maize matching the Italian application rate with some trials treated at later growth stages. Residues found were < 0.01(5) and < 0.02(8) mg/kg. Seven trials were available from northern Europe on maize matching the Dutch application rate with some trials treated at later growth stages. Residues found were < 0.01(5) and < 0.02(2) mg/kg.

The ranked order of concentrations of parent compound, median underlined, was < 0.01(10) and < 0.02(10) mg/kg.

Rice

The GAP for bentazone on rice in China is one application of 1.44 kg ai/ha, no PHI; the GAP in Greece is one application of 1.44 kg ai/ha, BBCH 12–21; the GAP in Japan is one application of 2.8 kg ai/ha, applied up to 60 days before harvest.

Two trials were available from China on rice matching Chinese GAP with residues of < 0.02(2) mg/kg. Two trials were available from China on rice at about 1.5× maximum Chinese GAP rate with residues of < 0.02(2) mg/kg.

Two trials were available from Japan on rice matching Japanese GAP with residues of < 0.01(2) mg/kg. Two trials were available from Japan on rice at about 1.5× maximum Japanese GAP rate with residues of < 0.01(2) mg/kg.

Two trials were available from Portugal on rice matching Greek GAP with two trials treated at later growth stage with residues of < 0.02(2) mg/kg.

One trial was available from France on rice against about 1.3× maximum Greek GAP with residues of < 0.02 mg/kg.

All 11 trials in Asia and Europe were treated at maximum rate or 1.3–1.6× the maximum rate and resulted in non-detectable residues in rice or brown rice.

Sorghum

The critical GAP for bentazone on sorghum is from Luxembourg (one application of 1.2 kg ai/ha, from emergence to 6-leaf stage (BBCH 16)). Six trials were available from France on sorghum matching the GAP of Luxembourg with residues of < 0.05(6) mg/kg.

The Meeting noted that no residues above LOQ (0.01–0.05 mg/kg) were observed in the samples of barley, oats, wheat, maize, rice and sorghum from 47 supervised trials in various countries following treatment at early growth stages. The Meeting agreed to estimate a maximum residue level 0.01 mg/kg and an STMR 0.01 mg/kg for cereal grains and to withdraw the previous recommendations of 0.1 mg/kg for barley, oat, rice, rye, sorghum and wheat and 0.2 mg/kg for maize.

Oilseeds

Linseed

The critical GAP for bentazone on linseed in France is for one application of 1.2 kg ai/ha with a PHI of 70 days. Three trials were available from France on linseed matching the French application rate. Residues found were < 0.02(3) mg/kg. Three trials were available from Canada on linseed matching French GAP showed residues of < 0.02(3) mg/kg.

Considering residues from the French and Canadian trials were similar, the Meeting decided to combine the two dataset and estimated an STMR of 0.02 mg/kg, and maximum residue level of 0.02* mg/kg for linseed, respectively.

Peanuts

The critical GAP for bentazone on peanuts in the USA is for two applications of 1.12 kg ai/ha, up to 28 days after ground crack stage for the second application. Six trials were available from USA on peanut matching the application rate of the US GAP with residues of < 0.05(6) mg/kg. Two trials were available from USA on peanuts with exaggerated application rates resulting in residues of < 0.05(2) mg/kg.

The Meeting estimated a maximum residue level and an STMR value for peanut of 0.05* and 0 mg/kg and replaced the previous maximum residue level recommendation of 0.05 mg/kg.

Herbs

The GAP for bentazone on herbs in Germany is for one application of 0.96 kg ai/ha with a PHI of 42 days; in France the GAP consists of one application at 1.13 kg ai/ha with a PHI of 28 days. Two trials were available from Germany on peppermint matching German GAP with residues of < 0.05(2) mg/kg. Two trials were available from France on melissa (lemon balm) matching French GAP with residues of < 0.02 and 0.037 mg/kg.

As the residues from the European trials were considered similar, the Meeting decided to combine the data and estimated a maximum residue level and an STMR value for herbs, except dry hops, of 0.1 and 0.0435 mg/kg, respectively.

Sugar beet

One trial from USA on sugar beet was received however as no associated GAP was provided the Meeting could not estimate a maximum residue level.

*Animal feedstuffs**Pea vines (green)*

The critical GAP for bentazone on peas in USA is two applications of 1.12 kg ai/ha with a PHI of 10 days. Ten trials were available from USA on peas matching US GAP from which residues found, median underlined, were: 0.11, 0.12, 0.17, 0.19, 0.22(2), 0.31, 1.05, 7.05 and 13.1 mg/kg.

The Meeting estimated a median and highest residue for bentazone in pea vines (green) of 0.22 and 13.1 mg/kg.

Pea hay

The critical GAP for bentazone on peas in USA is for two applications of 1.12 kg ai/ha with a PHI of 10 days. Three trials were available from USA on peas matching US GAP from which residues found were: 0.48, 1.45 and 1.99 mg/kg.

Three trials on peas hay (dry) were considered insufficient for maximum residue level estimation.

Bean forage (green)

The critical GAP for bentazone on beans, except broad bean and soya bean in France is for one application of 1.22 kg ai/ha with a PHI of 42 days. Five trials were available from Southern Europe on green beans matching French GAP with residues found in forage of < 0.01(3), 0.01 and 0.02 mg/kg. Three trials were available from Northern Europe on green beans against French GAP with residues in forage of < 0.01 and 0.01(2) mg/kg.

As the residues from the European trials were considered similar, the Meeting decided to that the data may be combined, median underlined, < 0.01(4), 0.01(3) and 0.02 mg/kg. The Meeting estimated median and highest residue for bentazone in green beans forage of 0.01 and 0.02 mg/kg.

Soya bean forage (green)

The GAP for bentazone on soya beans (dry) in the USA is for two applications of 1.12 kg ai/ha, with no grazing or cutting for forage or hay for at least 30 days after the last treatment. Four trials were available from USA on soya bean forage matching US GAP with residues of < 0.05, 0.06, 0.12 and 0.15 mg/kg.

The Meeting considered four trials an insufficient number for the estimation of median and the highest residue levels for soya bean forage.

Soya bean straw and fodder

The critical GAP for bentazone on soya beans (dry) in USA, two applications of 1.12 kg ai/ha, not graze or cut for forage or hay for at least 30 days after the last treatment. Four trials were available from USA on soya bean hay against the GAP of the USA with residues of < 0.05, 0.10, 0.45 and 0.62 mg/kg.

The Meeting considered four trials an insufficient number for the estimation of median and the highest residue levels for soya bean straw and fodder.

Alfalfa forage (green)

The critical GAP for bentazone on legume animal feeds in France is one application of 0.6 kg ai/ha, BBCH 12 or 1 trifoliate leaf; in the Netherlands the GAP is one application of 1.44 kg ai/ha, 1–2 trifoliate (true) leaves. Four trials were available from Southern Europe on alfalfa forage matching

French GAP with residues of 0.01(2) and 0.03(2) mg/kg. Two trials were available from Northern Europe on alfalfa forage matching French GAP with residues of 0.06 and 0.07 mg/kg.

Considering residues from European trials were comparable, the Meeting decided they could be combined. The combined residues, in rank order, were: 0.01(2), 0.03(2), 0.06 and 0.07 mg/kg. The Meeting estimated a median of 0.03 mg/kg and the highest residue of 0.07 mg/kg, respectively.

Alfalfa fodder

The critical GAP for bentazone on legume animal feeds in France is one application of 0.6 kg ai/ha, BBCH 12 or 1 trifoliolate leaf; the GAP of the Netherlands is one application of 1.44 kg ai/ha, 1–2 trifoliolate (true) leaves. Four trials were available from Southern Europe on alfalfa hay matching French GAP with residues of 0.04, 0.07, 0.08 and 0.12 mg/kg. Two trials were available from Northern Europe on alfalfa hay matching French GAP with residues of 0.10 and 0.23 mg/kg.

As the residues from the European trials were considered parable, the Meeting decided to they could be combined. The residues in rank order were: 0.04, 0.07, 0.08, 0.10, 0.12 and 0.23 mg/kg. Noting the residues from European trials were consistent and based on an average dry-mass of 89% residues in alfalfa fodder (dry weight) were: 0.04, 0.08, 0.09, 0.11, 0.13 and 0.26 mg/kg. The Meeting estimated a median of 0.09 mg/kg, the highest residue of 0.23 mg/kg and a maximum residue level of 0.5 mg/kg for alfalfa fodder (dry), respectively.

Clover forage

The critical GAP for bentazone on clover in the US is one application of 1.12 kg ai/ha with a PHI of 50 days (for grazing of forage or hay). Two trials were available from the US on clover forage against US GAP with residues of < 0.05 and 0.06 mg/kg.

The Meeting considered two trials an insufficient number for the estimation of median and the highest residue levels for clover forage.

Clover hay or fodder

The critical GAP for bentazone on clover in US is one application of 1.12 kg ai/ha with a PHI of 50 days (for grazing of forage or hay). Two trials were available from the USA on clover forage against US GAP with residues of < 0.05 and 0.07 mg/kg.

The Meeting considered two trials an insufficient number for the estimation of STMR and a maximum residue levels for clover hay.

Peanut fodder

The critical GAP for bentazone on peanuts in the US is two application of 1.12 kg ai/ha, up to 28 days after ground crack stage for the second application. Noting that no trials were in line with US GAP the Meeting agreed that the maximum residue level for peanut fodder could not be recommended.

Grass forage

The critical GAP for bentazone on grasses in Sweden is one application of 1.0 kg ai/ha with a PHI of 21 days. Thirteen trials were available from Northern Europe on grass forage matching Swedish GAP from which residues found were: 0.04(2), 0.12, 0.17(2), 0.20 and 0.22 mg/kg.

The Meeting estimated a median and the highest residue for bentazone in grass forage of 0.17 and 0.37 mg/kg, respectively.

Hay or fodder (dry) of grasses

The critical GAP for bentazone on grasses in Sweden is one application of 1.0 kg ai/ha with a PHI of 21 days. Ten trials were available from Northern Europe on grass hay matching Swedish GAP with residues of < 0.02, 0.03, 0.07, 0.08, 0.16, 0.22, 0.39, 0.48, 0.61 and 1.02 mg/kg.

Based on an average dry-mass of 88% residues in grass hay (dry weight) were: < 0.02, 0.03, 0.08, 0.09, 0.18, 0.25, 0.44, 0.55, 0.69 and 1.16 mg/kg.

The Meeting estimated a maximum residue level, an STMR and the highest residue for bentazone in grass hay of 2 mg/kg (DM based), 0.215 mg/kg and 1.16 mg/kg (air dry), respectively.

Straw and fodder (dry) of cereal grain

Barley, millet, oats, rye, triticale, and wheat straw and fodder, dry

The critical GAP for bentazone on cereal grains in Finland is one application of 1.48 kg ai/ha, 2–3 leaf stage. Five trials were available from southern Europe on barley matching Finnish GAP with residues of 0.04(2), 0.06(2) and 0.14 mg/kg.

Residue from one German oat trial, at higher application rate than that of the Finnish GAP, was below the LOQ (0.05 mg/kg).

Three trials were available from southern Europe on wheat matching Finnish GAP with residues of 0.03(2) and 0.04 mg/kg.

As the residues from the Southern and Northern European trials were comparable, the Meeting decided to combine these datasets. The residues from the combined European residue trials in rank order, median underlined, were: 0.03(2), 0.04(3), < 0.05, 0.06(2) and 0.14 mg/kg.

Based on an average dry-mass of 88% residues in grass hay (dry weight) were: 0.03(2), 0.04(3), < 0.06, 0.07(2) and 0.16 mg/kg.

The Meeting estimated a maximum residue level, an STMR and a highest residue for bentazone in barley, millet, oats, rye, triticale, and wheat straw and fodder (dry) of 0.3 mg/kg (DM based), 0.05 mg/kg and 0.16 mg/kg (air dry), respectively.

Maize fodder

The critical GAP for bentazone on cereal grains in Italy is one application of 1.48 kg ai/ha, at the 2–4 true leaf growth stage for dicotyledonous weeds. The GAP of the Netherlands is one application of 1.44 kg/ha, (at the 5-leaf stage). Thirteen trials were available from southern Europe on maize straw matching Italian GAP with residues of < 0.01, 0.01, < 0.02(6), 0.04, 0.05, 0.13, 0.14 and 0.24 mg/kg. Seven trials were available from northern Europe on maize straw against Dutch GAP with residues of 0.01, < 0.02(2), 0.03(2), 0.06 and 0.08 mg/kg.

As the residues from the southern and northern European trials were comparable, the Meeting decided to combine the two datasets. The residues from the combined European residue trials in rank order, were: < 0.01, 0.01(2), < 0.02(8), 0.03(2), 0.04, 0.05, 0.06, 0.08, 0.13, 0.14 and 0.24 mg/kg.

Based on an average dry-mass of 83% residues in maize fodder (dry weight) were: < 0.01, 0.01(2), < 0.02(8), 0.04(2), 0.05, 0.06, 0.07, 0.10, 0.16, 0.17 and 0.29 mg/kg.

The Meeting agreed to estimate a median of 0.02 mg/kg, the highest residue 0.24 mg/kg and a maximum residue level of 0.4 mg/kg for maize fodder replacing its previous recommendation of 0.2 mg/kg.

Rice straw, dry

The critical GAP for bentazone on rice in China is one application of 1.44 kg ai/ha, no PHI; The GAP in Greece is one application of 1.44 kg ai/ha, BBCH 12–21. The GAP in Japan is one application of 2.80 kg ai/ha, up to 60 days before harvest. Two trials were available from China on rice straw against Chinese GAP with residues of < 0.02(2) mg/kg. Two trials were available from Japan on rice straw against Japanese GAP with residues of 0.06 and 0.07 mg/kg.

The Meeting considered the number of trials insufficient for the estimation of a maximum residue level for rice straw.

Fate of residues during processing

The Meeting received information on the fate of bentazone residues during the food processing of rice.

Portion Analysed	Mean Processing Factor	STMR (mg/kg)	STMR-P (mg/kg)
Rice hulls	8.9	0.01	0.089
bran	0.37		0.0037
polished rice	0.08		0.0008

Residues in animal commodities***Estimated maximum and mean dietary burdens of farm animals***

Dietary burden calculations for beef cattle, dairy cattle, broilers and layers are provided in Annex 6. The calculations were made according to the animal diets from US-Canada, EU, Australia and Japan in the OECD Feed Table 2009.

The calculations are then summarized and the highest dietary burdens are selected for MRL and STMR estimates on animal commodities.

	Animal dietary burden, bentazone, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.24	0.06	11.3	0.54	32 ^a	0.8 ^b	0.57	0.14
Dairy cattle	5.94	0.41	11.4	0.60	22 ^c	0.76 ^d	1.0	0.24
Poultry—broiler	0.0091	0.0091	0.013	0.013	0.019	0.0019	0.018	0.012
Poultry—layer	0.091	0.091	5.4 ^e	0.17 ^f	0.019	0.019	0.01	0.01

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian meat.

^b Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat.

^c Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for mammalian milk.

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs.

^f Highest mean poultry dietary burden suitable for STMR estimates for meat and eggs.

Lactating goats were orally administered bentazone at the equivalent to 15 ppm and 75 ppm on the basis of an individual feed intake of 3 kg of feed per animal per day and incorporating an allowance for the difference in dry matter percentage between the type of diet offered (cereal/protein concentrate feed and hay) and fresh herbage, respectively. Residues of bentazone in the whole milk of goats in the 15 and 75 ppm groups were < 0.02 mg/kg and < 0.02 mg/kg respectively, goat tissues were not analysed.

Since no analysis of tissues was carried out in the goats feeding study, the Meeting decided that no recommendations could be made on the basis of this study.

In the animal metabolism study on lactating goats, residues in fat were significantly higher than that in muscle. However, it is not expected that bentazone, with a log P_{ow} of -0.45, would accumulate in fat. The Meeting decided not to estimate maximum residue levels for animal tissues on the basis of this study.

Residues in poultry tissues and eggs are estimated using the data from the poultry metabolism study in which the dose rate was 100 ppm and the highest and mean residues in tissues and eggs were determined.

Estimation of residues in poultry tissues and eggs

	Feed level	Residues	Feed level	Residues (mg/kg) in

	(ppm) for egg residues	(mg/kg) in egg	(ppm) for tissue residues	Muscle	Liver	Fat
Maximum residue level broiler or layer poultry						
Feeding study ^a	100	0.15	100	0.42	1.1	0.11
Dietary burden and residue estimate	5.4	0.008	5.4	0.023	0.059	0.006
STMR broiler or layer poultry						
Feeding study ^b	100	0.15	100	0.42	1.1	0.11
Dietary burden and residue estimate	0.17	0.0003	0.17	0.0007	0.002	0.0002

^a Highest residue for tissues and mean residue for egg

^b Mean residues for tissue and egg

The Meeting noted that the LOQ of the analytical method was 0.01 mg/kg, and agreed to estimate maximum residue level of 0.03 mg/kg for poultry meat (fat) and estimate maximum residue level of 0.01* for eggs and estimated a maximum residue level of 0.07 mg/kg for poultry edible offal. The Meeting estimated STMRs of 0 mg/kg for poultry meat (fat), edible offal and for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue concentrations listed below are suitable for establishing MRLs and for assessing IEDIs and/or IESTIs.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake for animal and plant commodities): *bentazone*.

CCN	Commodity	MRL, mg/kg		STMR or STMR-P, mg/kg	highest residue mg/kg
		new	previous		
AL 1021	Alfalfa fodder	0.5	—	0.09	0.23

DIETARY RISK ASSESSMENT

Long term intake

The evaluation of bentazone resulted in recommendations for MRLs and STMR values for raw and processed commodities. Data on consumption were available for 17 food commodities and were used to calculate dietary intake. The results are shown in Annex 3 of the 2013 Report.

The International Estimated Daily Intakes (IEDIs) of bentazone, based on the STMRs estimated, were 0% of the maximum ADI of 0.09 mg/kg bw for the thirteen GEMS/Food cluster diets. The Meeting concluded that the long-term intake of residues of bentazone resulting from its uses that have been considered by JMPR is unlikely present a public health concern.

Short-term intake

The 2012 Meeting decided that an ARfD for bentazone is unnecessary and concluded that the short-term intake of residues resulting from the use of bentazone is unlikely to present a public health

			2011/1074523, GLP; Unpublished.
1994/11112	Tuerk, W	1994	Bentazone: Spectra of Bentazone Reg.No. 051 929 (PAI). BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 1994/11112, GLP; Unpublished.
2000/1018683	Daum, A	2000	Bentazone: 13C NMR-spectrum of Bentazone (Reg.No. 51929, BAS 351 H). BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2000/1018683, GLP; Unpublished.
2011/1074524	Class, T	2001	Bentazone: Determination of the solubility in water for Bentazone (BAS 351 H, Reg.No. 51 929). PTRL Europe GmbH, Ulm, Germany Fed. Rep. 2011/1074524, GLP; Unpublished.
2011/1074525	Class, T	2001	Bentazone: Determination of the solubility in organic solvent for Bentazone (BAS 351 H, Reg.No. 51 929) TGAI. PTRL Europe GmbH, Ulm, Germany Fed. Rep. 2011/1074525, GLP; Unpublished.
2000/1018475	Daum, A	2000	Bentazone: Determination of the partition coefficient (n-octanol/water) of Bentazon (BAS 351 H, Reg.No. 51929) at 20 °C by flask shaking method. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2000/1018475, GLP; Unpublished.
1986/5018	Eswein, RP & Panek, EJ	1986	Bentazone: Hydrolysis of Bentazon in PH 5, 7 and 9 solutions at 25 °C. BASF Corp., Parsippany NJ, United States of America, 1986/5018, Not GLP; Unpublished.
2011/7002318	Singh, M	2011	Bentazone: Aqueous photolysis of ¹⁴ C-BAS 351 H. BASF Agricultural Research Center, Research Triangle Park NC, United States of America, 2011/7002318, GLP; Unpublished.
2002/1007049	Daum, A	2002	Bentazone: Ionization of Bentazone. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2002/1007049, Not subject to GLP regulations; Unpublished.
2011/1074526	Gundrum, C	2012	Bentazone: Evaluation of physical and chemical properties according to Directive 94/37/EC (Regulation (EC) No 440/2008). BASF SE, Ludwigshafen/Rhein, Germany Fed. Rep. 2011/1074526, GLP; Unpublished,
1990/10080	Gueckel, W	1990	Bentazone: Physical properties report: Bentazon-Na 600 g/L. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 1990/10080, GLP; Unpublished.
2004/1038794	Genari, G	2004	Bentazone: Certificate of analysis: Bentazon. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2004/1038794, GLP; Unpublished.
1990/10351	Giese, U	1990	Bentazone: Dosing of lactating goats with [¹⁴ C]-bentazone (BAS 351 H) for the isolation and identification of metabolites. Limburgerhof, Germany Fed. Rep. 1990/10351, GLP; Unpublished, 29,03,1990.
1991/10702	Giese, U	1991	Bentazone: Dosing of lactating goats with [¹⁴ C]-6-hydroxy-bentazone (6-Hydroxy-BAS 351 H) for the isolation and identification of metabolites. Limburgerhof, Germany Fed. Rep. 1991/10702, GLP; Unpublished, 12,08,1991.
1991/10703	Giese, U	1991	Bentazone: Dosing of lactating goats with [¹⁴ C]-8-hydroxy-bentazone (8-Hydroxy-BAS 351 H) for the isolation and identification of metabolites. Limburgerhof, Germany Fed. Rep. 1991/10703, GLP; Unpublished, 12,08,1991.
1991/11137	Großhans	1991	Bentazone: The metabolism of [¹⁴ C] bentazone in lactating goats. Limburgerhof, Germany Fed. Rep. 1991/11137, GLP; Unpublished, 09,12,1991.
1992/10161	Giese, U	1992	Bentazone: Addendum 1 to report NA 899746 (1990/10351). Dosing of lactating goats with [¹⁴ C] bentazone (BAS 351 H) for the isolation and identification of metabolites. Limburgerhof, Germany Fed. Rep. 1992/10161, GLP; Unpublished, 19,02,1992.
1995/10011	Hafemann, C	1995	Bentazone: The metabolism of [¹⁴ C]-6-OH-bentazone in lactating goats. Limburgerhof, Germany Fed. Rep. 1995/10011, GLP; Unpublished, 20,03,1995.
1995/10062	Kohl, W	1995	Bentazone: The metabolism of [¹⁴ C]-8-OH-bentazone in lactating goats. Limburgerhof, Germany Fed. Rep. 1995/10062, GLP; Unpublished, 03,01,1995.
1988/0432	Hawkins	1988	Bentazone: The metabolism of [¹⁴ C]-bentazone and its hydroxylated metabolites in hens. Limburgerhof, Germany Fed. Rep. 1988/0432, GLP; Unpublished, 12,10,1988.
1976/5060	Clark, JR etc.	1976	Bentazone: Metabolic fate of bentazone in corn. BASF Wyandotte Corporation, Agricultural Chemicals Department, Parsippany, New Jersey, 07054, Not GLP; 1976/5060, Unpublished, 02,07,1976.
1988/5543	Clark, J &	1988	Bentazone: [¹⁴ C] bentazone metabolism in green bean. BASF Corporation

Code	Author	Year	Title, Institute, Report reference
	Winkler, V		Chemicals Division, Agricultural Chemicals Group, Not GLP; 1988/5543, Unpublished, 27,04,1988.
1989/10248	Hofmann, M	1989	Bentazone: Plant uptake study with [¹⁴ C] bentazone in potatoes. Limburgerhof, Germany Fed. Rep. 1989/10248, GLP; Unpublished, 12,04,1989.
1994/5106	Ellenson, JL	1994	Bentazone: Metabolism of [¹⁴ C]-BAS 351 H in potato tubers. Agricultural Products Agricultural Research Center, Research Triangle Park, NC 27709, 1994/5106, GLP; Unpublished, 15,07,1994.
2010/1062115	Rabe, U & Kloeppner, U	2011	Bentazone: Metabolism of BAS 351 H in wheat. BASF SE, Limburgerhof, Germany Fed. Rep. 2010/1062115, GLP; Unpublished.
2010/1057318	Staudenmaier, H & Kuhnke, G	2010	Bentazone: Aerobic soil metabolism of [¹⁴ C] Bentazone. BASF SE, Limburgerhof, Germany Fed. Rep. 2010/1057318, GLP; Unpublished.
2011/1276919	Hassink, J	2012	Bentazone: Soil photolysis of [¹⁴ C] Bentazone. BASF SE, Limburgerhof, Germany Fed. Rep. 2011/1276919, GLP; Unpublished.
2011/1000621	Tornisielo, A & Sacchi, RR	2011	Bentazone: Rate of degradation of BAS 351 H in European soils under aerobic conditions. BASF SA, Guaratingueta, Brazil. 2011/1000621, GLP; Unpublished.
2002/1011918	Smelt, JH	2003	Bentazone: Laboratory studies on the degradation rates of Bentazone in Dutch soil profiles. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2002/1011918, GLP; Unpublished.
2002/1008886	van de Veen, JR	2003	Bentazone: Kinetic evaluation of the degradation rates of Bentazone in 5 soil profiles. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2002/1008886, Not GLP; Unpublished.
2001/1021063	Leistra, M <i>et al.</i>	2001	Bentazone: Rate of Bentazone transformation in four layers of a humic sandy soil profile with fluctuating water table. 2001/1021063, Not GLP; Published.
2005/1026922	Class, T	2005	Bentazone: Aerobic soil degradation of N-Methyl-Bentazone in three standard soils at 20°C. PTRL Europe GmbH, Ulm, Germany Fed. Rep. 2005/1026922, GLP; Unpublished.
2010/1143715	Radzom, M <i>et al.</i>	2011	Bentazone: Confined rotational crop study with BAS 351 H. BASF SE, Limburgerhof, Germany Fed. Rep. 2010/1143715, GLP; Unpublished.
2000/1000243	Linder, G <i>et al.</i>	2000	Bentazone: Technical procedure—Method for the determination of Bentazon, 6-OH-Bentazon and 8-OH-Bentazon in plant matrices—Method 438/1. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2000/1000243, Not GLP; Unpublished.
2005/1027613	Mackenroth, C & Kerl, W	2005	Bentazone: Applicability of an enzymatic cleavage in analytical method No. 438/1 used to determine bentazone and its metabolites 6-OH-bentazone and 8-OH-bentazone as glucoside derivatives. BASF AG Agrarzentrum Limburgerhof, Limburgerhof, Germany Fed. Rep. 2005/1027613, Not GLP; Unpublished.
2007/1013924	Class, T	2007	Bentazone: Bentazone and its two OH-metabolites: Validation of residue method 438/2 for plant materials using LC/MS/MS. PTRL Europe GmbH, Ulm, Germany Fed. Rep. 2007/1013924, GLP; Unpublished.
2007/1013926	Schulz, H & Meyer, M	2007	Bentazone: Determination of Bentazone, 6-OH-Bentazone and 8-OH-Bentazone in plant matrices—Independent laboratory validation of the analytical method No. 438/2. SGS Institut Fresenius GmbH, Taunusstein, Germany Fed. Rep. 2007/1013926, GLP; Unpublished.
1996/5278	Abdel-Baky, S	1995	Bentazone: Method for determination of Bentazon and its metabolites residues in rice grain and bran, soya bean seed, hulls, forage and refined oil, corn grain, and dry peas. BASF Corp. Agricultural Products Center, Research Triangle Park NC, United States of America. 1996/5278, GLP; Unpublished.
1998/11399	Class, T & Bacher, R	1998	Bentazone: Lueckenindikation Pfefferminze und Melisse: Untersuchung auf Rueckstaende nach Behandlung mit Basagran: Wirkstoff: Bentazon. PTRL Europe GmbH, Ulm, Germany Fed. Rep. 1998/11399, GLP; Unpublished.
2007/1013925	Bacher, R	2007	Bentazone: Bentazone and its two OH-metabolites: Validation of residue method 438/2 for animal materials using L/MS/MS. PTRL Europe GmbH, Ulm, Germany Fed. Rep. 2007/1013925, GLP; Unpublished.
2007/1013927	Schulz, H & Meyer, M	2007	Bentazone: Determination of Bentazone, 6-OH-Bentazone and 8-OH-Bentazone in animal matrices—Independent laboratory validation of the analytical method. No. 438/2. SGS Institut Fresenius GmbH, Taunusstein, Germany Fed. Rep. 2007/1013927, GLP; Unpublished.
2009/1091211	Penning, H	2009	Bentazone: Validation of analytical method L0136/01 for the LC-MS/MS determination of BAS 351 H (Bentazon) and its metabolite BH 351-N-Me (Reg.No. 79520) in soil and sediment. BASF SE, Limburgerhof, Germany Fed. Rep. 2009/1091211, GLP; Unpublished.
2009/1076476	Penning, H	2009	Bentazone: Validation of analytical method L0141/01 for the LC-MS/MS determination of BAS 351 H (Bentazon) in surface water and groundwater. BASF SE, Limburgerhof, Germany Fed. Rep. 2009/1076476, GLP;

BIXAFEN (262)

First draft was prepared by Mr Christian Sieke, the Federal Institute for Risk Assessment, Berlin,, Germany

EXPLANATION

Bixafen (ISO common name) is a pyrazole-carboxamide fungicide used to control diseases on rape plants and cereals. Bixafen inhibits fungal respiration by binding to mitochondrial respiratory complex II. It was considered for the first time by the 2013 JMPR for toxicology and residues.

IDENTITY

ISO common name Bixafen

Chemical name

IUPAC N-(3',4'-dichloro-5-fluorobiphenyl-2-yl)-3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamide

CA 1H-pyrazole-4-carboxamide, N-(3',4'-dichloro-5-fluoro[1,1'-biphenyl]-2-yl)-3-(difluoromethyl)-1-methyl-

CIPAC No. 819

CAS No. 581809-46-3

Structural formula

Molecular formula $C_{18}H_{12}Cl_2F_3N_3O$

Molecular mass 414.21 g/mol

Specifications

Specifications for bixafen are not yet developed by FAO.

PHYSICAL AND CHEMICAL PROPERTIES

Property	Results	Method (test material)	Reference
Melting point	The melting point of pure bixafen (purity 98.9%) at atmospheric pressure is 146.6 °C The melting point of bixafen technical (purity 95.8%) at atmospheric pressure is 142.9 °C	EC A.1, OECD 102 batch 1 + batch 2	Smeykal, H 2007, BIXAFEN_001 & Smeykal, H 2007, BIXAFEN_002

Property	Results	Method (test material)	Reference
Boiling point & temperature of decomposition	No boiling before decomposition at approx. 250 °C observed	EC A.2, OECD 103 + OECD 113 batch 1 + batch 2	Smeykal, H 2007, BIXAFEN_001 & Smeykal, H 2007, BIXAFEN_002
Relative density	Bixafen, pure (purity 98.9%): $D_4^{20} = 1.43$ Bixafen, technical (purity 95.8%): $D_4^{20} = 1.51$	EC A.3, OECD 109 batch 1 + batch 2	Bogdoll, B and Strunk, B 2007, BIXAFEN_003
Vapour pressure	Extrapolated: 4.6×10^{-8} Pa at 20 °C 1.1×10^{-7} Pa at 25 °C 5.9×10^{-6} Pa at 50 °C	EC A.4, OECD 104 batch 3 (purity 98.8%)	Smeykal, H 2006, BIXAFEN_004
Henry's Law Coefficient	Henry's law constant at 20 °C (calculated): 3.89×10^{-5} Pa m ³ mol ⁻¹	Calculation	Bogdoll, B and Lemke, G 2007, BIXAFEN_005
Physical state, colour	Active substance, pure: no noticeable odour Active substance as manufactured: no noticeable odour	OPPTS 830.6302 OPPTS 830.6303 batch 1 (purity 98.9%) + batch 2 (purity 95.8%)	Bogdoll, B and Strunk, B 2007, BIXAFEN_006
Odour	Active substance, pure: white powder Active substance as manufactured: light brown powder		
Solubility in water including effect of pH	0.49 mg/L at 20 °C Investigation on different pH is not necessary, because bixafen has no acidic or basic properties in the range of pH 1 to pH 12.	EC A.6, OECD 105 batch 4 (purity 99.2%)	Jungheim, R, 2005, BIXAFEN_007 & Bogdoll, B 2008, BIXAFEN_008
Solubility in organic solvents	[g/L at 20 °C] n-heptane 0.056 dichloromethane 102 methanol 32 toluene 16 acetone > 250 ethylacetate 82 dimethylsulfoxide > 250	CIPAC MT 157 based on EC A.6, OECD 105 batch 1 (purity 98.9%) + batch 3 (purity 98.8%)	Bogdoll, B and Eyrich, U, 2007, BIXAFEN_009
Dissociation constant	No dissociation constant of bixafen was found in the pH range of pH 1–pH 12. This result is in line with the chemical structure of bixafen which does not contain an acidic or a basic group.	OECD 112 batch 3 (purity 98.8%)	Bogdoll, B and Wiche, A 2007, BIXAFEN_010
Partition coefficient n-octanol / water	Determination of the partition coefficient of Bixafen in 1-octanol / water (HPLC column 40 °C) P _{ow} 2046	EC A.8, OECD 117 (HPLC-method)	Bogdoll, B and Lemke, G 2005, BIXAFEN_011

Property	Results	Method (test material)	Reference
	log P _{ow} 3.3	batch 3 (purity 98.8%)	
Hydrolysis rate	Pyrazole-[¹⁴ C] Bixafen had shown no hydrolytic breakdown at pH 4, 7 and 9 over 5 days (120 hours) at 50 °C.	EPA 161-1, OECD 111, EC C.7 batch 5 (purity 99.2%)	Oddy, AM 2005, BIXAFEN_012
Photochemical degradation	In sterile aqueous buffer solution at 25 °C under artificial sunlight exposure ($\lambda > 290$ nm) the calculated experimental half-life was 82 days of intensive continuous irradiation (791 W/m ² in the wavelength range 300–800 nm).	EPA 161-2 batch 6	Muehmel, T and Fliege, R 2006, BIXAFEN_013

Hydrolysis of bixafen

A hydrolysis study was carried out by Oddy, AM (2005, BIXAFEN_012). Pyrazole-¹⁴C-bixafen at concentrations of 0.25 mg/L was investigated in aqueous buffer solutions at three pH values at 50 °C for up to 120 h.

Duplicate samples were analysed after 2.4, 48 and 120 hours by HPLC-LSC and TLC for confirmation purposes.

A summary of the results is presented in the following table:

Table 1 Summary of radioactive residues in sterile buffer solutions fortified with [¹⁴C] pyrazole labelled bixafen at a concentration of 0.25 mg/L

Time (hours)	pH 4		pH 7		pH 9	
	% TRR recovered	% recovered as bixafen in mg eq/kg	% TRR recovered	TRR recovered as bixafen in mg eq/kg	% TRR recovered	TRR recovered as bixafen in mg eq/kg
0	97 101	100 100	101.49	100 100	103 103	100 100
2.4	96 93	100 100	97 96	100 100	93 96	100 100
48	100 95	100 100	99 90	100 100	99 101	100 100
120	97 94	100 100	99 93	100 100	95 92	100 100

The hydrolysis of bixafen under processing conditions is described under fate of residues in storage and processing.

Formulations

Bixafen is registered as the following EC formulations:

Table 2 Formulations registered containing bixafen as active ingredient

Formulation	Content of active ingredients
EC 125	125 g/L bixafen
EC 190	40 g/L bixafen 50 g/L fluoxastrobin 100 g/L prothioconazole

Formulation	Content of active ingredients
EC 216	50 g/L bixafen 166 g/L tebuconazole
EC 225	75 g/L bixafen 150 g/L prothioconazole
EC 235	75 g/L bixafen 160 g/L prothioconazole
EC 260	60 g/L bixafen 200 g/L prothioconazole
EC 275	75 g/L bixafen 100 g/L prothioconazole 100 g/L tebuconazole
EC 275	75 g/L bixafen 110 g/L prothioconazole 90 g/L tebuconazole
EC 285	75 g/L bixafen 110 g/L prothioconazole 100 g/L tebuconazole
EC 400	50 g/L bixafen 250 g/L spiroxamine 100 g/L prothioconazole

METABOLISM AND ENVIRONMENTAL FATE

Metabolism studies were conducted using [^{14}C -5-pyrazole]-bixafen (pyrazole-label) and [^{14}C -dichlorophenyl-UL]-bixafen (dichlorophenyl-label). The position of the label for both substances is presented in the following figures:

Figure 1 [pyrazole-5- ^{14}C]-bixafen

Figure 2 [dichlorophenyl-UL- ^{14}C] bixafen

Chemical names, structures and code names of metabolites and degradation products of bixafen are shown in Table 3.

Table 3 Known metabolites of bixafen

Animal metabolism

The Meeting received metabolism studies on laboratory animals, poultry and lactating goats using the pyrazole- and the dichlorophenyl-label of bixafen.

The metabolism of bixafen in livestock animals was limited, showing unchanged parent bixafen as main residue in all matrices except liver. Besides the unchanged parent substance the metabolite M21 (bixafen-desmethyl) was found as major residue in all tissues, and represented the main residue in liver following exhaustive extraction involving hydrolysis. The sum of parent and M21 represented more than 50% of the total residue in all samples of animal origin, often more than 80% TRR. The only other major metabolites present at > 10% of the TRR were the two isomers of M23 in goat livers and kidneys.

The most important metabolic reaction was the demethylation of the pyrazole ring resulting in bixafen-desmethyl. Further biochemical reactions included substitution of the fluorine atom by a hydroxy group and an adjacent glutathione conjugation, an unspecified hydroxylation of an aromatic ring and conjugation with various sugar molecules, and hydroxylation of the pyrazole ring.

In general the metabolic pathway of bixafen was comparable between ruminants and hens. All metabolites identified in goats were also found in rats. The metabolites M26, M25 and M18 found in eggs and poultry liver were not directly identified in the rat.

Laboratory animals

Rats

In rats given (dichlorophenyl-U-¹⁴C)-labelled bixafen orally by gavage, absorption was rapid and accounted for at least 83% of the total administered radioactivity after a single low dose (2 mg/kg bw). The maximum plasma concentrations of radioactivity were reached approximately 2–4 and 8 hours after administration of the low and high doses (2 and 50 mg/kg bw), respectively. Radioactivity was widely distributed throughout the body. Elimination of the radioactivity was mainly via faeces (≥ 91%), whereas elimination via urine accounted for 1–3% of the administered dose. In bile duct-cannulated rats, extensive biliary excretion (up to 83%) was demonstrated. Elimination of the radioactivity from the body was rapid, with a half-life in plasma of 8–9 hours and a mean residence time of 13–19 hours (for the low dose). Residues in tissues at 72 hours after a single oral dose as well as after repeated oral dosing accounted for 0.1–3% of the administered radioactivity, with liver and kidneys containing the highest concentrations of residues.

Metabolism of bixafen in rats was extensive, and more than 30 metabolites were identified. The main metabolic routes included demethylation, hydroxylation of the parent and bixafen-desmethyl, and conjugation with glucuronic acid or glutathione. A minor metabolic reaction was the cleavage of the amide bridge of bixafen.

Lactating goats

The kinetic behaviour and the metabolism of [pyrazole-5-¹⁴C]-bixafen was investigated in the lactating goat by Spiegel, K and Koester, J (2007, BIXAFEN_014). One goat (41 kg bw) was dosed orally five times in 24 h intervals with 2.0 mg radiolabelled bixafen per kg body weight per day (equivalent to 34.7 ppm in the diet). The goat was sacrificed about 24 hours after the last dose. Milk, plasma, urine and faeces were collected during the whole dosing period. After sacrifice liver, kidney, muscle and fat were sampled.

Analysis of the total radioactive residues (TRR) was carried out using combustion and liquid scintillation counting (LSC).

Milk pools, muscle and kidney were extracted with acetonitrile/water mixtures. The resulting extracts were degreased by a clean-up step using a C₁₈-SPE cartridge. Milk sugar was removed in a second clean-up step using an XAD-4 cartridge.

Liver was extracted analogously to muscle and kidney but the solids after conventional extraction were additionally subjected to four exhaustive extraction steps at increased temperature with microwave assistance. In the third and fourth step formic acid and hydrochloric acid, respectively were added to the acetonitrile/water mixtures. These extracts were also degreased by a clean-up step using a C₁₈-SPE cartridge in the same way as the conventional extracts.

An aliquot of the fat composite was extracted subsequently with hexane and acetonitrile. The hexane phases were partitioned with acetonitrile and vice versa. The acetonitrile phases were combined, concentrated and analysed.

The radioactivity in all extracts was determined by LSC. Aliquots were concentrated and analysed by radio-HPLC and UV detection (254 nm) using a reversed phase column and an acidic acetonitrile/water gradient. The identification of metabolites was conducted either by comparison with reference substances and/or confirmation by LC-MS/MS.

At the end of the dosing period most of the administered radioactivity was excreted via the urine (5.42% AR) and the faeces (82.088% AR).

The total radioactive residues (TRR) found were highest in liver with 1.178 mg eq/kg, followed by fat (perirenal: 0.318 mg eq/kg, omental: 0.544 mg eq/kg), kidney (0.203 mg eq/kg) and muscle (round muscle: 0.057 mg eq/kg, loin muscle: 0.063 mg eq/kg). In milk the TRR increased from 0.003 mg eq/kg directly after the first administration up to a plateau of 0.153 mg eq/kg after three days. The TRR levels found are summarized in Table 5. The radioactivity in milk and plasma are presented in Tables 5 and 6.

Table 4 TRR in goats milk and tissues after administration of pyrazole-¹⁴C-bixafen at 2.0 mg/kg bw and day (34.7 ppm in the diet)

120		0.041	0.040

Samples of tissues and milk were further analysed for the composition of the radioactivity. Extraction rates using acetonitrile/water were generally > 90%, except for liver, which required additional exhaustive extraction including hydrolysis. Parent bixafen was the major residue in milk (73.8% TRR, 0.127 mg eq/kg), muscle (55.8% TRR, 0.032 mg eq/kg), fat (88.5% TRR, 0.413 mg eq/kg) and kidney (44.1% TRR, 0.089 mg eq/kg). In liver bixafen was more strongly degraded being present at levels of 17.6% of the TRR (0.207 mg eq/kg).

Besides the parent compound M21 (bixafen-desmethyl) was a major metabolite in all matrices investigated: 17.6% TRR in milk (0.03 mg eq/kg), 43.2% TRR in muscle (0.025 mg eq/kg), 10.6% TRR in fat (0.05 mg eq/kg) and 37.9% TRR in kidney (0.077 mg eq/kg). In liver, the conventional and exhaustive extraction released a total of 33.6% of the TRR (0.397 mg eq/kg) as bixafen-desmethyl.

The only other major metabolite found was M23 in milk, liver and kidney. The sum of both isomers reached levels of 13.8% of the TRR in liver (isomer 1: 8.6% TRR, 0.102 mg eq/kg; isomer 2: 5.2% TRR, 0.062 mg eq/kg) and of 14.5% of the TRR in kidney (isomer 1: 4.3% TRR, 0.009 mg eq/kg; isomer 2: 10.2% TRR, 0.021 mg eq/kg). In milk M23 was present in lower amounts (isomer 2 only: 1.4% TRR, 0.002 mg eq/kg)

In the following table the extraction rates and the metabolites identified are summarised.

Table 6 Characterisation and identification of compounds in milk and tissues of the lactating goats after administration of pyrazole-¹⁴C-bixafen at 2.0 mg/kg bw and day (34.7 ppm in the diet)

In a second study by Spiegel, K and Koester, J (2007, BIXAFEN_015) the metabolism of [dichlorophenyl-UL-¹⁴C]-bixafen was investigated in one lactating goat. The goat (39 kg bw) was dosed orally five times in 24 h intervals with 2.0 mg radiolabelled BYF 00587 per kg body weight per day. This amount corresponded to 46.08 ppm in the diet. The goat was sacrificed about 24 hours after the last dose.

Analysis of the total radioactive residues and the extraction of samples collected was conducted as described in the metabolism in goats study using [pyrazole-5-¹⁴C]-bixafen by Spiegel, K and Koester, J (2007, BIXAFEN_014).

From the total dose administered approximated 1.75% of the AR was excreted via the urine and 71.88% via the faeces. The total radioactive residues (TRR) found were highest in liver with 0.737 mg eq/kg, followed by fat (0.611 mg eq/kg), kidney (0.143 mg eq/kg) and muscle (0.047 mg eq/kg). In milk the TRR increased from 0.03 mg eq/kg after the first administration up to a plateau of 0.126 mg eq/kg after four days. The TRR levels found are summarized in Table 7. The radioactivity in milk and plasma are presented in Tables 8 and 9.

Table 7 TRR in goats milk and tissues after administration of dichlorophenyl-¹⁴C-bixafen at 2.0 mg/kg bw and day (46.08 ppm in the diet)

Matrix	% of total dose administered	TRR [mg eq/kg]

Samples of tissues and milk were further analysed for the composition of the radioactivity. Extraction rates using acetonitrile/water were generally > 90%, except for liver, which required additional exhaustive extraction including hydrolysis. Parent bixafen was the major residue in milk (77.2% TRR, 0.05 mg eq/kg), muscle (65.6% TRR, 0.031 mg eq/kg), fat (89.4% TRR, 0.547 mg eq/kg) and kidney (46.3% TRR, 0.066 mg eq/kg). In liver bixafen was more strongly degraded being present at levels of 22.8% of the TRR (0.168 mg eq/kg) in the conventional extract plus 3.7% of the TRR (0.027 mg eq/kg) in the exhaustive extract for a total of 26.5% of the TRR (0.195 mg eq/kg).

Besides the parent compound M21 (bixafen-desmethyl) was a major metabolite in all matrices investigated: 15.6% TRR in milk (0.001 mg eq/kg), 34.4% TRR in muscle (0.016 mg eq/kg), 10.4% TRR in fat (0.064 mg eq/kg) and 36.5% TRR in kidney (0.052 mg eq/kg). In liver, the conventional and exhaustive extraction released a total of 38.7% of the TRR (0.286 mg eq/kg) as bixafen-desmethyl.

The only other metabolite found was M23 in milk, liver and kidney. The sum of both isomers reached levels of 2.3% of the TRR in milk (isomer 1: 0.8% TRR, < 0.001 mg eq/kg; isomer 2: 1.5% TRR, 0.001 mg eq/kg), 18.9% of the TRR in liver (isomer 1: 13.1% TRR, 0.097 mg eq/kg; isomer 2: 5.8% TRR, 0.043 mg eq/kg) and of 9.3% of the TRR in kidney (isomer 1: 2.8% TRR, 0.004 mg eq/kg; isomer 2: 6.5% TRR, 0.009 mg eq/kg).

In the following table the extraction rates and the metabolites identified are summarised:

Table 9 Characterisation and identification of compounds in milk and tissues of the lactating goats after administration of dichlorophenyl-¹⁴C-bixafen at 2.0 mg/kg bw and day (46.08 ppm in the diet)

Figure 3 Proposed metabolic pathway of bixafen in lactating goats

Laying hens

The metabolism of [pyrazole-5-¹⁴C]-bixafen was investigated in laying hens by Koester, J (2007, BIXAFEN_016). Six hens were orally dosed 14 times in intervals of 24 h with 2.04 mg radiolabelled bixafen per kg body weight per day (corresponding to 25.75 ppm in the diet). The animals were sacrificed about 24 hours after the last dose. The total radioactivity was measured daily in the excreta and in eggs, and at sacrifice in the dissected tissues muscle, liver, fat and skin.

Analysis of the total radioactive residues (TRR) was carried out using combustion and liquid scintillation counting (LSC).

For metabolism investigations, composite samples of muscle (leg and breast), liver, subcutaneous fat and eggs (day 1 to 6 and day 7 to 14) of all animals were used. Aliquots of egg pools, muscle, liver and excreta were extracted with acetonitrile/water mixtures. The solids obtained by conventional extraction of liver were further extracted at increased temperature (approx. +120 °C) under microwave conditions. The fat sample was extracted with acetonitrile/n-hexane mixtures and partitioned into an acetonitrile and n-hexane phase. The acetonitrile extract was concentrated and analysed.

All samples were analysed by radio-HPLC using a reversed phase column and an acidic acetonitrile/water gradient. The identity of the major components was confirmed by LC-MS/MS in the egg. The identification of parent compound and metabolites in other matrices of the laying hen was achieved by co-chromatography of original extracts with isolated metabolites or radiolabelled reference items or by comparison of known metabolic profiles.

After the dosing period a total of 88.33% of the applied radioactivity was excreted. The total radioactive residues (TRR) found were highest in eggs with up to 1.019 mg eq/kg after 13 days of dosing. A plateau of the total radioactivity in eggs was observed after approximately one week. In tissues liver contained the highest TRR (0.641 mg eq/kg), followed by fat (0.227 mg eq/kg), kidney (0.193 mg eq/kg) and muscle (0.032 mg eq/kg). The TRR levels found are summarized in Table . The time course of radioactivity in eggs is presented in Table and Table .

Samples of tissues and eggs were further analysed for the composition of the radioactivity. Extraction rates using acetonitrile/water were generally > 90%, except for liver, which required additional exhaustive extraction including hydrolysis.

Parent bixafen was the major residue in eggs found at levels of 68.6% of the TRR after 1–6 days (0.416 mg eq/kg) and 55.4% of the TRR after 7–14 days (0.498 mg eq/kg). Besides the parent compound M21 (bixafen-desmethyl) was a major metabolite being present at levels of 26% TRR after 1–6 days (0.157 mg eq/kg) and 35.4% TRR (0.318 mg eq/kg) after 7–14 days. M24 and M26 were also detected in eggs (7–14 days only) with 0.6% TRR (0.006 mg eq/kg) and 1.0% TRR (0.009 mg eq/kg), respectively.

Fat mainly contained unchanged parent as major residue (79.6% TRR, 0.181 mg eq/kg). M21 (bixafen-desmethyl) was the only other metabolite with 19.9% TRR (0.045 mg eq/kg).

In muscle M21 (bixafen-desmethyl) gave the highest residue (35.4% of the TRR, 0.011 mg eq/kg). The unchanged parent substance was the only other substance identified at levels of 23.4% of the TRR (0.008 mg eq/kg).

In liver a total of 42.3% of the TRR were identified as bixafen-desmethyl (conventional extract: 24.1% TRR, 0.155 mg eq/kg; exhaustive extract: 18.2% TRR, 0.116 mg eq/kg). The unchanged parent was present mainly in conjugated form cleaved by hydrolysis, resulting in a total of 0.14 mg eq/kg or 21.9% of the TRR (conventional extraction: 4.5% TRR, 0.029 mg eq/kg; exhaustive extraction: 17.4% TRR as conjugate, 0.111 mg eq/kg). Besides parent bixafen and M21 liver contained several minor metabolites all being present at levels below 10% of the TRR. M14 and M18 represented 2.3% TRR (0.015 mg eq/kg) and 1.5% TRR (0.01 mg eq/kg), respectively. In addition hydroxylated and conjugated metabolites following bixafen-desmethyl were identified: M24 with 1.8% TRR (0.012 mg eq/kg), M25 with 1.0% TRR (0.007 mg eq/kg), M26 with 8.8% TRR (0.057 mg eq/kg), M27 with 4.6% TRR (0.029 mg eq/kg) and M37 with 2.7% TRR (0.017 mg eq/kg).

In the following table the extraction rates and the metabolites identified are summarised:

In a second study on laying hens conducted by Koester, J (2007, BIXAFEN_017) [dichlorophenyl-UL-¹⁴C]-bixafen was administered to five hens orally for 14 days with 2.03 mg radiolabelled bixafen per kg body weight per day (corresponding to 32.42 ppm in the diet). The animals were sacrificed about 24 hours after the last dose. The total radioactivity was measured daily in the excreta and in eggs, and at sacrifice in the dissected tissues muscle, liver, fat and skin.

Analysis of the total radioactive residues and the extraction of samples collected was conducted as described in the metabolism in laying hens study using [pyrazole-5-¹⁴C]-bixafen by Koester, J (2007, BIXAFEN_016).

At the end of the dosing period approximately 92.54% of the administered doses were excreted. The total radioactive residues (TRR) found were highest in eggs with up to 0.826 mg eq/kg

after 7 days of dosing. A plateau of the total radioactivity in eggs was observed after approximately one week. In tissues liver contained the highest TRR (0.807 mg eq/kg), followed by fat (0.365 mg eq/kg), kidney (0.331 mg eq/kg) and muscle (0.037 mg eq/kg). The TRR levels found are summarized in Table . The time course of radioactivity in eggs and excreta is presented in Table and

Table .

Samples of tissues and eggs were further analysed for the composition of the radioactivity. Extraction rates using acetonitrile/water were generally > 90%, except for liver, which required additional exhaustive extraction including hydrolysis.

Parent bixafen was the major residue in eggs found at levels of 62.3% of the TRR after 1–7 days (0.327 mg eq/kg) and 51.1% of the TRR after 8–14 days (0.405 mg eq/kg). Besides the parent compound M21 (bixafen-desmethyl) was a major metabolite being present at levels of 33.2% TRR after 1–6 days (0.174 mg eq/kg) and 39.1% TRR (0.31 mg eq/kg) after 8–14 days. M24 and M26 were also detected in eggs with 0.9% TRR (0.007 mg eq/kg, 8–14 days only) and 0.9 to 1.2% TRR (0.005 to 0.009 mg eq/kg), respectively.

Fat mainly contained unchanged parent as major residue (80.3% TRR, 0.305 mg eq/kg). M21 (bixafen-desmethyl) was the only other metabolite with 18.6% TRR (0.071 mg eq/kg).

In muscle M21 (bixafen-desmethyl) gave the highest residue (50.8% of the TRR, 0.019 mg eq/kg). The unchanged parent substance was the only other substance identified at levels of 40.8% of the TRR (0.015 mg eq/kg).

In liver a total of 45.7% of the TRR were identified as bixafen-desmethyl (conventional extract: 25.7% TRR, 0.207 mg eq/kg; exhaustive extract: 20% TRR, 0.161 mg eq/kg). The unchanged parent was present mainly in conjugated form cleaved by hydrolysis, resulting in a total of 0.27 mg eq/kg or 31.5% of the TRR (conventional extraction: 6.7% TRR, 0.054 mg eq/kg; exhaustive extraction: 26.8% TRR as conjugate, 0.216 mg eq/kg). Besides parent bixafen and M21 liver contained several minor metabolites all being present at levels below 10% of the TRR. M14 represented M14 (bixafen-5-hydroxyphenyl-6-cysteinyl) was found with 3.5% TRR (0.029 mg eq/kg). In addition hydroxylated and conjugated metabolites following bixafen-desmethyl were identified: M24 with 3.1% TRR (0.025 mg eq/kg), M26 with 8.4% TRR (0.067 mg eq/kg) and M27 with 5.1% TRR (0.041 mg eq/kg).

In the following table the extraction rates and the metabolites identified are summarised.

Figure 4 Proposed metabolic pathway of bixafen in laying hens

Plant metabolism

The fate of bixafen in plants was investigated following foliar application of ^{14}C -radiolabelled active substance to soya beans and wheat. In all samples unchanged bixafen was the major residue, normally

amounting nearly 90% of the TRR or more. Except for soya bean seeds, the only other metabolite found was M21 (bixafen-desmethyl), however its levels were below 3% of the TRR in all samples.

In soya bean seeds, which were not directly affected by the spray solution, parent bixafen was still the main residue but represented only 29.5% of the TRR. In addition the tautomers M44 & M45 (BYF 00587-desmethyl-pyrazole-4-carboxylic acid, 18.8% TRR, 0.004 mg eq/kg) and M47 (pyrazolone-4-carboxylic acid, 12.1% TRR, 0.003 mg eq/kg) were identified. No M21 (bixafen-desmethyl) was found in soya bean seeds.

Soya beans

The metabolism of bixafen was investigated (Spiegel, K 2007, BIXAFEN_018) in soya beans (var. Merlin) after three spray applications with [pyrazole-5-¹⁴C]-bixafen formulated as an EC 125. The first application was performed when the first flowers opened (BBCH 60), the second at the end of flowering (BBCH 69) and the third when approximately 80% of the pods were ripe (BBCH 88). Each application was conducted with a nominal amount of 0.06 kg ai/ha, however a total amount of 0.188 kg ai/ha was actually applied. The plants were grown in a greenhouse.

Forage was harvested at growth stage BBCH 70–71 (5 days after the 2nd application), hay at growth stage BBCH 75 (29 days after the 2nd application), and straw and seeds at maturity (BBCH 96, 26 days after the 3rd application).

The samples were homogenised with liquid nitrogen and extracted three times with a mixture of acetonitrile/water (4/1, v/v) using an Ultra-Turrax homogeniser. After each extraction step, the extracts were separated from the solids by centrifugation. The radioactivity of each extract was determined by LS measurement. The extracts were combined, diluted or, if necessary concentrated, for HPLC analysis. The remaining solids were lyophilised, and the radioactivity was determined by combustion followed by LSC. The TRR was calculated as the sum of the radioactivity determined in the extracts and in the solids.

For seeds, a subsequent exhaustive extraction was conducted with acetonitrile/water 4/1 (v/v) and with acetonitrile/acetic acid 4/1 (v/v) with microwave assistance, both at 80 °C. The microwave extracts were concentrated to the aqueous remainder and partitioned three times with heptane. The heptane phase contained only negligible amounts of radioactivity and was discarded. The aqueous phase was concentrated and analysed by HPLC.

Parent compound and metabolites were identified by HPLC and TLC co-chromatography (by spiking) or HPLC and TLC comparison with reference compounds (peak retention times, comparison of chromatographed zones).

The TRRs found in the samples collected amounted 5.32 mg eq/kg in forage, 4.0 mg eq/kg in hay, 12.9 mg eq/kg in straw, and 0.024 mg eq/kg in the seed. In forage, hay and straw unchanged bixafen was the major residue being present at levels > 89.9% of the TRR. The only other metabolite present was M21 (bixafen-desmethyl) found at 0.5% to 2.6% of the TRR.

In the seeds parent bixafen was also identified as major residue; however, the levels of 29.7% of the TRR (0.007 mg eq/kg) were lower compared to other plant parts. Besides the parent substance the tautomers M44 & M45 (BYF 00587-desmethyl-pyrazole-4-carboxylic acid, 18.8% TRR, 0.004 mg eq/kg) and M47 (pyrazolone-4-carboxylic acid, 12.1% TRR, 0.003 mg eq/kg) were found as major metabolites. M21 (bixafen-desmethyl) was not present in soya bean seeds.

An overview of the TRR levels found in the collected samples and the composition of the residue is presented in the following table.

Table 18 Total radioactive residues and their composition after application of [pyrazole-5-¹⁴C]-bixafen to soya beans

A second study investigating the metabolism of bixafen in soya beans was conducted by Spiegel, K (2007, BIXAFEN_019). [Dichlorophenyl-UL-¹⁴C]-bixafen was formulated as an EC 125. The first application was performed when the first flowers opened (BBCH 60), the second at the end of flowering (BBCH 69) and the third when approximately 80% of the pods were ripe (BBCH 88). Each application was conducted with a nominal amount of 0.06 kg ai/ha, however a total amount of 0.187 kg ai/ha was actually applied. The plants were grown in a greenhouse.

Forage was harvested at growth stage BBCH 70–71 (5 days after the 2nd application), hay at growth stage BBCH 75 (29 days after the 2nd application), and straw and seeds at maturity (BBCH 96, 26 days after the 3rd application).

The samples were homogenised with liquid nitrogen and extracted three times with a mixture of acetonitrile/water (4/1, v/v) using an Ultra-Turrax homogeniser. After each extraction step, the extracts were separated from the solids by centrifugation. The radioactivity of each extract was determined by LS measurement. The extracts were combined, diluted or, if necessary concentrated, for HPLC analysis. The remaining solids were lyophilised, and the radioactivity was determined by combustion followed by LSC. The TRR was calculated as the sum of the radioactivity determined in the extracts and in the solids.

Parent compound and metabolites were identified by HPLC and TLC co-chromatography (by spiking) or HPLC and TLC comparison with reference compounds (peak retention times, comparison of chromatographed zones).

The TRRs found in the samples collected amounted 3.98 mg eq/kg in forage, 2.81 mg eq/kg in hay, 9.52 mg eq/kg in straw, and 0.005 mg eq/kg in the seed. In forage, hay and straw unchanged bixafen was the major residue being present at levels > 91.8% of the TRR. The only other metabolite present was M21 (bixafen-desmethyl) found at 0.6% to 1.9% of the TRR.

In the seeds total radioactive residues were too low for identification. The described extraction methods released 53% of the TRR.

An overview of the TRR levels found in the collected samples and the composition of the residue is presented in the following table.

Wheat

The metabolism of bixafen in wheat (var. Thassos) was investigated by Miebach, D and Bongartz, R (2007, BIXAFEN_020) after two spray applications with [pyrazole-5-¹⁴C]-bixafen formulated as an EC 200. The first application with 0.125 kg ai/ha (actual 132 g ai/ha) was performed at the end of tillering / beginning of stem elongation (BBCH 29–31), and the second with 0.15 kg ai/ha (actual 154 g ai/ha) at the end of flowering (BBCH 69). Plants were grown in plastic containers under natural temperature and light conditions in Monheim, Germany. The glass roof of the vegetation area was open during the sunshine periods and was automatically closed during rainfall. Plants were irrigated as needed.

Forage was harvested at growth stage BBCH 38 (9 days after 1st application), hay at growth stage BBCH 77 (9 days after 2nd application), and straw and grain at maturity (BBCH 89, 50 days after 2nd application).

The homogenised samples were extracted three times with a mixture of acetonitrile/water (4/1, v/v) and once with acetonitrile using an Ultra-Turrax homogeniser. The extracts were separated from the solids by suction through a filter. The ¹⁴C-radioactivity of liquid samples was determined by liquid scintillation counting (LSC). The remaining solids were air dried. Solid samples were combusted and the released ¹⁴CO₂ was absorbed in an alkaline scintillation cocktail and radio-assayed by LSC. The TRR of each RAC was determined by summation of the radioactivity in the combined extracts and in the solids.

The corresponding extracts of wheat RAC were combined and concentrated to a volume suitable for HPLC chromatography. Parent compound and metabolites were quantified by HPLC. The TRRs and the quantified amounts of compounds were expressed as mg bixafen-equivalents per kg sample material.

Parent compound in the extracts of straw and grain was identified by LC-MS-spectroscopy. Metabolites in straw and grain were identified by HPLC co-chromatography with radiolabelled reference compounds. Parent compound and metabolites in forage and hay were assigned by comparison of the metabolite patterns obtained for straw and grain.

The TRRs found in the samples collected amounted 1.67 mg eq/kg in forage, 6.57 mg eq/kg in hay, 24.27 mg eq/kg in straw, and 0.162 mg eq/kg in grain. In all samples unchanged bixafen was the major residue being present at levels > 89.5% of the TRR. The only other metabolite present was M21 (bixafen-desmethyl) found at 0.8% to 2.4% of the TRR.

In the samples one further analyte (BYF 00587-4'-deschloro) was identified, which was also found at levels of 1% to 1.3% of the active ingredient in the spray solution, suggesting impurities of the tank-mix used.

An overview of the TRR levels found in the collected samples and the composition of the residue is presented in the following table.

An additional plant metabolism study on wheat (var. Thassos) using [dichlorophenyl-UL-¹⁴C]-bixafen was conducted by Miebach, D and Bongartz, R (2007, BIXAFEN_021). The active ingredient was formulated as an EC 200. The first application with 0.125 kg ai/ha (actual 128 g ai/ha) was performed at the end of tillering / beginning of stem elongation (BBCH 29–31), and the second with 0.15 kg ai/ha (actual 158 g ai/ha) at the end of flowering (BBCH 69). Plants were grown in plastic containers under natural temperature and light conditions in Monheim, Germany. The glass roof of the vegetation area was open during the sunshine periods and was automatically closed during rainfall. Plants were irrigated as needed.

Forage was harvested at growth stage BBCH 38 (9 days after 1st application), hay at growth stage BBCH 77 (9 days after 2nd application), and straw and grain at maturity (BBCH 89, 50 days after 2nd application).

All samples were analysed according to the procedures described for the wheat metabolism study conducted with [pyrazole-5-¹⁴C]-bixafen by Miebach, D and Bongartz, R (2007, BIXAFEN_020).

The TRRs found in the samples collected amounted 1.57 mg eq/kg in forage, 7.64 mg eq/kg in hay, 22.85 mg eq/kg in straw, and 0.229 mg eq/kg in grain. In all samples unchanged bixafen was the major residue being present at levels > 91.7% of the TRR. The only other metabolite present was M21 (bixafen-desmethyl) found at 0.8% to 2.1% of the TRR.

In the samples one further analyte (BYF 00587-4'-deschloro) was identified, which was also found at levels of 1% to 1.3% of the active ingredient in the spray solution, suggesting impurities of the tank-mix used.

An overview of the TRR levels found in the collected samples and the composition of the residue is presented in the following table.

Figure 5 Proposed metabolic pathway of bixafen in plants

Environmental fate in soil

For the investigation of the environmental fate of bixafen the Meeting received studies on photolysis on soil, the aerobic soil metabolism, the behaviour in confined and field rotational crops and short- and long-term field dissipation studies.

Soil photolysis of bixafen was not observed. In the soil bixafen is highly persistent, showing about 80–90% of the applied dose remaining after 120 days observed in aerobic soil metabolism

studies. The only metabolites found in minor proportions were M44 (BYF 00587-desmethyl-pyrazole-4-carboxylic acid) and M21 (Bixafen-desmethyl), the tautomers M44 & M45 later in soil of below mentioned confined rotational crop studies.

In confined rotational crop studies conducted at rates equivalent to 0.785 and 0.847 kg ai/ha bixafen and M21 (bixafen-desmethyl) were the major residue. After application of the [pyrazole-5-¹⁴C]-labelled active substance, the labelled cleavage products M43 (BYF 00587-pyrazole-4-carboxamide), M44 (BYF 00587-desmethyl-pyrazole-4-carboxylic acid (tautomer 1)) and M45 (BYF 00587-desmethyl-pyrazole-4-carboxylic acid (tautomer 2)) were also identified as major metabolites.

In field rotational crop studies conducted on four locations in Europe, residues of bixafen and M21 were mostly below the LOQs of 0.01 mg/kg, except for two single detects in wheat straw (0.03 mg/kg total residue) and lettuce of pre-mature growth stage (0.06 mg/kg total residue).

Field dissipation studies confirmed the slow degradation of bixafen in the soil observed in aerobic metabolism studies. Over 5 years of annual treatment the bixafen peak concentrations in soil under field conditions still represented approximately 32–47% of the total dose applied within these years. Most of the residue was present as unchanged parent substance.

Photolysis on soil

The photodegradation of [¹⁴C] bixafen (pyrazole and dichlorophenyl labels) on the soil surface was investigated under artificial sunlight (Muehmel, T and Fliege, R 2007, BIXAFEN_022). The two labels of the test item were individually applied to a 3 mm thick layer of soils (see Table) on glass dishes at a rate equivalent to 0.25 kg ai/ha. The 8 days of irradiation corresponded to about 30 days of midsummer sunlight at Phoenix, Arizona (USA).

The soil moisture was maintained at 75% field capacity at a temperature of 20 °C. Irradiated and dark control samples were taken at a range of intervals during the 8 days irradiation/incubation periods.

Table 22 Soil characteristics used in soil photolysis experiments

	Dichlorophenyl label test	Pyrazole label test

¹⁴CO₂ and volatile organic radioactivity not measured*Soil metabolism**Aerobic soil metabolism*

The aerobic soil metabolism of bixafen was investigated in several soil types using [pyrazole]- and [dichlorophenyl]-¹⁴C-bixafen.

In the study conducted by Sneikus, J and Koehn, D (2005, BIXAFEN_023) soil samples were extracted several times by shaking at ambient temperature and microwave extraction with acetonitrile/water (80/20, v/v), and the bixafen residues were analysed by TLC. HPLC was used as confirmation method. The identity of the test item was confirmed by co-chromatography using non-labelled reference item. Identification of transformation products was performed by LC/MS/MS.

In addition to the study presented, De Souza, TJT (2011, BIXAFEN_024) investigated the aerobic degradation of [pyrazole]-¹⁴C-bixafen in four Brazilian soils. Microbial viable soil samples were collected freshly from the field and treated with a rate of 0.4909 mg ai/kg soil.

The soils were extracted with methanol/water. The quantification was performed by high pressure liquid chromatography (HPLC) with radioactivity detector. Unextracted residues were determined by combustion. The liberated ¹⁴CO₂ was absorbed in an appropriate scintillation cocktail and measured by LS counting.

A third study investigating the aerobic soil metabolism of bixafen was presented by Menke, U (2008, BIXAFEN_025). In this study soils (0–15 cm depth) obtained from a confined rotational crop metabolism study involving application of [pyrazole]- and [dichlorophenyl]-¹⁴C-bixafen at target rates of 0.75 kg ai/ha.

Aliquots of acetonitrile/water extracts were analysed and radioactivity quantified by HPLC (¹⁴C-radio- and UV-detector). The limit of quantification (LOQ) was 0.4% TRR. TLC was used as a method to confirm formation of metabolites. Unextracted residues were determined by combustion followed by LSC and were not characterised further.

Table 37 Distribution of radioactive residues in soil from rotational crop metabolism studies after application of 0.75 kg ai/ha [pyrazole-¹⁴C]-bixafen (sandy loam, 38.4% MWHC, 1.36% OC, pH 7.3)

Confined rotational crop studies

The metabolism of [pyrazole-5-¹⁴C]-bixafen was investigated by Weber, E, Spiegel, K and Koehn, D (2007, BIXAFEN_029) in the rotational crops wheat, Swiss chard and turnips from three consecutive rotations. The active ingredient was applied uniformly to the soil of a planting container by spray application (day 0) at a rate of 0.785 kg ai/ha. Crops of the first, second and third rotation were sown at day 30, day 138 and day 285. Immature samples investigated were wheat forage and hay. Wheat straw and grain, Swiss chard, turnip leaves and roots were harvested at maturity. Residues in soil were reported in the aerobic metabolism section by Menke, U (2008, BIXAFEN_025).

The samples were extracted with acetonitrile/water (4/1, v/v) subjected to a clean-up step using a C₁₈-SPE cartridge (conventional extraction). For the exhaustive extraction (only conducted for hay and straw), the solids were extracted in a first step with acetonitrile/water (4/1, v/v) and in a second step with acetonitrile/acetic acid (4/1, v/v), both with microwave assistance at increased temperature (80 °C). Each microwave extract was purified using a C₁₈-SPE cartridge. The purified fractions were combined, evaporated and the aqueous remainder was partitioned with dichloromethane.

The total radioactivity was determined by LSC (LOQ: 0.01 mg eq/kg, LOD: 0.001–0.009 mg eq/kg based on background noise level). The extracts were analysed by HPLC. Major metabolites were identified by HPLC and TLC co-chromatography using authentic reference compounds. The conventional extract of Swiss chard of the first rotation showed nearly all metabolites of the other RACs and was used to isolate the polar metabolites which were identified by HPLC-MS/MS. The metabolites in all other samples were assigned by comparison of the HPLC profiles.

In the following table the TRR found in plant samples are summarized.

Table 39 Total radioactive residues in confined rotational crops (three rotations) after application of [pyrazole-5-¹⁴C]-bixafen onto soil at a rate of 0.785 kg ai/ha

	TRR (mg eq/kg)						
	wheat				Swiss	turnip	
	forage	Hay	straw	grain	chard	leaves	roots
first rotation (PBI 30 days)	0.045	0.288	0.434	< 0.01	0.064	0.077	0.047
second rotation (PBI 138 days)	0.058	0.176	0.337	< 0.01	0.059	0.027	0.012
third rotation (PBI 285 days)	0.025	0.153	0.217	n.e.	0.040	0.021	0.015

n.e. = Not extracted

The identification of the radioactive residues revealed the parent substance and seven other metabolites, most of them cleavage products characteristic for the radiolabelled side of the parent molecule. In Table –42 the extracted and identified radioactivity is presented. In wheat grain the TRR was too low for an identification of the residue.

Figure 6 Proposed metabolic pathway of bixafen in rotational crops following application of [pyrazole-5-¹⁴C]-bixafen

For [dichlorophenyl-UL-¹⁴C]-bixafen the metabolism was investigated in the rotational crops wheat, Swiss chard and turnips from three consecutive rotations by Kuhnke, G, Weber, E., and Koehn, D (2007, BIXAFEN_028). The active ingredient was applied uniformly to the soil of a planting container by spray application (day 0) at a rate of 847 g ai/ha. Crops of the first, second and third rotation were sown at day 30, day 138 and day 285. Immature samples investigated were wheat forage and hay. Wheat straw and grain, Swiss chard, turnip leaves and roots were harvested at maturity. No residues in soil were reported.

The samples were extracted with acetonitrile/water (4/1, v/v) subjected to a clean-up step using a C₁₈-SPE cartridge (conventional extraction). For the exhaustive extraction (only conducted for hay and straw), the solids were extracted in a first step with acetonitrile/water (4/1, v/v) and in a second step with acetonitrile/acetic acid (4/1, v/v), both with microwave assistance at increased temperature (80 °C). Each microwave extract was purified using a C₁₈-SPE cartridge. The purified fractions were combined, evaporated and the aqueous remainder was partitioned with dichloromethane.

The total radioactivity was determined by LSC (LOQ: 0.01 mg eq/kg, LOD: 0.001–0.009 mg eq/kg based on background noise level). The extracts were analysed by HPLC. Major metabolites were identified by HPLC and TLC co-chromatography using authentic reference compounds.

In the following table the TRR found in plant samples are summarized:

Table 43 Total radioactive residues in confined rotational crops (three rotations) after application of [dichlorophenyl-UL-¹⁴C]-bixafen at a total field rate of 0.847 kg ai/ha

	TRR (mg eq/kg)						
	wheat				Swiss	turnip	
	forage	Hay	straw	grain	chard	leaves	roots
first rotation (PBI 30 days)	0.020	0.195	0.492	0.001	0.033	0.025	0.033
second rotation (PBI 138 days)	0.035	0.193	0.269	0.002	0.041	0.013	0.012
third rotation (PBI 285 days)	0.013	0.129	0.241	n.a.	0.027	0.007	0.011

n.a. = Not analysed

The identification of the radioactive residues revealed the parent substance, M20 (BYF 00587-hydroxy-glycoside-sulfate) and M21 (bixafen-desmethyl) as major metabolites. Further degradation or breakdown products were not identified. In Table –46 the extracted and identified radioactivity is presented. In wheat grain the TRR was too low for an identification of the residue.

Field crop rotation studies

Four rotational crop studies (limited field studies) were carried out on bixafen during the 2006 and 2007 season. Two studies were performed in Germany and one study each in northern France and Spain.

For investigation of the residue levels that may arise in succeeding crops after a short plant back interval simulating crop failure (30 days), the bixafen was applied once as a spray application at a rate of 0.281 kg ai/ha to bare soil. For longer rotations split spray applications to barley as primary crops were carried out. At all locations, the first spray application on barley was performed at a rate of 0.156 kg ai/ha at growth stage of BBCH 47 (“flag leaf sheath opening”). The second application was carried out at a rate of 0.125 kg ai/ha at growth stage BBCH 69 (“end of flowering”). The grain was harvested normally and the straw was left on the field and ploughed. Until plating/sowing of succeeding crops, no other crop was cultivated.

In all plots turnips/carrots, lettuce and wheat were planted as succeeding crops with plant back intervals of 30, 60–180 and 270–365 days.

In the following table an overview of the studies, involved plots and cultivated crops is presented.

Table 47 Overview of field crop rotation studies for bixafen

Study Report, Location, Reference	Succeeding crop, plant back interval		
Rotation 1: 0.281 kg ai/ha to bare soil			
RA-2143/06, Northern France, Fresnoy les Roye, Schoening, R and Erler, S (2008, BIXAFEN 031)	Turnip, 30 days	Lettuce, 30 days	Wheat, 30 days

RA-2144/06, Germany, Monheim, Schoening, R and Erler, S (2008, BIXAFEN 032)	Turnip, 30 days	Lettuce, 27 days	Wheat, 28 days
RA-2139/06, Germany, Burscheid, Schoening, R and Erler, S (2008, BIXAFEN 030)	Turnip, 30 days	Lettuce, 27 days	Wheat, 30 days
Rotation 2: primary crop: barley; 0.156 kg ai/ha at BBCH 47 plus 0.125 kg ai/ha at BBCH 69 (RA-2145/06 at BBCH 71)			
RA-2143/06, Northern France, Fresnoy les Roye, Schoening, R and Erler, S (2008, BIXAFEN 031)	Turnip/carrot, 60 days	Lettuce, 60 days	Wheat, 120 days
RA-2145/06, Spain, Llorona, Schoening, R and Erler, S (2008, BIXAFEN 033)	Turnip/carrot, 70 days	Lettuce, 70 days	Wheat, 184 days
RA-2144/06, Germany, Monheim, Schoening, R and Erler, S (2008, BIXAFEN 032)	Turnip/carrot, 60 days	Lettuce, 60 days	Wheat, 136 days
RA-2139/06, Germany, Burscheid, Schoening, R and Erler, S (2008, BIXAFEN 030)	Turnip/carrot, 61 days	Lettuce, 61 days	Wheat, 140 days
Rotation 3: primary crop: barley; 0.156 kg ai/ha at BBCH 47 plus 0.125 kg ai/ha at BBCH 69 (RA-2145/06 at BBCH 71)			
RA-2143/06, Northern France, Fresnoy les Roye, Schoening, R and Erler, S (2008, BIXAFEN 031)	Turnip/carrot, 331 days	Lettuce, 298 days	Wheat, 298 days
RA-2145/06, Spain, Llorona, Schoening, R and Erler, S (2008, BIXAFEN 033)	Turnip/carrot, 302 days	Lettuce, 302 days	Wheat, 278 days
RA-2144/06, Germany, Monheim, Schoening, R and Erler, S (2008, BIXAFEN 032)	not sampled—damaged by animals	Lettuce, 331 days	Wheat, 304 days
RA-2139/06, Germany, Burscheid, Schoening, R and Erler, S (2008, BIXAFEN 030)	Turnip/carrot, 314 days	Lettuce, 328 days	Wheat, 300 days

Sampling was done as follows: Samples of lettuce, turnip body and leaf (northern Europe) or carrot root and leaf (southern Europe) were taken 14 days prior to harvest date and at commercial harvest following all plant back-intervals. Wheat green material was sampled at growth stage BBCH 29/30, while samples of grain and straw were collected at full maturity of the crop (BBCH 89) from all rotations.

Samples of plant material were analysed for bixafen and M21 (bixafen-desmethyl) using method no. 01012 (see analytical methods).

In nearly all samples collected not residues of bixafen or its metabolite M21 (bixafen-desmethyl) above the LOQ of 0.01 mg/kg for each analyte were found. The only exceptions were residues 0.05 mg/kg for bixafen in lettuce (early growth stage, BBCH 46) grown in Burscheid, Germany (1st rotation, sampled 60 days after treatment) and of 0.02 mg/kg for M21 in wheat straw grown Llorona, Spain (1st rotation, sampled 262 days after treatment). In the following table a summary of all residue data is presented:

Rotation	Crop, variety	Treatment	Portion analysed	DALT (d)	Bixafen (mg/kg)	M21 (mg/kg)	Total (mg/kg)

Field dissipation studies

The dissipation of bixafen in soil was investigated at six sites under European field conditions (Heinemann, O, 2007, BIXAFEN_026). The active ingredient was applied at nominal rates of 0.125 kg ai/ha as a 450 SC formulation onto the ground in Burscheid (Germany), Little Shelford (Great Britain), Esloe (Sweden), Vatteville (Northern France), Vilobi d'Onyar (Spain) and Albaro (Italy).

Soil samples were taken at day 0 to approximately 730 days post application at a maximum depth of 50 cm. The samples were extracted in a microwave extractor using acetonitrile/water (4/1, v/v). Identification and quantitation of the analytes was achieved by high performance liquid chromatography using MS/MS detection in the Multiple Reaction Monitoring mode. The limit of quantitation (LOQ) of the method was 5.0 µg/kg for bixafen and bixafen-desmethyl. The limit of detection (LOD) of the method was 1.5 µg/kg for both analytes.

In the soil only the first 0–10 cm contained significant residues above the LOQ. Other layers are not summarized. The soil characteristics investigated are summarized in Table .

Table 48 Soil characteristics (0–30 cm depth) used for bixafen soil dissipation studies

Long-term soil accumulation

The possibility of the accumulation of bixafen and M21 (bixafen-desmethyl) in soil under European field conditions was investigated after annual applications of bixafen on bare soil plots at two sites in Monheim am Rhein (Germany) and Tarascon (France) by Heinemann, O and Weuthen, M (2013, BIXAFEN_027). The sites were located in the Monheim, Germany and Les Cayades, Southern France. Each plot received annual treatments to bare soil equivalent to 0.138 kg ai/ha. During the year grass was sown on these plots and incorporated before the next application.

Table 51 Soil properties for the long-term soil dissipation study with bixafen

Since 2005 soil samples were collected and analysed for residues of bixafen and M21. Soil samples were extracted with acetonitrile/water (4/1, v/v). Identification and quantitation of the analytes was done by high performance liquid chromatography using MS/MS detection in the Multiple Reaction Monitoring mode. The limit of quantitation (LOQ) of the method was 5.0 µg/kg, the limit of detection (LOD) was 1.5 µg/kg for both analytes.

Following the 1st application in spring 2005, the experiments were either terminated when a plateau concentration was reached (France in autumn 2010), or due to technical reasons (Germany in autumn 2012).

Following eight consecutive annual treatments in Germany, the total soil residue of Bixafen was degraded to 47% (based on a nominal concentration of 734 µg/kg resulting from eight applications of 137.7 g/ha each and the highest peak concentration of 347.5 µg/kg soil). However, a plateau in the soil concentration of bixafen was not observed.

Following six consecutive annual treatments in France, the total soil residue of Bixafen in autumn, i.e. prior to winter dormancy, was degraded to 32.5% (based on a nominal concentration of 551 µg/kg resulting from six applications of 137.7 g/ha each and the highest peak concentration of 179.2 µg/kg soil). A plateau was reached at the end of the study.

At both sites, the residues of M21 were low and represented less than 5% of the nominal Bixafen concentration applied until the respective sampling point in time.

In the following tables the residues of bixafen and M21 (bixafen-desmethyl) in soil over 2720 days are summarized. Although soil samples up to a depth of 100 cm were collected, residues are only presented for soil layers containing detectable residues.

RESIDUE ANALYSIS

Analytical methods

For bixafen and M21 bixafen-desmethyl analytical method were provided following a comparable pattern. The samples (plant, animal and soil) are extracted using acetonitrile/water (4/1, v/v) or in case of fatty matrices n-hexane (saturated with acetonitrile). For some matrices the extraction is supported by using microwaves. After filtration and a clean-up with C18 SPE the residue is measured by HPLC-MS/MS with two specific mass transitions for each analyte. All methods were validated with an LOQ of 0.01 mg/kg.

The applicability of multi residue methods was investigated for the DFG S19; however, the results did not confirm sufficient applicability.

Table 54 Overview of analytical methods for bixafen

Method	Matrix	Extraction	Clean-Up	Detection, LOQ
Method 00983	Plants (high acid, high, starch, high oil, high water)	acetonitrile/water (4/1, v/v), using microwaves	filtration	HPLC-MS/MS Bixafen: m/z 414 → 394 and m/z 414 → 266 LOQ: 0.01 mg/kg
Method 01063	Animals (eggs, milk, muscle, kidney, fat, liver)	eggs, muscle, kidney and milk: acetonitrile/water (4/1, v/v) liver: acetonitrile/water (4/1, v/v), using microwaves fat: n-hexane (saturated with acetonitrile), partitioning with acetone (saturated with n-hexane)	filtration & C18 SPE	HPLC-MS/MS Bixafen: m/z 414 → 394 and m/z 414 → 266 LOQ: 0.01 mg/kg M21: m/z 398 → 378 and m/z 398 → 358 LOQ: 0.01 mg/kg
Method 00959 & Method 00959/M001	Soil	acetonitrile/water (4/1, v/v), using microwaves	centrifugation	HPLC-MS/MS Bixafen: m/z 414 → 394 and m/z 414 → 266 LOQ: 5 µg/kg M21: m/z 398 → 378 and m/z 398 → 358 LOQ: 5 µg/kg
Method 01012	Plants (high, starch, high water)	acetonitrile/water (4/1, v/v), using microwaves	filtration	HPLC-MS/MS with isotopically-labelled ISTD Bixafen: m/z 414 → 394 and m/z 414 → 266 LOQ: 0.01 mg/kg M21: m/z 398 → 378 and m/z 398 → 358 LOQ: 0.01 mg/kg
Method 01013	Plants (high acid, high, starch, high oil, high water)	acetonitrile/water (4/1, v/v) containing cysteine hydrochloride	filtration	HPLC-MS/MS with isotopically-labelled ISTD Bixafen: m/z 414 → 394 and m/z 414 → 266 LOQ: 0.01 mg/kg M21: m/z 398 → 378 and

Method	Matrix	Extraction	Clean-Up	Detection, LOQ
				m/z 398→ 358 LOQ: 0.01 mg/kg
Method 01036	Animals (eggs, milk, muscle, kidney, fat, liver)	eggs, muscle, kidney and milk: acetonitrile/water (4/1, v/v) liver: acetonitrile/water (4/1, v/v), using microwaves fat and milk cream: n-hexane (saturated with acetonitrile), partitioning with acetone (saturated with n-hexane)	filtration & C18 SPE	HPLC-MS/MS with isotopically-labelled ISTD Bixafen: m/z 414 → 394 and m/z 414→ 266 LOQ: 0.01 mg/kg M21: m/z 398 → 378 and m/z 398→ 358 LOQ: 0.01 mg/kg

ISDT = Internal standard

Plant materials

For plant materials a suitable enforcement method (method 00983) was developed by Bardel, P and Schoening, R (2006, BIXAFEN_034). The residues are extracted from 5 g of plant material with acetonitrile/water (4/1, v/v), using microwaves. After filtration and dilution, the solution was analysed by HPLC-MS/MS (m/z 414 → 394 and m/z 414→ 266). Residues were quantified against external bracketing matrix-matched standards.

The applicability of the method was confirmed in an independent laboratory by Ballesteros C and Portet, M (2007, BIXAFEN_035). In both laboratories parent bixafen was analysed with a validated LOQ of 0.01 mg/kg (see Table).

The applicability of the DFG method S 19 multi-residue method was investigated by Class, T (2006, BIXAFEN_036). However, even though GC gave acceptable peak shapes for bixafen, it was assessed that the DFG method S 19 used in combination with GC/MS is not applicable as a multi-residue enforcement method due to a lack of sensitivity, even when the most prominent fragment ion observed was monitored, and a lack of specificity, as no other ions were observed with sufficient sensitivity to serve as confirmatory ions. Thus, it was shown that DFG method S 19 is not suitable for the determination of bixafen residues.

Animal materials

For the enforcement of bixafen and M21 (bixafen-desmethyl) in animal commodities method 01063 was developed by Billian, P and Druskus, M (2007, BIXAFEN_037). The residues were extracted from 5 g of milk, muscle, liver, kidney and egg with acetonitrile/water (4/1, v/v) using an ultra-turax (for liver with microwave assistance).

The extraction of fat samples was performed with n-hexane (saturated with acetonitrile) in a blender. After filtration, addition of acetonitrile (saturated with n-hexane) and subsequent shaking, the acetonitrile phase was separated.

The solutions were cleaned up on a C18 cartridge, made up to volume, diluted, and subjected to reversed phase HPLC-MS/MS in positive (parent compound, M21 bixafen-desmethyl) or negative (bixafen-desmethyl) ion modes. Two MRM transitions were monitored for bixafen (m/z 414 → 394 and m/z 414 → 266) and M21 (bixafen-desmethyl, m/z 398 → 378 and m/z 398 → 358). Residues were quantified against matrix-matched standards (without using the ISTD signal for calculation of the results).

The applicability of the method was confirmed in an independent laboratory by Ballesteros, C (2007, BIXAFEN_038). In both laboratories parent bixafen and M21 (bixafen-desmethyl) were validated with a LOQ of 0.01 mg/kg (see Table & Table).

Soil

For the analysis of bixafen in soil method 00959 was developed by Brumhard, B and Freitag, T (2006, BIXAFEN_039). Residues of bixafen are extracted from approx. 20 g of soil in a microwave extractor with 40 mL of a mixture of acetonitrile/water (4+1, v+v). Then a subsample is centrifuged to remove fine particles of the soil.

Identification and quantitation of the test items is done by high performance liquid chromatography using MS/MS detection in the Multiple Reaction Monitoring mode (MRM). The first MRM transition of bixafen is the quantification ion with the mass 394 [m/z 414 → 394] and the second MRM transition is the confirmatory ion with the mass 266 [m/z 414 → 266]. The analytical method was successfully validated with a LOQ of 5 µg/kg soil.

An extension of this method for the determination of the metabolite M21 (bixafen-desmethyl) was reported by Brumhard, B and Koch, V (2008, BIXAFEN_048). The extraction of the residue is identical to the methodology described for parent bixafen. For the HPLC-MS/MS measurement the following mass transitions are used for bixafen-desmethyl: m/z 398 → 378 and m/z 398 → 358.

Specialised methods

For the data generation in supervised field trials and processing studies method 01012 was developed by Schoening, R (2006, BIXAFEN_040). Residues were extracted from 5 g of plant material with acetonitrile/water (4/1, v/v), using microwaves. After filtration of the extract, the stable isotopically-labelled analytes were added as internal standards (ISTD). The solution was made up to volume, diluted and subjected to reversed phase HPLC-MS/MS in positive (bixafen, bixafen-desmethyl) or negative (bixafen-desmethyl) ion modes without further clean-up. Two MRM transitions for

quantitation and confirmation were monitored for each analyte and in each matrix tested (bixafen: m/z 414→394 and 414→266; bixafen-desmethyl: m/z 398→378 and 398→358).

The extraction efficiency of method 01012 was investigated on wheat samples from the [dichlorophenyl-UL-¹⁴C]-wheat metabolism study (Sur, R and Kuhnke, G, 2007, BIXAFEN_041) and on samples from the confined rotational crop study (Justus, K and Kuhnke, G, 2007, BIXAFEN_042). In summary method 01012 was validated with an LOQ of 0.01 mg/kg for each analyte. Validation data and the extraction efficiencies are summarised in Table

^a Sum of bixafen and M21 (bixafen-desmethyl), expressed as bixafen equivalents

For plant commodities a second study used in supervised field trials was conducted by Brumhard, B and Stuke, S (2008, BIXAFEN_043). Multi method 01013 was developed for the determination of residues of bixafen, prothioconazole, tebuconazole, trifloxystrobin and their metabolites bixafen-desmethyl, prothioconazole-desthio and CGA321113 in/on plant material (citrus fruit, pea green seed, wheat grain, rape seed and corn green material). All analytes are extracted from plant materials using a mixture of acetonitrile/water (4/1; v/v) containing cysteine hydrochloride by using a blender. After filtration of the extract, the stable isotopically labelled analytes were added. The solution was made up to volume, diluted and subjected to reversed phase HPLC-MS/MS without a further clean-up step.

Bixafen was detected using electrospray ionization in the positive ion mode (ESI+), while M21 (bixafen-desmethyl) was detected using electrospray ionization in the negative ion mode (ESI-). Two MRM transitions for quantitation and confirmation were monitored for each analyte and in each matrix tested (bixafen: m/z 414→ 394 and 414→ 266; bixafen-desmethyl: m/z 398→ 378 and 398→ 358). Residues were quantified using internal stable-labelled standards.

In the following tables the validation data for bixafen and M21 (bixafen-desmethyl) are summarised. The analytical method was successfully validated with LOQs of 0.01 mg/kg for bixafen and M21 (bixafen-desmethyl).

In the livestock animal feeding study the analytical method 01036 was used, which was described by Schoening, R and Willmes, J (2008, BIXAFEN_044).

Skim milk and cream first were separated by using a centrifuge. The residues were extracted from 5 g of whole milk, skim milk, muscle, kidney, and egg with acetonitrile/water (4/1, v/v) using an ultra-turax. After filtration and clean-up on a C18 Cartridge the stable labelled internal standards were added to the extracts.

Residues in fat and milk cream were extracted from 5 g sample material with n-hexane (saturated with acetonitrile) first in an ultra-turax. After filtration and clean-up through a syringe tube, acetonitrile (saturated with n-hexane) was added, and, after shaking, the acetonitrile phase was separated. Subsequently the stable isotopically labelled standards were added.

Residues in liver were extracted from 5 g sample material with acetonitrile/water (4/1, v/v), either directly by using a microwave (cattle liver) or for chicken liver by using a blender first and a subsequent microwave extraction of the solids with acetonitrile/water (7/3, v/v). After filtration and clean-up on a C18 cartridge, the stable isotopically labelled standards were added to the extracts.

The solutions were made up to volume, diluted, filtered through a membrane filter and subjected to reversed phase HPLC-MS/MS in positive (parent compound, BYF00587-desmethyl) or negative (BYF00587-desmethyl) ion modes. Two MRM transitions for quantitation and confirmation were monitored for each analyte and in each matrix tested (bixafen: m/z 414 → 394 and 414 → 266; bixafen-desmethyl: m/z 398 → 378 and 398 → 358). Residues were quantified using internal stable-labelled standards.

In the following tables the validation data for bixafen and M21 (bixafen-desmethyl) are summarised. The analytical method was successfully validated with LOQs of 0.01 mg/kg for bixafen and M21 (bixafen-desmethyl).

Stability of pesticides in stored analytical samples

The storage stability of bixafen and M21 (bixafen-desmethyl) has been investigated in wheat grain, wheat straw, wheat green material, lettuce head, potato tuber, rape seed and soil for a storage period of up to 24 months. No significant degradation of the residues was observed.

For animal matrices no storage stability data were provided. Samples in livestock metabolism or feeding studies were analysed within one month.

The storage stability of bixafen and its primary metabolite M21 (bixafen-desmethyl) was investigated in plant matrices (wheat grain, wheat straw, wheat green material, lettuce head, potato tuber and rape seed) for up to 24 months by Schoening, R and Billian, P (2009, BIXAFEN_045).

Homogenised samples were weighed into glass bottles and fortified individually at levels of 0.1 mg/kg for each analyte. After fortification, the solvent was allowed to evaporate. In addition, untreated samples of each sample material were prepared for control and recovery experiments. Subsequently the bottles were closed and stored deep frozen until analysis (except for the day 0 samples). At each sampling interval, three fortified and three control samples were removed from the deep-freezer. Subsequently, two of the control samples of each sample material were freshly fortified with a mixture of the test items to determine the concurrent recoveries. Fortification levels were at the same magnitude as the spiked storage samples. Bixafen and desmethyl-bixafen were spiked separately to separate control material.

The analytical method 01012 was used for the determination of bixafen and its metabolite desmethyl-bixafen in/on plant material. The analytes were extracted with acetonitrile/water (4/1, v/v) using a microwave. After filtration of the extract, the stable isotopically-labelled analytes were added as internal standards. The solution was made up to volume, diluted and subjected to reversed phase HPLC-MS/MS in positive and negative ion modes without further clean-up. Residues were quantified using internal stable-labelled standards. The LOQ was 0.01 mg/kg for all matrices and for both analytes investigated.

In the following table the recovered residues in stored samples are summarised:

Table 67 Storage stability of bixafen and M21 (bixafen-desmethyl) in plant commodities fortified at levels of 0.1 mg/kg

In addition to plant matrices the storage stability of bixafen (Brumhard, B and Freitag, T, 2008, BIXAFEN_046) and bixafen-desmethyl (Freitag, T and Hoffmann, M, 2009, BIXAFEN_047) in stored soil samples was investigated.

Untreated soil from Laacher Hof, Germany (sandy loam) and Höfchen, Germany (silt loam) was used for the storage stability study and individually fortified at levels of 50 µg/kg with both analytes. After 273/279, 456 and 587 days for bixafen and 134, 183, and 721 days for M21 (bixafen-desmethyl) samples were analysed for the remaining residue.

Soil samples were analysed for bixafen according to method 00952. The residue of M21 (bixafen-desmethyl) in soil was measured with the modified version 00950/M001. The LOQ for both methods was 5 µg/kg soil (see analytical methods).

Table 68 Storage stability of bixafen and M21 (bixafen-desmethyl) in soil fortified at levels of 50 µg/kg

Soil	Analyte, Reference	Storage period (days)	Residue level in stored samples (% nominal level)			Procedural recovery (% nominal level)

USE PATTERN

Bixafen is a protectant fungicide. The Meeting received uses involving foliar spray applications in the field to rape plants and cereal grains.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue levels were reported as measured. Application rates were always reported as bixafen equivalents. When residues were not detected they are shown as below the LOQ, e.g., < 0.01 mg/kg. Application rates and spray concentrations have generally been rounded to two significant figures. HR and STMR values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. These results are underlined.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for % recovery.

^a Expressed as bixafen

DALT = Days after last treatment

BBCH 63 = 30% of flowers on main raceme open

BBCH 64 = 40% of flowers on main raceme open

BBCH 65 = Full flowering: 50% of flowers on main raceme open

BBCH 67 = Flowering declining: majority of petals fallen

BBCH 69 = End of flowering

BBCH 71–78 = 10% to 80% of pods have reached final size

BBCH 79 = Nearly all pods have reached final size

BBCH 82 = 20% of pods ripe, seeds dark and hard

2011 (Hybrilux)											

–0 = Sampling directly before last treatment

^a Expressed as bixafen

DALT = Days after last treatment

BBCH 63 = 30% of flowers on main raceme open

BBCH 64 = 40% of flowers on main raceme open

BBCH 65 = Full flowering: 50% of flowers on main raceme open

BBCH 67 = Flowering declining: majority of petals fallen

BBCH 69 = End of flowering

BBCH 71–78 = 10% to 80% of pods have reached final size

BBCH 79 = Nearly all pods have reached final size

BBCH 82 = 20% of pods ripe, seeds dark and hard

BBCH 69 = End of flowering: all spikelets have completed flowering but some dehydrated anthers may remain

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of residue during processing

The hydrolysis of bixafen under processing conditions was investigated by Justus, K and Kuhnke, G (2008, BIXAFEN_061). [Pyrazole-5-¹⁴C]-bixafen was diluted in buffered drinking water at 0.25 mg ai/L, which corresponds to approximately 50% of the water solubility. The test solutions contained 0.7% acetonitrile. Incubation was done at three representative sets of hydrolysis conditions: 90 °C, pH 4 for 20 minutes (pasteurisation); 100 °C, pH 5 for 60 minutes (baking, brewing and boiling) and 120 °C, pH 6 for 20 minutes (sterilisation).

Parent compound and potential hydrolysis products were identified and quantified by HPLC. Thin layer chromatography was used for confirmation of the identity of the test item by co-chromatography with the non-labelled reference item. Material balances were established for each set of hydrolysis conditions.

In the following table the recovered radioactivity and its composition is summarised:

Table 78 Hydrolysis of bixafen under simulated processing conditions

Hydrolysis conditions	Incubation time (min)	Bixafen	
		mg/L	% applied radioactivity
pH 4, 90 °C	0	0.240	100
	20	0.236	98.2
pH 5, 100 °C	0	0.222	100
	60	0.222	100
pH 6, 120 °C	0	0.245	100
	20	0.240	98.0

Residues after processing

The fate of bixafen and its metabolite M21 (bixafen-desmethyl) during processing of raw agricultural commodity (RAC) was investigated in rapeseeds, barley grain and wheat grain using important processing procedures. As a measure of the transfer of residues into processed products, a processing factor (PF) was used, which is defined as:

$$PF = \frac{\text{Total residue in processed product (mg kg}^{-1}\text{)}}{\text{Total residue in raw agricultural commodity (mg kg}^{-1}\text{)}}$$

If residues in the RAC were below the LOQ, no processing factor could be derived. In case of residues below the LOQ, but above the LOD in the processed product, the numeric value of the LOQ

was used for the calculation. If residues in the processed product were below the LOD, the numeric value of the LOQ was used for the calculation but the PF was expressed as “less than” (e.g. < 0.5).

A summary of all processing factors for bixafen relevant for the estimation of maximum residue levels of the dietary intake is given in Table 79.

Rape seed

For the processing of oilseed, rape seed collected from three locations in Northern Europe (Freitag, T, Reineke, A and Krusell, L, 2010, BIXAFEN_057; Freitag, T, Reineke, A and Krusell, L, 2010, BIXAFEN_066 and Noss, G and Teubner, L, 2010, BIXAFEN_067) were processed into pomace, meal and different oils simulating the industrial practice at a laboratory scale (Freitag, T and Hoffmann, M, 2011, BIXAFEN_68; Freitag, T and Hoffmann, M, 2011, BIXAFEN_69 and Hoffmann, M and Teubner, L, 2012, BIXAFEN_70). The treatment program consisted of two spray applications at 0.06 or 0.075 kg ai/ha for each treatment. The first treatment was carried out at the growth stage BBCH 64 to 69 (end of flowering), and the second one at BBCH 69 to 75. The sampling dates were 35, 44 or 64 days after the final application was carried out.

The rape seeds were dried and cleaned using a sieve. The conditioned and cleaned rape seeds were pressed in a screw press yielding oil, screw-pressed and pomace.

An aliquot of the pomace was milled and then extracted with addition of n-hexane. In the rotary evaporator the n-hexane was removed, yielding oil, solvent extracted. The solvent-extracted meal was sampled after storing at room temperature or drying.

The oil fractions (screw-pressed oil and solvent extracted oil) were mixed yielding the sample of crude oil. The crude oil was filtered or hydrated and deslimed by adding water and phosphorus acid, heating and stirring, yielding the sample crude oil, preclarified.

The oily phase was heated while stirring and a sodium hydroxide solution was added. Water was added and the phases were allowed to separate. After phase separation the watery phase was removed. Crude oil, neutralised was sampled.

For bleaching, the oil was heated up to 90–100 °C while stirring. After addition of 1% pod sol the oil was bleached for 5 min without vacuum and 20 min with vacuum. Afterwards the pod sol was removed (filtration).

The oil was heated under vacuum up to 160 °C while stirring. After reaching 160 °C, steam was transferred through the oil for deodorization. After cooling to 160 °C the steam supply was stopped and then the oil was dried under vacuum until a temperature of ≤ 80 °C was reached. The refined oil was sampled.

All samples were analysed for bixafen and M21 (bixafen-desmethyl) according to method 01013. The limit of quantification (LOQ) was 0.01 mg/kg for the individual analytes, and consequently 0.02 mg/kg for the sum of both in all matrices. In the following table the residues found in the processed products are summarised:

Barley

In Northern Europe four supervised field trials on barley were conducted involving two treatments at BBCH 37 and 61 with 0.25 kg ai/ha each (Schoening, R and Wolters, A, 2007, BIXAFEN_062). Samples were collected 35 to 46 days after the last treatment.

The production of both beer and pearl barley from grain of these trials was performed on a technical scale simulating commercial procedures (Schoening, R, Billian, P and Wolters, A, 2007, BIXAFEN_063).

In order to prepare pearl barley, the grain was first cleaned to separate husks and other impurities from the barley. Then the seeds were conditioned by adjusting the moisture content to about 14–16%. Depending on the initial moisture content this was done by damping prior to further processing for two of the four samples. Finally, the seeds were decorticated in a mill where they were passed through a vertically rotating cylinder. An abrasion of 30–35% was reached. For analysis, samples of pearl barley and pearl barley rub-off were collected (see Figure).

The beer brewing process starts with sieving and cleaning of the specimen. Before the beginning of the malting, the barley grains undergo a 3-step steeping procedure (combination of wet and dry steeping) at a temperature of 13–14 °C, over 2 days, until a final steeping degree of 44.8–44.9% was reached. Germination took place at a temperature of 14 ± 1 °C for 5 days at a relative air humidity of > 90%. After germination, the malting process is terminated by kiln-drying at maximum 82 °C. At the end of drying, samples of brewing malt and malt culms (malt sprouts) were taken.

In a next step, the malt was ground. Mash was produced by adding water, and heating the mixture at stepwise increasing temperatures with a defined temperature and time regime. The mash was then lautered in a 2-step process (filtering and washing). This process resulted in brewer's grain, of which samples were taken, and wort. The wort was cooked and commercially bought hops were added. After boiling, the flocs (hops draff) were separated in a whirlpool. The deposited hops draff was sampled. After cooling and ventilating of the wort, yeast was added. After a period of 6–7 days, the yeast deposited on the tank bottom and was sampled as brewer's yeast. At the beginning of maturation the young beer was stored at room temperature (warm maturation) for 2 days in casks. Subsequently, the young beer was stored under pressure at 2 °C for about 4 weeks (cold maturation). During this time the remaining extract was fermented and sludge particles and yeast settled at the bottom. The rack beer was then filtered and filled into bottles. Following filtration, beer samples were taken (see Figure & 12).

All samples were analysed for bixafen and M21 (bixafen-desmethyl) according to method 01012. The limit of quantification (LOQ) was 0.01 mg/kg for the individual analytes, and consequently 0.02 mg/kg for the sum of both in all matrices. In the following table the residues found in the processed products are summarised:

Wheat

In 2006, four residue studies on winter wheat were conducted in Northern Europe by Schoening, R and Erler, S (2007, BIXAFEN_064). The treatment program consisted of two spray applications at BBCH 47 and BBCH 69 with application rates of 0.232 to 0.250 kg ai/ha each. The sampling dates were 39 to 53 days after the final application.

The processing of wheat grain samples collected from three of the locations into processed fractions (white flour, white flour bran, semolina, semolina bran, white bread, whole-meal, whole-meal bread and wheat germs) was performed in specialised pilot plants to simulate industrial procedures of the milling and bakery industry (Schoening, R and Erler, S, 2007, BIXAFEN_065). The sample originating from the United Kingdom was divided in two portions (A and B). The second portion (B) was processed at a different processing site than portion A.

In order to prepare flour and semolina, the grain was first cleaned and a moisture content of about 17% was adjusted. The cleaned grain was then milled to either white flour and white flour bran, to whole meal flour, or to semolina and semolina bran.

For preparation of white bread the ingredients of the dough were weighed, combined and kneaded. After kneading the dough was placed into the fermentation chamber for fermentation. The bread was baked on one level in the baking oven at a constant heat of 230 °C (oven setting) for 30 min.

For preparation of whole-meal bread the sourdough was prepared one day before the baking process. Whole-meal and water were mixed together with the starter. The mixture was placed into the fermentation chamber. The ingredients of the dough were weighted, combined and kneaded. After kneading the dough was placed into the fermentation chamber for fermentation. The bread was baked on one level in the baking oven at a constant heat of 207 °C (oven setting) for nearly 1 hour.

All samples were analysed for bixafen and M21 (bixafen-desmethyl) according to method 01012. The limit of quantification (LOQ) was 0.01 mg/kg for the individual analytes, and consequently 0.02 mg/kg for the sum of both in all matrices. RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

For the estimation of residues of bixafen and its metabolite M21 (bixafen-desmethyl) in animal matrices laying hens and lactating cow feeding studies were submitted to the Meeting.

Poultry

The magnitude of the residue of bixafen and its metabolite M21 (bixafen-desmethyl) has been studied in laying hens by Billian, P, Barfknecht, R and Wolters, A (2008, BIXAFEN_071). Adult chickens (12 birds per diet group divided into three subgroups with four animals each, one control group with four birds) were exposed for 28 consecutive days to levels of 1.5 ppm (1× dose group), 4.5 ppm (3× dose group), or 15 ppm feed/day (10× dose group) corresponding to approximately 0.1 , 0.3 and 1.0 mg/kg bw/day. For a depuration study, three groups of hens were fed at the 10× dose rate for 28 consecutive days followed by untreated feed for another 7 days, 14 days or 21 days. Each subgroup comprised five birds.

Eggs were collected during the whole dosing period. On day 29 after the first dose, the hens were sacrificed, and liver, fat and overlaying skin, and muscle from breast and leg were collected for analysis.

Tissues and eggs were pooled and analysed using method 01036 (see analytical method section). The analytical method was validated for bixafen and M21 at a LOQ of 0.01 mg/kg for each analyte. The LOQ of the total bixafen residues (sum of bixafen and bixafen-desmethyl) was calculated to be 0.02 mg/kg. Residue data were obtained by high performance liquid chromatography-electrospray ionization/tandem mass spectrometry (HPLC-MS/MS) using isotopically labelled internal standards.

In the following table the residues found in eggs are summarised. Prior to dosing of bixafen, eggs collected contained no detectable residues of bixafen or M21 (bixafen-desmethyl). The results for these samples are not presented.

Table 83 Residues of bixafen and M21 (bixafen-desmethyl) in eggs after administration of bixafen at 0.1, 0.3 or 1.0 mg/kg bw and day

^a Depuration sub-group

The distribution of the residue between egg yolk and egg white was investigated for the 10× group on eggs collected after 22, 25 and 27 days. In the following table the residues of bixafen and M21 (bixafen-desmethyl) are presented:

Table 84 Distribution of bixafen and M21 (bixafen-desmethyl) in egg yolk and egg white after administration of bixafen at 1.0 mg/kg bw and day (10×)

Day	Residues in egg yolk [mg bixafen equiv./kg]			Residues in egg white [mg bixafen equiv./kg]			Residues in whole egg [mg bixafen equiv./kg]		
	bixafen	M21	total	bixafen	M21	total	bixafen	M21	total
22	0.13	0.20	0.33	0.04	0.01	0.05	0.07	0.08	0.15
25	0.14	0.24	0.38	0.05	0.02	0.07	0.08	0.09	0.17
27	0.10	0.20	0.30	0.03	0.01	0.04	0.05	0.07	0.12

For poultry, tissues residues of bixafen and M21 (bixafen-desmethyl) found directly at the end of the dosing period are presented in the following table. In samples collected from animal after depuration, no detectable residue of bixafen or M21 (bixafen-desmethyl) were present.

Table 85 Residues of bixafen and M21 (bixafen-desmethyl) in tissues of laying hens after administration of bixafen at 0.1, 0.3 or 1.0 mg/kg bw and day (1×, 3× or 10×)

Commodity	Residues in mg bixafen-equivalents per kg [mean]		
	1× (1.5 ppm, 0.1 mg/kg bw)	3× (4.5 ppm, 0.3 mg/kg bw)	10× (15 ppm, 1.0 mg/kg bw)
Skin with fat	bixafen: < 0.01, < 0.01, 0.01 [0.01] M21: < 0.01(3) Total: < 0.02, < 0.02, 0.02 [0.02]	bixafen: 0.04, 0.04, 0.05 [0.043] M21: 0.01, 0.01, 0.02 [0.013] Total: 0.05, 0.06, 0.06 [0.057]	bixafen: 0.05, 0.05, 0.07 [0.057] M21: 0.01, 0.01, 0.02 [0.013] Total: 0.06, 0.06, 0.09 [0.07]

Lactating cows

Residues in lactating cows were investigated by Schoening, R and Wolters, A (2007, BIXAFEN_072). Thirteen lactating Holstein dairy cows (*Bos taurus*; three cows/treatment group, one control cow and a depuration group consisting of three cows) were dosed orally, via capsule, for 29 consecutive days with bixafen with either 0 ppm (control, 0×), 4 ppm (1× dose group), 12 ppm (3× dose group), or 40 ppm (10× dose group), corresponding to 0, 0.15 mg/kg bw, 0.45 mg/kg bw and 1.5 mg/kg bw, respectively.

Milk was collected twice daily. On day 29 after the administration of the first dose, the animals with the exception of the cows of the depuration group were sacrificed and liver, kidney, composite muscle, subcutaneous fat, mesenteric fat and perirenal fat were collected for analysis. For the depuration group (10×), milk for analysis was additionally sampled during the depuration phase. The animals of this group were sacrificed on day 8, 15 or 22 after the last dosing (corresponding to day 36, 43 or 50 after the first dosing), and animal tissues were collected for analysis.

Tissue and milk samples were analysed for bixafen and M21 (bixafen-desmethyl) residue by high performance liquid chromatography-electrospray ionization/tandem mass spectrometry (LC-

MS/MS) using isotopically labelled internal standards (method 01036, see section for analytical methods). The limit of quantitation (LOQ) was 0.01 mg/kg for each analyte, expressed as bixafen equivalents. The LOQ of the total residue of bixafen was calculated to be 0.02 mg/kg.

In milk residues of bixafen and M21 (bixafen-desmethyl) are presented in the following table:

Table 86 Residues of bixafen and M21 (bixafen-desmethyl) in milk after administration of bixafen at 0.15, 0.45 or 1.5 mg/kg bw and day

Days	Residues in mg bixafen-equivalents per kg [mean]

APPRAISAL

Bixafen (ISO common name) is a pyrazole-carboxamide fungicide used to control diseases on rape plants and cereals. Bixafen inhibits fungal respiration by binding to mitochondrial respiratory complex II. It was considered for the first time by the 2013 JMPR for toxicology and residues.

The IUPAC name of bixafen is N-(3',4'-dichloro-5-fluorobiphenyl-2-yl)-3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamide and the CA name is 1H-pyrazole-4-carboxamide, N-(3',4'-dichloro-5-fluoro[1,1'-biphenyl]-2-yl)-3-(difluoromethyl)-1-methyl-.

Bixafen labelled either in the pyrazole- or dichlorophenyl-moiety was used in the metabolism and environmental fate studies.

The following abbreviations are used for the metabolites discussed below:

M14	S-[3',4'-dichloro-6-({[3-(difluoromethyl)-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)-3-hydroxybiphenyl-2-yl]cysteine (IUPAC)	
M18	3',4'-dichloro-6-({[3-(difluoromethyl)-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)-2-(methylthio)biphenyl-3-yl beta-L-glucopyranosiduronic acid (IUPAC)	
M20	not nomenclature possible - position of hydroxy group not specified	 or isomer
M21 (bixafen-desmethyl)	N-(3',4'-dichloro-5-fluorobiphenyl-2-yl)-3-(difluoromethyl)-1H-pyrazole-4-carboxamide (IUPAC)	
M23	not nomenclature possible - structure not specified	 glucuronide

M24	not nomenclature possible - structure not specified	 glycoside
M25	not nomenclature possible - structure not specified	 OH glycoside
M26	not nomenclature possible - structure not specified	 OH pentoside
M27	not nomenclature possible - structure not specified	
M37	S-[3',4'-dichloro-6-({[3-(difluoromethyl)-1H-pyrazol-4-yl]carbonyl}amino)-3-hydroxybiphenyl-2-yl]cysteine (IUPAC)	
M43	3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamide (IUPAC)	

M44	3-(difluoromethyl)-1H-pyrazole-4-carboxylic acid (IUPAC)	 proposal for tautomer 1
M45	5-(difluoromethyl)-1H-pyrazole-4-carboxylic acid (IUPAC)	 proposal for tautomer 2
M47	3-hydroxy-1H-pyrazole-4-carboxylic acid (IUPAC)	

Animal metabolism

Information was available on the metabolism of bixafen in laboratory animals, lactating goats and laying hens.

In rats given (dichlorophenyl- U - ^{14}C)-labelled bixafen orally by gavage, absorption was rapid and accounted for at least 83% of the total administered radioactivity after a single low dose (2 mg/kg bw). The maximum plasma concentrations of radioactivity were reached approximately 2–4 and 8 hours after administration of the low and high doses (2 and 50 mg/kg bw), respectively. Radioactivity was widely distributed throughout the body. Elimination of the radioactivity was mainly via faeces ($\geq 91\%$), whereas elimination via urine accounted for 1–3% of the administered dose. In bile duct-cannulated rats, extensive biliary excretion (up to 83%) was demonstrated. Elimination of the radioactivity from the body was rapid, with a half-life in plasma of 8–9 hours and a mean residence time of 13–19 hours (for the low dose). Residues in tissues at 72 hours after a single oral dose as well as after repeated oral dosing accounted for 0.1–3% of the administered radioactivity, with liver and kidneys containing the highest concentrations of residues.

Metabolism of bixafen in rats was extensive, and more than 30 metabolites were identified. The main metabolic routes included demethylation, hydroxylation of the parent and bixafen-desmethyl, and conjugation with glucuronic acid or glutathione. A minor metabolic reaction was the cleavage of the amide bridge of bixafen.

Two studies on metabolism in lactating goats were available. The goats received five daily doses of [pyrazole- ^{14}C]-bixafen or [dichlorophenyl- ^{14}C]-bixafen at rates equivalent to 35 ppm and 46 ppm in the diet, respectively. The animals were sacrificed approximately 24 hours after the last dose. In both studies approximately 1.3% of the total dose was recovered from milk or tissues of the animals. Most of the radioactivity was excreted via faeces (74–82% AR) and urine (1.8–5.4% AR).

The metabolic pattern in both studies was comparable. In milk (TRR: 0.064–0.17 mg eq/kg), muscle (TRR: 0.047–0.057 mg eq/kg) and fat (TRR: 0.47–0.61 mg eq/kg) unchanged bixafen was the major residue, representing 74–77%, 56–66% and 89% of the total radioactivity, respectively. M21 (bixafen-desmethyl) was the only major metabolite being present at 16–18% of the TRR in milk, 34–43% in muscle and 10–11% in fat.

For kidney (TRR: 0.14–0.2 mg eq/kg) and liver (TRR: 0.74–1.2 mg eq/kg) parent bixafen was also a major residue, representing 44–46% of the total radioactivity in kidney and 18–23% in liver. Significant metabolites identified were M21 (bixafen-desmethyl), representing 37–38% of the TRR in

kidney and 19–21% TRR in liver, followed by the two M23 isomers counting for a total of 9.3–15% of the TRR in kidney and 14–19% in liver.

For laying hens groups of hens received daily doses of [pyrazole-¹⁴C]-bixafen or [dichlorophenyl-¹⁴C]-bixafen at rates equivalent to 26 ppm and 32 ppm in the diet for 14 consecutive days. The animals were sacrificed ca. 24 hours after the last dose. Approximately 1.5% of the total dose in both studies was recovered from eggs or tissues of the animals. Most of the radioactivity administered was found in the excreta (88–93% AR). Total radioactive residues were 0.53–0.9 mg eq/kg in eggs, 0.032–0.037 mg eq/kg in muscle, 0.23–0.38 mg eq/kg in fat and 0.64–0.81 mg eq/kg in liver.

Parent bixafen was a major residue in eggs and all tissues except liver, representing 51–69% of the TRR in eggs, 23–41% in muscle and 80% in fat. In hens liver, only minor amounts of bixafen were detected (4.5–6.7% TRR).

M21 (bixafen-desmethyl) was the only major metabolite found in poultry tissues and eggs. It was found at levels of 26–39% of the TRR in eggs, 35–51% in muscle, 19–20% in fat and 24–26% in liver. In liver, M14, M18, M24, M25, M26, M27 and M37 were identified as minor metabolites, representing 1.0–8.8% of the TRR (0.007–0.067 mg eq/kg) each.

In summary bixafen is the major residue in most tissues, milk and eggs. It is moderately metabolized in goats and hens mainly resulting in M21 (bixafen-desmethyl). All major metabolites were also identified in the rat. The metabolites M18, M25 and M26, mainly found in poultry liver, were not directly identified in the rat.

Plant metabolism

The Meeting received plant metabolism studies for bixafen following foliar application of either [pyrazole-¹⁴C]-bixafen or [dichlorophenyl-¹⁴C]-bixafen to soya beans or wheat.

Soya beans were independently treated with both bixafen-labels with three foliar applications of 0.06 kg ai/ha each when the first flowers opened (BBCH 60), at the end of flowering (BBCH 69) and finally when approximately 80% of the pods were ripe (BBCH 88). Samples were collected containing forage (5 days after 2nd application), hay (29 days after 2nd application), straw and seed (26 days after the 3rd application). Total radioactive residues were 4.0–5.3 mg eq/kg for forage, 2.8–4.0 mg eq/kg for hay, 9.5–13 mg eq/kg for straw and 0.005–0.024 mg eq/kg for seeds.

In all plant parts directly affected by the spray solution, unchanged bixafen was the major residue representing 96–98% of the TRR in forage, 92% in hay and 90–92% in straw. The only other metabolite identified was M21 (bixafen-desmethyl), present at 0.5–2.6% of the TRR.

For soya bean seeds, only samples following application of the pyrazole-label contained sufficient total radioactive residues for further investigation. Bixafen was the major residue with 30% of the TRR. Metabolites identified were M44 and M45 (19% TRR, 0.004 mg eq/kg) and M47 (12% TRR, 0.003 mg eq/kg). M21 (bixafen-desmethyl) was not identified in soya bean seeds.

Wheat was independently treated with both bixafen-labels using one foliar application of 0.125 kg ai/ha at the end of tillering / beginning of stem elongation (BBCH 29–31) followed by a second spraying with 0.15 kg ai/ha at the end of flowering (BBCH 69). Forage was harvested 9 days after the 1st application, hay 9 days after the 2nd application and straw and grain at maturity (50 days after the 2nd application). Total radioactive residues were 1.6–1.7 mg eq/kg for forage, 6.6–7.6 mg eq/kg for hay, 23–24 mg eq/kg for straw and 0.16–0.23 mg eq/kg for seeds.

In all samples unchanged bixafen was the major residue, representing > 90% of the TRR. The only other metabolite identified was M21 (bixafen-desmethyl) at 0.8–2.4% of the TRR.

In summary the plant metabolism of bixafen in the plants investigated is very limited. In plant parts directly affected by the spray solution, unchanged bixafen was the only residue significant. M21 (bixafen-desmethyl) was present at low levels up to 2.6% of the TRR.

In soya bean seeds, which were protected by the pod during treatment, bixafen was present at lower concentrations of 0.007 mg eq/kg (30% TRR). Major metabolites in soya bean seeds were M44, M45 and M47, probably taken up from the soil and distributed systemically, however at low levels not exceeding 0.004 mg eq/kg. All three of these metabolites were not identified in the rat.

Environmental fate in soil

The Meeting received information on the fate of bixafen after aerobic degradation in soil and after photolysis on the soil surface. In addition, the Meeting received information on the uptake and metabolism of bixafen soil residues by rotational crops, its dissipation under field conditions and long-term accumulation in soil.

In soil photolysis studies degradation of bixafen was not observed.

In aerobic soil metabolism studies under laboratory conditions bixafen was highly persistent with 80–90% remaining after 120 days. The only metabolite found was M44 (maximum 2.9% of AR), while the rest of the radioactivity remained unextracted or was recovered as $^{14}\text{CO}_2$. DT_{50} values could not be calculated due to the minimal degradation observed within 120 days.

In soil samples from the confined rotational crop metabolism studies mentioned below, bixafen was also slowly degraded. The only metabolite found was identified as M21 (bixafen-desmethyl), slowly increasing from 0.5% (day 30) to 2.3% TRR at the end of the study (day 418). M44 was not detected.

In summary it can be concluded that bixafen is persistent in soil, being degraded to a very minor extent.

Confined rotational crop studies on Swiss chard, turnips and wheat were conducted at rates equivalent to 0.79 kg ai/ha (pyrazole-label) and 0.85 kg ai/ha (dichlorophenyl-label). In plant commodities bixafen (11–78% TRR) and M21 (bixafen-desmethyl, 3–73% TRR) were the major residue components found for both labels. Quantified concentrations for the sum of both analytes were 0.016–0.024 mg eq/kg for Swiss chard, 0.005–0.035 mg eq/kg in turnip roots and tops and 0.011–0.041 mg eq/kg, 0.106–0.18 mg eq/kg and 0.152–0.462 mg eq/kg for wheat forage, hay and straw, respectively. In grain TRR levels were too low for identification ($0.001 < 0.01$ mg eq/kg).

Following application of the pyrazole-labelled active substance, the cleavage products M43 (3–15% TRR), M44 (0.3–37% TRR) and M45 (2–23% TRR) were identified as major metabolites. Concentrations were between 0.001–0.015 mg eq/kg each.

Following treatment with the dichlorophenyl-label, M20 was found in Swiss chard only at levels of 25–38% of the TRR (0.007–0.016 mg eq/kg).

The residue concentrations of bixafen and M21 in plants declined moderately in animal feed commodities while in food commodities only a slow decline of the residue was observed over the three crop rotations investigated. In all commodities investigated, except for wheat grain, detectable residues above the LOQ of 0.01 mg/kg were found for bixafen.

Field rotational crop studies were conducted at four locations in Europe. Bixafen was either applied to bare soil to simulate crop failure (0.28 kg ai/ha) or to barley as a primary crop (0.16 kg ai/ha at BBCH 56 plus 0.125 kg ai/ha at BBCH 69). Turnip/carrots, lettuce and wheat were planted as rotational crops at three rotations. Samples analysed for residues of bixafen and M21 were below the LOQ of 0.01 mg/kg for each analyte, except for one sample of wheat straw (M21: 0.02 mg/kg) and lettuce at a pre-mature growth stage (BBCH 46; bixafen: 0.05 mg/kg).

Field dissipation studies at six locations in Europe (four in the north, two in the south) confirmed the slow degradation of bixafen in soil observed in the aerobic metabolism studies. Within the first 100 days, a significant degradation of the residue concentration in soil was observed, leaving 42–63% of the initial concentrations. However, the decline after this period up to 730 days was minimal, leaving 17–47% of the initial concentration. M21 was not found above the LOQ of the analytical method.

The Meeting observed that the degradation of bixafen in soil follows a bi-phasic kinetics, starting with a fast decline within the first 100 days. After that initial interval, bixafen is highly persistent in soil, accumulating with subsequent treatments over multiple years.

In a long-term soil accumulation study under field conditions residues of bixafen and M21 (bixafen-desmethyl) in soil were investigated involving five and seven years of annual treatment with 0.14 kg ai/ha to the ground. In the first location in France a plateau for the bixafen concentration in soil was reached after five years, resulting in concentrations of up to 0.18 mg per kg soil. In Germany, the study was terminated after 7 years, due to technical reasons, without reaching a plateau, showing a bixafen peak concentration of 0.35 mg per kg soil. Most of the residue (> 95%) was present as unchanged parent substance located in the initial 10 cm soil layer. Based on an average density of 1.5 g/cm³ for soil these concentrations are equivalent to single application rates to the bare soil of 0.27 kg ai/ha in the French trial and 0.53 kg ai/ha in the German trial.

The Meeting concluded that bixafen residues accumulate in soil after annual treatments. Under consideration of the highest annual application rate reported in the authorised GAPs of 0.25 kg ai/ha, soil residue concentrations equivalent to single application rates to bare soil of 0.9 kg ai/ha could be reached.

In summary the Meeting concluded that bixafen is persistent in soil, accumulating after subsequent years of annual treatment. Confined rotational crop studies indicate a potential uptake of residues for bixafen and M21 (bixafen-desmethyl) into plant commodities. The Meeting also recognized that field rotational crop studies involved soil treatment rates not addressing the soil concentrations expected after subsequent annual treatment.

Methods of residue analysis

The Meeting received analytical methods for the analysis of bixafen and M21 (bixafen-desmethyl) in plant and animal matrices. The basic principle employs extraction by homogenisation with acetonitrile/water (4/1, v/v) or n-hexane with acetonitrile partitioning for fatty samples. The extracts were cleaned with filtration and C18 solid-phase extraction. Residues are determined by liquid chromatography (LC) in combination with tandem mass spectroscopy (MS/MS). Mass-transitions are m/z 414→394 (m/z 414→266 for confirmation) for bixafen and m/z 398→378 (m/z 398→358 for confirmation) for M21 (bixafen-desmethyl). The methods submitted are suitable for measuring residues of bixafen and M21 in plant and animal commodities with a LOQ of 0.01 mg/kg for each analyte.

The extraction efficiency with acetonitrile/water (4/1, v/v) was tested for wheat (forage, grain straw) obtained from plant metabolism and confined rotational crop studies. Extraction rates were of > 90% for primary treated commodities and 68–73% (corresponding to 72–99% of the TTR) for commodities from rotational crops.

For the application of multi-residue methods the DFG S-19 was tested, but found to be unsuitable for analysing bixafen or M21 in plant matrices.

Stability of residues in stored analytical samples

The Meeting received information on the storage stability of bixafen and M21 (bixafen-desmethyl) in plant matrices. In wheat grain, wheat straw, wheat green material, lettuce head, potato tuber, rape seed and in soil, no significant degradation of both analytes was observed within 24 months.

For animal matrices no storage stability data were provided. Samples in livestock metabolism or feeding studies were analysed within one month of sampling.

Definition of the residue

Livestock animal metabolism studies were conducted on laying hens (36–32 ppm) and lactating goats (35–46 ppm).

In goats parent bixafen and M21 (bixafen-desmethyl) were the major residue. Bixafen represented 74–77% TRR in milk, 56–66% TRR in muscle, 44–46% TRR in kidney, 18–23% TRR in

liver and 89% TRR in fat. M21 was the major metabolite present at 16–18% TRR in milk, 34–43% TRR in muscle, 37–38% TRR in kidney, 19–21% TRR in liver and 10–11% TRR in fat. In kidney and liver the two isomers of M23 were found at 9–15% of the TRR in kidney (isomer 1: 2.8–4.3%; isomer 2: 6.5–10% TRR) and of 14–19% in liver (isomer 1: 8.6–13% TRR; isomer 2: 5.2–5.8% TRR).

In laying hens again bixafen was the major residue in eggs and all tissues except liver, representing 51–69% TRR in eggs, 23–41% in muscle and 80% in fat. In liver only minor amounts of bixafen were detected (4.5–6.7% of the TRR). M21 (bixafen-desmethyl) was the major metabolite found in poultry tissues and eggs. It accounted for 26–39% of the TRR in eggs, 35–51% in muscle, 19–20% in fat and 24–26% in liver. In liver, M14, M18, M24, M25, M26, M27 and M37 were identified as minor metabolites, representing 1.0–8.8% of the TRR (0.007–0.067 mg eq/kg) each. Of these, M18, M25 and M26 were not identified in the rat, however the exposure of M18 was below the respective acute and chronic TTCs for Cramer class III while M25 and M26 have structural similarity to bixafen-desmethyl and are covered by the ADI for bixafen. As a consequence no consideration of dietary intake is required.

M21 (bixafen-desmethyl) was identified as the major residue in rat studies, suggesting that it is covered by toxicological reference values for parent bixafen. The Meeting concluded that parent bixafen and M21 (bixafen-desmethyl) are suitable marker compounds in animal commodities and should be included into the residue definition for compliance with MRLs and for the estimation of the dietary intake. Analytical methods are capable of measuring both analytes.

In livestock feeding studies the distribution of bixafen and M21 between skim milk/cream and egg white/egg yolk was investigated. The average ratio for cream/skim milk was > 93 for bixafen and 39 for M21. Egg yolk concentrations of bixafen were three times higher than in egg white while M21 showed ratios of 12–20. For the parent substance a log P_{ow} of 3.3 was measured.

The data for milk and eggs suggests that bixafen and M21 partition in the fat portion. In addition, residues in fat tissues were about ten times higher when compared to muscle. The Meeting decided that residues of bixafen are fat-soluble.

The fate of bixafen in plants was investigated following foliar application to soya beans and wheat. In all samples unchanged bixafen was the major residue, normally representing at least 90% of the TRR. M21 was present at very low levels, not exceeding 3% of the TRR. In soya bean seeds, which were not directly exposed to the spray solution due to the pods, only 30% of the TRR (0.007 mg eq/kg) was present as bixafen. Further major metabolites in soya bean seeds were identified as the tautomers M44 and M45 (19% TRR, 0.004 mg eq/kg) and M47 (12% TRR, 0.003 mg eq/kg).

In confined rotational crop studies, plant commodities Swiss chard, wheat and turnips contained concentrations of radioactive residues as high as 0.49 mg eq/kg, in wheat straw. Bixafen (11–78% TRR) and M21 (bixafen-desmethyl, 3–73% TRR) were the major compounds identified. In addition, M43 (3–15% TRR), M44 (0.3–37% TRR) and M45 (2–23% TRR) were identified as major metabolites in all rotational crops. M20 was only found in Swiss chard (25–38% TRR, 0.007–0.016 mg eq/kg). Wheat grain did not contain TRR levels allowing further identification (0.001–< 0.01 mg eq/kg).

The Meeting concluded that parent bixafen is a suitable marker for compliance with MRLs in all plant commodities (primary treated or rotational). For the estimation of the dietary intake M21 was insignificant in wheat and soya beans directly treated, but was identified in high relative amounts in rotational crops. Therefore, the Meeting decided to include M21 (bixafen-desmethyl) into the residue definition for dietary intake with the parent substance. The metabolites M20, M44, M45 and M47, mainly found in rotational crops, were not identified in the rat. However, the estimated exposure levels based on the confined rotational crop study are below the respective acute and chronic TTCs for Cramer class III. As a result, no consideration is required for dietary intake.

Analytical methods are capable of measuring bixafen and M21 (bixafen-desmethyl) in plant matrices.

Definition of the residue for compliance with MRL for plant commodities: *bixafen*

Definition of the residue for compliance with MRL for animal commodities and (for the estimation of dietary intake) for plant and animal commodities: *sum of bixafen and N-(3',4'-dichloro-5-fluorobiphenyl-2-yl)-3-(difluoromethyl)-1H-pyrazole-4-carboxamide (bixafen-desmethyl), expressed as bixafen*

The residue is fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised European trial data for applications of bixafen to rape seed, barley and wheat.

Residue values referred to as “total” describe the sum of bixafen and M21 (bixafen-desmethyl), expressed as bixafen.

The Meeting concluded that field rotational crop studies do not address residues in soil expected after subsequent annual application of bixafen. Confined rotational crop studies available are not considered representative of field conditions. In the absence of suitable data, residue concentrations in plant commodities taken up from the soil by annual crops could not be estimated. Therefore, the Meeting decided, that no recommendations on maximum residue levels and median/highest residues could be made for bixafen in non-permanent crops.

Nevertheless, for the benefit of potential future assessments of bixafen uses, the Meeting decided to evaluate GAPs and residue data following direct application.

Rape seed

Bixafen is registered in the UK for use on rape seed at rates of 2×0.075 kg ai/ha with a PHI of 56 days. Supervised field trials conducted in northern Europe, according to this GAP, were submitted.

For MRL compliance purposes residues of parent bixafen in rape seeds were (n=10): < 0.01(6), 0.01(3), 0.017 mg/kg.

For dietary intake purposes the total residues in rape seeds were (n=10): < 0.02(5), 0.02(4), 0.028 mg/kg.

Barley and oats

For barley and oats the maximum GAP in northern Europe was reported from the UK involving two foliar applications of up to 0.125 kg ai/ha each. The last application is conducted at BBCH 61 and the PHI is covered by the growth between treatment and harvest. Supervised field trials conducted in northern Europe according to this GAP were submitted.

For MRL compliance purposes residues of parent bixafen in barley grain in northern Europe were (n=10): 0.02, 0.04(3), 0.05, 0.07, 0.08, 0.09, 0.09, 0.1 mg/kg.

For dietary intake purposes the total residues in barley grain in northern Europe were (n=10): 0.03, 0.05(3), 0.06, 0.08, 0.1, 0.1, 0.11, 0.11 mg/kg.

In Southern Europe a GAP for barley and oats was reported from France with one application of 0.075 kg ai/ha up to BBCH 61 with a 35 day PHI. However, no corresponding residue data were submitted.

The Meeting decided to explore the use of global residue data as outlined in the 2011 JMPR Report (2.4) for the residue data originating from southern Europe against the GAP of the UK.

For MRL compliance purposes residues of parent bixafen in barley grain in southern Europe according to the UK GAP were (n=9): 0.03, 0.04, 0.04, 0.06, 0.06, 0.08, 0.1, 0.25, 0.34 mg/kg.

For dietary intake purposes the total residues in barley grain in southern Europe according to the UK GAP were (n=9): 0.04, 0.05, 0.05, 0.08, 0.08, 0.1, 0.11, 0.29, 0.38 mg/kg.

The Meeting decided to combine that data and evaluate all European supervised field trials against the UK GAP for barley:

For MRL compliance purposes residues of parent bixafen in barley grain in whole Europe (n=19): 0.02, 0.03, 0.04(5), 0.05, 0.06, 0.06, 0.07, 0.08, 0.08, 0.09, 0.09, 0.1, 0.1, 0.25 and 0.34 mg/kg.

For dietary intake purposes the total residues in barley grain in whole Europe were (n=19): 0.03, 0.04, 0.05(5), 0.06, 0.08(3), 0.1(3), 0.11(3), 0.29 and 0.38 mg/kg.

Wheat, rye, triticale and spelt

For wheat, rye and triticale the maximum GAP in Northern Europe was reported from the UK and involved two foliar applications of up to 0.125 kg ai/ha each. The last application is conducted at BBCH 69 and the PHI is covered by the growth between treatment and harvest. Supervised field trials conducted in Northern Europe according to this GAP were submitted.

For MRL compliance purposes residues of parent bixafen in wheat grain in northern Europe were (n=10): < 0.01(6), 0.01, 0.01, 0.03, 0.03 mg/kg.

For dietary intake purposes the total residues in wheat in northern Europe were (n=10): < 0.02(6), 0.02, 0.02, 0.04, 0.04 mg/kg.

In southern Europe a GAP for wheat, rye and triticale was reported from France with one application of 0.094 kg ai/ha up to BBCH 69 with a 35 day PHI. However, no corresponding residue data were submitted.

The Meeting decided to explore the use of global residue data as outlined in the 2011 JMPR Report (2.4) for residue data from southern Europe against UK GAP:

For MRL compliance purposes residues of parent bixafen in wheat grain in Southern Europe according to the UK GAP were (n=10): < 0.01(6), 0.01, 0.02, 0.02, 0.03 mg/kg.

For dietary intake purposes the total residues in wheat grain in southern Europe according to UK GAP were (n=10): < 0.02(6), 0.02, 0.03, 0.03, 0.04 mg/kg.

The Meeting decided to combine that data and evaluate all European supervised field trials against the UK GAP for wheat:

For monitoring purposes residues of parent bixafen in wheat grain in whole Europe (n=20): < 0.01(12), 0.01(3), 0.02, 0.02, 0.03, 0.03 and 0.03 mg/kg.

For dietary intake purposes the total residues in wheat grain in whole Europe were (n=20): < 0.02(12), 0.02(3), 0.03, 0.03, 0.04, 0.04 and 0.04 mg/kg.

Animal feeds

Oilseed rape, forage

The Meeting noted that the only authorisation submitted for bixafen in rape was from UK explicitly relating to oilseed rape. This GAP involves late treatment of the crop 56 days before harvest, which is normally beyond the common timeframe for utilization of oilseed rape as a forage crop, i.e., before winter and up to BBCH 39. This is supported by supervised field trials in northern Europe, where last applications were conducted at growth stages at the end of flowering or at early maturity.

The Meeting concluded that the reported GAP for bixafen is not relevant for the utilization of oilseed rape as an animal forage crop.

Barley, oats, rye, triticale and wheat – forage of cereals

GAPs for barley and oats in the UK are for a maximum of two foliar applications up to flowering (BBCH 61) with 0.125 kg ai/ha each. The PHI is covered by the interval between treatment and harvest (covered by growth stage).

For the calculation of the livestock animal dietary burden the total residues in barley forage (fresh) in northern Europe were (n=10): 2.1, 2.5, 2.6, 2.9, 3.5, 3.9, 4.0, 4.4, 4.5, 7.3 mg/kg.

In southern Europe a GAP for barley and oats was reported from France with one application of 0.075 kg ai/ha up to BBCH 61 with a 35 day PHI. However, no corresponding residue data were submitted.

The Meeting decided to explore the use of global residue data as outlined in the 2011 JMPR Report (2.4) for residue data from southern Europe against the UK GAP:

For the calculation of the livestock animal dietary burden the total residues in barley forage (fresh) in southern Europe were (n=9): 2.7, 3.0, 3.2, 3.4, 3.4, 3.7, 3.8, 4.3, 6.0 mg/kg.

The Meeting decided to combine that data and evaluate all European supervised field trials against the UK GAP for barley and oat forage:

For the calculation of the livestock animal dietary burden the total residues in barley forage (fresh) in whole Europe were (n=19): 2.1, 2.5, 2.6, 2.7, 2.9, 3.0, 3.2, 3.4, 3.4, 3.5, 3.7, 3.8, 3.9, 4.0, 4.3, 4.4, 4.5, 6.0, 7.3 mg/kg.

For wheat, rye and triticale the maximum GAP in northern Europe was reported for the UK involving two foliar applications of up to 0.125 kg ai/ha. The last application is at BBCH 69 with the PHI covered by growth between treatment and harvest. Supervised field trials conducted in northern Europe according to this GAP were submitted.

For the calculation of the livestock animal dietary burden the total residues in wheat forage (fresh) in northern Europe were (n=10): 1.5, 2.4, 2.8, 2.9, 3.1, 3.4, 3.8, 4.7, 4.8, 7.3 mg/kg.

In southern Europe a GAP for wheat, rye and triticale was reported from France with one application of 0.094 kg ai/ha up to BBCH 69 with a 35 day PHI. However, no corresponding residue data were submitted.

The Meeting decided to explore the use of global residue data as outlined in the 2011 JMPR Report (2.4) for residue data from southern Europe against the UK GAP.

For the calculation of the livestock animal dietary burden the total residues in wheat forage (fresh) in southern Europe were (n=10): 2.6, 2.7, 2.9, 3.0, 3.6, 3.9, 4.2, 4.5, 5.2, 5.5 mg/kg.

The Meeting decided to combine that data and evaluate all European supervised field trials against the UK GAP for wheat forage.

For the calculation of the livestock animal dietary burden the total residues in barley and wheat forage (fresh) in Europe were (n=20): 1.5, 2.4, 2.6, 2.7, 2.8, 2.9, 2.9, 3.0, 3.1, 3.4, 3.6, 3.8, 3.9, 4.2, 4.5, 4.7, 4.8, 5.2, 5.5, 7.3 mg/kg.

Barley, oats, rye, triticale and wheat – straw and fodder

GAPs for barley and oats in the UK are for a maximum of two foliar applications up to flowering (BBCH 61) with 0.125 kg ai/ha each. The PHI is covered by the interval between treatment and harvest (covered by growth stage).

For MRL compliance purposes residues of parent bixafen in barley straw (fresh) in northern Europe (n=10): 0.64, 0.7, 0.77, 0.86, 1.1, 1.1, 3.7, 4.8, 5.4, 10 mg/kg.

For the calculation of the livestock animal dietary burden the total residues in barley straw (fresh) in northern Europe were (n=10): 0.72, 0.74, 0.85, 1.0, 1.2, 1.2, 3.9, 5.2, 5.6, 11 mg/kg.

In southern Europe a GAP for barley and oats was reported from France with one application of 0.075 kg ai/ha up to BBCH 61 with a 35 day PHI. However, no corresponding residue data were submitted.

The Meeting decided to explore the use of global residue data as outlined in the 2011 JMPR Report (2.4) for residue data from Southern Europe against the UK GAP.

For MRL compliance purposes residues of parent bixafen in barley straw (fresh) in southern Europe (n=9): 0.46, 0.76, 1.2, 1.5, 1.9, 3.1, 5.2, 5.7, 6.2 mg/kg.

For the calculation of the livestock animal dietary burden the total residues in barley straw (fresh) in southern Europe were (n=9): 0.5, 1.0, 1.3, 1.6, 2.1, 3.3, 5.6, 6.1, 6.7 mg/kg.

Since both datasets are not significantly different (Mann-Whitney-U-testing), the Meeting decided to combine that data and evaluate all European supervised field trials against the UK GAP for barley and oat straw.

For MRL compliance purposes residues of parent bixafen in barley straw (fresh) in whole Europe (n=19): 0.46, 0.64, 0.7, 0.76, 0.77, 0.86, 1.1, 1.1, 1.2, 1.5, 1.9, 3.1, 3.7, 4.8, 5.2, 5.4, 5.7, 6.2 and 10 mg/kg.

For the calculation of the livestock animal dietary burden the total residues in barley straw (fresh) in whole Europe were (n=19): 0.5, 0.72, 0.74, 0.85, 1.0, 1.0, 1.2, 1.2, 1.3, 1.6, 2.1, 3.3, 3.9, 5.2, 5.6, 5.6, 6.1, 6.7, 11 mg/kg.

For wheat, rye and triticale the maximum GAP in Northern Europe was reported from the UK and involved two foliar applications of up to 0.125 kg ai/ha. The last application is at BBCH 69 and the PHI is covered by growth between treatment and harvest. Supervised field trials conducted in northern Europe according to this GAP were submitted.

For MRL compliance purposes residues of parent bixafen in wheat straw (fresh) in northern Europe (n=10): 0.52, 0.93, 0.95, 1.3, 1.8, 1.9, 3.6, 4.1, 8.4 and 10 mg/kg.

For the calculation of the livestock animal dietary burden the total residues in wheat straw (fresh) in northern Europe were (n=10): 0.78, 1.2, 1.3, 1.5, 2.1, 2.5, 3.9, 4.4, 9.6 and 11 mg/kg.

In southern Europe a GAP for wheat, rye and triticale was reported from France with one application of 0.094 kg ai/ha up to BBCH 69 with a 35 day PHI. However, no corresponding residue data were submitted.

The Meeting decided to explore the use of global residue data as outlined in the 2011 JMPR Report (2.4) for residue data from southern Europe against the UK GAP:

For MRL compliance purposes residues of parent bixafen in wheat straw (fresh) in southern Europe (n=10): 0.79, 1.4, 1.7, 1.8, 2.6, 3.2, 3.3, 3.6, 5.4 and 5.7 mg/kg.

For the calculation of the livestock animal dietary burden the total residues in wheat straw (fresh) in southern Europe were (n=10): 1.2, 1.9, 1.9, 2.2, 3.2, 3.7, 3.9, 4.1, 6.0 and 6.2 mg/kg.

The Meeting decided to combine that data and evaluate all European supervised field trials against the UK GAP for wheat, rye and triticale straw:

For MRL compliance purposes residues of parent bixafen in wheat straw (fresh) in whole Europe (n=20): 0.52, 0.79, 0.93, 0.95, 1.3, 1.4, 1.7, 1.8, 1.8, 1.9, 2.6, 3.2, 3.3, 3.6, 3.6, 4.1, 5.4, 5.7, 8.4 and 10 mg/kg.

For the calculation of the livestock animal dietary burden the total residues in wheat straw (fresh) in whole Europe were (n=20): 0.78, 1.2, 1.2, 1.3, 1.5, 1.9, 1.9, 2.1, 2.2, 2.5, 3.2, 3.7, 3.9, 3.9, 4.1, 4.4, 6.0, 6.2, 9.6 and 11 mg/kg.

Residues in rotational crops

Bixafen is highly persistent in soil, showing accumulation over subsequent years of treatment. In field rotational crop studies conducted at rates corresponding to the highest annual application rates registered, no significant residues were found in plant commodities. However, the long-term field accumulation study submitted suggests plateau residues in soil after up to seven years of annual treatment are equivalent to 2–3 times the soil residues expected after a single treatment at the registered maximum annual application rate. In confined rotational crop studies approximating this plateau level observed in soil, residues above the LOQ of 0.01 mg/kg were found for bixafen and M21 (bixafen-desmethyl) in all plant commodities investigated except for wheat grain.

The Meeting concluded that the accumulation of bixafen in soil results in residue concentrations in follow crops which are relevant for MRL compliance, dietary intake assessment and the estimation of livestock dietary burden. However, the Meeting recognized that the available field rotational crop studies were underdosed compared to the soil concentrations following long-term use of bixafen, while confined rotational crop studies are not considered representative for field conditions.

The Meeting decided that further information on bixafen in rotational crops under field conditions are required involving application rates approximating the plateau levels in soil after subsequent years of treatment. The estimation of maximum residue levels and median or highest residues for annual crops is not possible without considering the contribution of residues taken up from soil and will be postponed to a future meeting when new data becomes available to assess the rotational crop situation.

Fate of residues during processing

The Meeting received information on the hydrolysis of radio-labelled bixafen as well as processing studies using unlabelled material on grown residues in oilseed rape, barley and wheat.

In a hydrolysis study using radio-labelled bixafen typical processing conditions were simulated (pH 4,5 and 6 with 90 °C, 100 °C and 120 °C for 20, 60 and 20 minutes). In duplicate samples of sterile buffer solution no degradation was observed.

The Meeting concluded that no recommendations on bixafen residues in plant commodities can be made (see residues in rotational crops section) and therefore no processing factors are required. For an overview of the available information on the fate of bixafen during processing please refer to the 2013 Evaluation.

Residues in animal commodities

Farm animal feeding studies

The Meeting received feeding studies involving bixafen on lactating cows and laying hens.

Three groups of lactating cows were dosed daily at levels of 4, 12 and 40 ppm in the diet (0.15, 0.45 and 1.5 mg/kg bw) for 28 consecutive days. Milk was collected throughout the whole study and tissues were collected on day 29 within 24 hours of the last dose.

In milk highest mean total residues were 0.039 mg/kg for the 4 ppm group, 0.077 mg/kg for the 12 ppm group and 0.218 mg/kg for the 40 ppm group. Investigation of the distribution of the residue in cream gave a 9.9 fold higher concentration than in whole milk (15 between whole milk and milk fat).

Total residues in muscle for the 4, 12 and 40 ppm groups were 0.039–0.065 mg/kg (mean: 0.052 mg/kg), 0.081–0.26 mg/kg (mean: 0.162 mg/kg) and 0.63–1.0 mg/kg (mean: 0.82 mg/kg), respectively. In liver residues were 0.42–0.69 mg/kg (mean: 0.57 mg/kg) for the 4 ppm group, 1.2–1.7 mg/kg (mean: 1.4 mg/kg) for the 12 ppm group and 4.8–5.4 mg/kg (mean: 5.0 mg/kg) for the 40 ppm group. Kidney contained total residues of 0.1–0.15 mg/kg (mean: 0.14 mg/kg), 0.28–0.37 mg/kg (mean: 0.34 mg/kg) and 1.0–1.3 mg/kg (mean: 1.2 mg/kg) for the for the 4, 12 and 40 ppm group.

For fat three different tissues were analysed (perirenal, mesenteric and subcutaneous fat). Highest residues were found in perirenal fat with 0.14–0.21 mg/kg (mean: 0.18 mg/kg) for the 4 ppm group, 0.33–0.48 mg/kg (mean: 0.43 mg/kg) for the 12 ppm group and 0.8–1.9 mg/kg (mean: 1.4 mg/kg) for the 40 ppm group.

For laying hens three groups of animals were dosed with rates of 1.5, 4.5 and 15 ppm in the dry weight feed (0.1, 0.3 and 1.0 mg/kg bw) for 28 consecutive days. Eggs were collected throughout the whole study and tissues were collected on day 29 after the last dose.

In eggs total residues at the plateau phase were < 0.02–0.02 mg/kg (highest daily mean: 0.02 mg/kg) for the 1.5 ppm group and ranged between 0.05 to 0.07 mg/kg (highest daily mean: 0.063 mg/kg) for the 4.5 ppm and between 0.13 to 0.22 mg/kg (highest daily mean: 0.178 mg/kg) for the 15 ppm group.

In tissues no residues above the LOQ were found in muscle. Total residues in fat for the 1.5, 4.5 and 15 ppm groups were < 0.02–0.02 mg/kg (mean: 0.02 mg/kg), 0.05–0.06 mg/kg (mean: 0.057 mg/kg) and 0.06–0.09 mg/kg (mean: 0.07 mg/kg), respectively. In liver residues were < 0.02–0.02 mg/kg (mean: 0.02 mg/kg) for the 1.5 ppm group, 0.02–0.04 mg/kg (mean: 0.03 mg/kg) for the 4.5 ppm group and 0.03–0.05 mg/kg (mean: 0.04 mg/kg) for the 15 ppm group.

Estimated maximum and mean dietary burdens of livestock and animal commodities maximum residue levels

The Meeting noted that the uptake of bixafen and M21 (bixafen-desmethyl) from soil contributes significantly to the overall residues in annual crops. Based on the information available (see residues in rotational crops), no estimation on livestock animal dietary burdens and the corresponding residue levels in animal commodities can be made.

RECOMMENDATIONS

Definition of the residue for compliance with MRL for plant commodities: *bixafen*

Definition of the residue for compliance with MRL for animal commodities and (for the estimation of dietary intake) for plant and animal commodities: *sum of bixafen and N-(3',4'-dichloro-5-fluorobiphenyl-2-yl)-3-(difluoromethyl)-1H-pyrazole-4-carboxamide (bixafen-desmethyl), expressed as bixafen*

The residue is fat-soluble.

FURTHER WORK OR INFORMATION

The Meeting considered that the currently available information on residues in rotational crops was not sufficient to make recommendations on maximum residue levels in plant and animal commodities. For future recommendations field rotational crop studies approximating plateau concentrations of bixafen in soil are required.

DIETARY RISK ASSESSMENT

The Meeting concluded that the contribution of residues in plant commodities from soil uptake cannot be estimated based on the available data. Thus no estimations on median or highest residues in food commodities of plant and animal origin could be made, precluding both long and short-term dietary risk assessments for bixafen.

Consequently, the dietary risk assessment will be undertaken at a future meeting when the residues derived from both direct application and those taken up from the soil in a rotational crop situation can be evaluated together.

CHLORANTRANILIPROLE (230)

*First draft prepared by professor Eloisa Dutra Caldas University of Brasilia
Brasilia, Brazil*

BACKGROUND

Chlorantraniliprole is a selective ryanodine receptor agonist insecticide which was evaluated by the JMPR in 2008 (T, R) and 2010 (R). The ADI for chlorantraniliprole is 0–0.03 mg/kg bw and ARfD was considered to be unnecessary. The compound was listed by the Forty-fourth Session of the CCPR (2012) for the evaluation by the 2013 JMPR. This submission presents additional proposed/registered uses of chlorantraniliprole and residue data for strawberries, blueberries, cranberries, legumes, soya bean, radish, carrots, globe artichokes, rice, barley, sorghum, wheat, canola seed, sunflower seed, coffee, avocados, pomegranates, hops and citrus.

USE PATTERNS

Chlorantraniliprole is registered around the world to be used as foliar or seed application, in the field or protected, terrestrial or aerial application. Table 1 shows the uses of chlorantraniliprole in crops and regions that are relevant for this submission.

Table 1 Registered ground uses of chlorantraniliprole on crops included in this evaluation

RESIDUES RESULTING FROM SUPERVISED TRIALS

Supervised residue trials conducted with chlorantraniliprole on a variety of crops in Europe, Brazil, Canada and USA were submitted to the Meeting. Studies were conducted according to GLP, and specified concurrent determination of residues in untreated crops gave residues < LOQ. Residues of chlorantraniliprole arising from use patterns where rate or PHI or $\pm 25\%$ of GAP are underlined and considered for estimation of maximum residue levels and STMRS. When residues in samples harvested at a later stage were higher than those found at the critical PHI, they were used for the estimations. In the tables, DAT means days after treatment. In Canada and USA trials, two samples were analysed and the mean residues reported.

Berries and other small fruit

Seventeen trials were conducted in blueberry and cranberry in Canada and USA in 2007 (Table 2) and 16 trials were conducted in strawberry in Europe and USA from 2008–2011 (Table 3).

^a highest residue values of two individual field samples.

Oil seeds

Twelve trials were conducted with canola and sunflower in Canada and USA in 2010. The results are shown in Table 11.

Table 11 Results of residue trials conducted with chlorantraniliprole in oil seeds (DuPont-26888)

Coffee

Eight trials were conducted in coffee in Brazil in 2007 and 2010. The coffee cherries were dried for 24 days in the field and the coffee beans were mechanically separated from the skin. The residues found in the coffee beans are shown in Table 12.

Hops

Four trials were conducted in hops in USA in the period of 2009-2012. After harvest, the hop cones were dried in ovens/dryer rooms/kilns simulating commercial practices. The hop cones were dried at approximately 60–65 °C for up 2.5 to 24 hours. The results are shown in Table 13.

FATE OF RESIDUES IN PROCESSING

Rice

Two processing studies were conducted with rice in USA in 2007. Rice seed was treated once at 0.2 mg ai/seed and grain harvested after 148 days were processed using two different procedures (DuPont-21999). The results are shown in Table 17.

Table 17 Processing studies in rice

Matrix	Test No. 12		Test 15		Best estimate (median)
		PF		PF	
Grain	0.048		0.044		
Polished rice (mechanical processing)	0.003	0.07	0.003	0.07	0.11
Polished rice (parboil processing)	0.008	0.16	0.007	0.15

APPRAISAL

The insecticide chlorantraniliprole was evaluated by the JMPR 2008 (T, R) and 2010 (R). The ADI for chlorantraniliprole is 0–2 mg/kg bw and an ARfD was considered unnecessary. The compound was listed by the Forty-fourth Session of the CCPR (2012) for the evaluation by the 2013 JMPR of residue data for avocados, pomegranates, strawberries and other berries, soya bean, radish, carrots, globe artichokes, wheat, rape seed, sunflower seed, coffee and hops.

The residue definition for compliance with MRL and for dietary intake for plant and animal commodities is chlorantraniliprole. The residue is considered fat-soluble.

Results from supervised residue trials on crops*Berries and other small fruits*

Currently, there is a Codex MRL of 1 mg/kg for chlorantraniliprole in Berries and other small fruits, which replaced the previous MRL of 1 mg/kg in grapes.

In the USA, GAP for chlorantraniliprole in strawberry is for up to 4×0.05 – 0.07 kg ai/ha (7 days interval; total 0.225 kg ai/ha/season). Eight trials conducted in the USA in 2011 at 2×0.11 kg ai/ha (7 days interval) gave residues at 1 day PHI of 0.18, 0.21, 0.22, 0.23, 0.24 (2), 0.40 and 0.68 mg/kg. Eight indoor trials were conducted in southern Europe, where there is no approved use.

Residues of chlorantraniliprole in grapes from 17 trials in Canada and the USA evaluated by the 2008 JMPR complying with GAP of the USA (3×0.07 – 0.11 kg ai/ha and 14 days PHI) were 0.02, 0.04 (3), 0.08, 0.09 (2), 0.11, 0.12, 0.18, 0.20, 0.26, 0.32, 0.34, 0.46, 0.48 and 0.52 mg/kg.

In the USA and Canada, GAP in bushberries (include cranberry and blueberry) is 3×0.07 – 0.11 kg ai/ha and 1 day PHI, total 0.

225 kg ai/ha/season). Seventeen trials were conducted in Canada and USA in cranberry and blueberry using 2 applications of the maximum GAP rate, with residues at 1 day PHI of 0.11, 0.12 (2), 0.13 (2), 0.16, 0.18 (2), 0.21 (2), 0.23, 0.24, 0.29, 0.32, 0.46, 0.75 and 0.84 mg/kg.

Data evaluated by the 2010 JMPR on residues of chlorantraniliprole in caneberries (raspberries and blackberries) from eight trials in Canada and the USA complying with GAP of the USA were: 0.05, 0.09 (2), 0.24, 0.44, 0.48 (2) and 0.51 mg/kg

The Meeting confirms its previous recommendation of a maximum residue level of 1 mg/kg for chlorantraniliprole in berries and other small fruits.

Avocado

The GAP of chlorantraniliprole in avocado in New Zealand is 2×0.09 kg ai/ha (21 days interval) and a 14 day PHI. Two trials conducted in the country according to GAP gave residues in fruit of 0.03 and 0.08 mg/kg. Six other trials conducted at higher or lower GAP gave residues ranging from 0.07 to 0.31 mg/kg at 14 days DAT.

As only two trials were conducted according to GAP, the Meeting could not recommend a maximum residue level for chlorantraniliprole in avocado.

Pomegranate

The GAP of chlorantraniliprole in pomegranate in USA is 3×0.07 – 0.11 kg ai/ha (7 days interval; max. 0.2 kg ai/ha/season) and a 1 day PHI. Five trials conducted in the country according to GAP gave residues of 0.09, 0.10 (2) and 0.12 (2) mg/kg.

The Meeting recommended a maximum residue level of 0.4 mg/kg and a STMR of 0.10 mg/kg for chlorantraniliprole in pomegranate.

Radish tops

Currently, there is a Codex MRL of 20 mg/kg for chlorantraniliprole in leafy vegetables.

In the USA, chlorantraniliprole is registered in root and tuber vegetables at a maximum rate of 4×0.07 kg ai/ha (3 day interval; max of 0.22 kg ai/ha/season) and a 1 day PHI. In six trials conducted in radish at 2×0.11 kg ai/ha gave residues in radish tops at a 1 day PHI of 3.9, 7.7, 10, 11, 19 and 22 mg/kg.

The Meeting recommended a maximum residue level of 40 mg/kg and a STMR of 10.5 mg/kg for chlorantraniliprole in radish leaves (including radish tops).

The Meeting agreed to withdraw its previous recommendation of 20 mg/kg for leafy vegetables for 20 mg/kg in leafy vegetables, except radish leaves.

Legume vegetables

In Italy, chlorantraniliprole is registered in beans at up to 2×0.04 kg ai/ha with a 3 day PHI. In five trials conducted in France, Italy and Spain in 2008/2009, according to this GAP, residues in fresh bean pods with seeds were 0.15, 0.16, 0.40 (2) and 0.41 mg/kg. Five residue trials conducted in southern Europe according to the Italian GAP and submitted to the 2010 JMPR gave residues in fresh pods with seeds of 0.08, 0.09, 0.12, 0.16 and 0.25 mg/kg.

Trials conducted in southern Europe according to GAP (n=9) gave residues in bean pods with seeds of 0.08 (2), 0.12, 0.15, 0.16 (2), 0.40 (2) and 0.41 mg/kg.

In USA, the rate for legume vegetables is up to 4×0.07 kg ai/ha (max. of 0.225 kg ai/ha/season) and a 1 day PHI. In nine trials conducted in the USA and Canada (2008) at 2×0.11 kg ai/ha, residues in bean pods with seeds were: < 0.01, 0.10, 0.12 (3), 0.14 (2), 0.16 and 0.41 mg/kg.

In Australia, GAP for legume vegetable is 3×0.02 kg ai/ha and a 1 day PHI. In two trials conducted according to GAP, residues in bean pods with seeds were 0.08 (2) mg/kg.

Based on the European trials, the Meeting recommended a maximum residue level of 0.8 mg/kg and a STMR of 0.16 mg/kg for chlorantraniliprole in beans, except broad bean and soya bean (green pods and immature seeds).

In four trials conducted in peas in the USA and Canada according to GAP, residues in pea pods with seeds were 0.45, 0.48, 0.61 and 0.64 mg/kg.

In three trials conducted in Australia according to the Australian GAP for legume vegetables (3×0.02 kg ai/ha, 1 day PHI), residues in pea pods with seeds were 0.04, 0.06 and 0.47 mg/kg.

Based on the US and Canadian trials, and with the support of the Australian trials, the Meeting recommended a maximum residue level of 2 mg/kg and a STMR of 0.545 mg/kg for chlorantraniliprole in Peas (pods and succulent = immature seeds).

In six trials conducted in the USA and Canada, according to GAP, residues in pea seed were 0.01, 0.02 (2) and 0.03 (3) mg/kg. In two trials conducted in Australia according to GAP, residues in pea seed were < 0.01 (2) mg/kg.

Based on trials conducted in Canada and the USA, and with the support of the Australian trials, the Meeting recommends a maximum residue level of 0.05 mg/kg and a STMR of 0.025 mg/kg for chlorantraniliprole in peas, shelled.

Soya bean, dry

The GAP chlorantraniliprole in soya bean in Brazil is 2×0.01 kg ai/ha, and a PHI of 21 days. Four trials conducted in 2010 according to GAP gave residues of < 0.01 mg/kg (4).

Four trials submitted to the 2010 JMPR used a furrow application (0.1 kg ai/ha) followed by two applications at the GAP rate gave residues at 21 days PHI of 0.10, 0.11 (2) and 0.12 mg/kg.

As only four trials according to GAP were submitted, the Meeting could not recommend a maximum residue level for chlorantraniliprole in soya beans.

Root and tuber vegetables

The current Codex MRL for chlorantraniliprole in Root and tuber vegetables is 0.02 mg/kg, following the recommendation made by the 2008 JMPR based on rotation crop data (0.01 mg/kg on radish root) and foliar trials on potatoes (< 0.01 mg/kg, n=27).

In the USA, chlorantraniliprole is registered in Root and tuber vegetables at a maximum rate of 4×0.07 kg ai/ha (3 days interval; max of 0.22 kg ai/ha/season) and a 1 day PHI. Six trials conducted in radish at 2×0.11 kg ai/ha gave residues at a 1 day PHI of 0.03, 0.04, 0.05, 0.06, 0.08 and 0.26 mg/kg in the radish root. The Meeting agreed that the contribution from previous use on the rotation regime would not significantly impact the final residues.

The Meeting estimates a maximum residue level of 0.5 mg/kg and a STMR of 0.055 mg/kg for chlorantraniliprole in radish.

Chlorantraniliprole is registered to be used in Italy in carrots at up to 2×0.04 kg ai/ha (7–10 days interval) and 21 days PHI. Nine trials conducted in southern Europe in 2009/2010 according to this GAP gave residues of < 0.004 (3), 0.004, 0.005 (2), 0.025, 0.03, and 0.036 mg/kg. Eight trials conducted in northern Europe at the same rate gave residues of < 0.004 (5) 0.01, 0.021, and 0.027 mg/kg. Residues in Europe can be combined as < 0.004 (8), 0.004, 0.005 (2) 0.01, 0.021, 0.025, 0.027, 0.03 and 0.036 mg/kg.

Considering the contribution from rotation crops (0.01 mg/kg), the Meeting estimated a maximum residue level of 0.08 mg/kg and a STMR of 0.02 mg/kg for chlorantraniliprole in carrots.

The Meeting agreed to replace its previous recommendation of 0.02 mg/kg for chlorantraniliprole in Root and tuber vegetables for 0.02 mg/kg in Root and tuber vegetables, except carrot and radish.

Globe artichoke

Chlorantraniliprole is registered for use in Italy in globe artichoke at 2×0.03 kg ai/ha (14 days interval) and a 3 day PHI. Four trials conducted in southern Europe at this GAP gave residues of 0.06, 0.07, 0.08 and 0.16 mg/kg.

The product is registered in the USA at 4×0.05 –0.11 kg ai/ha (4 days interval; max of 0.22 kg ai/ha/season) and a 3 day PHI. Four trials conducted with 2 applications of the GAP rate gave residues of 0.47, 0.53, 0.59 and 0.69 mg/kg.

Based on the US trials, the Meeting recommended a maximum residue level of 2 mg/kg and a STMR of 0.56 for chlorantraniliprole in globe artichoke.

Rice

Chlorantraniliprole is registered to be used in Brazil in rice as a foliar treatment at 1×0.03 kg ai/ha and a 15 day PHI. In eight trials conducted in the country according to GAP, residues were < 0.01, 0.02, 0.03, 0.10, 0.13 (2) and 0.16 (2) mg/kg.

In the USA, the product is registered as seed treatment at 0.06 mg ai/seed (0.09 kg ai/ha). Sixteen trials conducted at 0.10 mg ai/seed (0.56 kg ai/ha) gave residues ranging from 0.01 to 0.09 mg/kg. Three trials conducted within GAP gave residues in the grain of 0.01 (2) and 0.02 mg/kg.

Based on the Brazilian foliar trials conducted according to GAP, the Meeting estimated a maximum residue level of 0.4 mg/kg and a STMR of 0.115 mg/kg for chlorantraniliprole in rice grain.

Two processing studies were submitted to the Meeting. In each, two different procedures were used to produce polished rice, with processing factors of 0.07 (2), 0.15 and 0.16, median of 0.11. This PF was applied to the residue data on rice grain to derive data on polish rice.

The Meeting estimates a maximum residue level of 0.04 mg/kg and a STMR of 0.013 mg/kg for chlorantraniliprole in polished rice.

Cereals, except rice

Currently, the Codex MRL for chlorantraniliprole in cereals is 0.02 mg/kg, following the recommendation made by the 2008 JMPR based on rotation crop data.

In the USA, three trials were conducted in barley, three in sorghum and five trials were conducted in wheat using 2×0.11 kg ai/ha. Residues in samples harvested at 1 DAT ranged from 0.19 to 2.2 mg/kg. As the compound is not registered for use in these crops in the USA, no estimations were made.

The Meeting replaced its previous recommendation of 0.02 mg/kg for cereals for 0.02 mg/kg in cereals, except rice.

Rape and sunflower seeds

Chlorantraniliprole is registered in Canada for oilseeds, except cotton, at 3×0.025 –0.07 kg ai/ha (max of 0.2 kg ai/ha/season) and a 1 day PHI. Twelve trials were conducted in the USA and Canada in rape seed (canola) and sunflower according to this GAP.

Six trials conducted in rape seed (canola) gave residues at of 0.14, 0.23, 0.25, 0.34, 0.83 and 1.0 mg/kg.

Six trials conducted in sunflower gave residues at of 0.03, 0.12, 0.16, 0.21, 0.79 and 0.82 mg/kg.

The Meeting estimates a maximum residue level of 2 mg/kg for chlorantraniliprole in rape seed and sunflower seed.

The Meeting estimates a STMR of 0.295 mg/kg for chlorantraniliprole in rape seed and of 0.185 mg/kg for sunflower seed.

Coffee

Chlorantraniliprole is registered in Brazil for use on coffee at 2×0.03 kg ai/ha with a 21 day PHI. Eight trials were conducted in Brazil matching this GAP, giving residues of < 0.01, 0.01 (3), 0.02 (3) and 0.03 mg/kg.

The Meeting recommended a maximum residue level of 0.05 mg/kg and a STMR of 0.015 mg/kg for chlorantraniliprole in coffee.

Hops

Chlorantraniliprole is registered in the USA for use in hops at 4×0.072 kg ai/ha (max. of 0.22 kg ai/ha/season) with a 0 day PHI. Four trials conducted at GAP (2×0.1 kg ai/ha) gave residues in dried cones of 7.6, 8.9, 13 and 19 mg/kg.

The Meeting estimated a maximum residue level of 40 mg/kg and a STMR of 10.9 mg/kg for chlorantraniliprole in hops, dry.

Animal feeds

Three Australian trials conducted according to GAP gave residues at a 1 day PHI in bean and pea foliage of 0.31, 0.78 and 2.2 mg/kg. In two pea trials, residues in empty pods were 0.05 and 0.20 mg/kg.

Five trials conducted in southern Europe in beans according to Italian GAP gave residues at a 3 day PHI in bean plants without pods of 2.4, 4.3, 4.5, 6.6 and 6.8, mg/kg.

The US label has no additional information covering the grazing of legume vegetables. Nineteen trials conducted in Canada and USA according to US GAP (4×0.07 kg ai/ha; max. of 0.225 kg ai/ha/season) gave residues at a 1 day PHI in bean or pea plants with pods of 0.01, 1.7, 2.8, 3.0, 3.4, 3.8, 3.8, 4.3, 4.4, 4.5, 4.8, 4.9, 4.9, 5.2, 5.3, 5.5, 6.0, 6.2 and 6.4 mg/kg.

Based on Canadian and US data, the Meeting estimated a median residue of 4.4 mg/kg and a highest residue of 6.4 mg/kg for chlorantraniliprole in bean forage (green) and pea vines (green).

In ten trials conducted in wheat, sorghum and barley in the USA, residues were determined in forage, hay and straw. However, as these are not registered uses for chlorantraniliprole in USA, the data was not considered further.

Sixteen trials conducted in rice after seed treatment at a higher than GAP rate in USA, residues in straw ranged from 0.05 to 0.24 mg/kg.

Fate of residues during processing

At the present Meeting, a STMR of 0.115 mg/kg was estimated for rice grain. Two studies were conducted in rice.

The best Pf estimated for rice bran (n=4) was 1.7, leading to an estimated STMR-P of 0.196 mg/kg.

The best Pf estimated for rice hull (n=4) was 3.3. For animal dietary burden purposes, a median of 0.368 mg/kg was calculated for rice hull.

*Residues in animal commodities**Farm animal dietary burden*

The Meeting estimated the dietary burden of chlorantraniliprole in farm animals on the basis of the OECD Animal Feed data published in the 2009 FAO Manual, the STMR, STMR-Ps or highest residue levels estimated at the present and previous JMPR Meetings (2008 and 2010). Dietary burden calculations are provided in Annex 6 of the 2013 Report.

Livestock dietary burden for chlorantraniliprole, ppm of dry matter diet

Commodity	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	7.6	3.4	19.9	10.7	31.7 ^a	15.7 ^c	3.5	1.5
Dairy cattle	13.4	6.0	22.4 ^b	10.1	26.8	13.1 ^d	15.8	6.7
Poultry - broiler	0.06	0.06	0.06	0.032	0.11	0.11	1.06	0.55
Poultry - layer	0.06	0.06	4.42 ^c	2.51 ^f	0.11	0.11	0.05	0.05

^a Highest maximum beef or dairy cattle dietary burden suitable for maximum residue level estimated for mammalian tissues

^b Highest maximum dairy cattle dietary burden suitable for maximum residue level estimated for mammalian milk

^c Highest mean beef or dairy cattle dietary burden suitable for STMR estimated for mammalian tissues.

^d Highest mean dairy cattle dietary burden suitable for STMR estimated for milk.

^e Highest maximum poultry dietary burden suitable for maximum residue level estimated for poultry tissues and eggs.

^f Highest mean poultry dietary burden suitable for STMR estimated for poultry tissues and eggs.

Animal commodity maximum residue level

The dietary burden estimated by the present Meeting for cattle is similar to that estimated by the 2010 JMPR and would not impact the previous recommendations for chlorantraniliprole in edible offal (mammalian), meat (from mammals other than marine mammals) and milk fats.

The calculated maximum poultry dietary burden suitable for maximum residue level estimated for poultry tissues and eggs was 4.4 ppm, about 2.4 times higher than the previous estimation. The calculated dietary burden for STMR estimation is 0.007 ppm.

In a metabolism study evaluated by the 2008 JMPR, poultry laying hens were dosed with [¹⁴C]chlorantraniliprole for 14 days at 10 ppm in the diet. Residues found in eggs, muscle, liver and skin/fat and the residues expected in poultry commodities based on the calculated animal burden are shown in the table below. The levels which the estimations were based are in bold.

	Feed level, ppm, for	Residue, mg/kg			
	Tissues and eggs residues	Eggs	Muscle	Liver	Fat
Highest residue level, hens					
Feeding study	10	0.308	0.0008	0.0196	0.009
Calculated burden	4.42	0.135	0.0004	0.008	0.004
STMR, hens					
Feeding study	10	0.282	0.0008	0.0196	0.009
Calculated burden	2.5	0.07	0.0002	0.005	0.002

The Meeting confirms its previous maximum residue level recommendation of 0.01* mg/kg for chlorantraniliprole in poultry meat (fat) and poultry edible offal, and estimated a STMR of 0 for poultry meat (fat) and 0.005 for poultry edible offal.

The Meeting estimated a maximum residue level of 0.2 mg/kg and a STMR of 0.07 for chlorantraniliprole in eggs.

The meeting withdraws its previous recommendation of 0.1 mg/kg for chlorantraniliprole in eggs.

RECOMMENDATIONS

Definition of the residue for compliance with for compliance with maximum residue levels and estimation of dietary intake in plant and animal commodities: *chlorantraniliprole*.

CCN	Commodity name	Maximum residue level (mg/kg)		STMR, STMR (P) mg/kg
		New	Previous	
VS 0620	Artichoke, globe	2		0.56
VP 0061	Beans, except broad bean and soya bean (green pods and immature seeds)	0.8		0.16
VR 0577	Carrot	0.08		0.02
GC 0080	Cereal grains	W	0.02	

CCN	Commodity name	Maximum residue level (mg/kg)		STMR, STMR (P) mg/kg
		New	Previous	
GC 0080	Cereal grains, except rice	0.02		0.01
SB 0716	Coffee beans	0.05		0.015
PE 0112	Eggs	0.2	0.1	0.07
DH 1100	Hops, dry	40		10.9
VL 0053	Leafy vegetables	W	20	
VL 0053	Leafy vegetables, except radish leaves	20		
VP 0063	Peas (pods and succulent = immature seeds)	2		0.545
VP 0064	Peas, shelled (succulent seeds)	0.05		0.025
FL 0355	Pomegranate	0.4		0.11
PM 0110	Poultry meat	0.01*	0.01*	0
PO 0111	Poultry , edible offal of	0.01*	0.01*	0.005
VR 0494	Radish	0.5		0.055
VL 0494	Radish leaves (includes radish tops)	40		10.5
SO 0495	Rape seed	2		0.295
GC 0649	Rice	0.4		0.115
	Rice, polished	0.04		0.013
	Rice, bran			0.196
VR 0075	Root and tuber vegetables	W	0.02	
VR 0075	Root and tuber vegetables, except carrot and radish	0.02		0.01
SO 0702	Sunflower seed	2		0.185

DIETARY RISK ASSESSMENT

Long-term intake

The ADI for chlorantraniliprole is 0–2 mg/kg bw. The International Estimated Daily Intakes (IEDI) for chlorantraniliprole was estimated for the 13 GEMS/Food cluster diets using the STMR or STMR-P values estimated by the current and previous JMPR. The results are shown in Annex 3 of the 2013 Report. The IEDI was 0% of the maximum ADI. The Meeting concluded that the long-term intake of residues of chlorantraniliprole from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The 2008 JMPR decided that an ARfD for chlorantraniliprole was unnecessary. The Meeting therefore concluded that the short-term intake of chlorantraniliprole is unlikely to present a public health concern.

CHLORPYRIFOS-METHYL (090)

*First draft prepared by Professor Eloisa Dutra Caldas University of Brasilia
Brasilia, Brazil*

APPRAISAL

Chlorpyrifos-methyl was evaluated for residues by the 2009 JMPR under the periodic review program, when a recommendation of 3 mg/kg for wheat, barley and maize was made based on post-harvest use. The long-term dietary risk assessment for the compound indicated an exceedance of up to 140% of the ADI of 0.01 mg/kg bw, with maize accounting for about 73% of the IEDI. This recommendation was made using an alternative Spanish GAP (2.2 g ai/ton).

The 2012 JMPR received a new Spanish label indicating that the post-harvest use of chlorpyrifos-methyl was no longer allowed on maize. The 2012 Meeting withdrew its previous recommendation of 3 mg/kg (Po) on maize, and the new long-term dietary risk assessment indicated that the highest IEDI was 60% of the ADI.

The 2013 JMPR received a request from CCPR to reconsider the current recommendation of chlorpyrifos-methyl in wheat and barley of 3 mg/kg (Po). The Meeting received a new label from Australia for post-harvest use of chlorpyrifos-methyl on cereals, except maize at up to 5 g ai/ton (for 3 to 6 months protection). Residues coming from post-harvest trials evaluated by the 2009 JMPR conducted in wheat and barley according to Australian GAP ranged from 1.6, 1.9 (2), 2.2, 2.3, 2.4, 2.6, 2.9 (2), 3.0 (2), 3.1 (2), 3.2 (3), 3.3, 3.5 and 4.7 mg/kg (n=19).

Processing studies on wheat evaluated by the 2009 JMPR gave processing factors (PF) of 0.25 for flour, 1 for whole meal, 1.9 for germ, 2.45 for bran, 0.05 for white bread, and 0.48 for whole bread. Based on a STMR of 3 mg/kg, the Meeting estimated a STMR-P of 0.75 mg/kg for wheat flour, 3 mg/kg for whole meal wheat, 5.7 mg/kg for wheat germ, 7.35 mg/kg for wheat bran, 0.15 mg/kg for white bread and 1.44 in whole meal bread. The Meeting also estimated a HR-P of 11.5 mg/kg for wheat bran, unprocessed, of 10.8 mg/kg in wheat germ, and 4.7 in wheat whole meal. These estimations were extended to triticale processed products. A processing study on barley lead to a PF of < 0.01 for beer and a STMR-P of 0.03 was estimated for beer.

As no processing studies were submitted on rice, the Meeting considered the published study conducted by Cogburn *et al.* (1990). Harvested rice grain were treated with 6 or 12 mg/kg chlorpyrifos-methyl and stored for 1, 6 and 12 weeks. After storage, treated grain was processed to brown rice (husked) or milled to produce polished rice and bran. The mean processing factors (n=6) were 0.22 for husked rice, 0.033 for polished rice, 1.7 for rice bran and 0.012 for cooked polish rice. The data are shown in Table 1.

Table 1 Residues of chlorpyrifos-methyl in rice grain and processed commodities (Cogburn *et al.* (1990))

Rice grain	Husked rice		Polished rice		Rice bran		Cooked polish rice	
Residues, mg/kg	Residues, mg/kg	PF	Residues, mg/kg	PF	Residues, mg/kg	PF	Residues, mg/kg	PF
4.45	0.87	0.20	0.14	0.03	6.7	1.5	0.07	0.016
3.23	0.75	0.23	0.07	0.02	4.7	1.4		
2.3	0.58	0.25	0.15	0.06	5.7	2.5	0.06	0.026
9.9	1.85	0.19	0.25	0.02	15.3	1.5	0.08	0.008
8.3	1.99	0.24	0.18	0.02	10.3	1.2	0.04	0.004
7.43	1.61	0.22	0.28	0.04	13.3	1.8	0.04	0.005
Mean of PF		0.22		0.034		1.67		0.012

The Meeting agreed to estimate a maximum residue level of 5 mg/kg, a STMR of 3 mg/kg and a HR of 4.7 mg/kg for chlorpyrifos-methyl in cereals, except maize and rice

Rice grain is not a trade commodity. Hence the Meeting agrees to use the residue data for wheat and barley according to Australian GAP and the processing factors estimated for husked rice and polished rice to estimate maximum residue levels, STMR-Ps and HR-Ps for these commodities.

The Meeting estimated a maximum residue level of 1.5 mg/kg for rice, husked and of 0.2 mg/kg for rice, polished.

The Meeting estimated a STMR-P of 0.661 mg/kg for husked rice, of 0.101 mg/kg for polished rice, of 5.0 mg/kg for rice bran and of 0.036 mg/kg for cooked polished rice

The Meeting estimated a HR of 1.04 mg/kg for rice, husked of 0.15 mg/kg for rice, polished, of 7.8 mg/kg for rice bran and of 0.056 mg/kg for cooked polished rice.

The Meeting withdrew its previous recommendation of 3 mg/kg for chlorpyrifos-methyl in barley and wheat.

RECOMMENDATION

Residues: For plant and animal commodities is chlorpyrifos-methyl for compliance with the MRL and for the estimation of the dietary intakes.

CCN	Commodity name	Recommended maximum residue level (mg/kg)		STMR (P) mg/kg	HR (P) mg/kg
		New	Previous		
GC 0640	Barley	W	3		
GC 0080	Cereals, except maize and rice	5 Po		3	4.7
CM 0649	Rice, husked	1.5 Po		0.66	1.04
CM 1205	Rice, polished	0.2 Po		0.101	0.15
GC 0654	Wheat	W	3		
	Barley beer			0.03	
CM0654	Rice bran, unprocessed				7.8
	Rice, polished, cooked			0.036	0.056
CF 1211	Wheat flour			0.5	
CF 1210	Wheat germ			5.7	10.8
CF 1212	Wheat wholemeal			3	4.7
CM 0654	Wheat bran, unprocessed			7.35	11.5
CP 1211	White bread			0.15	
CP 1212	Wholemeal			1.44	

DIETARY RISK ASSESSMENT

Long-term intake

The IEDI of chlorpyrifos-methyl based on the STMRs estimated by this and previous Meetings for the 13 GEMS/Food regional diets were 0-110% of the maximum ADI of 0–0.01 mg/kg bw (see Annex 3 of the Report).

The highest % of the ADI (110%) was found in the Cluster diet J, for which 95% of the IEDI was from the consumption of millet and sorghum (include raw grain, flour and beer for both commodities). Processing studies on other cereal grains treated with chlorpyrifos-methyl have shown that residues decrease during processing, including cooking grain in water. It is expected that the fate of residues during processing will be similar for millet and sorghum. The Meeting concluded that the long-term dietary intake of residues of chlorpyrifos-methyl are unlikely to present a public health concern.

Short-term intake

An ARfD for chlorpyrifos-methyl is 0.1 mg/kg bw. The International Estimated Short-Term Intake (IESTI) for chlorpyrifos-methyl was calculated for the plant commodities for which STMRS, HRs and maximum residue levels were estimated by the current Meeting and for which consumption data were available. The results are shown in Annex 4. The IESTI represented a maximum of 10% of the ARfD for husked rice. The Meeting concluded that the short-term intake of chlorpyrifos-methyl residues from uses considered by the current Meeting was unlikely to present a public health concern.

CYANTRANILIPROLE (263)

The first draft was prepared by Mr. David Lunn New Zealand Food Safety Authority, Wellington, New Zealand

EXPLANATION

Cyantraniliprole is a diamide insecticide with a mode of action (ryanodine receptor activation) similar to chlorantraniliprole and flubendiamide. It has root systemic activity with some translaminar movement and is effective against the larval stages of lepidopteran insects; and also on thrips, aphids, and some other chewing and sucking insects.

Authorisations exist for the use of cyantraniliprole in Canada, Columbia, Malaysia, New Zealand, Vietnam and the CLISS countries in West Africa. Authorisations are also being progressed in Australia, Europe and USA under an OECD Joint Review exercise.

Cyantraniliprole was scheduled by the Forty-fourth Session of the CCPR as a new compound for consideration by the 2013 JMPR. Residue and analytical aspects of cyantraniliprole were considered for the first time by the present meeting. The manufacturer submitted studies on metabolism, analytical methods, supervised field trials, processing, freezer storage stability, environmental fate in soil and rotational crop residues.

In this evaluation, the values presented in the tables are as reported in the various studies, but in the accompanying text, they have generally been rounded to two significant digits. Abbreviations have also been used for the various cyantraniliprole metabolites mentioned in the study reports. These include:

IN-F6L99	3-Bromo-N-methyl-1 <i>H</i> -pyrazole-5-carboxamide
IN-HGW87	N-[2-(Aminocarbonyl)-4-cyano-6-methylphenyl]-3-bromo-1-(3-chloro-2-pyridinyl)-1 <i>H</i> -pyrazole-5-carboxamide

Formulations

Formulations of cyantraniliprole are available for use as foliar applications and soil or seed treatments.

Formulation type	Active substance/s and content	Application type
OD (Oil Dispersion)	Cyantraniliprole 100 g/L	Foliar applications
SC (Soluble Concentrate)	Cyantraniliprole 200 g/L	Soil and seed treatments
FS (Flowable suspension)	Cyantraniliprole 625 g/L	Seed treatment

METABOLISM AND ENVIRONMENTAL FATE

The Meeting received cyantraniliprole metabolism studies on animals (rats, lactating goats and laying hens), plants, soil and rotational crops. Cyantraniliprole radiolabelled on the 4-cyano or the pyrazole carbonyl groups were used in these studies. The label positions are given below:

[CN-¹⁴C]-cyantraniliprole (CN-label)
*=location of the radiolabel

[PC-¹⁴C]-cyantraniliprole (PC-label)
#=location of the radiolabel

Major metabolites identified in these studies and discussed in this evaluation are listed below.

Table 1 Major cyantraniliprole metabolites identified in plant, animal and soil matrices

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens, following oral dosing with [3-¹⁴C-thienyl] dimethenamid (the racemic mixture).

Rats

The metabolism of cyantraniliprole in rats was evaluated by the WHO Core Assessment Group of the 2013 JMPR, where it was concluded that majority of the dose was excreted within 24 to 48 hours, with about 1-5.5% TRR being recovered in tissues. Tissue elimination half-lives ranged from 2.6 days (fat) to 5.1 days (kidney).

The metabolic pathway was primarily through hydroxylation (to form IN-N7B69 and IN-MYX98), with IN-N7B69 being further metabolized to a glucuronide. Cyantraniliprole undergoes ring closure to generate IN-J9Z38 which is then in turn hydroxylated to form IN-NBC94, its carboxylic acid, and its glucuronide conjugate. IN-MYX98 is also metabolized to the closed-ring metabolite IN-MLA84, which, like IN-NBC94, is further oxidized to a hydroxylated metabolite, a carboxylic acid, and the glucuronide of the hydroxyl metabolite. Further, the hydroxylated metabolite IN-MYX98 can be N-dealkylated to form IN-HGW87 as well as being hydroxylated a second time to form bis-hydroxy-HGW86. Cyantraniliprole can also be hydroxylated on the pyridine ring, followed by a ring closure analogous to the conversion of cyantraniliprole to IN-J9Z38. Cyantraniliprole can also be N-dealkylated and cleaved at the carbonyl bridge to form IN-DBC80glutathione conjugation, with other pathways involving reductive dechlorination, oxidation, hydroxylation, *O*-demethylation and cyclization as well as conjugation with glucuronic acid.

Lactating goats

One lactating goat was orally administered [CN-¹⁴C]-cyantraniliprole in a gelatine capsule at a dose rate equivalent to 13.7 ppm in the diet for seven consecutive days and a second goat was similarly

dosed with the dietary equivalent of 12.5 ppm [PC-¹⁴C]-cyantraniliprole. The results of this study have been reported by McLellan, Vance and Lowry, 2008 [Ref: DP-16987].

Urine and faeces were collected before the first dose and daily thereafter. Milk samples were collected twice daily, in the morning before each dosing and in the afternoon, about 7 hours after dosing, with the afternoon milk being combined with the milk collected the next morning. The animals were sacrificed 23 hours after last of the seven daily doses.

Samples were double or triple-extracted with acetonitrile/water mixtures, centrifuged and radioactivity was measured by LSC with the liver samples being further processed by enzyme (protease) digestion. Milk samples were extracted with acetonitrile and partitioned with hexane. Extracts were analysed using reversed phase HPLC (UV detection at 254 nm) to detect reference standards, with quantification either by on-line radiodetection with peak integration or by fraction collection and LSC. LC-MS/MS (electrospray positive ion mode) was used to confirm the presence of cyantraniliprole and major metabolites. All samples were stored at -20 °C and were extracted within 25 days and analysed within 33 days of sampling.

Overall ¹⁴C recoveries were 96–97% of the administered dose, primarily in faeces (84–88%), urine (7%), milk (1–2%), liver (0.3%) and 0.01% or less in kidney, muscle and fat.

Table 2 Total radioactive residues in dissected tissues, excreta and milk of the lactating goat following 7 daily oral administrations of [¹⁴C]-cyantraniliprole

Matrix	[CN- ¹⁴ C]-cyantraniliprole		[PC- ¹⁴ C]-cyantraniliprole	
	% administered dose	TRR (mg/kg)	% administered dose	TRR (mg/kg)
Urine	6.7	NA	6.9	NA
Faeces	87.5	NA	84.3	NA
Total excreted ^a	95.5		93.5	
Liver	0.3	0.46	0.3	0.495

Total body fat	NA	0.137	NA	0.336
Milk (day 1)	0.123	0.074	0.154	0.099
Milk (day 2)	0.16	0.089	0.239	0.148
Milk (day 3)	0.132	0.082	0.289	0.181
Milk (day 4)	0.151	0.078	0.27	0.156
Milk (day 5)	0.15	0.092	0.259	0.171
Milk (day 6)	0.135	0.093	0.314	0.18
Milk (day 7)	0.186	0.109	0.287	0.164
Milk composite (day 1-7)	1.04	0.08	1.81	0.147
Total	96.8			95.6

^a Total excreted includes bile and cage wash

Solvent extraction was able to retrieve 99% TRR from milk, 90–98% TRR from fat, 61–81% TRR from muscle, 63–79% TRR from kidney and while the solvent extractable TRR in the liver were lower (54–60% TRR), an additional 21–27% TRR were recovered following digestion of the post extracted solids (PES) with protease.

Characterization and identification of residues used HPLC and/or LC/MS/MS with 88–90% TRR in milk, 69–70% TRR in liver and 75–80% TRR in fat being characterised and/or identified. In kidney and muscle, 42–43% of the CN-¹⁴C label and 71% of the PC-¹⁴C label was able to be characterised and/or identified.

In milk from the goat dosed with [CN-¹⁴C]-cyantraniliprole, TRR on Day 1 were 0.07 mg/kg, reaching a plateau about Day 2 (0.09 mg/kg) and up to 0.11 mg/kg on Day 7. The major

radiochemical residue was cyantraniliprole, accounting for 40% TRR (0.03 mg/kg) with IN-MYX98 (15% TRR–0.01 mg/kg) being the significant metabolite found.

IN-N7B69 (12% TRR), IN-JCZ38 (7.2% TRR), IN-K7H19 (2.6% TRR), IN-HGW87 (1% TRR) and IN-J9Z38 (0.48% TRR) were identified as minor metabolites in milk, all present at less than 0.01 mg/kg.

In the goat dosed with [PC-¹⁴C]-cyantraniliprole, results were similar, with TRR in milk on Day 1 being 0.1 mg/kg, reaching a plateau about Day 3 (0.18 mg/kg). Cyantraniliprole was the major residue, representing 50% TRR (0.07 mg/kg). The major metabolite was IN-MYX98, comprising 18% of TRR (0.03 mg/kg).

Other metabolites were identified as IN-K7H19, IN-JCZ38, IN-N7B69, IN-HGW87, IN-K5A78, IN-MLA84 and IN-J9Z38, each representing ≤ 0.01 mg/kg and $< 4\%$ TRR.

^a Day 1–7 composite sample

Liver from the goat dosed with [CN-¹⁴C]-cyantraniliprole contained 0.43 mg/kg TRR with cyantraniliprole being the major residue, accounting for 17% TRR (0.07 mg/kg). IN-K5A77 and IN-MLA84 were also found at up to 0.02 mg/kg (5% TRR).

Other minor components (0.6–2.6% TRR) were IN-K7H19, IN-JCZ38, IN-N7B69, IN-K5A79, IN-MYX98, IN-HGW87 and IN-K5A78, each at ≤ 0.01 mg/kg. About 32% TRR was made up of a large number of unknown components, none of which were found at levels greater than 0.006 mg/kg (1.5% TRR).

In the goat dosed with [PC-¹⁴C]-cyantraniliprole, liver contained 0.5 mg/kg TRR, the major component being cyantraniliprole at 27% TRR (0.14 mg/kg). IN-K5A77 and IN-MLA84 were each present at 0.02–0.03 mg/kg (5–6% TRR) with IN-K5A78 and IN-MYX98 also found at about 3.5% TRR (< 0.02 mg/kg).

Other minor components were IN-K7H19, IN-HGW87, IN-J9Z38, IN-K5A79, IN-JCZ38 and IN-N7B69, each at ≤ 0.01 mg/kg and not more than 1% TRR. About 18% TRR was made up of a number of unknown components, none of which were found at levels above 0.009 mg/kg (1.8% TRR).

In kidney from the goat dosed with [CN-¹⁴C]-cyantraniliprole, TRR were 0.14 mg/kg with the major residue being cyantraniliprole, accounting for 13% TRR (0.02 mg/kg).

Minor metabolites, present at up to 7% TRR (0.01 mg/kg or less) were IN-MYX98, IN-MLA84, IN-K7H19, IN-J9Z38 and IN-HGW87. Unknown peaks (13% TRR) individually accounted for ≤ 0.01 mg/kg.

In the goat dosed with [PC- ^{14} C]-cyantraniliprole, kidney contained TRR of 0.21 mg/kg, 19% of which was cyantraniliprole (0.04 mg/kg). The IN-MYX98 metabolite (7.1% TRR–0.014 mg/kg) and one unknown component, more polar than parent, (present at 11% TRR–0.02 mg/kg) were the only residues found at levels above 0.01 mg/kg.

IN-K7H19, IN-JCZ38, IN-N7B69, IN-HGW87, IN-K5A77 and IN-MLA84 were identified as minor metabolites ($< 2.5\%$ TRR) each representing ≤ 0.01 mg/kg parent equivalents.

In muscle from the [CN- ^{14} C]-cyantraniliprole dosed goat, TRR were 0.03 mg/kg with the only significant residue being cyantraniliprole, this making up 30% TRR (0.01 mg/kg).

IN-K7H19 was also identified as a minor metabolite (< 0.01 mg/kg). Minor unknowns totalled 7.6% TRR for three peaks each < 0.01 mg/kg parent equivalents.

In the goat dosed with [PC- ^{14} C]-cyantraniliprole, muscle contained 0.04 mg/kg TRR the principal ^{14} C-residue was IN-MYX98, accounting for 33% TRR (0.01 mg/kg parent equivalents) with cyantraniliprole making up 15% TRR (0.01 mg/kg).

IN-K5A77 and IN-J9Z38 each represented ≤ 0.01 mg/kg and unidentified components accounted for a total of 17% TRR (0.01 mg/kg).

For fat, omental, subcutaneous and renal fat were sampled and analyzed separately. TRR levels were similar in the three types of fat, with the respective PC-label residues of 0.117, 0.119 and 0.115 mg/kg and 0.047, 0.046 and 0.049 mg/kg for the CN-label. Results are reported as the mean values of the three types of fat in this evaluation.

For the goat dosed with [CN- ^{14} C]-cyantraniliprole, the calculated mean TRR in fat was 0.05 mg/kg with cyantraniliprole (31% TRR–0.02 mg/kg) being the major residue. In the three types of fat, cyantraniliprole residues were 23% TRR (omental), 42% TRR (subcutaneous) and 34% TRR (renal). The metabolite IN-J9Z38 accounted for an average of 27% TRR (0.01 mg/kg), present at 24% TRR in omental fat, 22% TRR in subcutaneous fat and 37% TRR (0.02 mg/kg) in renal fat.

All other individual metabolites accounted for ≤ 0.01 mg/kg each (IN-K7H19, IN-N7B69, IN-K5A79, IN-MYX98, IN-NBC94, IN-K5A78, and IN-MLA84. Unknown metabolite peaks individually accounted for ≤ 0.01 mg/kg.

For the goat dosed with [PC- ^{14} C]-cyantraniliprole, the calculated mean TRR in fat was 0.12 mg/kg. Cyantraniliprole was the major residue, representing 45% TRR (0.05 mg/kg) on average, with 58% TRR (0.07 mg/kg) in omental fat, 43% TRR in subcutaneous fat and 36% TRR in renal fat. The IN-J9Z38 metabolite was present at 24% TRR (0.03 mg/kg) on average with 0.5% TRR in omental fat, 17% TRR in subcutaneous fat and 56% TRR (0.06 mg/kg) in renal fat.

IN-K7H19, IN-DBC80, IN-N7B69, IN-K5A79, IN-MYX98, IN-K5A77, IN-NBC94, IN-K5A78, and IN-MLA84 were all identified as minor metabolites, each accounted for < 0.01 mg/kg. Individual unknowns accounted for < 0.01 mg/kg parent equivalents.

Cyantraniliprole was rapidly eliminated by the lactating goat, primarily in the excreta (94–96% of the applied dose). There was no significant transfer of residues of cyantraniliprole and its metabolites to fat, meat or edible offal as these tissues contained only ca. 1–2% of the total administered dose. Approximately 1–2% of the total administered dose was eliminated via the milk.

Significant metabolites found at more than 10% TRR or 0.01 mg/kg were IN-MYX98 in milk and muscle and IN-J9Z38 in fat.

The biotransformation of cyantraniliprole in the goat is consistent with pathways proposed for poultry (laying hens) and the rat and is outlined below.

Figure 1 Proposed metabolic pathway of cyantraniliprole in lactating goats

Laying hens

In a study reported by McLellan Lowry, 2008 [Ref: DP-16988], one group of five hens was orally administered [CN-¹⁴C]-cyantraniliprole in gelatine capsules at a dose rate equivalent to 11.6 ppm in the diet for 14 consecutive days and a second group of five hens was similarly dosed with the dietary equivalent of 11.2 ppm [PC-¹⁴C]-cyantraniliprole.

For each group, eggs were collected twice daily, excreta were collected daily, and tissues were collected after sacrifice, approximately 23 hours after the last dose.

Samples were triple-extracted with acetonitrile:water (9:1) centrifuged and the radioactive content was determined by LSC analysis of duplicate aliquots. Liver samples were further processed by enzyme digestion using protease. Extracts were analysed using reversed phase HPLC (UV detection at 254 nm) eluted with a gradient of acetonitrile and water containing 0.1% formic acid and quantification of radioactive residues was accomplished either by on-line radio detection with peak integration or by fraction collection and LSC. Identification of radioactive residues was based on comparison of HPLC retention times with those of authentic reference standards. LC-MS/MS in electrospray positive ion mode was conducted to confirm the presence of parent and selected metabolites. All samples were stored frozen (-20 °C) for no more than 55 days before extraction and analyzed within 62 days after sampling.

The overall ^{14}C recoveries of the administered dose for both radiolabels were consistent with 97–100% of the total administered dose found in the excreta. Based on composite Day 1–14 samples, egg whites accounted for 0.4–0.5% (0.20–0.26 mg/kg) while egg yolks contained 0.07% (0.09 mg/kg) of the total administered dose. The highest concentrations of total radioactivity in tissues were observed in liver (0.2 mg/kg PC- ^{14}C label, 0.14 mg/kg CN- ^{14}C label). Abdominal fat, skin with fat and muscle each contained $\leq 0.1\%$ of the total administered dose for either label, each equivalent ≤ 0.01 mg/kg.

The concentration of radioactivity in egg whites was variable, increasing to 0.26 mg/kg (PC- ^{14}C label) and 0.56 mg/kg (CN- ^{14}C label) in eggs sampled 2 days after the first dose, decreasing to a steady state of about 0.2–0.24 mg/kg after 7 days but with concentrations of the PC- ^{14}C label dropping to 0.12 mg/kg on day 13 and increasing to 0.38 mg/kg on day 14. Radioactivity in egg yolks increased steadily reaching a plateau concentration of about 0.1 mg/kg after 5 days (CN- ^{14}C label) and 7 days (PC- ^{14}C label).

Solvent extraction was able to retrieve more than 99% TRR from egg white, 79–83% TRR in egg yolk and 17–23% TRR in liver. An additional 38% TRR were recovered following digestion of the post extracted solids (PES) with protease. Low levels of radioactivity (< 0.001 mg/kg) were

detected in muscle, abdominal fat and skin + fat, with solvent extraction recovering 100% TRR in muscle, 63% TRR (PC-¹⁴C label) and 120% TRR (CN-¹⁴C label) in abdominal fat and 53% TRR (PC-¹⁴C label) and 72% TRR (CN-¹⁴C label) in skin + fat.

Characterization and identification of residues by HPLC (with LC-MS confirmation) was conducted on composite egg white and egg yolk samples (day 1–14) and liver. No analysis was carried out with muscle, abdominal fat or skin + fat samples because of the low residues (< 0.004 mg/kg) present. About 95% TRR in egg white, 71% TRR in egg yolk and 35–42% TRR in liver was able to be characterised and/or identified.

In egg white, TRRs were 0.26 mg/kg (CN-¹⁴C label) and 0.2 mg/kg (PC-¹⁴C label). Cyantraniliprole was the major ¹⁴C-residue representing 32–42% TRR (0.09 mg/kg). IN-MLA84 (18–19% TRR) and IN-J9Z38 (17–29% TRR) were principal egg white metabolites, found at 0.04–0.05 mg/kg and 0.03–0.08 mg/kg respectively.

IN-HGW87, IN-K7H19, IN-MYX98, and IN-NBC94 were also identified in each composite sample, present at ≤ 8.1% TRR (≤ 0.017 mg/kg).

In egg yolk, TRRs were 0.09 mg/kg, with cyantraniliprole making up about 9–10% TRR (0.01 mg/kg). Significant metabolites were IN-MLA84, IN-HGW87 and IN-J9Z38, each present at 12–17% TRR (up to 0.015 mg/kg).

IN-JSE76, IN-K5A77, IN-K5A79, IN-MYX98, and IN-NBC94 were also found in egg yolks as minor metabolites each representing 1–6% TRR (≤ 0.006 mg/kg).

In liver, TRRs were 0.14 mg/kg (CN-¹⁴C label) and 0.17 mg/kg (PC-¹⁴C label). Cyantraniliprole was not found any samples. IN-JCZ38, IN-K5A78, IN-K5A79, IN-K7H19, IN-MLA84, IN-MYX98 and IN-N7B69 were found as minor metabolites, each representing < 4% TRR (< 0.01 mg/kg).

Cyantraniliprole was rapidly eliminated in laying hens with more than 97% being excreted, mostly as unchanged parent compound (68–74%). About 0.5–0.6% of the total administered dose was observed in eggs, fat, liver, and muscle, with unchanged cyantraniliprole being the principal (0.08 mg/kg) residue found in egg whites and found at lower levels in yolks (0.01 mg/kg). Cyantraniliprole was not detected in any of the liver samples.

A number of metabolites were identified in egg whites and egg yolks. IN-J9Z38 and IN-MLA84 were the principal metabolites (0.03–0.08 mg/kg) in egg whites but accounted for ≤ 0.02 mg/kg in yolks. In liver, about 35–40% TRR was characterized/identified with most of the TRR remaining bound following solvent and protease extractions.

The proposed metabolic pathway in laying hens was consistent with that proposed for rats and lactating goats, and is outlined below:

Figure 2 Proposed metabolic pathway of cyantraniliprole in laying hens

Plant metabolism

The Meeting received plant metabolism studies on cotton, lettuce, tomato and rice seedlings following foliar and soil treatments with [^{14}C]-cyantraniliprole. A 1:1 ($\mu\text{Ci}/\mu\text{Ci}$ ratio) mixture of [$\text{CN-}^{14}\text{C}$]-cyantraniliprole and [$\text{PC-}^{14}\text{C}$]-cyantraniliprole was used in the foliar treatments and separate treatments of the two radiolabels were applied as soil treatments.

The Meeting noted that the IN-DBC80 metabolite was the only cleavage product containing just the PC- ^{14}C label and as this was found only at low concentrations in some metabolism studies, it was agreed that the use of the mixed radiolabels in the foliar treatment studies did not significantly impact on the results of these studies.

Cotton

In a study reported by MacDonald, MacKinnon & Chapleo (2008) [Ref: DP-16984], three applications of [^{14}C]-cyantraniliprole equivalent to 150 g ai/ha/treatment, were made to cotton plants grown in 30 cm pots containing an acidic (pH 6.4) commercial growing medium (since abiotic degradation of cyantraniliprole occurs at alkaline pH). Foliar applications (SC formulation) were made to plants 3 weeks post-emergence and at 7 and 14 days after the initial application. Soil drench

applications (SC formulation), pipetted onto wetted soil were made 7 weeks post-emergence and at 7 and 14 days after the first application.

Leaves were collected from immature plants after the first application (foliar treatment only), immediately prior to and following the second and third applications, and at ca. 7 and 14 days after the third application. Cotton bolls (seed plus lint) and the remaining aerial portions (cotton-gin by-products, gin trash) were sampled at crop maturity (ca. 125 days after the third application). The bolls were separated into undelinted (fuzzy) seed and lint.

Selected samples from the foliar-treatment regime were surface washed with acetonitrile:water (7:3, v/v) immediately after sampling. Plant samples from both regimes were pulverized and total tissue residues determined by oxidative combustion analysis. Where characterization of radioactivity was warranted, samples were extracted three times using acetone:1N formic acid (9:1). The unextracted radioactivity in the post-extracted solids (PES) was determined by combustion analysis. Extracts containing significant radioactivity (≥ 0.01 mg/kg) were analysed by high performance liquid chromatography (HPLC) and identification of ^{14}C -residues was accomplished by HPLC and liquid chromatography mass spectrometry (LC-MS), with reference to authenticated reference standards. Samples were stored at ca -20°C for up to 28 days before analysis.

To assess if storage at -20°C resulted in degradation of radioactive residues, a subsample of stored tissue (7 days post-application 3, foliar treatment) was extracted with acetone:formic acid following a storage period of 392 days. The TRR and extractability values after prolonged storage (0.449 mg/kg, 74.4% TRR) were similar to those obtained originally (0.505 mg/kg, 81.5% TRR). The residue composition also remained unchanged with cyantraniliprole being the principle component (30.8% TRR, 0.138 mg/kg) and minor components individually making up $\leq 4.6\%$ TRR (≤ 0.021 mg/kg).

A comparison of the extraction efficiency of acetone:formic acid and acetonitrile:water showed similar results, with the extracted radioactivity from unwashed leaves from the foliar-treated plants being 76% TRR in the acetonitrile extract and 74% TRR in the acetone extract. HPLC analysis of the two extracts also reported comparable results, with cyantraniliprole making up 27% of the TRR in the acetone extract and 21% of the TRR in the acetonitrile extract.

In plants from the soil drench treatments, TRRs in leaves from immature plants, lint and undelinted seed were all ≤ 0.005 mg/kg with TRR values in cotton gin by-products being 0.1 mg/kg (CN-label) and 0.02 mg/kg (PC-label).

The majority of the radioactivity in cotton gin by-products (79.6–99.9% TRR) was extracted into acetone:formic acid. Additional amounts of radioactivity were extracted from the CN-label sample using enzymes (7.4% TRR), 1 M HCl at 60°C (3.9% TRR), 6 M HCl at 90°C (2.2% TRR) and 6 M NaOH at 90°C (1.8% TRR), each releasing < 0.01 mg/kg.

Cyantraniliprole was the major radioactive residue in gin by-products at concentrations of 25.6% TRR (0.02 mg/kg) for the CN-label and 46.8% TRR (0.01 mg/kg) for the PC-label.

Gin by-products from [CN- ^{14}C]-treated cotton also contained IN-J9Z38, IN-JCZ38, IN-JSE76, IN-HGW87, IN-QKV54 and unresolved IN-MLA84/IN-NXX70, each at ≤ 0.01 mg/kg and less than 8% TRR. The only identified metabolite in gin by-products from [PC- ^{14}C]-treated cotton was IN-J9Z38 (< 0.01 mg/kg).

^a 48 components; none greater than 0.002 mg/kg (2.6%TRR)^b One component

TRRs in cotton leaves following foliar treatment with the 1:1 mixture of [CN- ^{14}C]-cyantraniliprole + [PC- ^{14}C]-cyantraniliprole were 2.7 mg/kg immediately after the first application, 14.5 mg/kg immediately after the second application and 7.9 mg/kg just after the last application. Residues decreased to 0.43 mg/kg at 13 days after the last application. At harvest, TRRs in cotton gin by-products, lint and undelinted seed were 0.13, 0.01, and < 0.01 mg/kg, respectively.

The majority of the radioactivity (74–87%TRR) in immature leaves was removed by surface washing (56–70% TRR) and extraction into acidified aqueous acetone (27–33% TRR). Low concentrations of radioactivity were subsequently extracted using enzymes (4.1–7.7% TRR), 1 M HCl at 60 °C (2.9–4.7% TRR), 6 M HCl at 90 °C (0.6–4.5% TRR) and 6 M NaOH at 90 °C (1.1–8.0% TRR).

Cyantraniliprole was the major residue in leaves, decreasing from 69.7% TRR immediately after the first application to 19.7% TRR seven days later and accounted for 37.3 and 27.1% TRR, respectively, 7 and 13 days after the final application.

The photodegradate, IN-NXX70, found predominately in the surface wash, accounted for 21.7% TRR seven days after the first application, declining to 1.1% TRR 7 days after the third application.

The metabolite IN-QKV54 accounted for 10.3% TRR in leaf extracts 7 days after the first application. Other metabolites identified in leaf samples (IN-DBC80, IN-J9Z38, IN-JCZ38, IN-JSE76, IN-K5A77, IN-K7H19, IN-MYX98 and IN-N7B69) each did not exceed 5% TRR. Numerous other metabolites detected but not identified were each present at less than 10% TRR (0.04 mg/kg). Unextracted leaf residues accounted for ≤ 13.2% TRR (≤ 0.38 mg/kg).

Surface washing of cotton gin by-products removed about 19% TRR (0.025 mg/kg) with a further 40% TRR being extracted using acidified aqueous acetone. Additional radioactivity was extracted using enzymes (7.4% TRR), 1 M HCl at 60 °C (5.4% TRR), 6 M HCl at 90 °C (7.5% TRR) and 6 M NaOH at 90 °C (4.2% TRR), giving a total extraction efficiency of 83.8% TRR (0.11 mg/kg).

Cyantraniliprole was the main component, accounting for 34.4% TRR (0.04 mg/kg). Other metabolites including IN-J9Z38 (5.7% TRR), IN-JCZ38 (6.1% TRR) and IN-N7B69 (1.2% TRR) were present at ≤ 0.01 mg/kg. Other metabolites detected but not identified did not individually exceed 0.9% TRR or 0.001 mg/kg. Unextracted residues accounted for 16.2% TRR (0.02 mg/kg).

The proposed pathway is outlined below.

Figure 3 Proposed metabolic pathway for $[^{14}\text{C}]$ -cyantraniliprole in cotton plants

Lettuce

In a study reported by MacKinnon (2008) [Ref: DP-16986], three applications of $[^{14}\text{C}]$ -cyantraniliprole equivalent to 150 g ai/ha/treatment, were made to lettuce plants grown in 1 square metre outdoor sandy loam plots (pH 6.5) commercial growing medium (since abiotic degradation of cyantraniliprole occurs at alkaline pH). Foliar applications (SC formulation) were made to plants 3 weeks post-emergence and at 7 and 14 days after the initial application. Soil drench applications were made 7 weeks post-emergence and at 7 and 14 days after the first application.

Leaves were collected from immature plants after the first application (foliar treatment only), immediately before and after the second and third applications, and 7 and 14 days after the third application and mature plants were collected 32 days after the last application.

Selected samples from the foliar-treatment regime were surface washed with acetonitrile: water (7:3, v/v) immediately after sampling. Plant samples from both regimes were pulverized and total tissue residues determined by oxidative combustion analysis. Where characterization of radioactivity was warranted, samples were extracted three times using acetone:1 N formic acid (9:1). The unextracted radioactivity in the post-extracted solids (PES) was determined by combustion analysis. Extracts containing significant radioactivity (≥ 0.01 mg/kg) were analysed by high performance liquid chromatography (HPLC) and identification of ^{14}C -residues was accomplished by HPLC and liquid chromatography mass spectrometry (LC-MS), with reference to authenticated

reference standards. Samples were stored at ca -20 °C for up to 72 days before analysis (up to 28 days before extraction).

To assess if storage at -20 °C resulted in degradation of radioactive residues, a subsample of stored tissue (7 days after the third foliar treatment) was extracted with acetone:formic acid following a storage period of 405 days. Frozen storage did not influence the extractability (%) of TRR (97.3% TRR in stored samples and 98.4% TRR in the original samples). The residue composition also remained unchanged with cyantraniliprole making up 77.2% TRR (1.55 mg/kg) compared to 78.5% TRR (1.56 mg/kg) in the original samples. Minor components in the stored samples individually accounted for < 10% TRR (0.01–0.05 mg/kg).

A comparison of the extraction efficiency of acetone:formic acid and acetonitrile:water showed similar results, with the extracted radioactivity from unwashed leaves from the foliar-treated plants being 97.8% TRR in the acetonitrile extract and 98.4% TRR in the acetone extract. HPLC analysis of the two extracts also reported comparable results, with cyantraniliprole making up 72.1% of the TRR in the acetone extract and 71.6% of the TRR in the acetonitrile extract.

In plants from the soil drench treatments, TRR in leaves from the [CN-¹⁴C]-cyantraniliprole plots declined from 0.14 mg/kg (7 days after the first application) to 0.01 mg/kg at final harvest. TRRs following PC-label soil treatment were ≤ 0.06 mg/kg in immature leaves and at crop maturity. Higher residues were observed following foliar application.

The majority (76.7–98.4% TRR) of the radioactivity in lettuce leaves was extracted into acetone:formic acid.

Cyantraniliprole was the major radioactive component in leaves from the [CN-¹⁴C]-cyantraniliprole treated plants, accounting for up to 76.7% TRR in young leaves and 37.1% TRR in mature leaves. Minor components (IN-K5A79 and unresolved IN-MLA84/IN-NXX70) were detected at ≤ 0.01 mg/kg in samples taken prior to the second application. Cyantraniliprole was the only component detected (< 0.01 mg/kg) at maturity.

Following the PC-label soil drench treatment, cyantraniliprole was the only detectable component in immature lettuce samples accounting for 75.3% to 84.1.0% TRR and was the major residue (69% TRR–0.039 mg/kg) in mature leaves. Low level metabolites (< 10% TRR) detected in mature leaves were unresolved IN-MLA84/IN-NXX70 and IN-J9Z38, both present at < 0.01 mg/kg.

^a 13 components; none greater than 0.003 mg/kg (2.7% TRR)

^b 4 components; none greater than 0.001 mg/kg (2% TRR)

In plants from the foliar treatments of a 1:1 mixture of [CN-¹⁴C]-cyantraniliprole + [PC-¹⁴C]-cyantraniliprole, TRRs in leaves declined from 10.8 mg/kg (immediately after the first foliar application) to 0.03 mg/kg at maturity (32 days after the final application).

The majority of the radioactivity (more than 92% TRR) was removed from leaves by surface washing and/or extraction into acidified aqueous acetone.

Cyantraniliprole was the major residue in leaves, decreasing from about 98% TRR immediately after the first application to 50% TRR in mature leaves, 32 days after the last application.

The only metabolite accounting for more than 5% TRR was IN-J9Z38, present in mature leaves at about 23% TRR (0.011 mg/kg). Other metabolites identified in immature leaf samples (IN-MLA84/IN-NXX70, IN-DBC80, IN-QKV54, IN-K5A77, IN-K5A79, IN-N7B69, IN-HGW87 and IN-JSE76) each did not exceed 5% TRR or 0.06 mg/kg. Numerous other metabolites detected but not identified were each present at less than 1% TRR (0.01 mg/kg). Unextracted leaf residues accounted for ≤ 1.5% TRR (≤ 0.03 mg/kg).

The main HPLC method did not resolve the two components IN-MLA84 and the photodegradate IN-NXX70. Subsequent analysis indicated that the photodegradate, IN-NXX70, accounted for 1.9% TRR (0.03 mg/kg) seven days after the first application and was found predominantly in the surface wash. At 7 days after the first application, IN-MLA84 was present in tissue extracts at much lower levels (0.4% TRR, 0.01 mg/kg).

The metabolic fate of cyantraniliprole in lettuce grown outdoors was complex, with the formation of many low level metabolites. The proposed metabolic pathway is outlined below.

Figure 4 Proposed metabolic pathway for cyantraniliprole in lettuce

Tomatoes

In a study reported by MacKinnon (2008) [Ref: DP-16985], three applications of [^{14}C]-cyantraniliprole equivalent to 150 g ai/ha/treatment, were made to tomato plants grown in 24 cm pots containing an acidic (pH 6.4) commercial growing medium.). Foliar applications (SC formulation) were made to plants 3 weeks post-emergence and at 7 and 14 days after the initial application. Soil drench applications were made 7 weeks post-emergence and at 7 and 14 days after the first application.

Leaves were collected from immature plants after the first application (foliar treatment only), immediately prior to and following the second and third applications, and at ca. 7 and 14 days after the third application. Leaves and fruit were also sampled at crop maturity (ca. 125 days after the third application).

Selected samples from the foliar-treatment regime were surface washed with acetonitrile: water (7:3, v/v) immediately after sampling. Plant samples from both regimes were pulverized and total tissue residues determined by oxidative combustion analysis. Where characterization of radioactivity was warranted, samples were extracted three times using acetone:1 N formic acid (9:1). Insoluble residues from immature leaves were subjected to further sequential extraction using enzyme digestion (2 $\times$ 24 hours with cellulose, glucosidase, driselase), 1 M HCl (6 hours, 60 °C), 6 M HCl (6 hours, 90 °C) and 6 M NaOH (6 hours, 90 °C) hydrolysis. The unextracted radioactivity in the post-extracted solids (PES) was determined by combustion analysis.

Extracts containing significant radioactivity (≥ 0.01 mg/kg) were analysed by high performance liquid chromatography (HPLC) and identification of ^{14}C -residues was accomplished by HPLC and liquid chromatography mass spectrometry (LC-MS), with reference to authenticated reference standards. Samples were stored at ca -20 °C for up to 69 days before analysis.

To assess if storage at -20 °C resulted in degradation of radioactive residues, a subsample of stored leaf tissue (7 days post-application 3, foliar treatment) was extracted with acetone:formic acid following a storage period of 392 days. The TRR and extractability values after prolonged storage (1.86 mg/kg, 84.4% TRR) were similar to those obtained originally (2.21 mg/kg, 87.1% TRR). The residue composition also remained unchanged with cyantraniliprole being the principle component (55.3% TRR, 1.03 mg/kg) and minor components individually making up $\leq 5.4\%$ TRR (< 0.01 mg/kg).

A comparison of the extraction efficiency of acetone:formic acid and acetonitrile:water showed similar results, with the extracted radioactivity from unwashed leaves from the foliar-treated plants being 84% TRR in the acetonitrile extract and 82.8% TRR in the acetone extract. HPLC analysis of the two extracts also reported comparable results, with cyantraniliprole making up 43.4% of the TRR in the acetone extract and 36.6% of the TRR in the acetonitrile extract.

In plants from the soil drench treatments, TRRs in leaves from immature plants reached a maximum of 0.03 mg/kg seven days after the last CN-label application and 0.01 mg/kg 14 days after the last PC-label application. In mature leaves (125 days after the last application), TRRs were < 0.01 mg/kg in leaves and 0.001 mg/kg in fruit.

Only extractable residues from immature leaves taken 7 and 14 days after the last CN-label application were sufficiently high to permit HPLC analysis. Cyantraniliprole was the major radioactive component ranging from 22.2% to 26.1% TRR (0.01 mg/kg). Minor components (unresolved IN-MLA84/IN-NXX70 and IN-J9Z38) each at < 0.01 mg/kg, were also detected in leaves taken 7 days after the last application.

Table 15 Total radioactive residues (mg/kg) in tomato samples following soil drench treatments with [^{14}C]-cyantraniliprole

Treatment	Leaves				Leaves	Fruit
Sample point	7 DAT1	7 DAT2	7 DAT3	14 DAT3	125 DAT3

Extracted	86	0.026	78.4	0.02
Cyantraniliprole	22.2	0.006	26.1	0.008
IN-MLA84/ IN-NXX70	6.4	0.002	5.8	0.002
IN-J9Z38	5.4	0.002		ND
Unidentified	11.8	0.006	13.7	0.002

TRRs in tomato leaves immediately following foliar treatments with the 1:1 mixture of [CN-¹⁴C]-cyantraniliprole + [PC-¹⁴C]-cyantraniliprole ranged between 2.55 and 4.81 mg/kg and decreased to 1.3 mg/kg at 14 days after the last application. At harvest, 125 days after the last application, TRRs in leaves and fruit were < 0.01 mg/kg.

In immature leaves, 74–87% TRR was removed by surface washing and/or extraction into acidified aqueous acetone. Low concentrations of radioactivity were subsequently extracted using enzymes (1.2–5.6% TRR), 1 M HCl at 60 °C (1–3.4% TRR), 6 M HCl at 90 °C (0.2–3.7% TRR) and 6 M NaOH at 90 °C (0.7–2.9% TRR).

Cyantraniliprole was the major residue in leaves, decreasing from 95% TRR immediately after the first application to 61% TRR seven days later and accounted for 62 and 43% TRR, respectively, 7 and 14 days after the final application.

Concentrations of the unresolved radioactivity corresponding to both IN-MLA84 and IN-NXX70 were highest 7 days after the first application (11.5% TRR), decreasing to 5.8% TRR thereafter. Further analysis indicated that the photodegrade IN-NXX70 accounted for 12% TRR (0.23 mg/kg) 7 days after the first application, mostly (10% TRR) in the surface wash and declined to 3.8% TRR, 0.08 mg/kg, 7 days after final application. Seven days after the first application, IN-MLA84 was present in tissue extracts at lower levels ($\leq 2.3\%$ TRR, ≤ 0.02 mg/kg).

Other minor metabolites were identified as IN-J9Z38, IN-K7H19, IN-JCZ38, IN-DBC80, IN-N7B69, IN-MYX98, IN-JSE76, IN-K5A77 and IN-QKV54, with no single metabolite exceeding 5% TRR. Numerous other metabolites were detected which did not correspond to known reference standards, none exceeding 5.6% TRR (0.07 mg/kg). The unextracted residue accounted for $\leq 2.3\%$ TRR (≤ 0.03 mg/kg).

In leaves taken at maturity, low levels of radioactivity were present in the surface wash (< 0.01 mg/kg) and the acidified aqueous acetone extract (0.01 mg/kg). The unextracted residues also accounted for < 0.01 mg/kg.

The proposed pathway is outlined below.

Figure 5 Proposed metabolic pathway for $[^{14}\text{C}]$ -cyantraniliprole in tomatoes

Rice

In a study reported by Chapleo, Hobbs & Grant-MacDonald (2010) [Ref: DP-18780], single soil applications of $[^{14}\text{C}]$ -cyantraniliprole (granular formulations), equivalent to 300 g ai/ha, was applied at the 3–4 leaf stage to rice plants grown in a glasshouse in a sandy-loam soil (pH 6.2) and three foliar applications (SC formulation) of 0.15 kg ai/ha were made to other plants at the 3–4 leaf stage and 7 and 14 days later. In both cases the plants were grown under flooded conditions (pots immersed in about 3 cm water) from 2 days after the initial treatment until 2–3 days before harvest.

Leaves and shoots from foliar-treated plants were sampled 0 and 7 days after the first treatment, 7 days after the second treatment and 7, 14 days after the last treatment with roots being collected 7 days after each treatment. At maturity, 140 days after the last treatment, whole plants were separated into straw, roots, and panicles.

Leaves and shoots from plants grown in treated soil were sampled 3, 7, 14 and 56 days after treatment and roots were collected 7 and 56 days after treatment. At maturity (175 days after treatment), whole plants were separated into straw, roots, and panicles.

Selected samples from the foliar-treatment regime were surface washed with acetonitrile: water (9:1) immediately after sampling. Plant samples from both regimes were homogenised and residues extracted in acetonitrile:water (9:1 then 7:3). Where required, samples were subjected to

further sequential extraction using enzyme digestion (2×24 hours with cellulose, glucosidase, drisease), 1 M HCl (6 hours, 60 °C), 6 M HCl (6 hours, 90 °C) and 6 M NaOH (6 hours, 90 °C). The unextracted radioactivity in the post-extracted solids (PES) was determined by combustion analysis.

Extracts containing significant radioactivity (≥ 0.01 mg/kg) were analysed by reversed phase HPLC and identification of ^{14}C -residues was accomplished by HPLC and liquid chromatography mass spectrometry (LC-MS), with reference to authenticated reference standards. Samples were stored at ca -20 °C for up to 37 days before analysis.

In plants grown in treated soil, TRRs in immature leaves ranged from 0.4–0.42 mg/kg 56 days after treatment and were 0.28–0.37 mg/kg in roots. At maturity (175 days after treatment), TRRS were 0.28–0.3 mg/kg in straw and 0.01–0.03 mg/kg in grain.

Table 18 Total radioactive residues (mg/kg) in rice samples following granular soil treatments with [^{14}C]-cyantraniliprole

	Foliage				Roots		Roots	Straw	Grain
Sample point	3 DAT	7 DAT	14 DAT	56 DAT	7 DAT	56 DAT	175 DAT		
[CN- ^{14}C]-cyantraniliprole	ND	0.076	0.15	0.404	< 0.017	0.253	0.282	0.278	0.012
[PC- ^{14}C]-cyantraniliprole	0.153	0.068	0.145	0.42	< 0.04	0.297	0.367	0.297	0.029

The majority of the radioactivity was extracted into aqueous acetonitrile with 85–87% TRR extracted from immature foliage, 79–80% TRR from straw and 61–67% TRR from grain.

Cyantraniliprole was the major radioactive residue in immature 56 DAT foliage extracts, found at up to 49% TRR and 0.2 mg/kg (PC-label), 57% TRR and 0.23 mg/kg (CN-label). The IN-J9Z78 metabolite was found in these samples at 22% TRR (PC-label) and 16% TRR (CN-label). Other metabolites (including IN-JCZ78, IN-N7B69, IN-K5A77, IN-MLA84 and IN-DBC80) did not exceed 0.011 mg/kg or 3% TRR. The unextracted residue accounted for 4.1–9.8% TRR (< 0.02 mg/kg).

The major residue in straw was also cyantraniliprole (42–45% TRR, 0.125 mg/kg), with IN-J9Z38 (14–18% TRR) being the only significant metabolite, found at 14–18% TRR. Other minor metabolites, each present at less than 4% TRR or 0.01 mg/kg were IN-JCZ38, IN-K5A78, IN-K5A77, IN-MLA84 and IN-DBC80. The unextracted residue accounted for 8.9 % TRR (0.03 mg/kg).

In grain, cyantraniliprole accounted for 46–63% TRR, 0.007–0.014 mg/kg), with IN-J9Z38 (5.9–10.2 % TRR) being the only significant metabolite

^a Further extraction released a total of 9.6% TRR (0.038 mg/kg)

^b Further extraction released a total of 11.7% TRR (0.034 mg/kg)

^c Further extraction released a total of 10.4% TRR (0.043 mg/kg)

^d Further extraction released a total of 10.7% TRR (0.032 mg/kg)

TRRs in foliage following foliar treatments with the 1:1 mixture of [CN-¹⁴C]-cyantraniliprole + [PC-¹⁴C]-cyantraniliprole were 2.13 mg/kg immediately after the first application, decreasing to 0.38 mg/kg after 7 days. TRRS 7 and 14 days after the last application were 1.56 mg/kg and 1.21 mg/kg respectively. At harvest, 140 days after the last application, TRRs in straw were 0.45 mg/kg and 0.02 mg/kg in grain. In roots, TRRs increased from 0.24 mg/kg seven days after the first application to 0.68 mg/kg seven days after the last application and were 0.45 mg/kg at harvest (140 DAT3).

In immature leaves, 92–99% TRR was removed by surface washing and/or extraction into aqueous acetonitrile (75% TRR in the 7 DAT3 surface wash and 47% TRR in the 14 DAT3 wash). In straw, aqueous acetonitrile extraction removed 87% TRR and further 10.9% TRR was recovered in enzyme, acid and alkali digests. In grain, 49% TRR (0.012 mg/kg) was extracted in aqueous acetonitrile.

Cyantraniliprole was the major residue in immature foliage, making up more than 75% TRR and 0.35–2.13 mg/kg). IN-J9Z38 was the predominant metabolite found at 0.6% TRR immediately after the first application and increasing to 10.9% TRR 14 days after the last application. IN-JCZ38, IN-JSE76, IN-K5A77, IN-K5A78 IN-MLA84, and IN-N7B69 were also detected, none exceeding 2% TRR. Multiple unknown metabolites were detected, none exceeding 2.3% TRR. Unextracted residues accounted for 0.1–7.8% TRR.

In straw, cyantraniliprole was the major extractable component, accounting for 24.4% TRR (0.11 mg/kg). Significant metabolites included IN-JCZ38 (9.4% TRR) and IN-JSE76 (9.0% TRR). Other metabolites were identified as IN-K5A77 (5.3% TRR), IN-DBC80 (3.2% TRR), IN-J9Z38 (4.0% TRR), and IN-K7H19 (2.4% TRR) and seven unidentified metabolites were present (including 2 highly polar metabolites) at 6.6–8.1% TRR. 5.5% TRR (0.02 mg/kg) were not extracted.

Cyantraniliprole was the main extractable component in grain, accounting for 21% TRR (0.01 mg/kg). Metabolites included IN-J9Z38, IN-N7B69 and IN-K5A78 made up 1.5–2.6% TRR and 17 unidentified metabolites were also detected, each at less than 8.0% TRR.). Unextracted residues accounted for 51.3% TRR (0.01 mg/kg).

The metabolic fate of cyantraniliprole in rice growing under flooded conditions was complex with the formation of many low level metabolites. Metabolism following foliar and soil applications appear to be similar. The proposed metabolic pathway is outlined below.

Figure 6 Proposed metabolic pathway for $[^{14}\text{C}]$ -cyantraniliprole in rice

Environmental fate

The Meeting received information on the environmental fate and behaviour of cyantraniliprole, including hydrolytic stability, aerobic metabolism, photolysis and degradation in soil, water/sediment degradation and rotational crop metabolism and field studies.

Hydrolysis

The hydrolytic stability of cyantraniliprole in sterile buffer solutions was reported by Lowrie (2005) [Ref: DP-17058]. Sterile buffered solutions of $1\ \mu\text{g/ml}$ radiolabelled cyantraniliprole at pH 4, 7, and 9 were incubated in the dark at 15, 25 and $35\ ^\circ\text{C}$ for up to 30 days and sampled for analysis by LSC and HPLC at selected time intervals.

Hydrolysis of cyantraniliprole was pH and temperature dependant. At lower pH and temperature, the rate of hydrolysis was significantly less than at high pH and temperature. At all pHs, the only hydrolysis product detected at more than 5% of applied radioactivity (AR) was the cyclisation product IN-J9Z38, which accounted for a maximum of 28% AR (pH 4), 89% AR (pH 7) and 98% AR in the pH 9 samples. Calculated DT_{50} and DT_{90} values for cyantraniliprole and the IN-J9Z38 metabolite are summarised below.

Table 21 Calculated DT₅₀ and DT₉₀ values for cyantraniliprole and the IN-J9Z38 metabolite

Aerobic soil metabolism

In a study reported by Malekani & Mattson (2006) [Ref: DP-15775], a loam soil (pH 7.9, 2% organic matter) and a silty clay loam soil (pH 6.2, 2.7 % organic matter) were treated with the equivalent of 0.4 kg ai/ha [CN-¹⁴C]-cyantraniliprole or [PC-¹⁴C]-cyantraniliprole and incubated at 22 ± 3 °C in the dark for 358 days. The moisture content of the soils was maintained at 40–60% maximum water holding capacity (MWHC).

Samples were taken immediately following application and at selected intervals up to 358 days after application, extracted with CaCl₂ (to assess aged sorption of cyantraniliprole in conjunction with degradation) and then triple-extracted with acetone:formic acid (9:1) for analysis by LSC and HPLC.

The extractability of cyantraniliprole from both soils was quantitative at Day 0, but extractability decreased while the non-extractable residues (NER) increased as the study progressed, reaching a peak of approximately 16 to 22% in both soils.

Volatile organics were not produced in significant amounts in either soil. The amount of ¹⁴CO₂ evolved was significant, up to 11.8% AR for systems involving with [CN-¹⁴C]-cyantraniliprole and 4.1% AR for [PC-¹⁴C]-cyantraniliprole systems.

Cyantraniliprole levels declined to less than 5% AR in the loam soil and to 30–40% of AR in the silty clay loam by Day 121. Degradation continued past Day 121, with the silty clay loam containing 11–12% AR as cyantraniliprole on Day 358 and was not detected in the loam soil.

Seven major transformation products were observed in the study, with IN-JSE76 being the major component (43% AR) at the end of the study period, with IN-K5A78 and IN-PLT97 also present at 23–29% AR at day 358.

Table 22 Maximum percent of each metabolite in route of degradation study

^a IN-K5A79 and IN-PLT97, observed as significant metabolites in Namsheim soil, were not detected (ND) in Tama soil

In a similar study reported by Malekani (2008) [Ref: DP-17055], three additional soils (a silt loam—pH 7, 2.1% organic matter; a sandy loam soil—pH 4.6, 1.6 % organic matter and a silty clay loam—pH 8.05, 4.5% organic matter) were treated with the equivalent of 0.4 kg ai/ha [CN-¹⁴C]-cyantraniliprole or [PC-¹⁴C]-cyantraniliprole, the moisture content was adjusted to 45% MWHC and the soils were incubated at 20 ± 2 °C in the dark for 120 days. One soil was also incubated at 10 ± 2 °C for 120 days.

Observed degradation in all soils was similar to that described in the above study, with the major metabolites present at the end of the 120-day study period being IN-JSE76 and IN-JCZ38 (26-33% AR).

The residue decline data for the various soils were analyzed using a number of kinetics models. The FOMC model provided the best visual and statistical fit for the observed data across the entire data range.

The aerobic degradation of cyantraniliprole in soil is outlined below.

Figure 7 Proposed degradation pathway for cyantraniliprole in aerobic soil

Soil photolysis

The meeting received two studies investigating the soil photolysis of cyantraniliprole on a sandy loam soil (Nambshiem, pH 7.51, 1.22% organic carbon) under continuous irradiation for up to 15 days at 20 ± 2 °C in the study on air-dried soil reported by Morriss (2005) [Ref DP-17056] and up to 30 days at 20 ± 2 °C in the study on moist soil reported by Wardrope (2010) [Ref: DP-28730].

In the 2005 study [Ref DP-17056] the moisture content of the air dried soil was about 14% and the radiolabels were applied to achieve a nominal concentration of 0.4 µg ai/g soil (equivalent to 0.4 kg ai/ha soil) while in the 2010 study [Ref: DP-28730] a higher treatment rate equivalent to 1 kg ai/ha and the moisture level was maintained at about 75% field capacity throughout the study.

The experimental design of both studies were similar, with [CN-¹⁴C]-cyantraniliprole and [PC-¹⁴C]-cyantraniliprole being applied by pipette to thinly-layered soil and irradiated continuously in artificial irradiation (filtered to eliminate wavelengths of < 290 nm). Both studies included an NaOH trap for the collection of ¹⁴CO₂ and soil samples were extracted twice with acetone:formic acid (9:1)

followed by an extraction with acetone. The extracts were combined, concentrated to a small volume and analysed by reverse-phase HPLC. Identification of the degradation products was performed by HPLC and LC/MS/MS or TLC analysis.

No significant photolysis of cyantraniliprole was observed in the air-dried soil (2005) study, as the results from the irradiated and non-irradiated systems were very similar. One major degradation product, IN-J9Z38, was formed in both irradiated and non-irradiated systems, accounting for < 10% AR and three minor transformation products were observed, each of which were only observed at one sampling occasion and accounted for < 5% AR.

Using a first-order kinetic model, the DT₅₀ and DT₉₀ values for cyantraniliprole in non-irradiated samples were 115 days and 381 days, respectively. In irradiated samples the DT₅₀ and DT₉₀ values were 84 days and 278 days, respectively. Levels of IN-J9Z38 were rising at the end of the study.

To isolate the rate of degradation of cyantraniliprole due to photolysis only, the first order rate of degradation constant (k) in the non-irradiated samples was subtracted from the first order rate of degradation constant in the irradiated samples. The resulting corrected DT₅₀ and DT₉₀ values, extrapolated from this 15-day study, were 308 days and 1024 days, respectively.

In the 2010 moist soil study [Ref: DP-28730], cyantraniliprole residues decreased from a mean value of 102% AR at Day 0, to a mean of 1.2% AR after 30 days in the irradiated soil and to a mean of 33% AR in non-irradiated soil. Three significant degradation products were detected over the course of the study. One of these degradation products was identified as IN-J9Z38, reaching a maximum of 49% AR at Day 10 then declining to 34% AR in the irradiated soil and 49% AR in the non-irradiated soil by the end of the study. IN-J9Z38 was likely a result of non-photolytic reactions and has been seen earlier in all soil degradation studies in dark. Two additional degradation products were attributed to photo-degradations, and were identified as IN-RNU71 and IN-QKV54. IN-RNU71 reached a maximum mean value of 13% AR by the end of the study, while IN-QKV54 reached a maximum mean value of 14% AR at Day 10. A further six minor degradation products were also found at < 5% AR and with the exception of IN-NXX70 (3.8% AR), are likely due to non-photolytic reactions.

Using a simple first-order (SFO) model, the calculated DT₅₀ and DT₉₀ values for cyantraniliprole in irradiated soil were 6.9 days and 23 days, respectively and 16 days and 53.3 days, respectively in non-irradiated (dark control) samples.

To calculate the rate of degradation due to photolysis only, the first-order rate of degradation constant in the non-irradiated samples was subtracted from the first-order rate of degradation constant in the irradiated samples. The dark corrected DT₅₀ and DT₉₀ values were 12.2 days and 40.5 days respectively.

Table 26 Photodegradation, DT₅₀ and DT₉₀ for [¹⁴C]-cyantraniliprole in moist soil

Kinetic modelling suggested that nearly 34% of the parent compound degraded via the photolysis pathway while ca 64% degraded via the soil degradation pathway, indicating that photolysis on the surface of moist soil may be a significant dissipation pathway for cyantraniliprole in the environment.

Significant degradation of cyantraniliprole in irradiated moist soil samples occurred primarily via the non-photolytic soil degradation transformations observed in the absence of light. IN-J9Z38 observed as a major metabolite along with IN-JCZ38, IN-JSE76, IN-K5A77, IN-K5A79, and IN-K7H19 were all identified in the aerobic soil metabolism study. Photodegradation products observed, IN-NXX70 and IN-QKV54, were derived sequentially from photolysis of cyantraniliprole; while IN-RNU71 is proposed to be generated from photolysis of IN-J9Z38. Similar light induced transformations have been observed in the aqueous photolysis and the outdoor water sediment study.

Degradation in soil

Ten field studies were conducted to investigate the degradation and mobility of cyantraniliprole under field conditions. In all of the trials a single application of 0.3 kg ai/ha or 0.45 kg ai/ha was made to bare soil in late spring or early summer.

Soil samples were collected, down to a maximum depth of 90 cm, immediately prior to application and at pre-determined intervals over an 18 month period. Samples were extracted in aqueous acetone, cleaned up via SPE columns and analysed using reverse phase HPLC separation coupled to tandem mass spectrometry (LC-MS/MS). The Limit of Quantification (LOQ) for all analytes was 0.001 mg/kg and mean recovery rates ranged from 74–96%. Analytes included the major soil metabolites (IN-J9Z38, IN-JCZ38, IN-JSE76, IN-K5A77, IN-K5A78, IN-K5A79, and IN-PLT97) in addition to the parent compound. In order to determine the extent of formation of photodegradation products, analysis of IN-NXX70, IN-QKV54, and IN-RNU71 was also carried out in a number of the studies and reported by Vogl & Sharma (2010) [Refs: DP-29556 and DP-29557].

The field studies demonstrated rapid degradation of the cyantraniliprole in field soils (17–51 day half lives). While laboratory studies suggested that pH had some effect on degradation rates, degradation rate under field conditions does not appear to be pH-dependent. Approximately 75% or more of the applied mass dissipated in most of the field studies during the study duration. Downward mobility of the parent compound as well as its metabolites was limited, with residues rarely found below 15 cm. Uptake of the test compound or its metabolites by the crop was generally very low, despite the systemic nature of cyantraniliprole. Soil metabolites, especially those from the IN-JCZ38 side of the degradation pathway (IN-JCZ38, IN-JSE76, and IN-K5A79) were not observed in the field studies to the extent that was expected based on the lab studies. Photochemical degradation was only a minor degradation mechanism (<< 5%) in the field.

Figure 8 Overall degradation pathway for cyantraniliprole in soil

Degradation in water/sediment systems

A study on the fate of [^{14}C]-cyantraniliprole in the absence of light under anaerobic conditions in two aquatic sediment test systems was reported by McCorquodale & Wardrope, 2006 [Ref: DP-17059]. The sand sediment system, at a pH of 5.6 contained 2% organic carbon with overlying water at pH 6.1 and 56.4 mg/L organic carbon and the silt loam sediment system, at a pH of 7.7 contained 4.9% organic carbon with overlying water at pH 7.6 and 21.2 mg/L organic carbon. [$\text{CN-}^{14}\text{C}$]-cyantraniliprole and [$\text{PC-}^{14}\text{C}$]-cyantraniliprole were separately applied to the two sediment systems at a rate of 0.4 $\mu\text{g ai/g}$ and incubated for up to 100 days in the dark at $20 \pm 2^\circ\text{C}$.

Under anaerobic conditions, cyantraniliprole degraded in the water phase and also partitioned to the sediment where it was further degraded to other metabolites that eventually were incorporated into the sediment organic fraction.

The major metabolite in both systems was IN-J9Z38 which increased to about 23% AR (0.09 ppm) at Day 28 before declining to 7.3% AR (0.03 ppm) in the sand system at the end of the study period (Day 100) and increased to about 40% AR (0.16 ppm) at Day 7 before declining to 5.1% AR (0.02 ppm) by day 100 in the silt loam system.

The IN-K5A77 metabolite accounted for greater than 5% AR at two non-subsequent sampling occasions in the silt loam sediment, but was a minor metabolite in the sand system and silt loam surface water. Additional minor metabolites IN-K5A78 and IN-JSE76 were also observed at $\leq 1.6\%$ and 0.8% AR, respectively. The remaining, combined, unidentified metabolites did not exceed *ca* 1.3% of the applied radioactivity.

The first-order DT_{50} and DT_{90} values for dissipation from the water phase and degradation in the water phase, sediment and total system are summarised below.

Table 29 Cyantraniliprole and metabolite DT₅₀ and DT₉₀ in anaerobic water sediment systems (in the absence of light)

The aerobic degradation of [¹⁴C]-cyantraniliprole in two irradiated water/sediment systems was studied by Wardrope & Sharma, 2010 [Ref: DP-24798]. A sand sediment system (pH 5.6 containing 2% organic carbon with overlying water at pH 6.1 and 56.4 mg/L organic carbon) and a silt loam sediment system (pH 7.7 containing 4.9% organic carbon with overlying water at pH 7.6 and 21.2 mg/L organic carbon) were treated with [PC-¹⁴C]-cyantraniliprole at a rate of 0.5 µg ai/g and incubated outdoors for 14 days under natural sunlight at 23 ± 2 °C.

At zero time the majority of the radioactivity was detected in the surface water (92–94% AR) decreasing to about 16% AR (silt loam system) and 33% AR (sand system) by Day 14. Solvent extractable radioactivity in the sediment increased from 1% AR at Day 0, to a maximum value of 64% AR (silt loam system) and 55% AR (sand system) by Day 14. Non-extractable residues increased to a maximum value of 5–10% AR by the end of the study period. No radioactivity associated with ¹⁴CO₂ was detected throughout the study period.

HPLC analysis of irradiated water sediment systems demonstrated that [¹⁴C]-cyantraniliprole degraded rapidly in the water phase, from 90% AR at Day 0 to 1–2% AR at Day 14, through a combination of degradation and transfer into the sediment. One significant metabolite was identified as IN-J9Z38, found in the surface water at a maximum of about 15% AR at Day 3 (silt loam system) and 27% AR at Day 5 (sand system) then declining to 4.5% AR and 12% AR respectively on Day 14. Metabolite IN-RNU71 was present at about 4–10% AR and but not observed in dark controls, implying that it was a photolysis product of IN-J9Z38. Minor degradation products (14) accounted for a combined maximum of 6–11% AR and individually less than 3% AR.

The amount of [¹⁴C]-cyantraniliprole in the sediment of the irradiated silt loam system increased initially due to transfer from the water phase, from about 1% AR at Day 0 to a maximum of 22% AR at Day 2 (silt loam system) and 15% AR at Day 3 (sand system) before declining to 9% and 6% AR respectively at 14 days. Six to seven metabolites were detected in the sediment extracts including IN-J9Z38 which increased from about 2% AR at Day 1 to about 42% AR at Day 14. The IN-RNU71 metabolite was present at up to 5% AR and the remaining components each accounted for less than 3% AR.

Buffer control outdoor	Parent + 3 metabolites	cyantraniliprole	14.1	47
		IN-J9Z38	2.5	8.4
		IN-RNU71	12.1	40.3

^a Both sediments modelled as replicates

In summary, cyantraniliprole degrades rapidly in outdoor water sediment systems, with total system DT_{50} values of 3.5 and 4.4 days in the silt loam and sand systems, respectively. The corresponding parent only total system DT_{90} values were 11.6 and 14.8 days in the silt loam and sand systems, respectively. The degradation rate was significantly faster than corresponding systems shielded from sunlight. The degradation rate was also faster than degradation observed in sterilized buffer exposed to sunlight.

Significant metabolites formed in the water/sediment system exposed to sunlight were IN-J9Z38 and IN-RNU71. While IN-J9Z38 was also identified in the silt loam and sand system dark controls, degradation was faster in the presence of light, suggesting that photodegradation is an important pathway. The formation of IN-RNU71, a photodegrade of IN-J9Z38 supports this conclusion.

Cyantraniliprole degradation in water/sediment systems involved a number of pathways and is outlined below.

Figure 9 Degradation of cyantraniliprole in outdoor water-sediment

Residues in rotational crops

Rotational crops metabolism

The Meeting received information on the fate of residues in lettuce, red beet, wheat, soya bean and wheat grown as rotational crops in cyantraniliprole-treated soil.

In a preliminary glasshouse study reported by Scott, Swain & Young (2006) [Ref: DP-15513], a sandy loam soil was treated with the equivalent of 0.3 kg ai/ha of [PC-¹⁴C]-cyantraniliprole (SC formulation) and wheat, soya bean, and red beet seeds were sown 25 and 120 days after treatment.

Crop samples from each soil-aging interval were taken, pulverised in dry ice and total radioactive residues (TRR) determined by combustion analysis and LSC. Samples were extracted using acetonitrile:water (9:1) followed by acetonitrile:water (7:3 or 1:1), cleaned up by SPE and analysed by HPLC, with confirmation by LC-MS and LC-MS/MS.

TRRs in wheat straw were 1.15 mg/kg and 0.75 mg/kg (cyantraniliprole equivalents) from the 25 and 120 day soil aging intervals, respectively. Lower TRRs were observed in the corresponding wheat chaff (0.37 and 0.21 mg/kg) and grain (0.02 mg/kg). Cyantraniliprole was the predominant residue in wheat straw (0.52 mg/kg) and chaff (0.23 mg/kg) after the 25-day soil aging period and 0.36 and 0.1 mg/kg respectively after the 120-day aging period. Components in straw from the 25-day aging period included IN-N7B69 (0.01 mg/kg), IN-N7B69 glucoside (0.07 mg/kg), IN-JCZ38 (0.08 mg/kg), IN-K5A77 (0.03 mg/kg), IN-JSE76 (0.1 mg/kg), IN-J9Z38 (0.05 mg/kg), IN-MLA84 (0.01 mg/kg), IN-K5A78 (0.01 mg/kg), IN-K5A79 (0.01 mg/kg) and polars (0.03 mg/kg). In general all the components (with the exception of IN-K5A78) were observed in the straw from the 120-day soil aging period but at lower concentrations. In grain, residues included cyantraniliprole, IN-N7B69, IN-N7B69 glucoside, IN-JSE76 and polars, each at ≤ 0.01 mg/kg.

TRRs in soya bean foliage, pods, and seed grown in soil aged 25 days were 0.18, 0.09, and 0.04 mg/kg, respectively. TRRs in the corresponding soya bean fractions from the 120-day interval were 0.13, 0.07, and 0.02 mg/kg, respectively. Cyantraniliprole accounted for 0.07 and 0.02 mg/kg in soya bean foliage from the 25-day and 120-day soil aging periods, respectively. Other foliage components included IN-JCZ38 (0.01 mg/kg), IN-JSE76, IN-MLA84 (≤ 0.03 mg/kg) and IN-J9Z38 (0.02 mg/kg). Soya bean (seed) components included IN-JCZ38, IN-K5A78, IN-N7B69, and polar components, each at ≤ 0.01 mg/kg. No cyantraniliprole was detected in the soya bean seed.

^a Polars are one or more components individually present at ≤ 0.02 mg/kg^b IN-N7B69 glucoside

TRRs in red beet were 0.11 and 0.04 mg/kg for foliage samples; 0.02 mg/kg and 0.01 mg/kg in root samples taken from red beets grown in soil aged 25 and 120 days, respectively. No cyantraniliprole was found in beet foliage from either aging period. Foliage components included IN-N7B69 glucoside (≤ 0.05 mg/kg) and polars (0.01 mg/kg). Low levels (≤ 0.01 mg/kg) of cyantraniliprole, IN-N7B69 glucoside, IN-N7B69, IN-J9Z38, and IN-JCZ38 were found in beet roots.

Table 35 Distribution of residues in red beet planted as a rotational crop 25 days and 120 days after soil treatment with [PC-¹⁴C]-cyantraniliprole (0.3 kg ai/ha)

^a Polars are one or more components individually present at ≤ 0.02 mg/kg^b IN-N7B69 glucoside

In a glasshouse study reported by Chapleo & Green (2012) [Ref: DP-15778], a sandy loam soil (pH 6.2, 1.4% organic matter) was treated with the equivalent of 0.45 kg ai/ha of either [CN-¹⁴C]-cyantraniliprole or [PC-¹⁴C]-cyantraniliprole (SC formulation) and wheat, lettuce, and red beet seeds were sown 30 and 120 days after treatment. After 365 days aging, a further sowing of spring wheat was made into the soil which had received the 30 day sowing.

Crop samples from each soil-aging interval were taken, pulverised in dry ice and total radioactive residues (TRR) determined by combustion analysis and LSC. Samples were extracted using either acetone:1N formic acid (9:1) or acetonitrile:water (9:1) followed by acetonitrile:water

	Sowing	Maturity	Sowing	Maturity	Sowing	Maturity
Days after soil treatment	30	146	120	263	365	493
Extracted	0.195 (93.5%)	0.158 (81.3%)	0.167 (83.1)	0.150 (74.2%)	0.109 (66.7%)	0.141 (63.3%)
Unextracted	0.014 (6.5)	0.036 (18.7)	0.034 (16.9)	0.052 (25.8)	0.054 (33.3)	0.081 (36.7)
Total	0.209	0.194	0.201	0.202	0.163	0.222

The predominant residue was cyantraniliprole, contributing 14–36% TRR (≤ 0.02 mg/kg) in wheat grain, 21–24% TRR (< 0.01 mg/kg) in red beet roots, and 40–69% TRR (0.01 to 0.08 mg/kg) in lettuce. Cyantraniliprole was also the principal radioactive component (0.01 to 0.85 mg/kg, 6 to 73% TRR) in wheat forage (71–73% TRR, 0.2–0.23 mg/kg), hay (52–53% TRR, 0.78–0.85 mg/kg) and straw 941–45% TRR, 0.4–0.44 mg/kg). Unchanged cyantraniliprole in the beet foliage accounted for no more than 0.005 mg/kg (4.1% TRR).

The IN-MYX98 metabolite was found in lettuce at up to 16% TRR (0.007 mg/kg in the 120 day rotation. Minor components individually present at ≤ 0.01 mg/kg ($< 10\%$ TRR) included IN-J9Z38, IN-JCZ38, IN-K5A79, IN-K7H19, IN-MLA84, and IN-N7B69 in grain; IN-DBC80, IN-J9Z38, IN-K5A77, IN-MYX98, and IN-N7B69 in red beet roots; and IN-J9Z38, IN-JCZ38, IN-MLA84 in lettuce. Uncharacterised fractions accounted for ≤ 0.01 mg/kg.

The main metabolites detected in wheat forage, hay and straw were IN-J9Z38 (≤ 0.18 mg/kg, 12% TRR), IN-K7H19 (≤ 0.06 mg/kg, 11% TRR), and IN-MLA84 (≤ 0.11 mg/kg, 6.6% TRR) and IN-JCZ38 (≤ 0.05 mg/kg); concentrations of minor metabolites (IN-DBC80, IN-HGW87 IN-JSE76, IN-K5A77, IN-K5A78, IN-K5A79, IN-MYX98, IN-N7B69, and IN-NBC94) were individually ≤ 0.02 mg/kg. Unextracted residues in the wheat feed samples accounted for no more than 10% TRR.

Red beet foliage contained low level (≤ 0.01 mg/kg) metabolites, IN-DBC80, IN-HGW87, IN-J9Z38, IN-JCZ38, IN-JSE76, IN-K5A77, IN-K5A78, IN-K5A79, IN-K7H19, IN-MLA84, IN-MYX98, IN-N7B69, and IN-NBC94. Unidentified components accounted for up to 0.03 mg/kg. Following enzyme treatment, these unidentified components decreased and levels of cyantraniliprole and IN-N7B69 increased, indicating that both IN-N7B69 and cyantraniliprole were present in conjugated form or associated with soluble natural products. Unextracted residues accounting for no more 9.1% TRR and did not exceed 0.01 mg/kg.

The metabolic fate of cyantraniliprole in the confined rotational crop study was complex with the formation of over 20 metabolites. A proposed pathway for the metabolism of cyantraniliprole in confined rotational crops is presented below:

Figure 10 Proposed metabolic pathway for cyantraniliprole in confined rotational crops

Rotational crop field studies

In one European (Scotland) study reported by Haigh & Woodmansey, 2010 [Ref: DP-21447], bare soil plots were treated with two applications of 0.1 kg ai/ha cyantraniliprole (OD formulation) about 7 days apart to achieve a total application rate of 0.2 kg ai/ha and spinach, spring barley and radish were planted as rotational crops, 14, 30, 120, and 270 days after the last application.

In a further European study (Spain), reported by Old & Woodmansey, 2010 [Ref: DP-19678], bare soil plots were treated with three applications of 0.15 kg ai/ha cyantraniliprole (OD formulation) about 7 days apart to achieve a total application rate of 0.45 kg ai/ha and lettuce, spring oats, soya bean and radish were planted as rotational crops, 14, 30, 120, and 365 days after the last application.

All crop samples were harvested at normal maturity, with immature samples also being taken for some leafy crops. Samples were stored for up to 39 months before extraction and analysis (within 72 days after extraction) for cyantraniliprole and six metabolites using analytical method DP15736, with reported LOQs of 0.01 mg/kg. Mean recovery rates ranged from 76–102% (cyantraniliprole) and 71–109% (metabolites) in samples spiked with 0.01 to 0.5 mg/kg.

With the exception of soya bean (seeds and forage) and radish tops, residues of cyantraniliprole and metabolites were not found in succeeding crops following bare ground applications of 0.2–0.45 kg ai/ha.

Note: Residues of other metabolites (IN-J9Z38, IN-JCZ38, IN-K7H19, IN-MLA84 and IN-MYX98) not detected in any samples

Five field rotational crop studies were conducted in North America and two studies were conducted in Europe, all involving bare soil treatments with cyantraniliprole prior to planting a wide range of representative rotational crops.

In three North American studies, bare soil plots were treated with 2–3 applications of cyantraniliprole (OD formulation) about 5 days apart to achieve a total application rate of 0.45 kg ai/ha and four rotational crops (lettuce/spinach, oat, radishes and soya bean) were planted 14, 30, 120, and 365 days after the last application. These studies were reported by Thiel, 2009 and 2010 [Ref: DP-19640][Ref: DP-19639][Ref: DP-21446].

Residues of IN-MYX98 were not detected in any samples

In the North American studies, residues of cyantraniliprole and metabolites in the first rotation crops (30 day plant-back interval) were below 0.05 mg/kg in commodities for human consumption (cereal grains, root crops, legumes and pulses, leafy vegetables). Higher residues were

reported in animal feed commodities, up to 0.2 mg/kg in forage crops and 0.3 mg/kg in most hays and straws. Highest residues were found in soya bean hay, up to 0.63 mg/kg.

METHODS OF RESIDUE ANALYSIS

Analytical methods

The meeting received analytical method descriptions and validation data for cyantraniliprole and major metabolites in crop and animal commodities and in soil and water. A summary of the analytical methods for plant and animal commodities is provided below.

Table 50 Summary of cyantraniliprole analytical methods developed for plant and animal matrices

Matrix	Analyte	Method	Principle	LOQ	Reference
tomato wheat grain orange almond	cyantraniliprole	21328	DFG S19 extraction (aqueous acetone) LC-MS/MS analysis	0.01 mg/kg	DP-21328
cucumber tomato lime almond wheat straw grape apple peach almond (nutmeat) lettuce wheat grain potato lemon oilseed rape onion tomato (paste) tomato (dried)	cyantraniliprole IN-J9Z38 IN-JCZ38 IN-K5A79 IN-K7H19 IN-MLA84 IN-MYX98 IN-N7B69 IN-F6L99	15736 [1187]	Aqueous acetonitrile extraction LC-MS/MS analysis	0.05 mg/kg (wheat straw) 0.01 mg/kg (other matrices)	DP-15736 DP-18846 DP-2600 DP-15736-S1
meat liver milk eggs	cyantraniliprole	25544	DFG S19 extraction (aqueous acetone) SPE clean-up LC-MS/MS	0.01 mg/kg	DP-25544 DP17942
milk	cyantraniliprole IN-HGW87 IN-J9Z38 IN-JCZ38 IN-K5A79 IN-K7H19 IN-MLA84 IN-MYX98 IN-N7B69	25544	DFG S19 extraction (aqueous acetone) SPE clean-up LC-MS/MS	0.01 mg/kg	DP-25544
muscle fat liver kidney milk skim milk heavy cream eggs	cyantraniliprole IN-J9Z38 IN-JCZ38 IN-K5A79 IN-K7H19 IN-MLA84 IN-MYX98 IN-N7B69	18844 [1552]	aqueous acetonitrile extraction SPE clean-up LC-MS/MS analysis		DP-18844 DP-25543 DP-26458

Data collection methods

Method 21328 (plant matrices)

The analytical method 21328, based on the German method DFG S19, was described and reported by Bacher, 2009 [Ref: DP-21328] as suitable for as a data-collection method to measure residues of cyantraniliprole in plant commodities, with an LOQ of 0.01 mg/kg.

Cyantraniliprole was extracted from the plant tissue according to extraction module E 1 (tomato), E 2 (wheat grain), E 3 (orange), and E 7 for (almond) of the DFG Method S 19 method. Extracts of tomato, orange, wheat grain, and almond were analyzed by liquid chromatography with electrospray ionization and tandem mass spectrometry detection. The report noted that degradation of cyantraniliprole was observed under GC/MS conditions.

The E1 extraction module involved the addition of water and acetone prior to homogenization for 2 minutes and then the addition of 1:1 ethyl acetate:cyclohexane and NaCl. The sample was homogenized a second time for 1 minute, allowed to separate and the organic phase was removed and filtered through a cellulose folded filter, which was coated with Na₂SO₄. The extract was evaporated until only aqueous remained and a mixture of ethyl acetate and 1:1 Na₂SO₄:NaCl was added. An additional aliquot of cyclohexane was added to adjust the volume of the organic layer.

The E2 extraction module involved the addition of water and a 30-minute soaking period before the addition of acetone and homogenization. After the addition of 1:1 ethyl acetate:cyclohexane and 35 g NaCl, the sample was homogenized a second time for 1 minute and the phases were allowed to separate. The organic phase was removed and filtered through a cellulose folded filter coated with Na₂SO₄. The extract was evaporated until only aqueous remained and a mixture of ethyl acetate and 1:1 Na₂SO₄:NaCl was added. An additional aliquot of cyclohexane was added to adjust the volume of the organic layer.

The E3 extraction module involved mixing with NaHCO₃, the addition of water and after allowing the sample to stand for about 30 minutes, the addition of acetone prior to homogenization. This was followed by an addition of 1:1 ethyl acetate:cyclohexane and 35 g NaCl and a second homogenization. After the phases were allowed to separate, the organic phase was removed and filtered through a cellulose folded filter coated with Na₂SO₄. The extract was evaporated until only aqueous remained and a mixture of ethyl acetate and 1:1 Na₂SO₄:NaCl was added. An additional aliquot of cyclohexane was added to adjust the volume of the organic layer.

The E7 extraction module involved the addition of acetone, acetonitrile, Calflo E and Celite before homogenization and vacuum filtration through a Buchner porcelain funnel. The filtrate was then passed through a dry fluted cellulose filter paper coated with Calflo E and rotary evaporated into an oil residue and bathed at 40 °C. The samples were then mixed with ethyl acetate, sonicated until completely dissolved and after the addition of a 1:1 mixture of Na₂SO₄:NaCl, cyclohexane was added to adjust the volume of the organic layer.²

The extracts were purified using gel permeation chromatography using 1:1 ethyl acetate:cyclohexane as the eluant. The eluate was evaporated to dryness using a rotary evaporator, re-constituted in ethyl acetate, evaporated to dryness in a gentle stream of nitrogen and re-constituted in methanol/water.

The final extracts were analysed by liquid chromatography with tandem mass spectrometric detection (LC-MS/MS) using a C18 column gradient elution using 0.1% formic acid in water to 0.1% formic acid in acetonitrile as the mobile phase. MS/MS detection in the positive ionization mode was used to monitor ion transitions 475→286 and 475→112 for cyantraniliprole.

Average (n=2) recovery rates in tomato, orange, wheat grain and almond (nutmeat) ranged from 92–104% (RSD ≤ 8%) in samples spiked with 0.01 mg/kg cyantraniliprole and from 93–115% (RSD ≤ 7%) in samples spiked with 0.1 mg/kg. The LOQ was 0.01 mg/kg.

Method 21328 was independently validated in a study by Weber, 2010 [Ref: DP-21326] with similar average (n=5) recovery rates (94–107%, ≤ 11% RSD) in tomatoes, oranges, wheat grain and almond nutmeat spiked with 0.01 mg/kg or 0.1 mg/kg cyantraniliprole, demonstrating the reproducibility of this method.

While the DFG S 19 extraction procedures used in Method 21328 include a pre-soak in water followed by an acetone extraction, the cyantraniliprole metabolism study [Ref: DP-16986] demonstrated that incurred residues could be completely extracted using an acetonitrile:water, 9:1 extraction. Based on the physicochemical properties of cyantraniliprole, including the higher

solubility in acetone (6.45 g/L) than in acetonitrile (2.45 g/L), acetone is considered a suitable solvent for the extraction of incurred cyantraniliprole residues.

Method 15736 (plant matrices)

The analytical method 15736, described and reported by McClory, Stevens-Shreve & Hense, 2011, [Ref DP-15736] was developed to measure residues of cyantraniliprole and seven metabolites (IN-J9Z38, IN-JCZ38, IN-K5A79, IN-K7H19, IN-MLA84, IN-MYX98 and IN-N7B69) in representative commodities with a high water content (cucumber and tomato), a high acid content (lime), a high oil content (almond nutmeat) and a low water content (wheat straw). This method is also known as DuPont method 1187.

A supplement to this study, reported by McClory, Stevens-Shreve & Hense, 2011, [Ref DP-15736-S1] also validated this method for tomato paste and sun-dried tomato for the above analytes and for the IN-N5M09 and IN-F6L99 metabolites as potential breakdown products formed during processing.

Samples were extracted twice with 9:1 acetonitrile:water by high-speed shaking (2 minutes at 700 cycles/minute in the presence of ball bearings) and centrifugation. The supernatants from the two extracts were combined, diluted with acetonitrile:water and mixed vigorously. Aliquots of these extracts were filtered (0.2 µm PTFE) and after the addition of methanol and de-ionized water, were analyzed using LC/MS/MS.

The final extracts were analysed by liquid chromatography with tandem mass spectrometric detection (LC-MS/MS) using a C18 column gradient elution using formic acid/ammonium formate in water to formic acid/ammonium formate in methanol as the mobile phase. MS/MS detection in the positive ionization mode was used to monitor the following ion transitions:

Cyantraniliprole	475→286	and	475→443.9
IN-J9Z38	457→188	and	457→290
IN-JCZ38	493→286	and	493→462
IN-K5A79	480→286	and	480→463
IN-K7H19	479→286	and	479→462
IN-MLA84	443→298	and	443→407.4
IN-MYX98	491→444	and	491→473
IN-N7B69	491→285.7	and	491→473
IN-F6L99	204→173	and	204→66

Average (n=2) recovery rates in samples spiked with 0.01 mg/kg ranged from 74–121% (RSD ≤ 15) and in samples spiked with 0.1 mg/kg were 67–96% (RSD ≤ 13). The method LOQ was 0.01 mg/kg.

This method was validated under GLP by two additional laboratories. One of the additional validations reported by Kinney, 2008 [Ref: DP-18846] investigated the performance of Method 15736 for grapes, apples, peaches, tomatoes, almonds (nutmeat), lettuce, wheat grain, wheat straw, potatoes, lemons, and rape seed and the second validation, reported by Seal, 2010 [Ref: DP-26000] evaluated the performance of the method for almonds, onions, tomato paste, and sun-dried tomatoes.

Average (n=5) recovery rates in all matrices and for all analytes in samples spiked with 0.01 mg/kg, 0.05 mg/kg (wheat straw), 0.1 mg/kg or 0.5 mg/kg (wheat straw) were within the range 70–111% (RSD ≤ 13).

Extraction efficiency of this method was demonstrated in a study reported by Lowrie and MacKinnon, 2009 [Ref: DP-24754] where samples of lettuce leaf, beet foliage, wheat grain, and wheat hay from the confined rotational crop metabolism study [Ref: DP-15778] containing weathered residues of radiolabelled parent and metabolites were extracted using the Method 15736 extraction procedure. The levels of the parent and metabolites obtained using the residue method were within 89–100% of those found in the metabolism study, which indicates that the residue method provides acceptable extraction efficiency.

Method 15736 was shown to be suitable for the purposes of residue data collection and enforcement of MRLs, with an LOQ of 0.05 mg/kg for wheat straw and 0.01 mg/kg for all other matrices.

Method 25544 (animal matrices)

The analytical Method 25544, based on the German multi-residue method DFG S19 (module E1 extraction and module GPC clean-up) with LC-MS/MS detection, was described and reported by Bacher, 2010 [Ref: DP-25544] as suitable for use as a data-collection method to measure residues of cyantraniliprole in animal commodities, with an LOQ of 0.01 mg/kg and was also suitable to measure residues of the metabolites IN-J9Z38, IN-JCZ38, IN-HGW87, IN-K7H19, IN-MLA84, IN-MYX98, and IN-N7B69 in milk (but not other animal commodities).

Samples of meat, milk, egg and liver were mixed with water and after the addition of acetone, were homogenized for 2 minutes before the addition of 1:1 ethyl acetate:cyclohexane and NaCl and further homogenization for 1 minute. The phases were allowed to separate and the organic phase was filtered through cellulose folded filter coated with Na₂SO₄. After repeat rinsing with ethyl acetate:cyclohexane the filtrate was evaporated to an aqueous remainder (not to dryness), re-dissolved in ethyl acetate, mixed with 1:1 Na₂SO₄:NaCl and the volume adjusted with cyclohexane.

Extracts were cleaned up by gel permeation chromatography using a 1:1 mixture of ethyl acetate:cyclohexane as eluant (5.0 mL/min) and an automated gel permeation chromatograph. The collected eluate was evaporated to dryness, reconstituted in ethyl acetate, evaporated to dryness in a gentle stream of nitrogen and re-constituted in 1:1 methanol:water.

The final extracts were analysed by liquid chromatography with electrospray ionisation and tandem mass spectrometric detection (LC-MS/MS) using a C18 column gradient elution using formic acid in water to formic acid in methanol as the mobile phase. MS/MS detection in the positive ionization mode was used to monitor the following ion transitions:

Cyantraniliprole	475→444	and	475→286
IN-J9Z38	457→188	and	457→112
IN-JCZ38	493→462	and	493→286
IN-K7H19	479→462	and	479→286
IN-MLA84	443→298	and	443→407
IN-MYX98	491→444	and	491→442
IN-N7B69	491→286	and	491→473
IN-HGW87	459→284	and	459→112

Average (n=5) recovery rates in samples spiked with 0.01 mg/kg ranged from 74–107% (RSD ≤ 14%) and in samples spiked with 0.1 mg/kg were 70–103% (RSD ≤ 14%). The method LOQ was 0.01 mg/kg.

This method was independently validated for the detection, quantitative analysis, and confirmation of cyantraniliprole in milk, eggs, meat, and liver in a study reported by Weber, 2010

[Ref: DP-17942]. Average (n=5) recovery rates in all matrices spiked with 0.01 mg/kg ranged from 98–106% (RSD < 6%) and were 95–108% (RSD < 7%) in the 0.1 mg/kg spiked samples.

While the DFG S 19 extraction procedures used in Method 25544 include a pre-soak in water followed by an acetone extraction, the cyantraniliprole metabolism study [Ref: DP-16987] demonstrated that incurred residues could be completely extracted using an acetonitrile:water, 9:1 extraction. Based on the physicochemical properties of cyantraniliprole, including the higher solubility in acetone (6.45 g/L) than in acetonitrile (2.45 g/L), acetone is considered a suitable solvent for the extraction of incurred cyantraniliprole residues in animal commodities.

The residue Method 25544, is suitable for the determination of cyantraniliprole in milk, eggs, meat, and liver, with an LOQ of 0.01 mg/kg for animal commodities.

Method 18844 (animal matrices)

The analytical method 18844, also reported as DuPont method 1552, was described and reported by Henze and McClory, 2010 [Ref: DP-18844] as suitable for use as a data-collection method to measure residues of cyantraniliprole and the metabolites IN-J9Z38, IN-JCZ38, IN-HGW87, IN-K5A79, IN-K7H19, IN-MLA84, IN-MYX98, and IN-N7B69 in muscle, fat, kidney, liver, egg, whole milk, skim milk and heavy cream, with an LOQ of 0.01 mg/kg.

In this method, samples were extracted twice with acetonitrile, cleaned up by shaking with hexane and centrifugation, with the hexane fractions then being discarded. The extracts were then evaporated to near-dryness in a gentle stream of nitrogen and after the addition of methanol, made up to volume with water, vortexed, sonicated and filtered.

Residues of cyantraniliprole, IN-HGW87, IN-J9Z38, IN-JCZ38, IN-K5A79, IN-K7H19, IN-N7B69, IN-MLA84, and IN-MYX98 were separated from co-extracts by reversed phase liquid chromatography (C18 column gradient elution using formic acid/ammonium formate in water to formic acid/ammonium formate in methanol as the mobile phase) and detected by mass spectrometry/mass spectrometry (MS/MS) using positive ion atmospheric pressure chemical ionization to monitor the following ion transitions:

Cyantraniliprole	475→443	and	475→286
IN-J9Z38	457→298	and	457→188
IN-JCZ38	493→462		
IN-K7H19	479→462	and	479→286
IN-K5A79	480→463	and	480→286
IN-MLA84	443→298	and	443→407
IN-MYX98	491→444		
IN-N7B69	491→286		
IN-HGW87	459→284	and	459→112

Average (n=5) recovery rates in samples spiked with 0.01 mg/kg ranged from 80–116% (RSD ≤ 20% except 34% RSD for IN-JCZ38 in eggs) and in samples spiked with 0.1 mg/kg were 74–116% (RSD < 13%). The method LOQ was 0.01 mg/kg.

This method was validated in a study reported by Ward, 2010 [Ref: DP-25543] on the detection and measurement of cyantraniliprole and metabolites (except IN-K5A79) in bovine muscle, fat, kidney, liver, milk and in eggs. An independent validation study was also conducted by Schwartz, 2010 [Ref: DP-26458] for cyantraniliprole, IN-J9Z38, IN-MLA84 and IN-N7B69 in whole milk, kidney and muscle.

In these studies, average (n=5) recovery rates in all matrices spiked with 0.01 mg/kg ranged from 72–131% (RSD < 13%) and were 71–112% (RSD < 12%) in the 0.1 mg/kg spiked samples.

Extraction efficiency of this method was demonstrated in a study reported by Kinney and Melville, 2010 [Ref: DP-27356] where samples of muscle, milk, liver, egg yolks, and egg whites from the cattle metabolism study [Ref: DP-16987] containing weathered residues of radiolabelled parent and metabolites were extracted using the Method 18844 procedure. The levels of extracted radioactivity obtained using the residue method were equivalent to those found in the metabolism extraction; 75.5% (liver), 92.7% (muscle), 103.7% (milk), 99.5% (egg white), and 125.1% (egg yolk), indicating that the method 18844 provides acceptable extraction efficiency.

The residue method 18844 for the determination of cyantraniliprole, IN-N7B69, IN-K7H19, IN-K5A79, IN-JCZ38, IN-MYX98, IN-HGW87, IN-J9Z38, and IN-MLA84 in muscle, fat, kidney, liver, heavy cream, skim milk, whole milk, and eggs involves simple extraction, clean-up, and analytical determination by HPLC/MS/MS detection. A limit of quantification of 0.01 mg/kg can be achieved consistently for all tissues.

Method 25544 (soil)

The analytical Method 15440, involving acetone extraction, SPE clean-up and LC-MS/MS analysis was reported by Henze, Devine and McClory, 2006 [Ref: DP-15440] as suitable for use as a data-collection method to measure residues of cyantraniliprole and metabolites IN-J9Z38, IN-JCZ38, IN-JSE76, IN-K5A77, IN-K5A78, IN-K5A79, IN-K7H19, and IN-PLT97 in soil.

Soil samples were extracted twice with 9:1 acetone:formic acid by shaking at high speed on a platform shaker. After dilution with water, extracts were passed through an NH₂ and an ENV SPE column. The NH₂ removed co-extracts with cyantraniliprole and or its photoproducts being retained on the ENV SPE column. Cyantraniliprole and its photoproducts were eluted from the ENV column with ammonium hydroxide in acetonitrile. The extracts were evaporated to dryness, reconstituted in methanol:formic acid, filtered and analyzed by LC/MS/MS.

Average (n=5) recovery rates in samples spiked with 0.001 mg/kg ranged from 75–102% (RSD < 17% and in samples spiked with 0.01 mg/kg were 72–96% (RSD < 9%). The method LOQ was 0.001 mg/kg.

The method 15440 was independently validated in a study reported by Schwartz, 2010 [Ref: DP-18847] with average (n=5) recovery rates in sandy loam soil samples spiked with 0.001 mg/kg ranging from 81–99% (RSD < 10%) and were 78–118% (RSD < 15%) in samples spiked with 0.01 mg/kg. The method LOQ was 0.001 mg/kg.

Method 29747 (soil)

Method 29747, an extension of the above method 15440 to include the measurement of the cyantraniliprole photoproducts IN-NXX70, IN-QKV54, and IN-RNU71, was described in a report by Vogl, 2010 [Ref: DP-29747], with average (n=5) recovery rates of 93–116% (RSD ≤ 12%) in a sandy clay loam soil spiked with 0.001 mg/kg or 0.01 mg/kg.

Enforcement methods

Multi-residue method DFG S19

Method 21328, the German method DFG S19 with LC-MS/MS analysis is suitable for enforcement of the MRL for cyantraniliprole in plant commodities, based on the method validation for tomato (representing high water content), orange (high acid content), wheat grain (high starch content) and almond (high oil content).

Method 26459, a GC/ECD procedure for crops was developed and validated in DuPont-26459. This method is intended for monitoring purposes in regions where LC/MS/MS is not readily available.

FDA PAM Multi-residue method

Rockwell, 2010 [Ref: DP-21329] evaluated the suitability of the FDA PAM Multi-residue methods for measuring residues of cyantraniliprole and six metabolites. The test substances were naturally fluorescent (with the exception of IN-MLA84-000, which was not soluble in methanol) but were not capable of being evaluated further without modifying the methods outlined in Protocol A. IN-JCZ38-004 and IN-K7H19-001 were found to chromatograph according to one Module DG 18, Level II, in Protocol C. However the two analytes were insoluble in the solvents required for the methods outlined in Protocols D, E, and F and further testing was suspended. Based on these results, none of the FDA multi-residue method test procedures are suitable for the regulatory analysis of DPX-HGW86-307 and its metabolites.

Analytical (concurrent) recoveries in supervised crop trials

Analytical recovery rates were measured in all the supervised crop field trials, with control samples being fortified with cyantraniliprole and metabolites at 0.01 mg/kg and at higher levels that generally reflected the range of expected residues. In most trials analysis was with Method 15736.

For each study, average recoveries per fortification level generally fell within the 70–120% range, with a relative standard deviation of 20% or less). Information on the concurrent recovery rates for individual commodities are summarised in the relevant supervised crop field trial sections.

Stability of residues in stored analytical samples

Plant matrices

The Meeting received information on the stability of residues of cyantraniliprole and metabolites in various substrates with a high water content (apple), a high starch content (potato), a high protein content (dry bean seed), a high oil content (peanut) and a high acid content (grape) stored at freezer temperatures for 24 months.

In a study by Rodgers, 2010, [Ref: DP-16990], samples of the test commodities were fortified at 0.2 mg/kg of each analyte. Spiked and the control samples were sealed and stored in the dark at -20 ± 10 °C. Samples were taken for extraction and analysis after 0, 1, 3, 6, 12, 18 and 24 months (and also peanuts after 63 days), with the stored control samples being freshly fortified with each analyte and analysed concurrently to determine the procedural recovery efficiency. Analysis was by LC-MS/MS (Method 15736), with mean procedural recovery rates of 83–94% for all analytes and matrices (fortified at 0.2 mg/kg and also at 0.01 mg/kg in peanuts).

After 24 months storage the measured residues of cyantraniliprole and major metabolites in stored samples of representative plant matrices with high water, acid, starch and protein content were greater than 80% of the spiked levels.

For peanut (high oil content), 24-month stability was demonstrated for cyantraniliprole, IN-F6L99, IN-J9Z38, IN-MLA84, IN-MYX98 and IN-N5M09, with measured residues also greater than 80% of the spiked levels. However, for the IN-JCZ38, IN-K7H19, and IN-N7B69 metabolites, the results showed reduced recoveries, attributed to extractability issues associated with the higher lipid content of this matrix.

Table 51 Stability of cyantraniliprole residues in plant matrices spiked at 0.2 mg/kg and stored at -20 ± 10 °C

Commodity	Storage interval (months)	Residues remaining (mg/kg)	% Residues remaining	Procedural recovery (%)

Animal matrices

The stability of residues in animal matrices during frozen storage (at ca. -80 °C) was measured in the both milk and egg matrices as part of the cattle feeding study, reported by Ward & Vance, 2011 [Ref: DP-27180] in support of analyses conducted as part of the cattle and hen feeding studies

Cyantraniliprole and its seven metabolites (IN-HGW87, IN-J9Z38, IN-JCZ38, IN-K7H19, IN-MLA84, IN-MYX98, and IN-N7B69) were shown to be stable for at least 3 months in milk and eggs. Storage stability testing was not performed for residues in other cow or hen tissues given that all analysis was carried out within 30 days of sampling.

Table 60 Stability of cyantraniliprole and metabolite residues in milk stored at -80 °C

Analyte	% Residues remaining		Procedural recovery (%)
	Day 0	Day 99

USE PATTERNS

Information on GAP in Canada, Columbia, Malaysia, New Zealand, Vietnam and West Africa was provided to the Meeting. Proposed uses in Australia, Europe, and USA that are currently being progressed under an OECD Joint Review exercise and in Brazil, China and India were also provided but are not reported.

Cyantraniliprole is intended for use to control of larval stages of lepidopteran insects, thrips, aphids, and some other chewing and sucking insects in a wide range of fruit and vegetable crops, tree crops and oil seed crops as foliar applications and as seed treatments (potato seed pieces, oil seed crops) and as pre-plant soil 'in-furrow' treatments (potatoes and brassica vegetables).

	Sunflower	North America	149
Others	Coffee	Brazil	150

The supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation including procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ. In such cases, the residues found are noted as “c=nn mg/kg” in the Reference and Comments columns. Residue data are recorded unadjusted for recovery.

Results from replicated field plots are presented as individual values. When residues were not detected they are shown as ND. Residues and application rates have been reported as provided in the study reports, although the results from trials used for the estimation of maximum residue levels (underlined) have been rounded to two significant digits (or if close to the LOQ, rounded to one significant digit) in the Appraisal.

In some trials, samples were taken just before the final application and then, again on the same day after the spray had dried. In the data tables the notation for these two sampling times is '-0' and '0' respectively.

When multiple applications were made to a crop, the application rate, spray concentration and spray volume were not always identical from one application to the next. In most trials, the actual treatment rates were within 10% of the listed ‘target’ application rates, but if not, the actual treatment rates are listed.

The analytical methods used in the field trials were capable of analysing both cyantraniliprole and from 1 to 7 metabolites. In most cases, residues of these metabolites were not detected (LOD of 0.003 mg/kg in most trials) or in some cases were reported at levels below the LOQ of 0.01 mg/kg. Where metabolite residues were present at levels above the LOQ, these values are recorded in the following tables using the abbreviations listed below:

M1	IN-J9Z38	2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1 <i>H</i> -pyrazol-5-yl]-3,4-dihydro-3,8-dimethyl-4-oxo-6-quinazolinecarbonitrile
M2	IN-MYX98	3-Bromo-1-(3-chloro-2-pyridinyl)-N-[4-cyano-2-[(hydroxymethyl)amino]carbonyl]-6-methylphenyl]-1 <i>H</i> -pyrazole-5-carboxamide
M3	IN-N7B69	3-Bromo-1-(3-chloro-2-pyridinyl)-N-[4-cyano-2-(hydroxymethyl)-6-[(methylamino)carbonyl]phenyl]-1 <i>H</i> -pyrazole-5-carboxamide

M4	IN-MLA84	2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1 <i>H</i> -pyrazol-5-yl]-1,4-dihydro-8-methyl-4-oxo-6-quinazolinecarbonitrile
M5	IN-JCZ38	4-[[[3-Bromo-1-(3-chloro-2-pyridinyl)-1 <i>H</i> -pyrazol-5-yl]carbonyl]amino]- <i>N</i> '3',5-dimethyl-1,3-benzenedicarboxamide
M6	IN-N5M09	6-Chloro-4-methyl-11-oxo-11 <i>H</i> -pyrido[2,1- <i>b</i>]quinazoline-2-carbonitrile
M7	IN-F6L99	3-Bromo- <i>N</i> -methyl-1 <i>H</i> -pyrazole-5-carboxamide

Citrus fruits

Results from supervised trials from Brazil, Europe and USA on oranges, grapefruit, lemons and mandarins were provided to the Meeting.

Brazil

In four Brazilian trials on oranges, one plot was treated with two soil drench applications of cyantraniliprole (200 g ai/L SC), 30 days apart, using 1.4 g ai in 200 mL water/tree (equivalent to 0.7 kg ai/ha for a tree density of 500 trees/ha) and a second plot was treated with two foliar applications of cyantraniliprole (100 g/L OD) using 0.3 kg ai/ha in 1500 L water/ha. No adjuvants were used.

Samples were frozen within 4 hours of sampling, stored at –20 °C for up to 84 days before whole fruit analysis for cyantraniliprole and metabolite IN-J9Z38 using an adaptation of method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 108% (cyantraniliprole) and 99% (IN-J9Z38) in samples spiked with 0.01 and 0.1 mg/kg.

North America

In trials conducted in the USA on oranges, grapefruit and lemons, three foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 7 day intervals, either as high volume, concentrate or ultra-low-volume treatments, with adjuvant added. Band treatment plots also included in three trial sites, where band spray applications (200 SC formulation) were made on one side of the tree rows, targeting 950 mL spray solution per tree.

Duplicate samples were frozen within 5 hours of sampling, stored at –20 °C for up to 5 months 12 months for Test 2 peel) before extraction and analysis of pulp and peel for cyantraniliprole and metabolites (within 46 days of extraction) using an adaptation of method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries in peel and pulp were 91–96% (cyantraniliprole) and 75–110% (metabolites) in samples spiked with 0.01, 0.1 and 1.0 mg/kg (peel). Whole fruit residues were calculated from the pulp and peel analysis results.

Europe

In trials conducted in Europe on oranges and mandarins, 2–3 foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 7 day intervals, either as high volume or concentrate treatments, with added surfactant.

Samples were stored at –18 °C for up to 12 months before extraction and analysis of pulp and peel for cyantraniliprole and six metabolites (within 7 days of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries in peel and pulp were 88–98% (cyantraniliprole) and 80–102% (metabolites) in samples spiked with 0.01, 0.1 and 1.0 mg/kg (peel). Whole fruit residues were calculated from the pulp and peel analysis results.

Pome fruits

Results from supervised trials from Europe and North America on apples and pears were provided to the Meeting.

North America

In trials conducted in North America on apples and pears, three foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 7 day intervals, either as high volume or concentrate airblast applications, with adjuvant added (except in the processing study trials).

Duplicate samples were stored at –20 °C for up to 7 months before analysis (within 76 days of extraction) for cyantraniliprole and six metabolites using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 93–97% (cyantraniliprole) and 83–102% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Europe

In trials conducted in Europe on apples and pears, two foliar applications of 6–15 g ai/hL cyantraniliprole (SE or WG formulations) were applied at 7 day intervals, either as high volume or concentrate treatments, with and without added adjuvant. These trials included a number of reverse decline studies, where different plots were treated at staggered intervals so that the sampling dates coincided with normal commercial harvest.

Samples were stored at –18 °C for up to 4–5 months before analysis of whole fruit for cyantraniliprole and 6–7 metabolites (within 2–24 hours after extraction) using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 90–94% (cyantraniliprole) and 88–99% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Stonefruit

Results from supervised trials from Europe and North America on peaches, plums and cherries were provided to the Meeting.

North America

In trials conducted in North America, three foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 7 day intervals, either as high volume (1000–2000 L/ha) or concentrate (100–800 L/ha) airblast applications, with adjuvant added.

Duplicate samples were stored at –20 °C for up to 7 months before analysis of flesh (within 101 days of extraction) for cyantraniliprole and six metabolites using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 100–104% (cyantraniliprole) and 91–109% (metabolites) in samples spiked with 0.01, 0.1, 0.5 and/or 2 mg/kg. Residues in whole fruit were calculated from the flesh residue results and the relative flesh:stone weights.

Europe

In trials conducted in Europe on apricots, peaches and plums, two foliar applications of 0.15 kg ai/ha (10–30 g ai/hL) cyantraniliprole (SE or WG formulations) were applied 7 days apart, using 500–1500 L/ha, with and without added adjuvant. These trials included a number of reverse decline studies, where different plots were treated at staggered intervals so that the sampling dates coincided with normal commercial harvest.

Samples were stored at –18 °C for up to 9 months before analysis for cyantraniliprole and six to seven metabolites (within 1–23 days after extraction) using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 82–96% (cyantraniliprole) and 79–96% (metabolites) in samples spiked with 0.01, 0.1 and 0.5 or 1.0 mg/kg. Residues in whole fruit were calculated from residues measured in the flesh, and the relative weights of flesh and stones.

Blueberries

In trials conducted on blueberries in North America, three foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 4–7 day intervals, using between 200 and 650 L/ha (with one trial at 50 L/ha), with adjuvant added.

Duplicate samples were stored at –20 °C for up to 6 months before analysis (within 23 days of extraction) for cyantraniliprole and six metabolites using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 101–104% (cyantraniliprole) and 95–109% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Grapes

In trials on wine grapes conducted in Europe, two foliar applications of 0.12–0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 14 day intervals, using 1500 L/ha (300 L/ha in two trials), with no added adjuvant. These trials were reverse decline studies, where treatments were applied at staggered intervals to align the sampling times with the commercial harvest date.

Samples were stored at –18 °C for up to 10 months before analysis of berries (within 5 days of extraction) for cyantraniliprole and six metabolites using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 92–94% (cyantraniliprole) and 88–96% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Olives

In trials on olives conducted in Europe, two foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) were applied at 10 day intervals, using 2000 or 3000 L/ha with added adjuvant.

After the olive samples were weighed and the stoned removed in the field, flesh samples were stored at –18 °C for up to 17 months before analysis (within 7 days of extraction) for cyantraniliprole and six metabolites using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 88–94% (cyantraniliprole) and 86–108% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg. Whole fruit residues were calculated from the relative flesh:stone weights.

M1: Residues of metabolite IN-J9Z38

Pomegranate

In trials on pomegranates conducted in India, two to five foliar applications of 0.075–0.18 kg ai/ha cyantraniliprole (OD formulation) were applied at 10 day intervals, using 400–1000 L/ha with added adjuvant

Samples were stored at –20 °C for up to 1 month before analysis for cyantraniliprole and the IN-J9Z38 metabolite using analytical method DP-15736, with reported LOQs of 0.005 mg/kg. Average concurrent recoveries were 83–93% (cyantraniliprole) and 85–92% (IN-J9Z38) in samples spiked with 0.005, 0.025 and 0.05 mg/kg.

M1: Residues of metabolite IN-J9Z38

Bulb vegetables

Onion, bulb, Spring onion

In trials conducted in North America on dry bulb onions and on green onions, three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied at 4–6 day intervals, using 300–400 L/ha, with adjuvant added. In one trial on green onions, an additional plot was treated with two soil treatments of 0.23 kg ai/ha cyantraniliprole (SC formulation) applied through the drip-line irrigation system, 7 days apart using about 100 L/ha, without added surfactant.

Duplicate samples of dry onion bulbs and green onion plants (without roots) were stored frozen at –20 °C for up to 1 year before analysis for cyantraniliprole and six metabolites (within 55 days of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent

recoveries were 92% (cyantraniliprole) and 81–97% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Brassica vegetables

In trials conducted in North America on broccoli, cauliflower and head cabbage, two or three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD and SE formulations) were applied at 4–6 day intervals, using 200–500 L/ha, with adjuvant added. In several trials, separate plots were also treated with the equivalent of 0.2 kg ai/ha as a soil injection (soil shank) treatment at planting (without added surfactant).

Duplicate samples of broccoli florets, cauliflower heads, cabbage heads (including wrapper leaves) and trimmed cabbage heads (washed after removing the wrapper leaves) were stored at –20 °C for up to 8 months before extraction and analysis for cyantraniliprole and six metabolites (within 5 months of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 90–94% (cyantraniliprole) and 80–103% (metabolites) in samples spiked with 0.01, 0.05, 0.1 and 1.0 mg/kg.

Fruiting vegetable, Cucurbits

Results from supervised trials from Australia, Europe and North America on cucumber, summer squash and melons were provided to the Meeting.

North America

In trials conducted in North America on cucumber, melons and summer squash, two or three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied at 5–7 day intervals, using 200–500 L/ha with adjuvant added. Soil treatment plots were also included in three trial sites, where two soil treatments of 0.15 kg ai/ha cyantraniliprole (SC formulation) were applied through drip-line irrigation systems (adjusted to pH 4–5, with no added adjuvant).

Duplicate samples were stored at –20 °C for up to 9 months before analysis of whole fruit or pulp and peel for cyantraniliprole and six metabolites analysis (within 70 days of extraction) using an adaptation of method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 90–94% (cyantraniliprole) and 82–100% (metabolites) in samples spiked with 0.01, 0.1, 0.2 and 0.6 mg/kg.

Europe

In trials conducted in Europe on melons, cucumbers and summer squash (courgettes), two applications of 0.09 kg ai/ha cyantraniliprole (OD formulation) were applied to field crops using 800 L/ha or four applications of 0.12 kg ai/ha cyantraniliprole (OD formulation) using 1200 L/ha were applied to crops grown under protection. The retreatment intervals in all trials was 7 days and all foliar treatments included added surfactant. Soil treatment plots were also included in a number of trial sites, where 2–4 soil treatments of 0.075–0.1 kg ai/ha cyantraniliprole (SC formulation) were applied through the drip-line irrigation systems, with no added adjuvants.

Samples were stored at -18°C for up to 8 months before analysis of whole fruit or pulp and peel for cyantraniliprole and six metabolites analysis (within 10 days of extraction) using an adaptation of method DP-15736, with reported LOQs of 0.01 mg/kg. For melons, the peel and pulp (minus seeds) weights were used to calculate whole fruit residues. Average concurrent recoveries were 91–101% (cyantraniliprole) and 93–104% (metabolites) in samples spiked with 0.01, 0.1, and 0.5 mg/kg.

Australia

In trials conducted in Australia on rockmelons, cucumbers and summer squash (zucchini), two applications of 0.05, 0.075 and 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied to field crops using 400 L/ha. The retreatment intervals in all trials was 7 days and all treatments included added surfactant.

Samples were stored at -20°C for up to 6 months before analysis of whole fruit for cyantraniliprole and six metabolites analysis (within 1 day of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 76–77% (cyantraniliprole) and 75–92% (metabolites) in samples spiked with 0.01–2.0 mg/kg.

Fruiting vegetables, other than Cucurbits

Results from supervised trials from Australia, Europe and North America on tomatoes and peppers were provided to the Meeting.

North America

In trials conducted in North America on field tomatoes and peppers (bell and non-bell), two or three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied at 4–6 day intervals, using 200–500 L/ha, with adjuvant added. Soil treatment plots were also included in three trial sites, where two soil treatments of 0.15 kg ai/ha cyantraniliprole (SC formulation) were applied through drip-line irrigation systems (adjusted to pH 4–5, with no added adjuvant).

Duplicate samples of fruit were stored at –20 °C for up to 8 months before extraction and analysis for cyantraniliprole and six metabolites (within 3 months of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 88–92% (cyantraniliprole) and 83–99% (metabolites) in samples spiked with 0.01–1.0 mg/kg and also 4 mg/kg for tomatoes.

Europe

In trials conducted in Europe on protected sweet peppers, chilli peppers and tomatoes, four applications of 10 g ai/hL cyantraniliprole were applied using 1200 L/ha as foliar sprays (OD formulation) or four applications of 5 g ai/hL using 2000 L/ha as soil treatments (SC formulation), applied through the dripline irrigation systems. The retreatment intervals in all trials was 7 days and all foliar treatments included added surfactant.

In outdoor tomatoes, sweet and chilli peppers in Southern Europe, two foliar applications of 0.09 kg ai/ha cyantraniliprole (OD formulation) were applied using 800 L water/ha at 6–7 day intervals with added surfactant.

Samples were stored at –18 °C for up to 8 months before extraction and analysis for cyantraniliprole and six metabolites analysis (within 7 days of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 75–101% (cyantraniliprole) and 77–101% (metabolites) in samples spiked with 0.01, 0.1, 1.0 and 5.0 (peppers) mg/kg.

Australia

In trials conducted in Australia on outdoor tomatoes and sweet peppers (capsicums), two foliar applications of 0.05, 0.075 or 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied 7 days apart to separate plots using 400 L water/ha with added surfactant.

Leafy vegetables

Results from supervised trials from Australia, Europe and North America on lettuce, spinach, Lamb's lettuce and scarole were provided to the Meeting.

North America

In trials conducted in North America on head and leaf lettuce and spinach, two or three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied at 5 day intervals, using 200–500 L/ha, with adjuvant added. Soil treatment plots were also included at several trial sites, either as a soil shank (in furrow) treatment of 0.2 kg ai/ha (SC formulation) at planting or two soil treatments of 0.15 kg ai/ha cyantraniliprole (SC formulation) applied through drip-line irrigation systems (adjusted to pH 4–5, with no added adjuvant).

Duplicate samples of spinach and lettuce leaves, lettuce heads (trimmed/washed and also with wrapper leaves) and celery (with tops and also trimmed/washed) were stored at –20 °C for up to 9 months before extraction and analysis for cyantraniliprole and six metabolites (within 3 months of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 96–98% (cyantraniliprole) and 80–106% (metabolites) in samples spiked with 0.01–5.0 mg/kg and up to 10 mg/kg in celery and 17 mg/kg in spinach.

In trials conducted in the USA on mustard greens, two or three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD and SE formulations) were applied at 4–6 day intervals, using 200–500 L/ha, with adjuvant added. In several trials, separate plots were also treated with the equivalent of 0.2 kg ai/ha as a soil injection (soil shank) treatment at planting (without added surfactant).

Duplicate samples were stored at –20 °C for up to 8 months before extraction and analysis for cyantraniliprole and six metabolites (within 5 months of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 90–94% (cyantraniliprole) and 80–103% (metabolites) in samples spiked with 0.01 to 25 mg/kg.

Europe

In trials conducted in Europe on protected head lettuce, leaf (open head) lettuce, Lamb's lettuce and scarole, two to three applications of 3.7–10 g ai/hL cyantraniliprole were applied using 750–800 L/ha (0.078–0.096 kg ai/ha) as foliar sprays (OD formulation) or three to four applications of 0.075–

0.1 kg ai/ha using 2000 L/ha as soil treatments (SC formulation), applied through the dripline irrigation systems. The retreatment intervals in all trials was 7 days and no added surfactants were included.

In outdoor head lettuce, leaf (open head) lettuce, Lamb's lettuce and scarole in Southern Europe, three foliar applications of 0.078 kg ai/ha cyantraniliprole (OD formulation) were applied using 800 L water/ha (5 g ai/hL) or three soil treatments (SC formulation) were applied through the dripline irrigation systems at a rate equivalent to 0.1 kg ai/ha. The retreatment intervals in all trials was 7 days and no added surfactants were included.

Samples were stored at -18°C for up to 7 months before extraction and analysis for cyantraniliprole and six metabolites analysis (within 7 days of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 88–102% (cyantraniliprole) and 83–95% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg and also 2 and 10 mg/kg cyantraniliprole and 0.5 mg/kg IN-J9Z38 metabolite in leaf lettuce.

Legume vegetables

In trials conducted in Europe on common beans in the field and grown under protection, two applications of 0.09 kg ai/ha cyantraniliprole (OD formulation) were applied 7 days apart, using 800 L spray mix/ha with added surfactants in the protected crops but not in the field crops.

Samples of pods (with seeds) and foliage (leaves and stems) were stored at –18 °C for up to 7 months before extraction and analysis for cyantraniliprole and six metabolites analysis (within 2 days of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 90–106% (cyantraniliprole) and 84–93% (metabolites) in samples spiked with 0.01, 0.1, 0.2, 0.6 and 1.0 mg/kg and also 8 mg/kg cyantraniliprole in foliage.

Tuber vegetables

In trials conducted with cyantraniliprole on potatoes in North America, plots were treated with either a pre-planting seed treatment (FS formulation) followed by one late season foliar spray (OD formulation) or with three late season foliar spray applications (OD formulation). Potato seed was treated with 13.5 g ai cyantraniliprole/100 kg of seed (equivalent to 0.15 kg ai/ha based on 2200 kg seed/ ha) and the foliar application was 0.15 kg ai/ha with added surfactant.

In several trials, additional plots were treated with three late season foliar applications of an SE formulation of cyantraniliprole (with added surfactant) or with a pre-plant in-furrow soil treatment (0.3 kg ai/ha, SC formulation) followed by a single late season foliar spray application (0.15 kg ai/ha, OD formulation).

Samples of tubers were stored at -20 °C for up to 11 months before analysis (within 3 months after extraction) for cyantraniliprole and eight metabolites using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 95% (cyantraniliprole) and 97–102% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

M1: Average residues of metabolite IN-J9Z38

Note: Second sample from Test site 8 reported high residues (cyantraniliprole 3.1 ppm) attributed to the selection of a treated seed piece

In trials conducted with cyantraniliprole on potatoes in Europe, plots were treated with two foliar applications of cyantraniliprole (OD formulation) with and without added surfactant. Targeted application rates were 0.01 kg ai/ha or 0.08 kg ai/ha, applied about 7 days apart using 450–500 L water/ha.

Samples of tubers were stored at -18 °C for up to 8 months before analysis (within 2 days after extraction) for cyantraniliprole and six metabolites using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 97% (cyantraniliprole) and 88–101% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Stalk and stem vegetables

In trials conducted in the USA on celery, two or three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied at 5 day intervals, using 200–500 L/ha, with adjuvant added. Soil treatment plots were also included at several trial sites, either as a soil shank (in furrow) treatment of 0.2 kg ai/ha (SC formulation) at planting or two soil treatments of 0.15 kg ai/ha cyantraniliprole (SC formulation) applied through drip-line irrigation systems (adjusted to pH 4–5, with no added adjuvant).

Duplicate samples of celery (with tops and also trimmed/washed) were stored at –20 °C for up to 9 months before extraction and analysis for cyantraniliprole and six metabolites (within 3 months of extraction) using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 96–98% (cyantraniliprole) and 80–106% (metabolites) in samples spiked with 0.01–10 mg/kg.

M1: Average residues of metabolite IN-J9Z38

M2: Average residues of metabolite IN-MYX98

Cereals

In three trials on rice, conducted in China, cyantraniliprole (OD formulation) was applied two or three times as foliar sprays, using either 0.1 kg ai/ha or 0.15 kg ai/ha, with a 7 day retreatment interval. No adjuvants were used.

Samples of threshed brown rice, hulls and straw (leaves and stalks) were stored at -20 °C until analysed for cyantraniliprole and the metabolite IN-J9Z38 using an aqueous acetonitrile extraction and LC-MS/MS analysis method based on method DP-15736. The reported LOQs for cyantraniliprole were 0.01 mg/kg in grain and 0.05 mg/kg in hulls and straw, and the LOQs for IN-J9Z38 were 0.02 mg/kg in grain and 0.1 mg/kg in hulls and straw. Average concurrent recoveries were 78-103% (cyantraniliprole) and 79-102% (IN-J9Z38) in samples spiked with 0.01, 0.05, 0.1, 1.0 mg/kg and also 2.0 mg/kg ((IN-J9Z38).

M1: Residues of metabolite IN-J9Z38

Tree nuts

In trials conducted in the USA on almonds and pecans, three foliar (airblast) treatments of 0.15 kg ai/ha cyantraniliprole (OD formulation) were applied at about 7 day intervals using either high volume (1000–3000 L/ha), concentrate (100–800 L/ha) or ultra-low-volume (50 L/ha) sprays, all with adjuvant added. An additional soil (shank) injection side dressing treatment was included in one trial.

Duplicate samples of nutmeat and hulls were stored at –20 °C for up to 6 months before analysis (within 37 days of extraction) for cyantraniliprole and six metabolites using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries in peel and pulp were 81–93% (cyantraniliprole) and 76–97% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Oilseed crops

In trials conducted with cyantraniliprole on cotton in the USA, plots were treated with three late season foliar sprays (OD formulation) at a rate of 0.15 kg ai/ha, using 200–500 L water/ha, with added surfactant. In one trial, an additional plot was treated with a pre-plant in-furrow soil treatment (0.2 kg ai/ha, SC formulation) followed by two late season foliar spray applications (0.1–0.15 kg ai/ha, OD formulation).

Samples of cotton seed and cotton gin byproducts were stored at –20 °C for up to 8 months before extraction and analysed within 3 months after extraction for cyantraniliprole and eight metabolites using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 75–76% (cyantraniliprole) and 69–120% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg and also 1.0 and 1.6 mg/kg in cotton seed.

M1: Average residues of metabolite IN-J9Z38

M2: Average residues of metabolite IN-MYX98

In trials conducted in Australia on cotton, two foliar applications of 0.06 or 0.12 kg ai/ha cyantraniliprole (SE formulations) were applied at 7 day intervals using 120 L water/ha, with added adjuvant. Several of these trials were reverse decline studies, where different plots were treated at staggered intervals so that the sampling dates co-incided with normal commercial harvest.

Samples were stored at –20 °C for up to 1 month before analysis of forage (leaves, stems etc), seeds and field trash for cyantraniliprole and six metabolites (within 4 days after extraction) using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 95–99% (cyantraniliprole) and 77–101% (metabolites) in samples spiked with 0.01–2.0 mg/kg.

Rape seed

In trials conducted with cyantraniliprole on oil-seed rape (canola) in North America, plots were treated with three late season foliar sprays (OD formulation) at a rate of 0.15 kg ai/ha, using 200–500 L water/ha, with added surfactant. In several trials, seed treated with cyantraniliprole FS formulation) at a rate required to achieve an application rate about 0.08 kg ai/ha planted and the plots were also treated with two late season foliar spray applications (0.15 kg ai/ha, OD formulation).

Seed samples were stored at -20 °C for up to 6.5 months before extraction and analysed within 4 months after extraction for cyantraniliprole and six metabolites using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 92% (cyantraniliprole) and 85–99% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg and also 1.0 mg/kg cyantraniliprole in cotton seed.

M1: Average residues of metabolite INJ9Z38

In trials conducted in Australia on oilseed rape, single foliar applications of 0.015 or 0.03 kg ai/ha cyantraniliprole (SE formulations) were applied using about 100 L water/ha, with added adjuvant. One of these trials was a reverse decline study, where different plots were treated at staggered intervals so that the sampling dates co-incided with normal commercial harvest.

Samples, fodder (remaining straw/trash) and processed oil were stored at -20 °C for up to 3 months before extraction for analysis of seeds, trash and oil for cyantraniliprole and six metabolites (within 4 days after extraction) using analytical method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 91–102% (cyantraniliprole) and 75–102% (metabolites) in samples spiked with 0.01–2.0 mg/kg.

Coffee

In Brazilian trials on coffee, plots was treated with two soil drench applications of cyantraniliprole (SC formulation), 30 days apart, using from 0.01–0.06 g ai/100 mL/plant to achieve the equivalent of 0.2 kg ai/ha/treatment, followed by two late season foliar applications of 0.175 kg ai/ha cyantraniliprole (OD formulation), 30 days apart, using 400–600 L water/ha with no added adjuvants. In two trials, additional plots received only the two late season foliar sprays.

Samples of beans were dried at room temperature and manually peeled, with the dried beans being stored frozen until analysis for cyantraniliprole and the metabolite IN-J9Z38 using method DP-15736, with reported LOQs of 0.01 mg/kg. Average concurrent recoveries were 93% (cyantraniliprole) and 88% (IN-J9Z38) in samples spiked with 0.01 and 1.0 mg/kg.

Table 150 Residues in coffee beans from supervised trials in Brazil involving soil drench (SC formulation) and foliar applications of cyantraniliprole (OD formulation)

FATE OF RESIDUES IN STORAGE AND PROCESSING

High temperature hydrolysis

In a study reported by Lowrie, 2005 [Ref: DP-16989], the high-temperature hydrolysis of [¹⁴C]-cyantraniliprole in buffered solutions of pH 4, 5, and 6 was investigated to simulate representative processing conditions: pasteurization at 90 °C for 20 minutes in pH 4 solution; baking, brewing, or boiling at 100 °C for 60 minutes in pH 5 solution; and sterilization at 120 °C for 20 minutes in pH 6 solution.

Solutions of [CN-¹⁴C]-cyantraniliprole and [PC-¹⁴C]-cyantraniliprole were incubated at 90, 100, and 120 °C at pH 4, 5, and 6, respectively, using aqueous citrate buffer and samples analyzed

after 20 min. (pH 4 and 6) and 1 h (pH 5) by LSC and HPLC. Identification of parent and transformation products was by co-chromatography and the identifications made were confirmed using LC-MS analysis. The limit of quantification (LOQ) for both labelled forms was 1% AR.

Cyantraniliprole was susceptible to hydrolysis with IN-J9Z38 being the significant hydrolysis product, making up about 4–5% AR under conditions representative of pasteurization (20 minutes at 90 °C and pH 4) and 12–14% AR under sterilisation conditions (20 minutes at 120 °C and pH 6). Under conditions reflecting baking, brewing, or boiling (60 minutes at 100 °C and pH 5) levels of IN-J9Z38 were lower, at 4–6% AR with IN-F6L99 and IN-N5M09 making up a further 5–8% AR. Minor components were detected but represented < 1% AR.

Potatoes

In three field trials conducted in North America and reported by Thiel, 2010 [Ref: DP-27583], bulk samples of tubers were taken from plots planted with cyantraniliprole-treated seed pieces (13.5 g ai/100 kg seed) and treated with a single foliar application of 0.15 kg ai/ha cyantraniliprole (OD formulation), with added surfactant, 7 days before harvest.

Samples were shipped under ambient conditions to the processing facility where samples were processed to potato flakes, potato waste, peeled potatoes, potato chips, wet peel, culls, fries, cooking water, unpeeled boiled potatoes, and unpeeled microwaved potatoes.

Tubers were washed for 5 minutes and representative samples were batch steam peeled, batch scrubbed for 20 seconds and further processed into flake processing and french fries. The collected peel was hydraulically pressed and blended with the cut trim waste to derive the wet potato waste sample.

A representative sample of steam-peeled potatoes were cut into slabs, batch spray-washed in cold tap water for 30 seconds to remove free starch, precooked at 70–77 °C for 20 minutes in a steam jacketed kettle and cooled to less than 32 °C for 20 minutes. The cooled potato slabs were then steam-cooked at 94–100 °C for 40 minutes and mixed with an emulsion of pre-weighed food additives. The cooked mash was then hand fed onto a drum dryer to produce a thin sheet of potato flake which was then hammer-milled to give the final potato flakes sample.

An additional representative sample of steam-peeled potatoes were pre-cooked in 54 °C water for 40 minutes and then cut into 3/16" strips using a french fry cutter. After cutting, the strips were spray-washed for 30 seconds to remove free starch, blanched in 79–85 °C water for 5 minutes and then dipped in a solution of 0.5% sodium acid pyrophosphate and 0.5% dextrose for 30 seconds at 71–74 °C. The strips were then air dried (75 °C) to reduce the moisture content of the strips by about 15% and par-fried in vegetable oil for 45–50 seconds at 188–191 °C. After frying, the fried strips were drained to remove excess oil and placed in the freezer for rapid (12 minute) cooling before being labelled and placed back into freezer storage for subsequent analysis.

Potato chips were prepared from the washed potatoes by batch peeling and slicing the peeled potatoes into thin 16mm slices. The sliced potatoes were placed in a tub of hot water to remove free starch, drained and fried at 163–191 °C frying oil for 90 seconds. After draining and salting, samples were labelled and stored frozen for subsequent analysis.

For producing unpeeled boiled potatoes, washed potatoes were quartered and boiled in water until an internal temperature of 88–92 °C was achieved. Once the desired temperature was reached, the unpeeled boiled potato fraction was removed from the water and packaged, labelled and placed into frozen storage.

For producing unpeeled microwaved potatoes, the quartered potatoes were placed into the commercial microwave oven and microwaved in 5 minute increments until an internal temperature of 88–92 °C was achieved. After the desired temperature was reached, the unpeeled microwaved potato fraction was packaged, labelled and placed into frozen storage.

Tubers and processed fractions were stored at –20 °C for up to 9 months before analysis (within 3 months of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 91–95% (cyantraniliprole) and 79–113% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Residues of cyantraniliprole were detected at up to 0.02 mg/kg in fresh tubers, less than 0.01 mg/kg in wet peel and unpeeled microwaved potatoes and were not detectable in all other samples tested. The IN-JZ38 metabolite was also measured at < 0.01 mg/kg in tubers and wet peel, but was not detectable in other matrices. Residues of the other metabolites (IN-JCZ38, IN-K7H19, IN-MLA84, IN-MYX98, IN-N7B69, IN-N5M09, and IN-F6L99) were not detected in tubers or in processed fractions.

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

Spinach

The effects of cooking on residues of cyantraniliprole in spinach were investigated by Carringer & Vogl, 2010 [Ref: DP-25644]. Bulk samples of spinach were taken from three field trials in the USA, one day after the last of three foliar applications of 0.15 kg ai/ha cyantraniliprole (OD formulation), applied at 5–6 day intervals with added surfactant.

At each of the three field sites about 400 g spinach leaves were added to 3 L boiling water in a large pot and boiled in the uncovered pot for approximately 15 minutes, stirring as needed to keep the leaves submerged under the water. The cooked spinach was removed and squeezed to remove as much water as possible.

Fresh and cooked leaves and the cooking water were stored at –20 °C for up to 8 months before analysis (within 10 weeks of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 87–98% (cyantraniliprole) and 73–103% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Residues of the IN-J9Z38, IN-MLA84 and IN-N5M09 metabolites increased significantly during the cooking process, with IN-J9Z38 being the predominant residue in cooked spinach. Residues of the other metabolites (IN-MYX98, IN-N7B69, IN-JCZ38 and IN-F6L99) decreased and the metabolite IN-K7H19 was not detected in any samples.

Tomatoes

Processing studies on tomatoes were reported by Carringer & Vogl, 2009 [Ref: DP-25645]. In three field trials in the USA, involving three foliar applications of 0.3 kg ai/ha cyantraniliprole (OD formulation), applied at 5 day intervals, with added surfactant, bulk samples were taken one day after the last application and shipped under ambient conditions to the processing facility where samples were processed to washed tomatoes, peeled tomatoes, sun-dried tomatoes, canned tomatoes, juice, wet pomace, dried pomace, paste, and puree.

Canned tomatoes were prepared by spray-rinsing the field samples with high pressure warm water (68–74 °C) for 30 seconds and boiling the rinsed tomatoes for about a minute to crack the skin prior to removal and peeled by hand before packing in cans with a teaspoon of salt. The cans were steam heated for about 10 minutes to achieve a temperature of about 80 °C, sealed, cooked in a boiling water bath for about 15 minutes and cooled in cold tap water.

Sun-dried tomatoes were prepared from the rinsed samples by removing the cores and stems, quartering the fruit and spreading them with the peel down on a tray for drying to a moisture content of < 16%.

Washed tomato samples were prepared by batch soaking a representative sample of the field tomatoes in a 5 g/L solution of sodium hydroxide at about 52–60 °C for 3 minutes and then spray-rinsing with high pressure warm water (68–74 °C) for 30 seconds.

Pomace samples were prepared by crushing the washed tomatoes in a hammermill and then rapidly heating the crush to about 79–85 °C for 15–30 seconds (hot break) before separation into pomace and juice. The wet pomace was pressed and the recovered press juice was combined with the fresh juice from the pulper/finisher. A representative sample of the wet pomace was then bin-dried to less than 10% moisture.

Fresh juice was heated to not more than 82 °C in the steam jacketed kettle and an aliquot was vacuum-evaporated to produce puree with the addition of 1% salt and the Brix level adjusted to 12.0–13.0° by the addition of water. The puree was heated to 82–88 °C, canned, sealed and cooked in a boiling water bath for about 15 minutes at 96–100 °C and then cooled under running cold tap water

Fresh juice was also vacuum-evaporated to paste with the addition of 0.5–1.0% salt and the Brix level adjusted to 24.0–33° by the addition of water. The puree was heated to 82–88 °C, canned, sealed and cooked in a boiling water bath for about 15 minutes at 96–100 °C and then cooled under running cold tap water.

An aliquot of the paste was also diluted with hot water, mixed with 0.5%–1.0% salt and the Brix level adjusted to about 4.5–5.5°, to produce juice. This juice was then heated to about 85 °C, canned, sealed and cooked in a boiling water bath for about 15 minutes at 96–100 °C and then cooled in cold tap water.

Processed samples were stored at or below -17 °C for up to 7 months before analysis (within about 2 weeks of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 76–102% (cyantraniliprole) and 70–117% (metabolites) in samples spiked with 0.01 to 2.0 mg/kg.

Cyantraniliprole was the predominant residue in processed tomato products, with significant residues of the IN-J9Z38 metabolite also found in wet and dry pomace. In the wet and dry pomace, paste and sun-dried tomato samples, low levels (up to 0.04 mg/kg) of IN-MYX98, IN-MLA84 or IN-N5M09 were reported. Residues of the other metabolites (IN-N7B69, IN-K7H19 and IN-JCZ38) were not detected in any samples.

M2: Residues of metabolite IN-MYX98

M4: Residues of metabolite IN-MLA84

M6: Residues of metabolite IN-N5M09

M7: Residues of metabolite IN-F6L99

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

Oranges

In three field trials on oranges conducted in North America and reported by Rice, 2010 [Ref: DP-27554], plots were treated 7 days apart with three late season foliar applications of 0.15 kg ai/ha

cyantraniliprole (OD formulation) with added surfactant and bulk samples of fruit were taken 1 day after the last application for processing.

The samples were shipped under ambient conditions to the processing facility where samples were processed to juice, wet pulp, dry pulp, meal, molasses, marmalade, oil, and canned oranges.

Juice was prepared from batch-washing field oranges by scarifying the fruit in a Hobart Peeler for 45 seconds, collecting the oil-water emulsion and passing it through a 180 μm screen to remove flavedo fragments before separating the oil fraction through a cream separator and then an IEC centrifuge. The residual emulsion was then frozen, thawed and centrifuged to collect the remaining oil.

Juice extracted from the scarified oranges was transferred to a pulper/finisher and passed through an approximately 1.2 mm screen to remove the rag and seeds. Peel from the juice extraction process was shredded and combined with scarified flavedo fragments and the residual pulp from the juice extraction to generate wet peel. Lime (about 95% CaO) was mixed with this wet peel and the limed peel was pressed to obtain press liquor which was then vacuum-evaporated to produce molasses.

An aliquot of the wet pulp was also dried to below 10% moisture and hammer-milled to produce the dry pulp sample, with further milling producing the meal sample.

Washed oranges were also peeled, segmented, mixed with a light syrup (Brix 14.0–18.0 °) and canned, with the sealed cans being cooked in a boiling water bath for about 15 minutes at 96–100 °C and cooled with tap water.

For marmalade, the rinds from washed oranges were chipped in a food processor and cooked for 20 minutes and the chopped pulp (without seeds) was mixed with 20% w/w water and cooked for 45 minutes. The cooked rind and pulp (with about 45 mL lemon juice and 1.5 kg sugar added per kg) was then boiled for 3 minutes, pectin was added and the mixture was boiled for a further 2 minutes. After standing for 1–2 minutes, the finished marmalade was packed in sterilised jars for subsequent analysis.

Fruit and processed fractions were stored at -20 °C for up to 8 months before analysis (within 7 weeks of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 81–96% (cyantraniliprole) and 64–101% (metabolites) in samples spiked with 0.01, 0.1 and 0.2 mg/kg.

The storage stability of frozen samples was also evaluated as part of this study. Whole fruit were cut in half and one-half of each fruit comprising each whole fruit incurred residue sample was pooled, homogenized, and extracted for analysis to provide an initial residue value for incurred residue stability determinations for this high-acid content commodity. The other half of these fruit were homogenized per sample and analyzed ten months later, to complete a ten-month incurred residue storage stability determination for orange fruit. Residues of cyantraniliprole after 10 months storage were 79, 88, and 128% of the initial residues in three composite samples.

Cyantraniliprole was the predominant residue in processed orange products, with residues concentrating in oil. Significant residues of the IN-J9Z38 metabolite were also in oil and other matrices, together with trace levels of the IN-N5M09 metabolite in oil. Residues of the other metabolites (IN-N7B69, IN-MYX98, IN-MLA84, IN-N5M09 IN-K7H19, IN-F6L99 and IN-JCZ38) were not detected in any samples.

M6: Residues of metabolite IN-N5M09

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

Apples

In three field trials on apples conducted in North America and reported by Thiel, 2010 [Ref: DP-27438], plots were treated 7 days apart with three late season foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) with added surfactant and bulk samples of fruit were harvested 3 day after the last application for processing.

Samples were shipped under ambient conditions to the processing facility where samples were processed to washed apples, puree, canned apples, frozen apples, juice, wet pomace, dry pomace, and sauce.

To produce juice, fresh apples were ground in a hammer-mill and the wet mash was pressed to 2200–3000 psi for at least 5 minutes to extract the juice, leaving the wet pomace. A representative sample of the wet pomace was also dried for 1–4 hours using hot air at 60–88 °C, to achieve a moisture content of 10% or less.

Apple sauce was prepared from peeled, cored and diced apples by heating in a kettle with added water (approximately 25% by weight) at about 70 °C for 45 minutes and mashing to produce puree. Further heating at 82–93 °C for 6–10 hours allowed excess moisture to evaporate, producing

apple sauce. Apple slices were also prepared from peeled, cored and sliced (6–7 mm) fruit by heating to about 70 °C for 20 minutes, resulting in cooked slices in syrup.

Peeled and cored apples were also cut into sliced to 3 mm slices and dehydrated at 65–70 °C for 20–24 hours to achieve a moisture content of about 10%.

Fruit and processed fractions were stored at -20 °C for up to 8 months before analysis (within 11 weeks of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 91–101% (cyantraniliprole) and 81–109% (metabolites) in samples spiked with 0.01, 0.1 and 1.0 mg/kg.

Cyantraniliprole was the predominant residue in processed apple products, with residues concentrating in the dry pomace. Significant residues of the IN-J9Z38 metabolite were present in sauce and to a lesser extent in dry pomace. Residues of IN-N5M09 and IN-F6L99 were also found at levels up to 0.07 mg/kg in sauce. Residues of the other metabolites (IN-N7B69, IN-MYX98, IN-MLA84, IN-K7H19 and IN-JCZ38) were not detected in any samples.

M6: Residues of metabolite IN-N5M09

M7: Residues of metabolite IN-F6L99

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

Plums

In three field trials on plums conducted in North America and reported by Thiel, 2010 [Ref: DP-27437], plots were treated 7 days apart with three late season foliar applications of 0.15 kg ai/ha cyantraniliprole (SE formulation) with added surfactant and bulk samples of fruit were taken 3 day after the last application for processing.

Samples were shipped under ambient conditions to the processing facility where the plums were stored for up to three days at about 6 °C before processing. The plums were sliced in half, the stones were removed and the pitted plums, on dehydrator trays, were dried at 130°–150 °C for about 14 to 18 hours to produce dried prunes, with a moisture content of 15–18%.

Plums and dried prunes were stored at –20 °C for up to 9 months before analysis (within 15 weeks of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 101–104% (cyantraniliprole) and 92–109% (metabolites) in samples spiked with 0.01, 0.1, 0.2 and 0.5 mg/kg.

Cyantraniliprole was the predominant residue in dried prunes, found a levels up to twice those in plums (without stones). Residues of the IN-J9Z38 metabolite were also found in the dried prunes, with IN-N5M09 and IN-F6L99 also found at levels up to 0.01 mg/kg. Residues of the other metabolites (IN-N7B69, IN-MYX98, IN-MLA84, IN-K7H19 and IN-JCZ38) were not detected in any samples.

M7: Residues of metabolite IN-F6L99

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

Cotton seed

In three field trials on cotton conducted in North America and reported by Thiel, 2010 [Ref: DP-27565], plots were treated 7 days apart with three late season foliar applications of 0.75 kg ai/ha cyantraniliprole (OD formulation) with added surfactant and bulk samples of cotton seed were taken 7 day after the last application for processing.

Ginned cotton seed samples were saw-delinted to remove most of the remaining lint, the hulls were cracked using a roller mill and screened (4–5 mm mesh) to separate out the kernels. After adjusting the kernel moisture content to 12–13.5%, the kernel material was heated to 80–90 °C for 30 minutes, flaked in a roller mill and steam extruded (93–121 °C) to form collets (pellets) which were then dried for 30–40 minutes at 66–82 °C prior to solvent extraction.

Flakes and collets were soaked in hexane at 49–60 °C for 30 minutes (1st cycle) and then 15 minutes each (2nd and 3rd cycles) with the miscella (crude oil and hexane) from each cycle being drained off and combined with the residual hexane from the final extraction (at about 95 °C). The combined miscella was passed through a vacuum evaporator (91–96 °C) to remove the hexane, leaving the raw oil solvent extract. This crude oil was refined by mixing with sodium hydroxide (16 °

Baume) in a water bath, first at 20–24 °C then at 63–67 °C before centrifuging to separate the oil from the soapstock.

Samples of delinted seed were also cold-pressed using a Komet expeller and the crude oil obtained by mechanical pressing was filtered and alkali-refined to produce refined cold-pressed oil.

Samples were shipped under frozen conditions to the processing facility where they were processed to cottonseed raw oil, cottonseed refined oil, cottonseed meal, cottonseed hull, cottonseed raw oil (cold press), cottonseed refined oil (cold press), and cottonseed meal (cold press).

The processing samples were stored at -20 °C for up to 8 months before analysis (within 13 weeks of extraction) for cyantraniliprole and eight metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 75–114% (cyantraniliprole) and 65–120% (metabolites) in samples spiked with 0.01–1.0 mg/kg.

Cyantraniliprole was the predominant residue in the processed fractions, with residues of the IN-J9Z38 metabolite also present in most oil fractions. Residues of the other metabolites (IN-N7B69, IN-MYX98, IN-MLA84, IN-N5M09, IN-F6L99, IN-K7H19 and IN-JCZ38) were not detected in any samples.

M6: Residues of metabolite IN-N5M09

M7: Residues of metabolite IN-F6L99

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

Olives

In three field trials on olives conducted in Europe and reported by Haigh & Cairns, 2011[Ref: DP-27709], plots were treated about 10 days apart with two late season foliar applications of 5 g ai/hL (0.15 kg ai/ha) cyantraniliprole (OD formulation) without added surfactant and bulk samples of olives were taken 14 day after the last application for processing.

Samples were shipped under ambient conditions to the processing facility within 1 day of sampling and were immediately processed to canned olives, raw and refined oil. The fresh whole olives were washed by immersion, drained and placed in a brine solution (220 g salt/2 L/kg olives) and allowed to soak for 30 days at room temperature and stirred daily before being stored for 60 days at 5–10 °C. The olives in brine were then canned (500 g olives with 250 g brine) and sterilised for 10 minutes at 115–120 °C.

For oil production, the fresh olives were hammer-milled and the resulting pulp was mixed and heated for about 30 minutes in a thermo-malaxer with the addition of boiling water and centrifuged to separate the oil/margines/water from the solid cake. The liquid phase was left to settle and the floating oil was decanted, with one portion being filtered to produce raw (virgin) oil and the other portion used to obtain refined oil.

The raw (unfiltered) oil was mixed with 115 g/L soda, heated in an oven at 60–70 °C for at least 30 minutes and the oil decanted from the sediment (soap) and filtered to give refined oil.

The processed samples were stored at –20 °C for up to 5 months before analysis (within 1 week of extraction) for cyantraniliprole and six metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 84–103% (cyantraniliprole) and 87–107% (metabolites) in samples spiked with 0.01–1.0 mg/kg.

Cyantraniliprole was the predominant residue in the processed fractions, with levels concentrating in oil. Residues of the IN-J9Z38 metabolite were also measured in canned olives and trace residues (< 0.01 mg/kg) of IN-N5M09 and IN-F6L99 were also detected in canned olives and IN-MYX98 and IN-JCZ38 in oil. Residues of the other metabolites (IN-N7B69, IN-MLA84 and IN-K7H19) were not detected in any samples.

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as "less than" (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate 'total' residues.

Grapes

In three field trials on wine grapes conducted in Europe and reported by Aitken, 2011 [Ref: DP-27718], plots were treated about 14 days apart with two late season foliar applications of 0.15 kg ai/ha) cyantraniliprole (OD formulation) by either high volume (1500 L/ha) or concentrate (300 L/ha) applications without added surfactant and bulk samples of grapes were taken 14 days after the last application for processing.

Samples were shipped under ambient conditions to the processing facility where samples were processed to stems, must, must deposit, wet pomace, lees, dry pomace, alcoholic fermentation (AF) Wine, malolactic fermentation (MF) Wine, bottled wine, grape juice and raisins.

For wine, grape samples were crushed and stemmed with an electric crusher/stemmer and sub samples taken for storage and analysis. For red wine, potassium metabisulphite (0.06–0.08 g/L) was added to the crushed grapes (must) and dry active yeast (0.1 g/L) added to initiate alcoholic fermentation. For white wine, potassium metabisulphite (0.12 g/L) and pectolytic enzymes were added to the must, which was then allowed to settle for 24 hours, decanted and the yeast was added to initiate alcoholic fermentation. The remaining wet pomace was sub-sampled for subsequent analysis and the wet pomace was also oven-dried at about 60 °C for two days to produce dry pomace.

At the end of the fermentation period, when the wine density had stabilised, the red wine was decanted and the solids were pressed to extract the remaining wine from the wet pomace. The wet pomace and the 'alcoholic fermentation' wine (AF wine) were sub-sampled for subsequent analysis and the wet pomace was also oven-dried at about 60 °C for two days to produce dry pomace. The white wine was separated from the lees and de-acidified by the addition of potassium bicarbonate.

Both the red and white 'AF wine' was then subjected to malolactic fermentation in the absence of air at ambient temperature by the addition of lactic bacteria and on completion, potassium metabisulphite was added. After settling for 4 days, the 'after malolactic fermentation' wine (MF wine) was separated from the lees and the wine was further clarified by the addition of gelatine (0.1 g/L) and potassium metabisulphite (0.04 g/L). After cool storage, the wine was racked and pressure-filtered (cellulose filter plate—2.5 µm pore) under nitrogen and 0.1 g/L potassium metabisulphite added to protect against oxidation.

Grape juice was prepared from the fresh grape samples by removing the stems and manually crushing the berries. After the addition of pectolytic enzymes, the crush was heated to 50 °C, put in jars and sterilised for 2 hours at 45–60 °C before being water-pressed to separate the juice and pomace. The juice was then clarified (5 minutes at about 80 °C), cool stored, racked and pressure-filtered under nitrogen and pasteurised for 1 minute at +85 °C.

Raisins were produced by oven-drying the bunch samples at 60 °C until the weight of the dried grapes was less than 35% of the initial weight and the stems were then removed by hand.

The processed samples were stored at –18 °C for up to 21 months before analysis (within 5 days of extraction) for cyantraniliprole and six metabolites using LC/MS/MS method DP-15736. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 72–111% (cyantraniliprole) and 71–111% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Cyantraniliprole was the predominant residue in the processed fractions, with levels concentrating in the pomace and in raisins. Residues of the IN-J9Z38 metabolite were also measured in dry pomace, lees and juice, with trace levels (< 0.01 mg/kg) also found in wine and raisins. Low levels of IN-N5M09, IN-MYX98 and IN-F6L99 were also detected in pomace and juice. Residues of the other metabolites (IN-N7B69, IN-MLA84, IN-JCZ38 and IN-K7H19) were not detected in any samples.

M2: Residues of metabolite IN-MYX98

M6: Residues of metabolite IN-N5M09

M7: Residues of metabolite IN-F6L99

For calculation purposes, where the residue in the processed commodity was reported as ND (< LOD), a value of 0.003 mg/kg was used and where residues were above the LOD but below the LOQ, a value of 0.01 mg/kg was used. In both cases, the PF was expressed as “less than” (e.g. < 0.01). Where residues of IN-J9Z38 are below the LOQ in the RAC, a value of 0.01 has been used to calculate ‘total’ residues.

^a Each value represents a separate study where residues were above the LOQ in the RAC. The factor is the ratio of the combined cyantraniliprole plus IN-J9Z38 metabolite residues in the processed item divided by the residue of cyantraniliprole in the RAC.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Dairy cow

In a dairy cow feeding study reported by Ward & Vance, 2011 [Ref: 27180], cyantraniliprole was administered orally in gelatine capsules to four groups of lactating Holstein cows (three cows/group) twice daily for 28 consecutive days. Dosing was made at target treatment levels of 3, 10, 30, and 100 ppm feed. Based on the average dietary intake and average dosing levels of 0.088, 0.276, 0.82 and 3.15 mg/kg body weight, the actual average dose levels were equivalent to 3.53, 11.7, 35.0, and 112 ppm feed. An additional three cows were dosed at 112 ppm feed to obtain depuration data. Body weights ranged from 457–730 kg and remained relatively constant throughout the study period.

Milk was collected twice daily and samples from afternoon sampling were combined with samples from the next morning. Milk samples from the depuration group were collected during the dosing period and up until sacrifice during the depuration phase. Except for the depuration group, cows were sacrificed within 24 hours after the last dose. One of the animals from the depuration group was sacrificed on Days 4, 10, and 15 after the last dose. Samples of liver, kidney, muscle, and fat were collected from all animals at sacrifice.

Samples were stored at about -80 °C for a maximum of 42 days. Samples were stored at about -80 °C for a maximum of 42 days before analysis, with the liver and kidney samples being extracted on the day of collection. Analysis for cyantraniliprole and seven metabolites was by HPLC/MS/MS method 18844, with an LOQ of 0.01 mg/kg for all analytes in all matrices. Average concurrent recovery rates were 75–103% (cyantraniliprole) and 71–112% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Residues reached a plateau in milk after about 5 days and were concentrated in the cream fraction by a factor of approximately 1.7. Residues in skim milk were approximately 60% of those in raw milk.

Residues in milk were dose-dependant and were predominantly cyantraniliprole and IN-N7B69. In the 3 ppm dose group, the maximum average residue of cyantraniliprole was 0.03 mg/kg and for IN-N7B69, 0.028 mg/kg. In the 10 ppm dose group, residues of cyantraniliprole and IN-N7B69 were 0.11 and 0.074 mg/kg, respectively. In the 30 ppm group, residues of cyantraniliprole, IN-N7B69, IN-J9Z38, and IN-MYX98 were 0.25, 0.17, 0.01, and 0.025 mg/kg, respectively. In the 100 ppm dose group, residues of cyantraniliprole, IN-N7B69, IN-J9Z38, and IN-MYX98 were 0.71, 0.28, 0.034, and 0.085 mg/kg, respectively. Residues of all other metabolites were < LOQ.

Residues in cream were comparable on Days 14 and 21. The predominant residues in cream were cyantraniliprole, IN-N7B69, and IN-J9Z38. In the 3 ppm dose group, analytes present above the LOQ were cyantraniliprole (0.066 mg/kg), IN-N7B69 (0.021 mg/kg) and IN-J9Z38 (0.013 mg/kg).

In the 10 ppm dose group the average residues in cream were: cyantraniliprole, 0.18 mg/kg; IN-N7B69, 0.051 mg/kg; and IN-J9Z38, 0.03 mg/kg. In the 30 ppm dose group the average residues of analytes were: cyantraniliprole, 0.55 mg/kg; IN-N7B69, 0.13 mg/kg; IN-J9Z38, 0.078 mg/kg; IN-MLA84, 0.024 mg/kg; and IN-MYX98, 0.022 mg/kg. In the 100 ppm dose group the average residues were: cyantraniliprole, 1.8 mg/kg; IN-N7B69, 0.22 mg/kg; IN-J9Z38, 0.31 mg/kg; IN-MYX98, 0.073 mg/kg; and IN-MLA84, 0.04 mg/kg. All other residues were < LOQ.

Residues in skim milk were comparable on Days 14 and 21. The predominant residues in cream were cyantraniliprole and IN-N7B69. In the 3 ppm dose group the average residues of analytes present above the LOQ were: cyantraniliprole, 0.017 mg/kg and IN-N7B69, 0.02 mg/kg.

In the 10 ppm dose group the average residues in skim milk were: cyantraniliprole, 0.044 mg/kg and IN-N7B69, 0.052 mg/kg. All other residues were < LOQ. In the 30 ppm dose group the average residues were: cyantraniliprole, 0.14 mg/kg; IN-N7B69, 0.13 mg/kg; and IN-MYX98,

0.021 mg/kg. In the 100 ppm dose group the average residues were: cyantraniliprole, 0.47 mg/kg; IN-N7B69, 0.20 mg/kg; and IN-YX98, 0.059 mg/kg. All other residues were < LOQ.

In tissues, the highest residues were found in liver, followed by kidney, fat, and muscle, with cyantraniliprole being the predominant residue in all tissues and was dose dependent.

In the 3 ppm dose group, average residues of analytes present above the LOQ in liver were cyantraniliprole, 0.054 mg/kg and IN-MLA84, 0.032 mg/kg. In the 10 ppm dose group, the average residues were: cyantraniliprole, 0.15 mg/kg and IN-MLA84, 0.075 mg/kg. In the 30 ppm dose group, the average residues were: cyantraniliprole, 0.46 mg/kg; IN-MLA84, 0.22 mg/kg; and IN-N7B69, 0.042 mg/kg. In the 100 ppm dose group, average residues were: cyantraniliprole, 1.7 mg/kg; IN-MLA84, 0.41 mg/kg; IN-N7B69, 0.075 mg/kg; IN-MYX98, 0.025 mg/kg; IN-J9Z38, 0.015 mg/kg; and IN-HGW87, 0.010 mg/kg. All other residues were < LOQ.

In the 3 ppm dose group, average residues of analytes present above the LOQ in kidney were cyantraniliprole, 0.023 mg/kg and IN-N7B69, 0.012 mg/kg. In the 10 ppm dose group, the average residues were: cyantraniliprole, 0.084 mg/kg; IN-N7B69, 0.031 mg/kg; and IN-MLA84, 0.013 mg/kg. In the 30 ppm dose group, the average residues were: cyantraniliprole, 0.20 mg/kg; IN-N7B69, 0.071 mg/kg; IN-MLA84, 0.041 mg/kg; and IN-MYX98, 0.034 mg/kg. In the 100 ppm dose group, average residues were: cyantraniliprole, 0.73 mg/kg; IN-MYX98, 0.14 mg/kg; IN-N7B69, 0.12 mg/kg; IN-MLA84, 0.099 mg/kg; IN-J9Z38, 0.024 mg/kg; and IN-HGW87, 0.011 mg/kg. All other residues were < LOQ.

In the 3 ppm dose group, average residues of analytes present above the LOQ in fat were: cyantraniliprole, 0.014 mg/kg and IN-J9Z38, 0.010 mg/kg. In the 10 ppm dose group, the average residues were: cyantraniliprole, 0.042 mg/kg and IN-J9Z38, 0.023 mg/kg. In the 30 ppm dose group, the average residues were: cyantraniliprole, 0.12 mg/kg; IN-J9Z38, 0.082 mg/kg; and IN-N7B69, 0.01 mg/kg. In the 100 ppm dose group, the average residues were: cyantraniliprole, 0.51 mg/kg; IN-J9Z38, 0.38 mg/kg; and IN-N7B69, 0.02 mg/kg. All other residues were < LOQ.

In the 3 ppm dose group, there were no residues present in muscle above the LOQ. In the 10 ppm dose group, only cyantraniliprole was present above the LOQ (0.026 mg/kg). In the 30 ppm dose group, the average residues were: cyantraniliprole, 0.071 mg/kg and IN-J9Z38, 0.01 mg/kg. In the 100 ppm dose group, the average residues were: cyantraniliprole, 0.28 mg/kg and IN-J9Z38, 0.027 mg/kg. All other residues were < LOQ.

Following cessation of dosing residues declined rapidly. All residues were < LOQ in milk, liver and kidney within 10 days after the last dose, in muscle within 4 days, and in fat within 15 days of the last dose.

Poultry

In a poultry feeding study reported by Roberts & Ward, 2011 [Ref: DP-27181], cyantraniliprole was administered orally in gelatine capsules to three groups of hens (3 or 4 hens/sub-group with three groups/treatment) daily for 28 consecutive days. Dosing was made at treatment levels of 3, 10, and 30 ppm feed based on the animal diet on a dry weight basis, equivalent to 0.24, 0.86, and 2.34 mg/kg body weight. An additional group (three sub-groups) was dosed at 30 ppm feed (2.37 mg/kg body weight) to obtain depuration data. Body weights ranged from 1.3–1.96 kg and remained relatively constant throughout the study period.

Eggs were collected twice daily and samples from afternoon sampling were combined with samples from the next morning. Eggs from the depuration group were collected during the dosing period and up until sacrifice during the depuration phase. Except for the depuration group, hens were sacrificed within 6 hours after the last dose. Animals from the relevant sub-group from the depuration group were sacrificed on Days 5, 9, and 14 after the last dose. Samples of liver, muscle, and skin with

fat were collected from all animals at sacrifice and were pooled in approximately equal quantities according to sub-group.

Samples were stored at about -80 °C for a maximum of 97 days before analysis, with the liver samples being extracted on the day of collection. Analysis for cyantraniliprole and seven metabolites was by HPLC/MS/MS method 18844, with an LOQ of 0.01 mg/kg for all analytes in all matrices. Average concurrent recovery rates were 95–125% (cyantraniliprole) and 67–126% (metabolites) in samples spiked with 0.01 and 0.1 mg/kg.

Residues in eggs were dose dependant and were predominantly cyantraniliprole and IN-J9Z38. In the 3 ppm dose group, the maximum average residue of cyantraniliprole was 0.08 mg/kg and for IN-J9Z38, 0.04 mg/kg. Residues of IN-MLA84 and IN-MYX98 were also found at 0.016 and 0.014 mg/kg, respectively. In the 10 mg/kg dose group, residues of cyantraniliprole and IN-N7B69 were 0.17 and 0.077 mg/kg, respectively. Residues of IN-MLA84 and IN-MYX98 also exceeded the LOQ (0.038 and 0.035 mg/kg, respectively). In the 30 mg/kg group, residues of cyantraniliprole, IN-J9Z38, IN-MLA84, IN-MYX98, and IN-HGW87 were 0.80, 0.41, 0.12, 0.10, and 0.016 mg/kg, respectively. Residues of all other metabolites were < LOQ.

The predominant residues in egg whites were cyantraniliprole (0.08 mg/kg, 0.17 mg/kg and 0.64 mg/kg) and IN-J9Z38 (0.04 mg/kg, 0.07 mg/kg and 0.27 mg/kg) in the 3 ppm, 10 ppm and 30 ppm dose groups respectively. Other metabolites present were IN-MYX98 and IN-MLA84, at levels less than 0.02 mg/kg (3 ppm dose group), less than 0.04 mg/kg (10 ppm dose group) and less than 0.1 mg/kg in the 10 ppm dose group. All other residues were < LOQ.

The predominant residues in yolks were also cyantraniliprole and IN-J9Z38. In the 3 mg/kg dose group only cyantraniliprole was present above the LOQ (0.015 mg/kg). In the 10 mg/kg dose group the average cyantraniliprole residues were 0.03 mg/kg and were 0.1 mg/kg in the 30 ppm dose group. Residues of IN-J9Z38, IN-MYX98 and IN-MLA84 were less than 0.02 mg/kg in the 10 ppm dose group and less than 0.06 mg/kg in the 30 ppm dose group. All other residues were < LOQ.

In tissues, the highest residues were found in liver with cyantraniliprole, IN-MYX98 and IN-MLA84 being the predominant residues in all tissues. Residues of cyantraniliprole were dose dependant.

In liver, the predominant residue was IN-MYX98, present at average levels of 0.03 mg/kg (3 ppm dose group), 0.07 mg/kg (10 ppm dose group) and 0.19 mg/kg (30 ppm dose group). Average cyantraniliprole residues in these dose groups were 0.017, 0.04 and 0.13 mg/kg respectively and IN-MLA84 was also found at similar levels (0.015, 0.04 and 0.1 mg/kg) in the respective dose groups. Other metabolites found in the 10 ppm and 30 ppm dose groups were IN-HGW87 (0.03 and 0.06 mg/kg respectively) and IN-N7B69 (0.013 and 0.05 mg/kg respectively). All other residues were < LOQ.

In skin with fat, no residues were found above the LOQ, with cyantraniliprole (0.033 mg/kg) and IN-MYX98 (0.015 mg/kg) reported in the 10 mg/kg dose group. In the 30 mg/kg dose group, the average cyantraniliprole residues were 0.08 mg/kg with IN-MYX98, IN-J9Z38 and IN-HGW87 found at levels less than 0.03 mg/kg. All other residues were < LOQ.

In muscle, the only residues found above the LOQ were IN-MYX98, found at 0.012 mg/kg in the 10 ppm dose group and cyantraniliprole (0.025 mg/kg), IN-MYX98 (0.014 mg/kg and IN-HGW87 (0.011 mg/kg) in the 30 ppm dose group. All other residues were < LOQ.

Following cessation of dosing residues rapidly declined, with residues in eggs, muscle and skin with fat all being below the LOQ within 5 days after the last dose. Residues in liver were also below the LOQ after 9 days depuration (first sample taken).

Table 166 Average residues of cyantraniliprole and metabolites in eggs from hens dosed with cyantraniliprole for 28 days

NATIONAL RESIDUE DEFINITIONS

Table 170 Cyantraniliprole: National residue definitions for MRL-compliance and dietary intake estimation

Country	MRL-compliance	Dietary intake estimation		
	All commodities	Plant commodities (unprocessed)	Plant commodities (processed)	Animal commodities
Canada	cyantraniliprole	cyantraniliprole	cyantraniliprole + IN-J9Z38	
New Zealand	cyantraniliprole	cyantraniliprole	cyantraniliprole	Not established ^a
Global Joint Review (proposed)	cyantraniliprole	cyantraniliprole	cyantraniliprole + IN-J9Z38	cyantraniliprole + IN-J9Z38 + IN-MLA84 + IN-MYX98 + IN-N7B69

^a A residue definition has not yet been established as the current authorized GAPs are not expected to result in detectable residues in animal products.

APPRAISAL

Cyantraniliprole is a diamide insecticide with a mode of action (ryanodine receptor activation) similar to that of chlorantraniliprole and flubendiamide with root systemic and translaminar activity against the larval stages of lepidopteran insects; and also on thrips, aphids, and some other chewing and sucking insects.

It was scheduled by the Forty-fourth Session of the CCPR (REP12/PR) as a new compound for consideration by the 2013 JMPR. The manufacturer submitted studies on metabolism, analytical methods, supervised field trials, processing, freezer storage stability, environmental fate in soil and rotational crop residues.

Authorisations exist for the use of cyantraniliprole in Canada, Columbia, Malaysia, New Zealand, Vietnam and in a regional grouping of countries in West Africa (CLISS).

Cyantraniliprole is 3-bromo-1-(3-chloro-2-pyridyl)-4'-cyano-2'-methyl-6'-(methylcarbamoyl) pyrazole -5-carboxanilide. It is relatively insoluble in water (12 mg/L at pH 7, 6 mg/L at pH 9) and hydrolyses under alkaline conditions and at higher temperatures (above 25 °C), the major hydrolysis product being IN-J9Z38. It is not volatile (1.2×10^{-15} Pa at 20 °C), has a log P_{ow} of 1.9, its solubility in organic solvents ranges from < 1 g/L (octanol, xylene) to 5–7 g/L (methanol, dichloromethane, acetone) and is rapidly degraded by photolysis.

Cyantraniliprole (DPX-HGW86)
(MW 473.7)

The following abbreviations are used for the metabolites discussed below:

Animal metabolism

The Meeting received information on the metabolism of radiolabelled cyantraniliprole, separately ^{14}C -labelled at the 4-cyano (CN) and the pyrazole carbonyl (PC) groups, in rats, lactating goats and laying hens.

The WHO panel of the 2013 JMPR concluded that in rats, the majority of the dose was excreted within 24 to 48 hours, with about 1–5.5% TRR being recovered in tissues and that tissue elimination half-lives ranged from 2.6 days (fat) to about 6 days in whole blood.

The metabolic pathway was primarily through hydroxylation (to form IN-N7B69 and IN-MYX98), with IN-N7B69 being further metabolized to a glucuronide conjugate. Cyantraniliprole undergoes ring closure to generate IN-J9Z38 which is then in turn hydroxylated to form IN-NBC94, its carboxylic acid, and its glucuronide conjugate. IN-MYX98 is also metabolized to the closed-ring metabolite IN-MLA84, which, like IN-NBC94, is further oxidized to a hydroxylated metabolite, a carboxylic acid, and the glucuronide of the hydroxyl metabolite. Further, the hydroxylated metabolite IN-MYX98 can be N-dealkylated to form IN-HGW87 as well as being hydroxylated a second time to form bis-hydroxy-cyantraniliprole. Cyantraniliprole can also be hydroxylated on the pyridine ring, followed by a ring closure analogous to the conversion of cyantraniliprole to IN-J9Z38.

Lactating goats were orally dosed with $[\text{CN-}^{14}\text{C}]$ - or $[\text{PC-}^{14}\text{C}]$ -cyantraniliprole at doses equivalent to approximately 13 ppm in the feed for 7 consecutive days and sacrificed 23 hours after the last dose.

The majority of the administered dose was recovered in excreta (84–88% in faeces, 7% in urine). About 1–2% (0.08–0.15 mg/kg) of the applied radioactivity was retained in milk, with 0.5 mg/kg (0.3% AR) found in liver and < 0.01% AR in other tissues. Solvent extraction was able to retrieve 99% TRR from milk, 90–98% TRR from fat, 61–81% TRR from muscle and 63–79% TRR from kidney. Solvent extractable TRR in the liver were lower (54–60% TRR) but an additional 21–27% TRR were recovered following digestion of the post extracted solids (PES) with protease.

In milk, TRR reached a plateau of 0.09 and 0.18 mg/kg after 2–3 days in the CN and PC label studies respectively. Cyantraniliprole was the major residue component, making up 40–50% (0.03–0.07 mg/kg) of the radiochemical label. Metabolite IN-MYX98 was also present at 15–18% TRR (0.01–0.03 mg/kg). Other metabolites (except IN-N7B69 at 11% TRR in the CN-label study) were found each < 0.01 mg/kg and less than 10% TRR.

In liver, TRR were 0.43–0.5 mg/kg. Cyantraniliprole (0.07–0.14 mg/kg) made up about 17–23% of the TRR and in kidney (TRR 0.14–0.21 mg/kg) with the major residue was also cyantraniliprole, accounting for 13–19% TRR (0.02–0.04 mg/kg).

In muscle, TRR were 0.03–0.04 mg/kg with the significant residue being cyantraniliprole, found at about 30% TRR and 0.01 mg/kg in the CN-label study and 15% TRR, 0.006 mg/kg in the PC-label study. The IN-MYX98 metabolite also accounted for 33% TRR (0.01 mg/kg) in the PC-label study.

TRR in fat were 0.05 and 0.12 mg/kg in the CN-label and PC-label studies respectively, with consistent results in omental, subcutaneous and renal fat. Cyantraniliprole was the major residue, averaging 31–42% TRR (0.01–0.025 mg/kg) with the IN-J9Z38 metabolite also accounted for 24–27% TRR (0.01–0.03 mg/kg).

Laying hens were orally dosed with [CN-¹⁴C]- or [PC-¹⁴C]-cyantraniliprole at doses equivalent to approximately 11 ppm in the feed for 14 consecutive days and sacrificed 23 hours after the last dose.

The majority of the administered dose was excreted, with 0.4–0.5% (0.20–0.26 mg/kg) remaining in egg whites, 0.07% (0.09 mg/kg) in yolks. Radioactivity in liver (0.14–0.2 mg/kg) accounted for 0.3–0.4% of the applied dose with muscle, abdominal fat and skin with fat each containing $\leq 0.1\%$ AR (< 0.01 mg/kg).

In eggs, %TRR reached a plateau of about 0.1 mg/kg in yolks after 5–7 days. The %TRRs in egg white increased to 0.26–0.56 mg/kg over the first 2 days and decreased to a steady state of about 0.2–0.24 mg/kg after 7 days.

Solvent extraction was able to retrieve 79–99% TRR from eggs, 63–120% TRR from fat, 100% TRR from muscle and 53–72% TRR from skin with fat. Solvent extractable TRR in the liver were lower (17–23% TRR) but an additional 38% TRR were recovered following digestion of the post extracted solids (PES) with protease.

In eggs, cyantraniliprole was the major residue component, making up 33–42% TRR (0.09 mg/kg) in egg whites and 9–10% TRR (< 0.01 mg/kg) in yolks. Metabolite IN-J9Z38 made up about 17–29% TRR (0.03–0.08 mg/kg) in egg whites and 7–13% TRR (0.006–0.011 mg/kg) in yolks. IN-MLA84 was also present in egg whites at about 18–19% TRR (0.04–0.05 mg/kg) and in yolks at about 12–17% TRR (0.01–0.015 mg/kg).

In liver, TRR were 0.14–0.17 mg/kg. Cyantraniliprole was not found in any samples and while metabolites IN-JCZ38, IN-K5A78, IN-K5A79, IN-K7H19, IN-MLA84, IN-MYX98 and IN-N7B69 were identified, these were each present at $< 4\%$ TRR (< 0.01 mg/kg).

In muscle, abdominal fat and skin with fat, no further analysis was conducted because of the low TRR (< 0.004 mg/kg) present.

In summary, the metabolism of cyantraniliprole in lactating goats (ruminant) and laying hen was consistent with that in the rat. Cyantraniliprole residues were rapidly eliminated in the excreta (94–100% of the dose) in goats and laying hens, with less than 1% of the total administered dose remaining in tissues and eggs and 1–2% found in milk). Cyantraniliprole was the predominant residue, with IN-N7B69 (milk), IN-MYX98 (muscle and milk), IN-J9Z38 (fat and eggs) and IN-MLA84 (eggs) being the principal metabolites present at more than 10% TRR or > 0.01 mg/kg.

Plant metabolism

The Meeting received plant metabolism studies on cotton, lettuce, tomato and rice seedlings following foliar and soil treatments with [¹⁴C]-cyantraniliprole. A 1:1 ($\mu\text{Ci}/\mu\text{Ci}$ ratio) mixture of [CN-¹⁴C]-cyantraniliprole and [PC-¹⁴C]-cyantraniliprole was used in the foliar treatments and separate treatments of the two radiolabels were applied as soil treatments.

Cotton

In cotton plants, treated three times with the equivalent of 0.15 kg ai/ha per application as foliar sprays, 7 days apart from 3 weeks after emergence, TRR in leaves immediately after the first treatment were 2.7 and 7.9 mg/kg immediately after the last application and after 13 days had

decreased to 0.43 mg/kg. At harvest (124 days after the last application), TRRs in cotton gin by-products, lint and undelinted seed were 0.13, 0.01, and < 0.01 mg/kg, respectively.

Surface washing removed 56–70% TRR from immature leaves with a further 27–33% extracted into acidified aqueous acetone.

Cyantraniliprole was the major residue in leaves, decreasing from 70% TRR immediately after the first application to 20% TRR seven days later and accounted for 37% TRR (0.19 mg/kg) and 27% TRR (0.12 mg/kg), respectively, 7 and 13 days after the final application.

IN-NXX70, a photodegradate of IN-J9Z38, found predominately in the surface wash, accounted for 22% TRR seven days after the first application but decreased to 1% TRR in leaves sampled 7 days after the third application.

Surface washing of cotton gin by-products removed about 19% TRR (0.03 mg/kg) with a further 65% TRR (0.07 mg/kg) being extracted into acetone or with more aggressive extraction methods. Cyantraniliprole was the predominant residue, accounting for 34% TRR (0.04 mg/kg).

In plants from soil treatments where three applications of 0.15 kg ai/ha cyantraniliprole (SC formulation) were made to wetted soil at 7 day intervals from 7 weeks after emergence, TRRs in leaves from immature plants sampled up to 14 days after the last application were all ≤ 0.005 mg/kg. At maturity, 125 days after the last application, residues in lint and undelinted seed were < 0.001 mg/kg and TRR values in cotton gin by-products were 0.1 mg/kg (CN-label) and 0.02 mg/kg (PC-label).

Cyantraniliprole was the only significant residue in gin by-products, making up 26–47% TRR (0.01–0.03 mg/kg).

Lettuce

In lettuce plants, treated three times with the equivalent of 0.15 kg ai/ha per application as foliar sprays, 7 days apart from 3 weeks after emergence, TRR in leaves immediately after the first treatment was 11 mg/kg, 10 mg/kg immediately after the second application and about 8 mg/kg just after the last application. Seven days after the last application, TRRs had decreased to about 2 mg/kg and were 0.43 mg/kg at maturity, 32 days after the last application. Surface residues decreased from about 91% TRR immediately after the first application and 32 days after the last application surface residues were 13% TRR.

Cyantraniliprole was the major residue in leaves, decreasing from about 98% TRR immediately after the first application to 50% TRR in mature leaves, 32 days after the last application. The IN-J9Z38 metabolite, present in mature leaves at about 23% TRR (0.01 mg/kg) was only metabolite accounting for more than 5% TRR.

In plants from soil treatment where three applications of 0.15 kg ai/ha cyantraniliprole (SC formulation) were made to wetted soil at 7 day intervals from 7 weeks after emergence, TRRs (CN-label) in leaves from immature plants declined from 0.14 mg/kg immediately after the first application to about 0.05 mg/kg (7 days after the 2nd and 3rd applications) and were about 0.01 mg/kg at maturity. TRRs following the PC-label soil treatment were ≤ 0.06 mg/kg in immature leaves and at crop maturity.

Cyantraniliprole was the major radioactive component present in leaves, up to 77–84% TRR in young leaves and 37% TRR (0.004 mg/kg) and 69% TRR (0.04 mg/kg) in mature leaves for the CN-label and PC-labels respectively.

Tomatoes

In tomato plants, treated three times with the equivalent of 0.15 kg ai/ha per application as foliar sprays, 7 days apart from 3 weeks after emergence, TRR in leaves immediately after the first treatment were 2.5 mg/kg, 8.5 mg/kg immediately after the second application and 7.6 mg/kg just after the last application. Seven days after the last application, TRRs had decreased to about

2.2 mg/kg and were 1.3 mg/kg 14 days after the last application. Residues in fruit and leaves at harvest (132 days after the last treatment) were < 0.01 mg/kg. The majority of the TRR (66–85%) were found in the surface wash with 15–34% TRR present in the extract.

Cyantraniliprole was the major residue in leaves, decreasing from about 95% TRR immediately after the first application to 61% TRR seven days later and accounted for 64 and 43% TRR respectively, 7 and 14 days after the last application. In leaves taken at maturity, residues in the surface wash were < 0.01 mg/kg and 0.01 mg/kg in the tissue extracts.

Concentrations of the unresolved radioactivity corresponding to both IN-MLA84 and IN-NXX70, (mostly in the surface wash) reached 11.5% TRR 7 days after the first application, decreasing to 4.4% TRR thereafter.

In plants from soil treatments where three applications of 0.15 kg ai/ha cyantraniliprole (SC formulation) were made to wetted soil in pots at 7 day intervals from 7 weeks after emergence, TRRs reached a maximum of 0.03 mg/kg in immature leaves 7 days after the last application and were < 0.01 mg/kg in leaves and 0.001 mg/kg in fruit at harvest (125 days after the last application).

Cyantraniliprole was the major radioactive component in leaves 7–14 days after the last application, ranging from 22–26% TRR (< 0.01 mg/kg).

Rice

Rice seedlings were treated with three foliar applications of 0.15 kg ai/ha at the 3–4 leaf stage and 7 and 14 days later and grown under flooded conditions (pots immersed in about 3 cm water) from 2 days after the initial treatment until 2–3 days before harvest.

TRRs in foliage were 2.1 mg/kg immediately after the first application, decreasing to 0.38 mg/kg after 7 days. Seven and 14 days after the last application, TRRs in leaves were 1.6 mg/kg and 1.2 mg/kg respectively. At harvest, 140 days after the last application, TRRs in straw were 0.45 mg/kg and 0.02 mg/kg in grain. In roots, TRRs increased from 0.24 mg/kg seven days after the first application to 0.68 mg/kg seven days after the last application and were 0.45 mg/kg at harvest. In immature leaves, 7 days after the last application, the surface wash contained about 75% TRR, reducing to 47% TRR in leaves sampled 14 days after the last treatment.

Cyantraniliprole was the major residue in immature leaves, making up 76–81% TRR (about 1.0 mg/kg) in samples taken 7 and 14 days after the last application. IN-J9Z38 was the predominant metabolite found at 0.6% TRR immediately after the first application and increasing to 11% TRR 14 days after the last application.

In straw, cyantraniliprole was the major component, accounting for 24.4% TRR (0.11 mg/kg) and cyantraniliprole was also the predominant residue in grain, accounting for 21% TRR (0.005 mg/kg).

Rice seedlings were also treated with a single soil application of 0.3 kg ai/ha (as surface-applied granules) at the 3–4 leaf stage and the plants were grown under flooded conditions (pots immersed in about 3 cm water) from 2 days after the initial treatment until 2–3 days before harvest, 175 days after treatment.

TRRs in foliage increased from 0.08 mg/kg (7 days after treatment) to 0.15 mg/kg (14 days after treatment) and reached 0.4 mg/kg after 56 days. Residues in roots were about 0.3 mg/kg after 56 days and at harvest (175 days after treatment). At harvest, TRRs were 0.28–0.3 mg/kg in straw and 0.01–0.03 mg/kg in grain.

Cyantraniliprole was the major residue in leaves sampled 56 days after treatment (49–57% TRR and about 0.2 mg/kg). The IN-J9Z38 metabolite was found in these samples at 16–22% TRR (about 0.08 mg/kg).

The major residue in straw was also cyantraniliprole (42–45% TRR, 0.13 mg/kg), with IN-J9Z38 (14–18% TRR) being the only significant metabolite, found at 14–18% TRR and in grain, cyantraniliprole accounted for 46–63% TRR (0.007–0.014 mg/kg).

In summary, cyantraniliprole was the predominant residue in most crop fractions at various sampling points up to crop maturity. Metabolites identified in foliar treated samples (with the exception of the photodegrade IN-NXX70) were also found in samples from plants treated with a soil drench application, indicating that the main metabolic pathways were similar. Overall, total radioactive residues were greater following foliar treatment than following soil application. A similar profile was observed in all studies.

The metabolite IN-J9Z38 was present at levels above 10% TRR only in rice foliage and lettuce (after foliar applications) and also in rice foliage and straw after soil treatment. Where present, residues were significantly lower (10–50%) than the levels of cyantraniliprole.

The metabolism of cyantraniliprole in plants was generally consistent with those in animals, except for the minor plant photodegradation pathway leading to the formation of IN-NXX70 and IN-QKV54).

Environmental fate

The Meeting received information on the environmental fate and behaviour of cyantraniliprole, including aerobic degradation in soil, photolysis on the soil surface, field soil dissipation, hydrolytic stability, soil and water/sediment degradation and confined and field rotational crop studies. Separate treatments of [CN-¹⁴C]-cyantraniliprole and [PC-¹⁴C]-cyantraniliprole were used in the confined studies.

Hydrolysis

Hydrolysis of cyantraniliprole was pH and temperature dependant. The rate of hydrolysis was significantly higher at high pH and temperature. The half lives at 15 °C decreased from 362 days (pH 4) to 126 days (pH 7) and was about 3 days at pH 9. A similar pattern was observed at the higher temperature of 35 °C, with the respective half-lives being 55 days, 7.5 days and < 1 day at pH 9. Under environmental conditions (pH 7, 25 °C) the half-life for cyantraniliprole was 212 days.

At all pH's, the predominant hydrolysis product was the cyclisation product IN-J9Z38 which accounted for about 28% AR (pH 4), 89% AR (pH 7) and 98% AR in the pH 9 samples.

Photolysis

In aqueous solutions, cyantraniliprole is rapidly degraded by photolysis. Half-lives in natural water and pH 4 sterile buffer exposed to continuous artificial sunlight for 15 days at 25 °C were 4–5 hours, with the formation of IN-NXX69, IN-NXX70, IN-QKV54 and IN-QKV55 as photodegradates. DT_{90s} were less than 16 hours.

In moist (non-sterile) soil (75% field capacity), treated with [¹⁴C]-cyantraniliprole at the equivalent of 1 kg ai/ha parent residues decreased to about 1% AR after 30 days in the irradiated samples and to 33% AR in the non-irradiated samples. The IN-J9Z38 metabolite was the predominant residue (up to about 50% AR) with IN-RNU71 and IN-QKV54 also found at about 13–14% AR. Estimated photolysis DT₅₀ and DT₉₀ values for cyantraniliprole (derived from the difference in the degradation constants (k) for the irradiated and non-irradiated samples) were 12 and 41 days respectively. Kinetic modeling suggested that nearly 34% of the cyantraniliprole in soil is degraded by photolysis and about 64% through soil degradation pathway.

Aerobic soil metabolism

Two studies were conducted in five soils (one loam soil, two silty clay loams, one silt loam and a sandy loam) with the equivalent of 0.4 kg ai/ha [CN-¹⁴C]-cyantraniliprole or [PC-¹⁴C]-cyantraniliprole. In these studies, the moist soils were incubated in the dark for up to a year at 20 °C or 22 °C.

Half-lives for cyantraniliprole were 9 days in the loam soil, 21–39 days in the silty clay loams, 44 days in the silty loam and 92 days in the sandy loam.

DT₅₀ values for the seven major transformation products (average DT₅₀ values in brackets) were: IN-JCZ38 (8 days), IN-K5A79 (64 days), IN-K5A77 (132 days), IN-J9Z38 (139 days), IN-JSE76 (410 days), IN-K5A78 (423 days) and IN-PLT97 (1032 days).

Soil dissipation

Ten field studies were conducted to investigate the degradation and mobility of cyantraniliprole under field conditions. In all of the trials a single application of 0.3 kg ai/ha or 0.45 kg ai/ha was made to bare soil in late spring or early summer and cropped soils were also treated in three of these studies. Soil samples were collected to a maximum depth of 90 cm, immediately prior to application and at pre-determined intervals over an 18 month period.

Cyantraniliprole was rapidly degraded in field soils with half-lives ranging from 17 to 51 days. While laboratory studies suggested that pH had some effect on degradation rates, degradation rate under field conditions does not appear to be pH-dependent. Downward mobility of the parent compound as well as its metabolites was limited, with residues rarely found below 15 cm. Soil metabolites formed in the bare soil treatments at levels greater than 10% of the initial soil concentration were IN-J9Z38 (max 42%), IN-K5A78 (max 17%), IN-JSE76 (max 14%), IN-JCZ38 (max 13%) and IN-K5A77 (max 11%). Lower metabolite levels were observed in soil from the cropped soil treatments, predominantly IN-J9Z38 (max 27%) and IN-JCZ38 (max 13%).

The mean temperature-normalized field DT₅₀ value from all studies was 32 days, consistent with the mean laboratory derived value.

Water/sediment dissipation

Under anaerobic conditions, cyantraniliprole degraded in the water phase and also partitioned to the sediment where it was further degraded and incorporated into the sediment organic fraction. The major degradate was IN-J9Z38, present in the total system at up to 23–40% AR (0.09–0.16 ppm) during the first 28 days after treatment and declining to 5–7% AR (0.02–0.03 ppm) at the end of the study period (Day 100).

The aerobic degradation of [¹⁴C]-cyantraniliprole was studied in a water/silt-loam system and a water/sand system treated with [PC-¹⁴C]-cyantraniliprole at a rate of 0.5 µg ai/g and incubated outdoors for 14 days under natural sunlight at 23 ± 2 °C.

In the water phase, cyantraniliprole residues were 1–2% AR at the end of the 14-day study period and in the sediment phase, after reaching maximum levels of 15–22% AR after 2–3 days, residues declined to 6–9% AR on Day 14.

One significant degradate, IN-J9Z38, was found in the surface water at a maximum of about 15–27% AR after 3–5 days and declining to 4.5% AR (silt-loam system) and 12% AR (sand system) at the end of the 14-day study period. In the sediment extracts residues of IN-J9Z38 increased from about 2% AR at Day 1 to about 42% AR at Day 14.

The calculated half-lives in the water/sediment systems were 3.5–4.4 days for cyantraniliprole and 40 days for the IN-J9Z38 metabolite.

Residues in succeeding crops

In two rotational crop metabolism studies using [PC-¹⁴C]-cyantraniliprole or [CN-¹⁴C]-cyantraniliprole, wheat, soya bean, lettuce and red beet were planted as rotational crops 25–30 and 120 days after a single bare soil application of 0.3 kg ai/ha in one study and 0.45 kg ai/ha in the second study. In the second study, after 365 days aging, a further planting of wheat was made in the 30-day rotation plots.

In the first rotation crops, total radioactive residues in food items ranged from 0.02–0.06 mg/kg in wheat grain, 0.08–0.11 mg/kg in lettuce, 0.02–0.03 mg/kg in beet roots and 0.04 mg/kg in soya bean seeds. Higher residues were seen in animal feed items; wheat hay and straw (0.97–1.6 mg/kg), soya bean foliage (0.19 mg/kg) and beet foliage (0.11 mg/kg).

The metabolic fates of cyantraniliprole in the three rotational crops were similar. Cyantraniliprole was the predominant residue in wheat straw and hay (41–53% TRR, 0.4–0.85 mg/kg), wheat grain (10–36% TRR, < 0.01–0.02 mg/kg), soya bean foliage (36% TRR, 0.07 mg/kg), red beet roots (21–27% TRR, < 0.01 mg/kg) and lettuce (60–69% TRR, 0.05–0.08 mg/kg). No cyantraniliprole was detected in soya bean seeds and parent residues in beet foliage were 3–4% TRR.

In food commodities, IN-MYX98 was the only significant metabolite present above 10% TRR, being found in 2nd rotation (120 day) lettuce leaves at 16% TRR but < 0.01 mg/kg. In animal feed commodities, IN-J9Z38 was found in wheat hay, forage and straw at up to 13% TRR (0.18 mg/kg) and IN-K7H19 was present in wheat hay and straw at 10–11% TRR (0.04–0.06 mg/kg) in the 365 day rotation crop.

Overall, the metabolism in rotational crops was consistent with metabolism seen in primary crops and in the animal studies.

Rotational crop field studies were conducted in Europe and North America to estimate residue uptake in follow crops. In two European studies, where spinach, lettuce, spring barley, oats, soya bean and radish were planted into bare soil treated with 0.2 kg ai/ha or 0.45 kg ai/ha at plant-back intervals of 14, 30, 120, 270 and 365 days, with the exception of soya bean (seeds and forage) and radish tops, residues of cyantraniliprole and metabolites were not found in succeeding crops. In soya bean forage, residues of cyantraniliprole were 0.02–0.03 mg/kg and in soya bean seed, residues of the IN-N7B69 metabolite were < 0.01 mg/kg.

In five North American studies, bare soil was treated with three applications of cyantraniliprole at about 5 day intervals to achieve a total seasonal application rate of 0.45 kg ai/ha. In three of these studies, four rotational crops (lettuce/spinach, oats, radish and soya bean) were planted 14, 30, 120, and 365 days after the last application. In the other two studies, strawberries, turnip, sugar beet, garden beet, radish, carrot, bean, pea, soya bean, alfalfa, clover, field corn, sweet corn, sorghum, rice, wheat, Bermuda grass, brome grass, clover, bluegrass and peanut were planted 30 days after the last application.

Residues of cyantraniliprole and metabolites in the first rotation crops (30 day plant-back interval) were below 0.05 mg/kg in commodities for human consumption (cereal grains, root crops, legumes and pulses, leafy vegetables). Higher residues were reported in animal feed commodities, up to 0.2 mg/kg in forage crops and 0.3 mg/kg in most hays and straws. Highest residues were found in soya bean hay, up to 0.63 mg/kg in one sample.

In the first rotation crops (30 day plant-back interval (PBI)), highest residues of cyantraniliprole were above 0.01 mg/kg in radish roots (0.02 mg/kg), radish and turnip tops (0.02–0.04 mg/kg), legume forages (0.02–0.14 mg/kg), legume hays (0.05–0.63 mg/kg), leafy vegetables (0.03 mg/kg), cereal forages (0.01–0.11 mg/kg), cereal hays and straws (0.07–0.21 mg/kg), forage grasses (0.01–0.09 mg/kg) and grass hays (0.02–0.23 mg/kg).

Metabolites present at more than 0.01 mg/kg were IN-J9Z38 (up to 0.03 mg/kg in cereal and legume hays and straws), IN-JZ38 (in cereal and legumes, up to 0.06 mg/kg hays and 0.03 mg/kg in forages) and IN-MLA84 (in legumes, up to 0.02 mg/kg in forage and 0.07 mg/kg in hays).

Methods of analysis

Several analytical methods have been reported for the analysis of cyantraniliprole and up to eight metabolites in plant and animal commodities. The basic approach employs extraction with acetonitrile/water and analysis by high pressure liquid chromatography with tandem mass spectrometry.

For plant and processed plant commodities, the HPLC-MS/MS method used in most of the supervised residue field trials, was validated for the analysis of cyantraniliprole and its metabolites (IN-N7B69, IN-JCZ38, IN-K7H19, IN-MYX98, IN-MLA84 and IN-J9Z38) in a range of representative matrices. The LOQ is 0.01 mg/kg for each analyte. Adequate extraction efficiencies

were demonstrated in plant matrices using radiolabelled samples from metabolism and confined rotational crop studies.

For animal commodities, the HPLC-MS/MS method was validated for the analysis of cyantraniliprole, IN-HGW87, IN-N7B69, IN-K7H19, IN-JCZ38, IN-MYX98, IN-J9Z38 and IN-MLA84 in livestock tissues, milk and eggs. After extraction with acetonitrile, extracts are partitioned against hexane before SPE clean-up and analysis. The LOQ is 0.01 mg/kg for each analyte. The method was validated by an independent laboratory using kidney, muscle, and milk. The extraction efficiency was successfully demonstrated with samples of liver, muscle, milk, egg white, and egg yolk from livestock metabolism studies.

The DFG S19 multi-residue method with LC-MS/MS analysis was validated for the analysis of cyantraniliprole residues in tomato (representing high water content), orange (high acid content), wheat grain (high starch content) and almond (high oil content), and is suitable as an enforcement method for cyantraniliprole in plant commodities. It was also validated in milk, eggs, meat and liver as being a suitable enforcement method for cyantraniliprole residues in animal commodities.

The US-FDA PAM multi-residue methods were shown to be unsuitable for the detection and enforcement of cyantraniliprole and metabolites (Protocols A through F).

Stability of pesticide residues in stored analytical samples

Freezer storage stability of cyantraniliprole and metabolites IN-F6L99, IN-J9Z38, IN-JCZ38, IN-K7H19, IN-MLA84, IN-MYX98, IN-N5M09 and IN-N7B69 was investigated in five representative commodities: apples (high-water content), grapes (high-acid content), potatoes (high-starch content), dry bean seeds (high-protein content), and peanuts (high-oil content).

Residues were shown to be stable in these representative substrates for at least 24 months in frozen storage, with residues in the stored samples being greater than 80% of the spiked levels except in peanuts (high oil content), where reduced recoveries were observed at all storage intervals for the metabolites IN-JCZ38, IN-K7H19 and IN-N7B69.

Definition of the residue

In animal commodities, the predominant residues identified in the metabolism studies were cyantraniliprole, IN-J9Z38, IN-MLA84, IN-N7B69 and IN-MYX98. Where residues were found in animal tissues in the metabolism studies or the feeding studies, cyantraniliprole was the major or a significant component. Noting that a multi-residue method was available to measure cyantraniliprole in animal commodities, the Meeting agreed that for MRL-compliance, the residue definition for animal commodities should be cyantraniliprole.

The compound cyantraniliprole has a log K_{ow} of 1.9, suggesting that it is not fat soluble, and this is supported by the residue distribution in muscle and fat reported in a cow feeding study, where the residues in fat were generally only about 2-fold higher than in muscle. The Meeting therefore concluded that cyantraniliprole is not fat soluble.

For dietary intake estimation, in addition to the parent compound, metabolites found at significant levels in the animal metabolism studies were IN-N7B69 (milk), IN-MYX98 (muscle and milk), IN-J9Z38 (fat and eggs) and IN-MLA84 (eggs). In the feeding studies, at doses that reflect the expected animal burden, these individual metabolites were also found at levels ranging from about 20% to 100% of the parent concentrations in different matrices but when combined, were generally found at levels close to those of the parent.

IN-N7B69 was found in milk at a level equivalent to parent and at about half the parent concentration in kidney. IN-J9Z38 was present in eggs at about 50% parent concentration. IN-MLA84 was found in cattle liver at about 60% of the parent concentration and in eggs at about 50% parent concentration. IN-MYX98, found in eggs at about 20% parent and in poultry liver at about 135% of parent.

These metabolites also occur in rats, are not considered more toxic than the parent compound, are adequately covered in the derived toxicological reference dose and a validated HPLC-MS/MS method is available to analyse for them.

The Meeting agreed that while not all of these metabolites would occur in all tissues; these four metabolites (IN-N7B69, IN-J9Z38, IN-MLA84 and IN-MYX98) should be included in the residue definition for dietary intake estimation for animal commodities. The Meeting considered that if animal commodities were analysed only for cyantraniliprole, a conservative correction factor of 2 could be applied for the purpose of dietary intake estimation to account for these metabolites.

In plant commodities from treated crops, the metabolism studies indicated that cyantraniliprole was the major residue in rice, lettuce, cotton and tomato. In rotational crops, where residues are present, cyantraniliprole is also the main residue in food commodities. The Meeting noted that a multi-residue method exists to measure parent residues and agreed that for MRL-compliance, the residue definition for plant commodities should be cyantraniliprole.

The only metabolite identified in the plant metabolism studies at more than 10% TRR or greater than 0.01 mg/kg in commodities at harvest was IN-J9Z38, reported in leaves from foliar-treated rice (11% TRR and 0.13 mg/kg), rice straw from rice grown in treated soil (up to 18% TRR and 0.05 mg/kg) and in foliar-treated lettuce where residues of 23% TRR (0.01 mg/kg) were measured in mature leaves from seedling plants treated up to 32 days before sampling. The Meeting noted that in the supervised field trials, residues of IN-J9Z38 were also reported in some trials, but mostly < 0.01 mg/kg and rarely found at levels more than 10% of the cyantraniliprole residue.

In rotational crops, metabolite residues in food commodities did not exceed 0.01 mg/kg, with IN-J9Z38, IN-JZ38 and IN-MLA84 only present in animal feeds (cereal and legume forage, hays and straws) at up to 0.07 mg/kg.

In processed food commodities, metabolites IN-J9Z38 and to a lesser extent IN-N5M09 and IN-F6L99 were formed under conditions of heat and/or hydrolysis. In addition to cyantraniliprole, only IN-J9Z38 was observed at significant levels, being the predominant residue in cooked spinach, cottonseed oil and present at more than 50% of the parent levels in tomato paste, apple sauce and canned olives. IN-N5M09 and IN-F6L99 were only quantifiable in a few processed food commodities (e.g., cooked spinach, apple sauce) and were much lower than the levels of the parent compound and IN-J9Z38.

The main metabolite in some processed commodities (IN-J9Z38) was also observed in the animal metabolism studies and the toxicology of IN-J9Z38 is addressed in the rat studies and covered by the derived reference dose. Sufficient toxicological information is available to confirm that the IN-J9Z38 metabolite is no more toxic than cyantraniliprole and analytical methods are available to measure this metabolite.

The Meeting concluded that for dietary intake risk assessment, the residue definition for plant commodities should be cyantraniliprole but that for processed commodities, the IN-J9Z38 should also be included.

Proposed definition of the residue (for compliance with the MRL, animal and plant commodities): *cyantraniliprole*.

Proposed definition of the residue (for estimation of dietary intake for unprocessed plant commodities): *cyantraniliprole*.

Proposed definition of the residue (for estimation of dietary intake for processed plant commodities): *sum of cyantraniliprole and IN-J9Z38, expressed as cyantraniliprole*.

Proposed definition of the residue (for estimation of dietary intake for animal commodities: *sum of cyantraniliprole, 2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1H-pyrazol-5-yl]-3,4-dihydro-3,8-dimethyl-4-oxo-6-quinazolinecarbonitrile [IN-J9Z38], 2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1H-pyrazol-5-yl]-1,4-dihydro-8-methyl-4-oxo-6-quinazolinecarbonitrile [IN-MLA84], 3-Bromo-1-(3-chloro-2-pyridinyl)-N-[4-cyano-2-(hydroxymethyl)-6-[(methylamino)carbonyl]phenyl]-1H-pyrazole-*

5-carboxamide [IN- N7B69] and 3-Bromo-1-(3-chloro-2-pyridinyl)-N-[4-cyano-2[[hydroxymethyl]amino]carbonyl]-6-methylphenyl]-1H-pyrazole-5-carboxamide [IN- MYX98], expressed a cyantraniliprole.

The residue is not fat soluble.

Results of supervised residue trials on crops

The Meeting received supervised trial data for foliar and soil applications of cyantraniliprole on a range of fruit and vegetable crops, rice, tree nuts, oilseeds and coffee and for seed treatments (potatoes, oil-seed rape). These trials were conducted mainly in Europe and/or North America.

Where residues have been reported as ND (< LOD) the values have been considered as < LOQ (< 0.01 mg/kg) for the purposes of MRL setting. If a higher residue level was observed at a longer PHI than the GAP, the higher value has been used in MRL setting.

The Meeting noted that GAP has been authorised for the use of cyantraniliprole and that product labels were available from Canada, Columbia, New Zealand Malaysia, Vietnam and from a regional group of countries in West Africa. Supervised trial data were provided for citrus, grapes, olives, pomegranate, beans and sunflower, but no GAP information was available to support maximum residue level estimations for these commodities.

Pome fruits

The critical GAP for cyantraniliprole on pome fruit is in Canada, up to four foliar applications of 0.05–0.15 kg ai/ha applied at least 7 days apart with a PHI of 3 days and with a total of 0.45 kg ai/ha/season.

In trials on apples in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.06, 0.07, 0.1, 0.12, 0.13, 0.13, 0.15, 0.15, 0.16, 0.17, 0.18, 0.21, 0.26, 0.26, 0.29 and 0.31 mg/kg (n=16).

In trials on pears in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.08, 0.1, 0.12, 0.14, 0.16, 0.23, 0.42, 0.44, 0.56 and 0.58 mg/kg (n=10).

The Meeting noted that the GAP in Canada was for pome fruit and that the medians of the two data sets differed by less than 5-fold and agreed to consider a group maximum residue level. As the Mann-Whitney U-test indicated that the residue populations for apples and pears were not different it was agreed to combine the results to give a data set of: 0.06, 0.07, 0.08, 0.1, 0.1, 0.12, 0.12, 0.13, 0.13, 0.14, 0.15, 0.15, 0.16, 0.16, 0.17, 0.18, 0.21, 0.23, 0.26, 0.26, 0.29, 0.31, 0.42, 0.44, 0.56 and 0.58 mg/kg (n=26) for the pome fruit crop group.

The Meeting estimated an STMR of 0.16 mg/kg and a group maximum residue level of 0.8 mg/kg for cyantraniliprole on pome fruit.

Stone fruits

The critical GAP for cyantraniliprole on stone fruit is in Canada, up to four foliar applications of 0.05–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 7 days apart with a PHI of 3 days.

In trials on cherries in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues in whole fruit were: 0.3, 0.32, 0.7, 0.8, 0.89, 0.9 and 3.4 mg/kg (n=7). In flesh residues were: 0.33, 0.36, 0.89, 0.93, 0.96, 0.98 and 3.8 mg/kg (n=7).

In trials on peaches in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.16, 0.18, 0.19, 0.19, 0.23, 0.24, 0.28, 0.34, 0.39, 0.45, 0.51, 0.79 and 0.81 mg/kg. In flesh, residues were: 0.19, 0.19, 0.2, 0.23, 0.25, 0.27, 0.34, 0.35, 0.42, 0.49, 0.56, 0.89 and 0.94 mg/kg (n=13).

In trials on plums in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.03, 0.05, 0.06, 0.06, 0.06, 0.07, 0.12, 0.19 and 0.28 mg/kg. In flesh, residues were: 0.03, 0.05, 0.06, 0.06, 0.07, 0.07, 0.13, 0.2 and 0.29 mg/kg (n=9).

The Meeting noted that the GAP in Canada was for stone fruit and that the medians of the data sets for cherries, peaches and plums differed more than 5-fold and agreed not to consider a group maximum residue level for stone fruit.

The Meeting estimated an STMR of 0.93 mg/kg (based on residues in flesh), and based on residues in the whole fruit, estimated a subgroup maximum residue level of 6 mg/kg for cyantraniliprole on cherries.

The Meeting estimated an STMR of 0.34 mg/kg (based on residues in flesh, and based on residues in the whole fruit, estimated a subgroup maximum residue level of 1.5 mg/kg for cyantraniliprole on peaches.

The Meeting estimated an STMR of 0.07 mg/kg (based on residues in flesh) and based on residues in the whole fruit, estimated a subgroup maximum residue level of 0.5 mg/kg for cyantraniliprole on plums.

Bush berries

The critical GAP for cyantraniliprole on bush berries is in Canada, up to four foliar applications of 0.05–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 7 days apart with a PHI of 3 days.

In trials on blueberries in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.42, 0.51, 0.52, 0.52, 0.75, 0.8, 1.5, 1.5 and 2.0 mg/kg (n=9).

The Meeting noted that blueberry can be used as a representative crop for bush berries and estimated an STMR of 0.75 mg/kg and a subgroup maximum residue level of 4.0 mg/kg for cyantraniliprole on bush berries.

Bulb vegetables

The critical GAP for cyantraniliprole on bulb vegetables is in Canada, up to four foliar applications of 0.1–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5 days apart with a PHI of 1 day.

In trials on bulb onions in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: < 0.01, < 0.01, < 0.01, < 0.01, 0.01, 0.02, 0.02, 0.02, 0.02 and 0.03 mg/kg (n=10).

The Meeting noted that the GAP in Canada also includes use on garlic and shallot and agreed to extrapolate the data for bulb onions to these commodities.

The Meeting estimated an STMR of 0.02 mg/kg and a maximum residue level of 0.05 mg/kg for cyantraniliprole on onion, bulb, garlic and shallot.

In trials on spring onions (green onions) in North America matching the Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.38, 0.63, 1.3, 1.6 and 4.1 mg/kg (n=5).

The Meeting noted that the GAP in Canada also includes use Welsh onion and agreed to extrapolate the data for spring onions to onion, Welsh.

The Meeting estimated an STMR of 1.3 mg/kg and a maximum residue level of 8.0 mg/kg for cyantraniliprole on spring onion and onion, Welsh.

Brassica (cole or cabbage) vegetables

The critical GAP for cyantraniliprole on brassica vegetables is in Canada, up to four foliar applications of 0.025–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5–7 days apart with a PHI of 1 day.

In trials on broccoli in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.22, 0.28, 0.51, 0.59, 0.61, 0.69, 0.82 and 1.1 mg/kg (n=8).

In trials on cauliflowers in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues in the flower heads were: 0.01 and 0.08 mg/kg (n=2).

In trials on head cabbage in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues in cabbages (with wrapper leaves) were: 0.29, 0.32, 0.32, 0.42, 0.47, 0.56, 0.57, 0.65, 0.71, 0.86 and 0.95 mg/kg (n=11).

The Meeting noted that the GAP in Canada was for brassica vegetables and that the medians of the data sets for broccoli and cabbage differed by less than 5-fold (insufficient data on cauliflower) and agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, since a Mann-Whitney U-test indicated that the residue populations for broccoli and cabbage were not different, it was agreed to combine the results to give a data set of: 0.01, 0.08, 0.22, 0.28, 0.29, 0.32, 0.32, 0.42, 0.47, 0.51, 0.56, 0.57, 0.59, 0.61, 0.65, 0.69, 0.71, 0.82, 0.86, 0.95 and 1.1 mg/kg (n=21) for brassica vegetables.

The Meeting estimated an STMR of 0.56 mg/kg and a group maximum residue level of 2.0 mg/kg for cyantraniliprole on brassica (cole or cabbage) vegetables. The Meeting also estimated a highest residue of 1.1 mg/kg for calculating animal dietary burdens.

Fruiting vegetables, Cucurbits

The critical GAP for cyantraniliprole on cucurbit vegetables is in Canada, up to four foliar applications of 0.025–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5–7 days apart with a PHI of 1 day.

In trials on cucumber in North America matching the GAP of Canada (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.02, 0.02, 0.02, 0.03, 0.04, 0.05, 0.05, 0.07, 0.12 and 0.16 mg/kg (n=10).

In trials on summer squash in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.01, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09 and 0.11 mg/kg (n=9).

In trials on melons in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.04, 0.05, 0.08, 0.09, 0.09, 0.1, 0.11, 0.15 and 0.17 mg/kg (n=9). In these trials, cyantraniliprole residues in the melon edible portion were all < 0.01 (n=9).

The Meeting noted that the GAP in Canada was for cucurbit vegetables and that the medians of the data sets for cucumber, summer squash and melons differed by less than 5-fold and agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, since a Kruskal-Wallis H-test indicated that the residue populations for cucumber, summer squash and melons were not different, it was agreed to combine the results to give a data set of: 0.01, 0.02, 0.02, 0.02, 0.03, 0.03, 0.04, 0.04, 0.04, 0.05, 0.05, 0.05, 0.05, 0.06, 0.07, 0.07, 0.08, 0.08, 0.09, 0.09, 0.09, 0.1, 0.11, 0.11, 0.12, 0.15, 0.16 and 0.17 mg/kg (n=28) for cucurbit vegetables.

The Meeting estimated an STMR of 0.01 mg/kg for cucurbits with an inedible peel (based on the melon data on residues in flesh), an STMR of 0.065 mg/kg (based on the summer squash data) for

cucurbits with an edible peel and a group maximum residue level of 0.3 mg/kg for cyantraniliprole on fruiting vegetables, Cucurbits.

Fruiting vegetables, other than Cucurbits

The critical GAP for cyantraniliprole on fruiting vegetables (except cucurbits) is in Canada, up to four foliar applications of 0.025–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5–7 days apart with a PHI of 1 day.

In trials on tomatoes in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.04, 0.05, 0.06, 0.06, 0.07, 0.07, 0.07, 0.07, 0.08, 0.08, 0.08, 0.09, 0.09, 0.1, 0.12, 0.14, 0.14, 0.16, 0.17 and 0.26 mg/kg (n=20).

In trials on sweet peppers in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.03, 0.04, 0.06, 0.07, 0.07, 0.08, 0.08, 0.15, 0.21, 0.24 and 0.28 mg/kg (n=11).

In trials on chilli peppers (non-bell peppers) in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.07, 0.07, 0.08, 0.09, 0.1, 0.2, 0.25, 0.31 and 0.42 mg/kg (n=9).

The Meeting noted that the GAP in Canada was for fruiting vegetables (except cucurbits) and that the medians of the data sets for sweet peppers, tomatoes and chilli peppers differed by less than 5-fold and agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, since a Kruskal-Wallis H-test indicated that the residue populations for sweet peppers, tomatoes and chili peppers were not different, it was agreed to combine the results to give a data set of: 0.03, 0.04, 0.04, 0.05, 0.06, 0.06, 0.06, 0.07, 0.07, 0.07, 0.07, 0.07, 0.07, 0.07, 0.08, 0.08, 0.08, 0.08, 0.08, 0.08, 0.09, 0.09, 0.09, 0.1, 0.1, 0.12, 0.14, 0.14, 0.15, 0.16, 0.17, 0.2, 0.21, 0.24, 0.25, 0.26, 0.28, 0.31 and 0.42 mg/kg (n=40) for the non-cucurbit fruiting vegetables group.

The Meeting estimated an STMR of 0.08 mg/kg and a group maximum residue level of 0.5 mg/kg for cyantraniliprole on fruiting vegetables, other than Cucurbits (excluding sweet corn and mushrooms).

For dried chilli peppers, applying the default processing factor of 7 to the data set for fresh chilli peppers, the Meeting estimated an STMR-P of 0.7 mg/kg and a maximum residue level of 5 mg/kg for cyantraniliprole on dried chilli peppers.

Leafy vegetables (including Brassica leafy vegetables)

The critical GAP for cyantraniliprole on leafy vegetables is in Canada, up to four foliar applications of 0.025–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5–7 days apart with a PHI of 1 day.

In trials on head lettuce in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 0.02, 0.08, 0.16, 0.18, 0.64, 0.75, 0.83, 1.3, 1.6, 1.8, 2.1 and 2.7 mg/kg (n=12).

In trials on leaf lettuce in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 1.1, 1.2, 2.1, 2.4, 2.4, 2.5, 3.2, 3.3, 4.0, 5.3, 6.8 and 6.8 mg/kg (n=12).

In trials on spinach in North America matching the critical Canadian GAP (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 3.8, 4.1, 4.2, 4.6, 4.7, 4.9, 5.8, 8.2, 10 and 13 mg/kg (n=10).

In trials on mustard greens in North America matching the critical Canadian GAP for vegetable brassicas (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: 2.4, 3.4, 3.9, 5.5, 5.8, 6.0, 7.1, 7.2, 8.0, 13 and 19 mg/kg (n=11).

The Meeting noted that the GAP in Canada was for leafy vegetables and that the medians of the data sets for leaf lettuce, spinach and mustard greens (but not head lettuce) differed by less than 5-fold and agreed to consider a group maximum residue level for leafy vegetables except head lettuce. In deciding on the data set to use for estimating a group maximum residue level, since a Kruskal-Wallis H-test indicated that the residue populations for leaf lettuce, spinach and mustard greens were not different it was agreed to combine the results to give a data set of: 1.1, 1.2, 2.1, 2.4, 2.4, 2.4, 2.5, 3.2, 3.3, 3.4, 3.8, 3.9, 4.0, 4.1, 4.2, 4.6, 4.7, 4.9, 5.3, 5.5, 5.8, 5.8, 6.0, 6.8, 6.8, 7.1, 7.2, 8.0, 8.2, 10, 13, 13 and 19 mg/kg for leafy vegetables (n=33) except head lettuce and to use the head lettuce data to estimate a maximum residue level for head lettuce.

The Meeting estimated an STMR of 4.7 mg/kg and a group maximum residue level of 20 mg/kg for cyantraniliprole on leafy vegetables (except head lettuce).

The Meeting estimated an STMR of 0.79 mg/kg and a maximum residue level of 5 mg/kg for cyantraniliprole on head lettuce.

Root and tuber vegetables

The critical GAP for cyantraniliprole on root and tuber vegetables is in Canada, up to four foliar applications of 0.05–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5–14 days apart with a PHI of 7 days.

In trials on potatoes in North America matching the critical Canadian GAP for foliar applications to root and tuber vegetables (with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season), cyantraniliprole residues were: < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, 0.01, 0.02, 0.02 and 0.03 mg/kg (n=20).

The Meeting also noted that residues of cyantraniliprole may also arise in potatoes planted as rotational crops, and agreed to consider maximum residue level recommendations for potatoes when discussing rotational crop residues.

Stalk and stem vegetables

The critical GAP for cyantraniliprole on celery is in Canada, up to four foliar applications of 0.025–0.15 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 5–7 days apart with a PHI of 1 day.

In trials on celery in North America matching the critical Canadian GAP for leafy vegetables (including celery), with three applications of 0.15 kg ai/ha, 0.45 kg ai/ha/season, cyantraniliprole residues were: 0.28, 0.73, 1.0, 1.1, 1.2, 2.0, 2.3, 2.5, 4.7, 5.7 and 9.1 mg/kg (n=11).

The Meeting estimated an STMR of 2.0 mg/kg and a maximum residue level of 15 mg/kg for cyantraniliprole on celery.

Rice

The critical GAP for cyantraniliprole on rice is in Vietnam, for foliar applications of 0.05–0.1 kg ai/ha with a PHI of 5 days.

Results were available from six trials on rice in China where three foliar applications of cyantraniliprole were applied up to 7 days before harvest.

The Meeting agreed that these data did not match the GAP in Vietnam in that the PHI deviated from GAP by more than 25%.

Tree nuts

The critical GAP for cyantraniliprole on tree nuts is in Canada, up to four foliar applications of 0.05–0.1 kg ai/ha with a total of 0.45 kg ai/ha/season, applied at least 7 days apart with a PHI of 5 days.

In six trials on almonds in the USA, 3 foliar sprays of 0.15 kg ai/ha (0.45 kg ai/ha/season) were applied at 6–8 day intervals up to 5 days before harvest.

In six trials on pecans in the USA, 3 foliar sprays of 0.15 kg ai/ha (0.45 kg ai/ha/season) were applied at 6–8 day intervals up to 5 days before harvest.

The Meeting noted that since both the number of applications and the treatment rates in the trials for almonds and pecans did not match the Canadian GAP, the use of the proportionality approach to estimate maximum residue levels was not appropriate.

Oilseeds

The critical GAP for cyantraniliprole on cotton is in the region of West Africa, up to three foliar applications of 0.05 kg ai/ha with a total of 0.15 kg ai/ha/season, applied at least 14 days apart with a PHI of 7 days.

Results were available from trials conducted in the USA on cotton, where three foliar applications of 0.15 kg ai/ha cyantraniliprole were applied at 6–8 day intervals up to 7–9 days before harvest.

The Meeting noted that the application rates used in the USA trials were higher and the retreatment intervals were shorter than the GAP in West Africa and the Meeting agreed that the concept of proportionality could not be used to recommend a maximum residue level for cyantraniliprole on cotton seed.

The critical GAP for cyantraniliprole on oil seed crops (excluding cotton and peanut) is in Canada, up to 4 foliar applications of 0.025–0.1 kg ai/ha with a total of 0.11 kg ai/ha/season, applied at least 7 days apart with a PHI of 7 days.

Results were available from trials on oilseed rape and on sunflower in North America, where three foliar sprays of 0.15 kg ai/ha (0.45 kg ai/ha/season) were applied at 5–9 day intervals up to 7 days before harvest.

The Meeting noted that for both oilseed rape and sunflower, in addition to the application rate in the field trials differing from the Canadian GAP, the lower seasonal application rate associated with the Canadian GAP supports only a single application of the maximum recommended application rate of 0.1 kg ai/ha, compared to the three applications used in the field trials.

The Meeting concluded that these trials did not match the Canadian GAP.

Seed for beverages and sweets

The critical GAP for cyantraniliprole on coffee is in Columbia, one foliar application of 2.5–3.5 g ai/5 L/100 trees, equivalent to 0.125–0.175 kg ai/ha with a total of 0.3 kg ai/ha/season, with a PHI of 28 days.

In two Brazilian trials matching the Columbian GAP, cyantraniliprole residues were < 0.01 and 0.02 mg/kg.

The Meeting noted that in a further six trials in Brazil involving foliar applications that matched the Columbian GAP but where two soil drenches (0.01–0.06 g ai/100 mL/plant to achieve the equivalent of 0.2 kg ai/ha/treatment) were also applied approximately 90 and approximately 120 days before harvest, cyantraniliprole residues were < 0.01 (5) and 0.01 mg/kg.

The Meeting agreed that since the early season soil drench treatments did not appear to contribute to the final residue in coffee beans, the data from these two sets of results could be combined, giving a data set of: < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, 0.01 and 0.02 mg/kg, to recommend a maximum residue level for cyantraniliprole on coffee beans.

The Meeting estimated an STMR of 0.01 mg/kg and a maximum residue level of 0.03 mg/kg for cyantraniliprole on coffee bean.

Estimation of residues in plant commodities grown as potential succeeding crops

Residues of cyantraniliprole, while not persistent, can be taken up by following crops. In Canada, the GAP includes a maximum seasonal foliar application rate of 0.45 kg ai/ha for most crops except oil seeds where the maximum seasonal rate is 0.11 kg ai/ha. In Columbia, the maximum seasonal rate for onions and Welsh onions is 0.3 kg ai/ha and in West Africa, the total seasonal rate on cotton is 0.15 kg ai/ha.

In Canada, recommended plant-back intervals (PBIs) have been established for crops likely to be grown in rotation with treated crops. In general, for annual crops for human consumption and where MRLs have been established, there is no plant-back interval specified, but for crops likely to be used as animal feed (cereals, grasses, legumes etc) the label recommends a 30-day plant-back interval.

Field rotational crop studies conducted in the USA on a range of representative crops, involving treatment rates equivalent a 0.45 kg ai/ha maximum seasonal rate to bare soil, reported cyantraniliprole residues of less than 0.05 mg/kg in representative food commodities and higher residues in animal feed commodities.

The Meeting agreed that the results of the USA field rotational crop studies, in particular the cyantraniliprole residues reported from the 30 day PBI crops, could be used to estimate residues in follow crops.

Leafy vegetables (including Brassica leafy vegetables)

Highest cyantraniliprole residues in rotational leafy vegetables were < 0.01 mg/kg in spinach and beet tops, 0.02 mg/kg in lettuce and turnip tops and 0.04 mg/kg in radish tops. These levels are adequately covered by the recommendations for leafy vegetables.

Root and tuber vegetables

Cyantraniliprole residues in rotational root and tuber vegetables ranged from < 0.01 to 0.014 mg/kg (n=29, median < 0.01 mg/kg) in beet roots, turnip roots, carrot roots and radish roots.

The Meeting agreed to use the data from 20 field trials on potatoes in North America, treated according to the Canadian GAP for root and tuber vegetables (residues in tubers ranging from < 0.01 to 0.03 mg/kg, STMR 0.01 mg/kg, n=20) and the results of the rotational crop studies on root and tuber vegetables to recommend a group maximum residue level for potatoes (to accommodate residues in follow-crop potatoes that may also be treated with cyantraniliprole).

The Meeting established a maximum residue level of 0.05 mg/kg, a highest residue of 0.044 mg/kg (for estimating animal dietary burdens) and a median residue of 0.02 mg/kg for cyantraniliprole on potato.

The Meeting also agreed to use the rotational crop studies on root and tuber vegetables to recommend a group maximum residue level for the remaining root and tuber vegetables to accommodate residues in these crops grown as follow-crops.

The Meeting established a maximum residue level of 0.05 mg/kg, a highest residue of 0.014 mg/kg and a median residue of 0.01 mg/kg for cyantraniliprole on root and tuber vegetables except potato.

Miscellaneous fodder root crops

The Meeting also agreed to use the results of the rotational crop studies on root and tuber vegetables (residues ranging from < 0.01 to 0.014 mg/kg, median < 0.01 mg/kg, n=29) to recommend maximum residue levels for turnips and fodder beet to accommodate residues in these crops grown as follow-crops.

The Meeting established a maximum residue level of 0.02 mg/kg, a highest residue of 0.014 mg/kg and a median residue of 0.01 mg/kg for cyantraniliprole on fodder beet and turnip fodder.

Legume animal feeds

Cyantraniliprole residues in legume animal feeds (forage) ranged from < 0.01 to 0.14 mg/kg (n=24, median < 0.01 mg/kg) in clover forage, bean forage, pea forage, alfalfa forage and soya bean forage. For the purpose of estimating livestock dietary burdens, the Meeting agreed to combine the data on rotational crop residues in legume animal feeds to estimate residues in legume feed crops grown as follow-crops.

Meeting estimated a median residue of 0.01 mg/kg and a highest residue of 0.14 mg/kg for cyantraniliprole in legume forages (fresh weight).

Cyantraniliprole residues in legume animal feeds (fodders) ranged from < 0.01 to 0.58 mg/kg (n=24, median 0.017 mg/kg) in peanut hay, clover hay, pea hay, bean, alfalfa hay and soya bean hay. The Meeting agreed to combine the data on rotational crop residues in legume fodder crops to recommend a group maximum residue level to accommodate residues in these crops grown as follow-crops.

The Meeting established a median residue of 0.017 mg/kg and a highest residue of 0.58 mg/kg (0.67 mg/kg DM after correction for an average dry matter content of 87%) and recommended a maximum residue level of 0.8 mg/kg (dry weight) for cyantraniliprole in legume animal feeds.

Cereal and grass forages, straws and hays

Cyantraniliprole residues in cereal and grass forage ranged from < 0.01 to 0.053 mg/kg (n=23, median < 0.01 mg/kg) in corn forage, sorghum, Bermuda grass and brome grass forages, oat forage, bluegrass forage and wheat forage. For the purpose of estimating livestock dietary burdens, the Meeting agreed to combine the data on rotational crop residues in cereal and grass forages to estimate residues in cereal and grasses grown as follow-crops.

Meeting established an STMR of 0.01 mg/kg and a highest residue of 0.053 mg/kg for cyantraniliprole in cereal and grass forages (fresh weight).

Cyantraniliprole residues in cereal and grass straws and hays ranged from < 0.01 to 0.14 mg/kg (median < 0.01 mg/kg) in sorghum stover, rice straw, corn stover, brome grass hay, Bermuda grass hay, oat straw, wheat straw, oat hay, wheat hay bluegrass hay. The Meeting agreed to combine the data on rotational crop residues in cereal and grass straws and hays to recommend a group maximum residue level to accommodate residues in these crops grown as follow-crops.

The Meeting established a median residue of 0.01 mg/kg and a highest residue of 0.14 mg/kg (0.16 mg/kg DM after correction for an average dry matter content of 89%) and recommended a maximum residue level of 0.2 mg/kg (dry weight) for cyantraniliprole in straw, fodder (dry) and hay of cereal grains and other grass-like plants.

Miscellaneous fodder leaf crops

The Meeting agreed to use the results of the rotational crop studies on beet, turnip and radish tops (residues ranging from < 0.01 to 0.021 mg/kg (n=22, median < 0.01 mg/kg)) to estimate residues in fodder beet tops and the miscellaneous fodder leaf crops listed in the OECD Feedstuffs Table to accommodate residues in these commodities grown as follow-crops.

The Meeting established median residue of 0.01 mg/kg and a highest residue of 0.021 mg/kg for cyantraniliprole on sugar beet tops, fodder beet tops or leaves, kale forage, rape greens and turnip tops (fresh weight).

Fate of residues during processing

The effect of processing on the nature of residues was investigated in buffer solutions under conditions simulating pasteurisation, boiling and sterilisation. Cyantraniliprole was stable under most processing conditions. Hydrolysis to IN-J9Z38 was a significant pathway under sterilisation

conditions (20 minutes at 120 °C and pH 6) making up 12–14% AR. Other degradates present were IN-F6L99 and IN-N5M09 making up a further 5–8% AR.

The fate of cyantraniliprole residues has been examined in a number of studies simulating household and commercial processing of potatoes, spinach, tomatoes, oranges, apples, plums, cottonseed, olives and grapes. Estimated processing factors and STMR-Ps for the commodities considered at this Meeting are summarized below.

Summary of selected processing factors and STMR-P values for cyantraniliprole

RAC	Commodity (RAC: STMR mg/kg ^b)	Cyantraniliprole+IN-J9Z38 ^a			
		Processing factors	PF best estimate	RAC STMR (mg/kg)	STMR-P (mg/kg)
Potato	RAC: tubers			0.02	
	flakes	0.1	0.1		0.002
	waste	0.1	0.1		0.002
	peeled tubers	0.1	0.1		0.002
	chips	0.1	0.1		0.002
	wet peel	2.3	2.3		0.046 hi-res 0.1 ^c
	culls	1.0	1.0		0.02
	fries	0.1	0.1		0.002
	unpeeled, boiled	0.1	0.1		0.002
	unpeeled microwaved	< 0.33	< 0.33		0.006
Spinach	RAC: leaves			4.7	
	cooked leaves	0.81, 1.0, 1.2	1.0		4.7
Tomato	RAC: fruit (0.08 mg/kg)				
	washed	0.15, 0.17, < 0.29	0.17		0.014
	peeled	< 0.08, < 0.08, 0.1	< 0.08		0.006
	sun-dried	3.0, 3.7, 3.8	3.7		0.3
	canned	< 0.02, < 0.05, < 0.08	< 0.05		0.004
	juice	< 0.15, < 0.17, 0.19	< 0.17		0.014
	wet pomace	0.75, 1.0, 2.2	1.0		0.08
	dry pomace	1.7, 3.2, 4.0	3.2		0.26
	paste	0.62, 0.86, 1.0	0.86		0.07
	puree	0.23, 0.25, 0.43	0.25		0.02
Apple	RAC: fruit			0.16	
	washed	0.46, 0.58, 0.63	0.58		0.09
	puree	0.88, 1.0, 1.3	1.0		0.16
	canned	0.04, 0.13, 0.15	0.13		0.02
	frozen	0.62, 0.96, 1.5	0.96		0.15
	juice	0.19, 0.31, 0.38	0.31		0.05
	wet pomace	0.77, 1.0, 1.2	1.0		0.16
	dry pomace	2.0, 2.7, 3.9	2.7		0.43
	sauce	2.2, 2.4, 2.7	2.2		0.35
Plum	RAC: flesh			0.34	
	dried prunes	1.3, 1.6, 2.0	1.6		0.54

^a Each PF value represents a separate study where residues were above the LOQ in the RAC and is the ratio of the combined cyantraniliprole+IN-J9Z38 metabolite residues in the processed item divided by the combined residues of cyantraniliprole+IN-J9Z38 in the RAC.

^b Residues in the RAC are the sum of cyantraniliprole and IN-J9Z38

^c Based on the highest residue in the RAC (0.044 mg/kg)

The Meeting noted that in the studies available, cyantraniliprole residues did not concentrate in food commodities during processing except in apple sauce and in dehydrated commodities such as dried prunes and sun-dried tomatoes. Residues also concentrated in dry pomace (apple and tomato).

In three plum processing studies conducted in the USA, cyantraniliprole residues increased (median processing factor of 1.5) when fresh prunes (flesh) were dried to a moisture content of 15–18% (from about 85% in fresh fruit).

The Meeting estimated a maximum residue level for prunes of 0.8 mg/kg based on the maximum residue level estimated for plums of 0.5 mg/kg and a median processing factor of 1.6.

Residues in animal commodities

Farm animal dietary burden

The Meeting estimated the dietary burden of cyantraniliprole in farm animals on the basis of the diets listed in Annex 6 of the 2009 JMPR Report (OECD Feedstuffs Derived from Field Crops). Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6 and are summarized below.

Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden, cyantraniliprole, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.41	0.19	1.9 ^a	0.98 ^c	0.68	0.13	0.13	0.004
Dairy cattle	0.44	0.1	1.9 ^b	0.95 ^d	0.67	0.11	0.29	0.02
Poultry-broiler	0.0	0.0	0.05 ^e	0.02 ^f	0.0	0.0	0.0	0.0
Poultry-layer	0.0	0.0	0.37 ^g	0.19 ^h	0.0	0.0	0.0	0.0

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues

^b Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

^c Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues.

^f Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues.

^g Highest maximum poultry dietary burden suitable for MRL estimates for poultry eggs.

^h Highest mean poultry dietary burden suitable for STMR estimates for poultry eggs.

For beef and dairy cattle, the calculated maximum dietary burden suitable for estimating maximum residue levels in mammalian tissues and milk is 1.9 ppm dry weight of feed and the calculated mean dietary burdens, suitable for estimating STMRs in mammalian tissues and in milk are 0.98 ppm and 0.95 ppm dry weight of feed respectively.

For poultry, noting that in some countries, laying hens may also be consumed, the calculated maximum dietary burden suitable for estimating maximum residue levels in poultry tissues and eggs is 0.37 ppm dry weight of feed and the calculated mean dietary burden, suitable for estimating STMRs in poultry tissues and in eggs is 0.19 ppm dry weight of feed.

Farm animal feeding studies

The Meeting received information on the residue levels arising in animal tissues and milk when dairy cows were dosed with cyantraniliprole for 28 days at the equivalent of 3.5, 12, 35 and 112 ppm in the diet. A separate dose group (112 ppm) was used to estimate residue depuration of cyantraniliprole and its major metabolites.

In milk, residues reached a plateau after about 5 days. Average residues of cyantraniliprole were 0.03 mg/kg in the 3.5 ppm dose group and increased to 0.7 mg/kg in the highest dose group (112 ppm). In skim milk, cyantraniliprole residues were about 60% of the whole milk levels (0.016 mg/kg up to 0.47 mg/kg) and 0.066 mg/kg up to 1.8 mg/kg in cream. Residues of IN-N7B69, the predominant metabolite in milk, increased from 0.03 mg/kg to 0.28 mg/kg over the four dose groups while residues of the other metabolites (IN-MLA84, IN-J9Z38 and IN-MYX98) were present at levels at least ten-fold lower than parent.

In muscle, maximum residues of cyantraniliprole increased from 0.01 mg/kg to 0.33 mg/kg in the four dose groups, with IN-J9Z38 being the predominant metabolite, found at more than

0.01 mg/kg only in the two highest dose groups (up to 0.04 mg/kg). Other metabolites were $\leq$ 0.01 mg/kg at all dose levels.

In fat, maximum residues of cyantraniliprole increased from 0.015 mg/kg to 0.58 mg/kg in the four dose groups, with IN-J9Z38 being the predominant metabolite, found at 0.012 mg/kg (low dose) up to 0.45 mg/kg (highest dose). Other metabolites were found at lower levels, more than 5-fold lower than parent and only IN-N7B69 was present at more than 0.01 mg/kg, found at 0.02 mg/kg in the highest dose group.

In kidney, maximum residues of cyantraniliprole increased from 0.03 mg/kg to 0.89 mg/kg in the four dose groups, with IN-N7B69 being the predominant metabolite, found at 0.012 mg/kg (low dose) up to 0.15 mg/kg (highest dose). Other metabolites were found at levels more than 5-fold lower than parent, with residues of IN-J9Z38 and IN-MYX98 present above 0.01 mg/kg only in the two higher dose groups.

In liver, maximum residues of cyantraniliprole increased from 0.066 mg/kg to 2.1 mg/kg in the four dose groups, with IN-MLA84 being the predominant metabolite, present at 0.04 mg/kg in the lowest dose group and up to 0.57 mg/kg in the highest dose group. Metabolite IN-N7B69 residues were up to 0.01 mg/kg in the lowest dose group, increasing to 0.08 mg/kg in the highest dose group and other metabolites were all $<$ 0.01 mg/kg except in the highest dose group where levels of $<$ 0.03 mg/kg were found.

Residue depletion was studied in cows dosed orally for 28 days with the equivalent of 112 ppm cyantraniliprole. Parent residues depleted to $<$ 0.01 mg/kg in muscle within 4 days after the last dose, were $<$ 0.01 mg/kg in milk, liver and kidney within 10 days and $<$ 0.01 mg/kg in fat within 15 days. Metabolites were all $<$ 0.01 mg/kg in all matrices after 4 days except IN-J9Z38 ($<$ 0.01 within 10 days in kidney and 15 days in fat), IN-MLA84 ($<$ 0.01 mg/kg within 10 days in liver) and IN-N7B69 ($<$ 0.01 mg/kg within 10 days in kidney).

The Meeting also received information on the residues in tissues and eggs when laying hens were dosed with cyantraniliprole for 28 days at levels equivalent to 3, 10 and 30 ppm in the diet. A separate dose group (30 ppm) was used to estimate residue depuration of cyantraniliprole and its major metabolites.

In eggs, residues reached a plateau after about 3 days. Average residues of cyantraniliprole were 0.08 mg/kg in the 3 ppm dose group and increased to 0.8 mg/kg in the highest dose group (30 ppm). In egg whites, cyantraniliprole was the predominant residue, averaging 0.08 mg/kg in the low dose group up to 0.64 mg/kg in the high dose group. Lower levels of parent were found in egg yolks, averaging 0.015 mg/kg (low dose) up to 0.1 mg/kg (high dose). Residues of IN-J9Z38, the predominant metabolite in eggs, present at levels of about 50% of parent, increased from 0.04 mg/kg to 0.4 mg/kg over the three dose groups while residues of IN-MLA84 and IN-MYX98 were present at levels of 0.015 mg/kg in the low dose group up to 0.12 in the high dose group. In general, residues of these metabolites were about 2-fold higher in egg whites than in the yolks.

In muscle, maximum residues of cyantraniliprole increased from 0.003 mg/kg to 0.05 mg/kg in the three dose groups, with the only metabolites found at more than 0.01 mg/kg being IN-MYX98 and IN-HGW87 (up to 0.02 mg/kg in the highest dose group. Other metabolites were all $\leq$ 0.01 mg/kg at all dose levels.

In skin + fat, maximum residues of cyantraniliprole increased from 0.014 mg/kg to 0.16 mg/kg in the three dose groups, with IN-MYX98 being the predominant metabolite, found at 0.005 mg/kg (low dose) up to 0.05 mg/kg (highest dose). Other metabolites were found at lower levels, with IN-J9Z38 and IN-HGW87 present at more than 0.01 mg/kg only in the highest dose group (0.021 mg/kg and 0.023 mg/kg respectively).

In liver, maximum residues of cyantraniliprole increased from 0.03 mg/kg to 0.24 mg/kg in the three dose groups. Metabolite IN-MLA84 was present at levels similar to the parent (0.034 mg/kg in the lowest dose group and up to 0.32 mg/kg in the highest dose group). Maximum IN-MLA84, IN-

HGW87 and IN-N7B69 residues were 0.01–0.02 mg/kg in the lowest dose group and 0.07–0.1 mg/kg in the highest dose group. Other metabolites were all < 0.01 mg/kg in all dose groups.

In the residue depuration dose group (30 ppm), residues depleted to < 0.01 mg/kg in all matrices within 5 days of the last dose (within 9 days in liver, when the first sample was taken).

Animal commodity maximum residue levels

The maximum dietary burden for beef and dairy cattle is 1.9 ppm. The mean dietary burdens are 0.98 ppm (beef cattle) and 0.95 ppm (dairy cattle). Residue levels of cyantraniliprole and the metabolites included in the residue definition in milk and tissues were obtained by extrapolation below the 3.5 ppm feeding level in the dairy cow feeding study.

Cyantraniliprole feeding study	Feed level (ppm) for milk residues	Residues (mg/kg) in milk	Feed level (ppm) for tissue residues	Residues ^a (mg/kg) in			
				Muscle	Liver	Kidney	Fat
MRL beef or dairy cattle							
Feeding study ^b	3.5	0.03	3.5	0.011	0.066	0.031	0.015
Dietary burden and high residue	1.9	0.016	1.9	0.006	0.036	0.017	0.008
STMR beef or dairy cattle							
Feeding study ^c	3.5	0.03	3.5	0.008	0.094	0.042	0.024
Dietary burden and residue estimate	0.95	0.016	0.98	0.002	0.026	0.012	0.007

^a Residue values used in estimating STMRs are the sum of cyantraniliprole and metabolites IN-N7B69, IN-J9Z38, IN-MLA84 and IN-MYX98, expressed as cyantraniliprole

^b highest residues for tissues and mean residues for milk

^c mean residues for tissues and mean residues for milk

Residues of cyantraniliprole expected in cattle milk and tissues for use in estimating maximum residue levels are: 0.008 mg/kg (fat), 0.006 mg/kg (muscle), 0.036 mg/kg (liver) and 0.017 mg/kg (kidney) and the mean residue for milk is 0.016 mg/kg.

The Meeting estimated maximum residue levels of 0.01 mg/kg for cyantraniliprole in meat (from mammals other than marine mammals), 0.05 mg/kg for edible offal (mammalian), 0.01 mg/kg for mammalian fat and 0.02 mg/kg for milks. Estimated STMRs (parent plus metabolites) for dietary intake estimation are 0.002 mg/kg for meat, 0.026 mg/kg for edible offal, 0.007 mg/kg for fat and 0.016 mg/kg for milk.

For poultry, the maximum dietary burden is 0.37 ppm and the mean dietary burden is 0.19 ppm (based on the diet for laying hens). Residue levels of cyantraniliprole and the metabolites included in the residue definition in eggs and tissues were obtained by extrapolation below the 3.0 ppm feeding level in the dairy cow feeding study.

Cyantraniliprole feeding study	Feed level (ppm) for egg residues	Residues (mg/kg) in egg	Feed level (ppm) for tissue residues	Residues ^a (mg/kg) in			
				Muscle	Liver	Skin	Fat

^a Residue values used in estimating STMRs are the sum of cyantraniliprole and metabolites IN-N7B69, IN-J9Z38, IN-MLA84 and IN-MYX98, expressed as cyantraniliprole

^b highest residues for tissues and mean residues for egg

^c mean residues for tissues and mean residues for egg

Residues of cyantraniliprole expected in eggs and poultry tissues for use in estimating maximum residue levels are: 0.002 mg/kg (skin plus fat), 0.0007 mg/kg (muscle), 0.004 mg/kg (liver) and the mean residue for eggs is 0.01 mg/kg.

The Meeting estimated maximum residue levels of 0.01 mg/kg for cyantraniliprole in poultry meat, 0.01 mg/kg for poultry offal, 0.01 mg/kg for poultry fat and 0.015 mg/kg for eggs. Estimated STMRS for dietary intake estimation are 0 mg/kg for poultry fat, 0 mg/kg for poultry meat, 0.004 mg/kg for poultry offal and 0.01 mg/kg for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for compliance with the MRL, animal and plant commodities): *cyantraniliprole*.

Definition of the residue (for estimation of dietary intake for unprocessed plant commodities): *cyantraniliprole*.

Definition of the residue (for estimation of dietary intake for processed plant commodities): *sum of cyantraniliprole and 2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1H-pyrazol-5-yl]-3,4-dihydro-3,8-dimethyl-4-oxo-6-quinazolinecarbonitrile*.

Proposed definition of the residue (for estimation of dietary intake for animal commodities): *sum of: cyantraniliprole, 2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1H-pyrazol-5-yl]-3,4-dihydro-3,8-dimethyl-4-oxo-6-quinazolinecarbonitrile, 2-[3-Bromo-1-(3-chloro-2-pyridinyl)-1H-pyrazol-5-yl]-1,4-dihydro-8-methyl-4-oxo-6-quinazolinecarbonitrile, 3-Bromo-1-(3-chloro-2-pyridinyl)-N-[4-cyano-2-(hydroxymethyl)-6-[(methylamino)carbonyl]phenyl]-1H-pyrazole-5-carboxamide and 3-Bromo-1-(3-chloro-2-pyridinyl)-N-[4-cyano-2-[(hydroxymethyl)amino]carbonyl]-6-methylphenyl]-1H-pyrazole-5-carboxamide*.

The residue is not fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intake (IEDI) for cyantraniliprole was calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available. The results are shown in Annex 3 of the 2013 JMPR Report.

The International Estimated Daily Intakes of cyantraniliprole for the 13 GEMS/Food regional diets, based on estimated STMRs were 1–10% of the maximum ADI of 0.03 mg/kg bw (Annex 3). The Meeting concluded that the long-term intake of residues of cyantraniliprole from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The 2013 JMPR decided that an ARfD was unnecessary. The Meeting therefore concluded that the short-term intake of cyantraniliprole residues is unlikely to present a public health concern.

CYPROCONAZOLE (239)

The first draft was prepared by Professor Eloisa Dutra Caldas

University of Brasilia, Brasilia, Brazil

APPRAISAL

Cyproconazole was first evaluated by the 2010 JMPR (T, R), when an ADI of 0–0.02 mg/kg bw and an ARfD of 0.06 mg/kg bw were set, and maximum residue levels were recommended for a variety of crops. Cyproconazole was scheduled at the Forty-fourth Session of the CCPR (2012) for the evaluation of residues in coffee by the 2013 JMPR. The residue definition for cyproconazole in commodities of plant and animal origin is the parent compound.

Methods of analysis

Two methods for the analysis of cyproconazole in coffee beans or roasted coffee were submitted. Residues can be extracted with acetone:water (95:5), the extract cleaned by gel permeation chromatography and the analyte analysed by LC/MS/MS (m/z 292.2 and 70.1), or extracted with methanol and analysed by LC/MS/MS after centrifugation. In both cases, satisfactory recoveries were obtained at 0.01 mg/kg (LOQ). No study was submitted to evaluate the stability of the residues in coffee samples. Studies evaluated by the 2010 JMPR on various fruits, peanuts and wheat had shown that cyproconazole residues are stable for at least 39 months under frozen conditions. The Meeting agreed that this conclusion could be extended to coffee.

Results from supervised residue trials on crops

Cyproconazole is registered in various central and South American countries. The critical GAP is found in Colombia, 3×0.06 kg ai/ha and 15 days PHI. A total of nine supervised residue trials were conducted on coffee from 2010 to 2012 in the region.

In two trials conducted in Brazil according to Colombian GAP, residues were 0.02 and 0.03 mg/kg. In two trials conducted in Colombia and one in Guatemala according to Colombian GAP, residues were 0.03 (2) and 0.04 mg/kg. Two declining studies conducted in Colombia according to GAP showed that residues at 10 and 14 days DAT are the same, and can be considered at GAP. Residues are 0.02 and 0.03 mg/kg.

In two other Brazilian trials, a soil drench application was applied in addition to a foliar application at 0.5 kg ai/ha, giving residues of 0.03 and 0.04 mg/kg at 23–37 DAT. Although these trials are not conducted according to GAP, they can be used as supporting information.

The Meeting agreed to combined the residues from trials conducted according to Colombian GAP (n=7) as 0.02 (2), 0.03 (4) and 0.04 mg/kg.

The Meeting estimates a maximum residue level of 0.07 mg/kg, and a STMR of 0.03 mg/kg for cyproconazole in coffee beans.

Fate of residues in processing

In one study conducted in Guatemala, green coffee beans containing 0.094 mg/kg cyproconazole were processed to roasted beans and instant coffee. Residues were 0.119 mg/kg in roasted beans and 0.151 mg/kg in instant coffee, resulting in processing factors of 1.3 and 1.6, respectively.

Based on these processing factors, the Meeting recommends a maximum residue level of 0.1 mg/kg and a STMR of 0.039 mg/kg for cyproconazole in roasted coffee beans, and a STMR of 0.048 mg/kg for cyproconazole in instant coffee.

RECOMMENDATIONS

Definition of the residue for compliance with maximum residue levels and estimation of dietary intake in plant commodities: *cyproconazole*.

CCN	Commodity name	Maximum residue level (mg/kg)		STMR (P) mg/kg
		New	Previous	
SB 0716	Coffee beans	0.07		0.03
SM 0716	Coffee beans, roasted	0.1		0.039
	Instant coffee			0.048

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of cyproconazole calculated for the 13 GEMS/Food Consumption Cluster Diets using STMRs and STMR-Ps estimated by the 2010 Meeting ranged from 0.5 to 2% of the maximum ADI. The impact of coffee on the IEDI is unlikely to affect the previous conclusion that the long-term intake of residues of cyproconazole resulting from the uses considered by the current JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short-Term Intakes (IESTI) of cyproconazole was calculated for coffee using STMR-P estimated by the current Meeting (Annex 4). The ARfD is 0.06 mg/kg and the calculated IESTI was 0% of the ARfD. The Meeting concluded that the short-term intake of residues of cyproconazole, when used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

CYPRODINIL (207)

First draft prepared by Dr Samuel Margerison, Australian Pesticides and Veterinary Medicines Authority, Canberra, Australia

EXPLANATION

Cyprodinil is a fungicide belonging to the anilinopyrimidine group of chemicals. It is a systemic fungicide with uptake through the leaves and translocation throughout the plant. It is used as a foliar fungicide for control of a range of fungal diseases in cereals, grapes, pome fruit, stone fruit, strawberries, vegetables, field crops and ornamentals, and as a seed dressing for barley.

Cyprodinil was evaluated by JMPR for the first time in 2003, when an ADI of 0–0.03 mg/kg bw/day was established. An ARfD was deemed to be unnecessary. A residue definition of cyprodinil was recommended for plant and animal commodities, for both compliance with MRLs and estimation of dietary intake. The residue is fat soluble.

At the Forty-fourth Session of the CCPR (2012), cyprodinil was scheduled for evaluation of additional use patterns by the 2013 JMPR.

The Meeting received residue data for avocados, dry beans, lima beans, common beans (snap beans), blueberries, Brassica vegetables (broccoli and cabbage), cane berries, cucurbit fruiting vegetables (cantaloupe, cucumber and squash), other fruiting vegetables (sweet and chilli pepper, and tomatoes), herbs (parsley, basil and chives), kiwifruit, leafy vegetables (mustard greens, lettuce and spinach), lemons (including processing data), lychees, pome fruit, root vegetables (carrot and radish), strawberry and watercress.

SPECIFICATIONS

Specifications for cyprodinil technical active constituent, emulsifiable concentrates and suspension concentrates were published by FAO in 2009.

Formulations

Two formulations were used in the residue trials submitted for evaluation by JMPR; both water-dispersible granular (WG) formulations, one containing 750 g/kg cyprodinil as the only active constituent, and the second containing 375 g/kg cyprodinil and 250 g/kg fludioxonil.

RESIDUE ANALYSIS***Plant matrices******Method number AG-631A/AG-631B***

This method was used for determination of residues in pome fruit, dry beans, avocado, blueberry, broccoli, cabbage, mustard greens, raspberry, chilli and sweet pepper, tomato, basil, chives, kiwifruit, lettuce, spinach, lemon (including processed lemon commodities), lychee, parsley, carrot, radish, strawberry and watercress. Samples were extracted with methanol/water (80:20 v/v), then an aliquot of the extract was centrifuged, filtered and acidified with 1M hydrochloric acid. The extract was cleaned up using a strong cation exchange solid phase extraction cartridge. The cyprodinil residues were eluted with methanol/25% ammonia solution (95:5 v/v), before evaporation and reconstitution in a suitable solvent (e.g. 1:1 v/v methanol/water, 1:1 v/v acetonitrile/water). Samples were analysed by HPLC-UV (detection wavelength = 255 or 270 nm), or LC-MS/MS (quantification transition: 226.1 → 93.1). The calculated method LOQ was 0.01 mg/kg, although depending on the residue trial, the method was validated at various fortification levels, giving lowest limits of method validation (LLMV) of 0.01–0.1 mg/kg.

Method number 2213-01

This method was used for determination of cyprodinil residues in cucurbit fruiting vegetables. Samples were extracted with methanol/water (80:20 v/v), then the extract was filtered and diluted to volume, before evaporation of the solvent from an aliquot of the sample and reconstitution in 0.1% aqueous ammonium acetate, and analysis by LC-MS ($m/z=226$). The method LOQ was 0.01 mg/kg.

The methods were validated for each matrix in conjunction with the analyses of the residue trial samples. Recovery data are tabulated below. The mean recoveries were acceptable, being within 70–120%, at fortification levels ranging from 0.01 to 115 mg/kg.

Table 1 Cyprodinil recovery data for method number AG-631B and 2213-01

Matrix	Fortification level (mg/kg)	n	Mean recovery (%)	RSD (%)	Reference (Author, Year)
Avocado	0.02	8	84	3.5	Barney, 2005

Stability of pesticide residues in stored analytical samples

Plant matrices

Storage stability data was determined concurrently with sample storage as part of the analytical phase of the residue trials submitted to the Meeting. The storage intervals for the plant matrices in the residue trials are tabulated below, together with storage stability data.

Table 2 Storage stability data for cyprodinil residues in frozen plant matrices

Pear	356	—	—	—	—	Mazlo, 2010

Further storage stability data was evaluated by JMPR for the 2003 evaluation of cyprodinil. A study by Kissling (1995) evaluated the stability (at -18°C) of incurred cyprodinil residues in grapes, apples, wheat ears, and wheat stalks, and of fortified residues in strawberries, potatoes and wine. Acceptable stability was observed in all of these matrices over 24 months.

The maximum interval for which samples were stored in the residue trials considered by this Meeting was 670 days (spinach). Stability of cyprodinil residues has been verified in a study conducted for a range of plant matrices over 24 months. Mean concurrent storage stability data was generally within the range 70–120%, with the exception of avocado and watercress. For the latter, it is noted that the analytical recovery was also low (73%).

USE PATTERNS

Cyprodinil is registered in the USA for use on lemons and limes, pome fruit, bush berries, cane berries, strawberries, tropical fruits—inedible peel, Brassica vegetables, cucurbits, non-cucurbit fruiting vegetables, leafy vegetables (including Brassica leafy vegetables), beans (succulent and dry), root and tuber vegetables and herbs.

Table 3 Registered uses of cyprodinil in the USA relevant to the evaluation

Crop	Application			PHI (days), or latest growth stage at application
	Method	Rate (g ai/ha, max)	No. (max)	
Lemon Lime	Foliar	289–368	1	0
Pome fruits ^a	Foliar	158–263	6 (at the maximum rate, max. seasonal rate 1578 g ai/ha)	0

Citrus fruits

Lemon

Five residue trials were conducted in lemons in California, USA during 2004/05 (Thompson, 2007-a). Cyprodinil was applied as a water-dispersible granular (WG) co-formulation with fludioxonil. A single foliar application was made to the treated plot at each trial site at a target application rate of 368 g ai/ha. No spray adjuvants were included in the tank mix. Fruit was sampled on the day of application, after the spray had dried. Residues of cyprodinil were analysed using an LC/MS/MS method (method number AG-631B). Analyses were completed within 4 months of harvest.

Pome fruit

Apples

A series of twelve trials in apples was conducted in the USA during the 2008 and 2009 growing seasons (Mazlo, 2010). Five applications of cyprodinil as a 750 g/kg WG formulation were made at each site, at target intervals of 7 days, with application rates of 278–296 g ai/ha (1× the GAP of the USA). A spray adjuvant (non-ionic surfactant or crop oil concentrate) was included in the tank mix for all applications. Residues of cyprodinil in apples were determined using an LC/MS/MS method (method number AG-631B). Samples were stored frozen until analysis, which took place up to 12 months later.

Pears

A series of six trials in pears was conducted in the USA during the 2008 growing season (Mazlo, 2010). Five applications of cyprodinil as a 750 g/kg WG formulation were made at each site, at target intervals of 7 days, with application rates of 256–286 g ai/ha (1× the GAP of the USA). Residues of cyprodinil in pears were determined using an LC/MS/MS method (method number AG-631B). Samples stored frozen until analysis, which took place up to 12 months later.

^a Fruit samples were taken at day 0.

Berries and other small fruits

Blueberries

Residue trials in blueberries were conducted at eight sites across the USA during the 1998 and 1999 growing seasons (Thompson, 2001). Cyprodinil was applied as a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil.

Samples were analysed for cyprodinil using an HPLC-UV method (method number AG-631B, with minor modifications). Recoveries ranged from 75–118% at fortification levels of 0.02, 0.2 and 2 mg/kg. The samples were stored frozen for up to 11 months between harvest and analysis.

Raspberries

Five residue trials in raspberries were conducted in the USA during the 1998 growing season (Starner, 2001-a). A series of four applications of a water dispersible granular formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil was made. The first two applications were made during flowering, approximately 7 days apart, followed by a gap of around 2–5 weeks before the third and fourth applications, which were made around 7 days apart around the time of commercial harvest. Fruit was sampled on the day of the last application, after the spray had dried.

Residues of cyprodinil were determined using an HPLC-UV method (method number AG-631B, with minor modifications).

Strawberries

Eight trials using a water dispersible granule fungicide containing 375 and 250 g/kg respectively of cyprodinil and fludioxonil were conducted in strawberries in the USA during 2002 (Chen, 2004). Cyprodinil was applied as a foliar-directed spray at a target rate of 368 g ai/ha using a pressurised backpack sprayer with a hand-held boom; spray adjuvants were not included. Four applications were made, at target intervals of 7 days. Fruit was sampled on the day of the last application, after the spray had dried.

Residues of cyprodinil were determined using an HPLC-UV method (method number AG-631B, with minor modifications).

^a Fruit samples were taken at day 0.

^b Results may be rain affected, rain fell within < 2 hours of the final application.

Assorted tropical and sub-tropical fruits—inedible peel

Avocado

Six trials in avocados were conducted across the USA during 2003 (Barney, 2005). Four applications of a water dispersible granular formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil, was made to each treated plot. Fruit was harvested from the treated plot on the day of the last application. The fruit were quartered in the field, and the stones discarded. It appears that the results were determined on the fruit minus stone, not on the whole fruit, as weights of the stones were not recorded.

Residues of cyprodinil were determined using an HPLC-UV method (method number AG-631B), with minor modifications.

Kiwifruit

Three residue trials for cyprodinil in kiwifruit were conducted in California in 2004 (Thompson, 2007-b). Cyprodinil was applied to kiwifruit vines with near-mature fruit as a 750 g/kg water dispersible granule formulation twice at 7–10 day intervals at a target application rate of 526 g ai/ha. Treated and control fruit were sampled on the day of the final application, after the spray had dried.

Samples were analysed for cyprodinil using HPLC/UV method number AG-631B, with minor modifications.

Lychees

Three residue trials in lychees were conducted in Florida during 2000 (Chen, 2002-a). Cyprodinil was applied as a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg

fludioxonil. Between five and seven applications were made at a target rate of 368 g ai cyprodinil/ha, commencing at fruit setting and continuing at approximately 7 day intervals until commercial maturity. Fruit was sampled on the day of the last application, after the spray had dried.

Lychees were analysed for cyprodinil using an HPLC-UV method (method number AG-631B, with minor modifications). Fruit from one site was separated into peel and peeled fruit for analysis to determine the partitioning of the residue between peel and pulp. Good recoveries were achieved in whole and peeled lychees, and peel, ranging from 71–105%. The samples were stored frozen for up to 3.5 months between harvest and analysis; recoveries after storage of cyprodinil from stability samples fortified at 1 mg/kg and stored for 125 days ranged from 67–74% (it is noted that the concurrent recovery at analysis after storage was 73%). It is unlikely that samples were adversely affected by storage.

*Brassica (cole or cabbage) vegetables, Head Cabbage, Flowerhead Brassicas**Cabbage*

Residue trials were conducted at six sites in the USA for cabbage during 2000 (Arsenovic, 2002-a). Between four and six applications were made by foliar broadcast or foliar directed application at a target rate of 368 g ai/ha cyprodinil, with applications 1 and 2 being made at a target interval of 7 days, application 3 being made around 3 weeks after application 2, and all subsequent applications being made at a target interval of 7 days.

Cabbages, both with and without wrapper leaves, were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Broccoli

Seven residue trials was conducted in the USA and Canada for a 375 g/kg cyprodinil and 250 g/kg fludioxonil water dispersible granule formulation in broccoli (Arsenovic, 2002-b). Between four and six applications were made at a target rate of 368 g ai/ha cyprodinil, with the first two applications being made early in the season roughly 7 days apart, while the third application was made at a target interval of 3 weeks after the second depending on how quickly the crop was maturing. The remaining applications were made at target intervals of 7 days.

Residues of cyprodinil in broccoli were determined using an HPLC-UV method (method number AG-631B, with minor modifications)

With the exception of the sample from the Quebec site (where a low level of residue, 0.029 mg/kg, was found), no residues of cyprodinil were found in the untreated control samples at levels above the limit of quantitation.

^a Broccoli heads were sampled.

Fruiting vegetables, Cucurbits

Melons

Six trials in melons (cantaloupe variety) were conducted for a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil in the USA during 2004 and 2005 (Oakes, 2007). Four applications were made by foliar broadcast at a target application rate of 368 g ai/ha cyprodinil, at target intervals of 7 days, with the final application occurring around one week prior to scheduled harvest. Melons were sampled at all sites at target PHIs of 1 and 7 days after the last application. Additional samples were collected at the decline trial sites on days 0 (after the spray had dried), 3, 5 and 9 days after the last application.

Cyprodinil residues were determined using an LC/MS method (method number 2213-01, with modifications omitting the solid phase extraction clean-up stage).

Cucumber

Seven trials in cucumber were conducted using a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil in the USA during 2004 and 2005 (Oakes, 2007). Four applications were made by foliar broadcast using a backpack sprayer or tractor-mounted boom sprayer at a target application rate of 368 g ai/ha cyprodinil, at target intervals of 7 days, with the final application occurring around one week prior to scheduled harvest. Cucumbers were sampled at all sites at target PHIs of 1 and 7 days after the last application. Additional samples were collected at the decline trial sites on days 0 (after the spray had dried), 3, 5 and 9 days after the last application.

Cyprodinil residues were determined using an LC/MS method (method number 2213-01, with modifications omitting the solid phase extraction clean-up stage).

Summer squash

Six trials in summer squash were conducted using a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil in the USA during 2004 and 2005 (Oakes, 2007). Four applications were made by foliar broadcast at a target application rate of 368 g ai/ha cyprodinil, at target intervals of 7 days, with the final application occurring around one week prior to scheduled harvest. Squash were sampled at all sites at target PHIs of 1 and 7 days after the last application.

Additional samples were collected at the decline trial sites on days 0 (after the spray had dried), 3, 5 and 9 days after the last application.

Cyprodinil residues were determined using an LC/MS method (method number 2213-01, with modifications omitting the solid phase extraction clean-up stage). Recoveries of cyprodinil from squash fortified at concentrations between 0.01–1.0 mg/kg ranged from 73–116%. Samples were stored frozen for up to 20 months between collection and analysis.

^a Fruit samples were taken

Fruiting vegetables, other than Cucurbits

Peppers (sweet) and peppers chili

Fourteen trials were conducted in field-grown peppers (sweet peppers and chilli peppers) in the USA and Canada in 2006 (Lennon, 2011-a). At each site, a plot was treated with a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil. Four applications at a target rate of 368 g ai/ha cyprodinil were made by foliar application, with target intervals of 7 days between

applications 1 and 2, and 3 and 4, and 21 days between applications 2 and 3. Applications 1 and 2 generally took place during flowering or early fruiting, while applications 3 and 4 were to plants with near-mature fruit. Spray adjuvants were not included in the tank mix. Mature green peppers were harvested on the day of the last application, after the spray had dried.

Samples were analysed for residues of cyprodinil using an HPLC-UV method (method number AG-631B, with minor modifications).

A series of trials in greenhouse grown peppers (four trials in sweet peppers and one trial in chilli peppers) was conducted in the USA and Canada during 2005 and 2006 (Lennon, 2011-b). Plots were treated with a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil. Four applications were made at a target rate of 368 g ai/ha, with an interval of approximately 7 days between applications 1 and 2, and between 3 and 4, while the interval between applications 2 and 3 was generally around 21 days. Samples were collected at each site on the day of the final application, after the spray had dried. At one site, a decline trial was conducted, and additional samples were collected at later intervals.

Samples were analysed for cyprodinil using an HPLC/UV method (method number AG-631B, with minor modifications).

Tomato

A series of eighteen trials (fourteen in field-grown tomatoes, and four in greenhouse tomatoes) was conducted in tomatoes in the USA during the 2002 growing season (Thompson, 2005). At each site, plots were treated with four applications of a water dispersible granule containing 375 g/kg cyprodinil and 250 g/kg fludioxonil. Applications were made at target intervals of 7 days for applications 1 and 2, and applications 3 and 4, with a target interval of 21 days for applications 2 and 3. This resulted in the first two applications being conducted at late flowering/early fruiting, and the second two when fruit was maturing.

Residues of cyprodinil were determined using an HPLC-UV method (method number AG-631B).

With one exception, residues were not found above the limit of quantitation in any of the untreated control samples.

^a Fruit samples were taken at day 0

*Leafy vegetables (including Brassica leafy vegetables)**Lettuce*

A series of fourteen residue trials for cyprodinil in lettuce (both head and leafy varieties) was conducted in the USA during the 2001 growing season (Chen, 2003-a). At each site, a plot was treated with a water dispersible granule containing 375 g/kg cyprodinil and 250 g/kg fludioxonil. Four foliar applications at a target rate of 368 g ai/ha cyprodinil were made at target intervals of 7 days. Samples were collected on the day of the last application, after the spray had dried. At the head lettuce trial sites, samples both with and without wrapper leaves were collected. Additional samples were collected at 7 and 14 days after the last application at two of the leaf lettuce sites to generate decline data.

Residues of cyprodinil in lettuce were determined using an HPLC-UV method (method number AG-631B, with minor modifications).

Spinach

Eleven residue trials in spinach were conducted in the USA and Canada during 2008 and 2009 (Thompson, 2011). At each site, a plot was treated with a water dispersible granule containing 375 g/kg cyprodinil and 250 g/kg fludioxonil. Four applications at a target rate of 368 g ai/ha cyprodinil were made by foliar application, with target intervals of 7 days between applications 1 and 2 and 3 and 4, and 14 days between applications 2 and 3. Spray adjuvants were included in the tank mix at most of the sites. Samples were collected on the day of the last application, after the spray had dried. At one site, additional samples were collected at intervals of 2-14 days after the last application in order to generate decline data.

Residues of cyprodinil in spinach were determined using HPLC-UV (method number AG-631B, with minor modifications).

Residues were found in control samples at levels at or very slightly above the LOQ at two sites.

Watercress

Two field trials were conducted in watercress in Florida during 1999 (Starter, 2001-b). A water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil was applied four times at a target rate of 368 g ai/ha cyprodinil, with target intervals of 7 days. Samples were collected at on the day of the last application, after the spray had dried.

Residues of cyprodinil in watercress were determined using HPLC-UV (method number AG-631A, with minor modifications). Samples were stored frozen for up to 10 months before analysis. Untreated control samples of watercress fortified at 2 mg/kg and stored frozen for up to 10 months showed recoveries of 63–73% (mean recovery = 67%). It is noted that the recoveries are slightly below the generally accepted range of 70–120%; the samples may have been adversely affected by storage to a small extent.

Mustard greens

Seven field trials in mustard greens was conducted in the USA during 2000 (Arsenovic, 2001-c). Four applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil at a target rate of 368 g ai/ha cyprodinil were made at target intervals of 7 days between applications 1 and 2 and 3 and 4, and 14 days between applications 2 and 3. Samples were collected at a target interval of 7 days after the last application.

Residues of cyprodinil in mustard greens were determined using HPLC-UV (method number AG-631B, with minor modifications).

^a Product was over-applied by approximately 62–68% per application. The results were scaled for MRL determination; actual results are tabulated.

Legume vegetables

Beans (edible pods and succulent seeds)

Eight residue trials were conducted in the USA for cyprodinil in common beans (snap beans, succulent pods and seeds) during 2001 (Chen, 2003-b). Four late season applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made at target intervals of 7 days and a target application rate of 368 g ai/ha cyprodinil. Samples of succulent beans with pods were collected at a target PHI of 7 days after the last application. Additional duplicate samples at target intervals of 0 and 14 days were collected at two sites.

Bean samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Beans (succulent shelled)

Eight residue trials were conducted in the USA in succulent shelled lima beans during 2001 (Chen, 2003-c). A series of 4–6 late season applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil was made to the treated plot at target intervals of 7 days and a target application rate of 368 g ai/ha cyprodinil. Samples of succulent beans with and without pods were collected at a target PHI of 7 days after the last application.

Bean samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Where three replicates are reported, replicates 1 and 2 are replicate analyses of the same sample, while replicate 3 is an analysis of a second sample. Where two replicates are reported, replicates 1 and 2 are replicate samples.

*Pulses**Beans, dry*

Nine residue trials for cyprodinil in dry beans were conducted in the USA during 2001 (Chen, 2003-d). Four late season applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made to the treated plot at target intervals of 7 days and a target application rate of 368 g ai/ha cyprodinil. Samples of dry beans were collected at a target PHI of 7 days after the last application.

Dry bean samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

With the exception of the samples from the Salinas, California site (trial number CA25), where it appears that the control and treated samples were inadvertently switched, residues were not found in the untreated control samples at levels above the limit of quantitation.

*Root and tuber vegetables**Carrot*

Ten trials were conducted in the USA and Canada for cyprodinil in carrots during 2000 and 2004 (Chen, 2002-b and Barney, 2006-a). Four applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made at a target interval of 7 days (between applications 1 and 2 and between applications 3 and 4) and 21 days between applications 2 and 3 at a target application rate of 368 g ai/ha cyprodinil. Duplicate samples of treated carrot roots were collected at a target PHI of 7 days after the last application, and frozen within 3 hours of collection. Decline samples were collected at one site at intervals between 0 and 21 days after the last application.

Carrot root samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

^a Product was over-applied by 56–65% per application. The results were scaled for MRL determination; actual results are tabulated.

^b Product was under-applied at an average of 52% of the target rate per application. The results were scaled for MRL determination; actual results are tabulated.

Radish

Six trials were conducted in the USA for cyprodinil in radish during 2004 (Barney, 2007). Two late season applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made to the treated plot at a target interval of 7 days and a target application rate of 368 g ai/ha cyprodinil. Samples of radish roots and tops were collected at a target PHI of 7 days after the last application.

Radish root and top samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Herbs

Basil

Three residue trials were conducted in the USA during 2000 (Chen, 2002-c). Four applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made at a target rate of 368 g ai/ha cyprodinil. Applications 1 and 2 were timed for earlier in the growing season, and applications 3 and 4 closer to harvest. Samples were collected at a target PHI of 7 days after the final application. Additional samples were harvested at one site and dried, initially by lying out in the field, then indoors using an electric fan for 48 hours before frozen storage, to determine the effect of drying on residue levels.

Basil leaf samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Chives

Three residue trials were conducted in the USA during 2000 (Chen, 2002-d). Four applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made at a target rate of 368 g ai/ha cyprodinil. Applications 1 and 2 were timed for earlier in the growing season, and applications 3 and 4 closer to harvest. Samples were collected at a target PHI of 7 days after the final application. Additional samples were harvested at one site and air dried in a greenhouse before frozen storage, to determine the effect of drying on residue levels.

Chives samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Parsley

Four residue trials were conducted in the USA during 2003 (Barney, 2006-b). Four applications of a water dispersible granule formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil were made at a target rate of 368 g ai/ha cyprodinil. Applications 1 and 2 were timed for earlier in the growing season, and applications 3 and 4 closer to harvest. Samples of fresh parsley were collected at a target PHI of 7 days after the final application. Additional samples were collected at each site and dried for 1–7 days, either using an air dryer or in a greenhouse.

Parsley leaf samples were analysed for cyprodinil residues using an HPLC-UV method (method number AG-631B, with minor modifications).

Residues were not found in any of the untreated control samples of fresh parsley leaves at levels above the limit of quantitation. Low levels of residue just above the limit of quantitation were found in control samples of dried parsley leaves from one trial site.

FATE OF RESIDUES IN PROCESSING

Lemons

A processing study in lemons was conducted in the USA (Barney, 2010). Cyprodinil was applied as a water-dispersible granular formulation containing 375 g/kg cyprodinil and 250 g/kg fludioxonil using an airblast sprayer. A petroleum oil spray adjuvant was included in the tank mix. A single application

was made at 375 g ai/ha cyprodinil and fruit was sampled on the day of application after the spray had dried.

The lemons were transported fresh to the processing laboratory, and processing was completed within nine days of harvest. The fruit was washed in a tank, and undesirable fruit was removed. Washed fruit was then scarified using a modified Hobart abrasive peeler, and the collected emulsion was screened to remove flavedo fragments and passed through a cream separator and an IEC centrifuge to separate the oil from water. The first run free oil was removed, and the remaining emulsion frozen and stored overnight, thawed, centrifuged again, and the separated oil added to the first run oil. Scarified fruit was then transferred to a juice extractor and halved and juiced using a reaming auger. The extracted juice was then pulped and screened to remove solid material such as peel fragments, seeds, and vesicular and segment membranes. Finally, the peel was shredded, and flavedo fragments, rag and seeds from earlier stages added. The resulting wet pulp was then treated with lime, pressed and dried to < 10% moisture to give dried citrus pulp, before finally being milled using a hammer mill and the moisture content checked. Samples of fresh fruit, oil, juice and dried pulp were collected and frozen for transport to the analytical laboratory.

Residues of cyprodinil in lemon and processed fractions were determined using method number AG-631B, with analysis by HPLC with UV detection. The extraction procedure was modified for analysis of the oil samples by inclusion of an additional clean-up of the aqueous acidic extract by partition with hexane, prior to the solid phase extraction clean up using a strong cation exchange (SCX) cartridge. Samples were stored frozen until analysis, and all samples were analysed within 10 months of collection.

Tomatoes

A processing study in tomatoes was conducted as part of the package of residue trials in field and greenhouse tomatoes (Thompson, 2005).

The effect of washing tomatoes in the field was studied, with samples of tomatoes being washed and dried before dispatch to the laboratory. Samples were washed for approximately 10 seconds, patted dry, and then frozen for transport to the laboratory.

Additionally, large samples of tomatoes (both untreated control and treated) from a single site were shipped to a processing laboratory. Processing was completed within two days of harvest, and samples were frozen within an hour of collection.

Tomato samples were first washed by passing through a flume, and a spray washer, then a second flume, and finally a second spray washer. Washed tomatoes were crushed in a grinder, and then pumped into a hot break system where they were heated to approximately 96 °C using a heat exchanger, followed by pumping into a finisher where the resulting hog crush was screened to remove pomace (seeds and peel fragments). Pomace was weighed and discarded, and the filtered juice was passed to a vacuum evaporator, where the volume was reduced to a range of 8–16% solids content to give tomato purée. A weighed portion of the purée was transferred to a steam jacketed kettle, heated with stirring to 89–91 °C, and filled into cans, which were sealed, inverted and water cooled, then

dried, labelled and frozen. The remaining purée was transferred to a vacuum kettle evaporator, and the volume reduced by heating to a solids content of 24–35%. The resulting paste was transferred to a steam-jacketed kettle, heated to 89–91 °C, then filled into cans, which were sealed, inverted and water cooled, then dried, labelled and frozen.

Samples of unwashed and washed tomatoes, tomato purée and tomato paste were analysed by HPLC-UV (method number AG-631B, with minor modifications). Recoveries in tomatoes are summarised in the tomato residue data section above. Recoveries of cyprodinil from tomato puree ranged from 88–102% at fortification levels ranging from 0.02–2.0 mg/kg. Recoveries of cyprodinil from tomato paste ranged from 72–101% at fortification levels of 0.01–2.0 mg/kg.

RESIDUES IN ANIMAL COMMODITIES

No new animal feeding studies were supplied to the Meeting.

APRAISAL

Cyprodinil was first evaluated for residues and toxicological aspects by the 2003 JMPR. The 2003 Meeting established an ADI of 0–0.03 mg/kg bw for cyprodinil and concluded that an ARfD was not necessary. The 2003 Meeting recommended a number of maximum residue levels for cyprodinil. The residue definition was established as cyprodinil for both compliance with MRLs and dietary risk assessment, for both plant and animal commodities. The residue is fat soluble.

Cyprodinil was scheduled by the Forty-fourth CCPR meeting in 2012 for evaluation of residue data for additional crops by the 2013 JMPR.

Methods of analysis

The Meeting received two analytical methods for determination of cyprodinil residues in plant matrices which were relevant to this evaluation. The LOQ for the HPLC-UV and HPLC-MS/MS methods was 0.01 mg/kg.

Stability of residues in stored analytical samples

The Meeting received information on the storage stability of cyprodinil residues in plant matrices from trials conducted in conjunction with the residue studies submitted to the Meeting. These data and stability data from JMPR 2003 cover the maximum storage period for samples in the residue studies submitted to the Meeting.

Results of supervised residue trials on crops

The Meeting received supervised trial data for application of cyprodinil to dry beans, lima beans, common beans (snap beans), berry fruit (blueberries, caneberries and strawberries), brassica vegetables (broccoli and cabbage), cucurbit fruiting vegetables (cantaloupe, cucumber and squash), other fruiting vegetables (sweet pepper, chili pepper, and tomato), herbs (parsley, basil and chives), leafy vegetables (mustard greens, lettuce, spinach and watercress), lemons (including processing data), pome fruit (apples and pears), root vegetables (carrot and radish), and tropical fruits-inedible peel (avocado, kiwifruit and litchi).

Citrus fruits

Cyprodinil is registered in the USA for use on lemons and limes at a GAP of 1×0.37 kg ai/ha, and a 0-day PHI.

Three residue trials were conducted in lemons at GAP in the USA. Residues in lemons at the 0-day PHI were 0.19, 0.31 and 0.34 mg/kg.

The Meeting determined that there were insufficient data for the estimation of a maximum residue level in lemons.

Pome fruits

The 2003 JMPR estimated a maximum residue level of 0.05 mg/kg in apple based on a previous GAP in the USA of 4×0.26 kg ai/ha, with applications only until the end of flowering. The 2003 JMPR estimated a maximum residue level of 1 mg/kg in pear based on the European GAP of 3×0.38 kg ai/ha, with a 14-day PHI.

The Meeting received new residue data from the USA for both apples and pears at a different GAP from those previously considered. Cyprodinil is registered in the USA for use in apples and pears at a GAP of 6×0.26 kg ai/ha, and a 0-day PHI.

Nine residue trials were conducted in apples at GAP in the USA. Residues in apples at the 0-day PHI were 0.20, 0.28, 0.40, 0.50, 0.51, 0.52, 0.70, 0.94, and 1.3 mg/kg.

Five residue trials were conducted in pears at GAP in the USA. Residues in pears at the 0-day PHI were 0.17, 0.35, 0.36, 0.46, and 0.65 mg/kg.

The Meeting noted that the USA GAP is for the pome fruits group, and considered a group maximum residue level. To consider a group maximum residue level, residues in individual crops should be similar (e.g., medians should not differ by more than 5×). The Meeting agreed to estimate a maximum residue level for the crop group Pome fruits. In deciding whether to combine the datasets for apple and pear for use in the statistical calculator or to only utilize the data from the commodity with the highest residues, the Meeting recognized the similarity of the datasets (confirmed by the Mann-Whitney U test), and decided to combine the datasets for apples and pears for the purposes of determining a group maximum residue level for pome fruit. Residues found were: 0.17, 0.20, 0.28, 0.35, 0.36, 0.40, 0.46, 0.50, 0.51, 0.52, 0.65, 0.70, 0.94 and 1.3 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg for pome fruit, and a STMR of 0.48 mg/kg. The Meeting withdrew its previous maximum residue level recommendations of 0.05 mg/kg for apple and 1 mg/kg for pear.

Berries and other small fruits

Cyprodinil is registered in the USA for use in bushberries at a GAP of 4×0.37 kg ai/ha with a 0-day PHI.

Five residue trials were conducted at GAP in blueberries in the USA. Residues in blueberries at the 0-day PHI were 0.50, 0.62, 1.0, 1.4 and 1.9 mg/kg.

The 2003 JMPR estimated a maximum residue level of 0.5 mg/kg in raspberries, red, black based on the Swiss GAP of 2×0.45 kg ai/ha, with a 14-day PHI.

The Meeting received residue data from the USA for raspberries. Cyprodinil is registered in the USA for use in caneberries at a GAP of 4×0.37 kg ai/ha, with a 0-day PHI.

Five residue trials were conducted in raspberries in the USA. Residues in raspberries at the 0-day PHI were 1.5, 1.6, 2.2, 2.5, and 5.9 mg/kg.

The 2003 JMPR estimated a maximum residue level of 2 mg/kg in strawberries, based on various GAPs in Europe.

The Meeting received residue data from the USA in strawberries. Cyprodinil is registered in the USA for use in strawberries at a GAP of 4×0.37 kg ai/ha, with a 0-day PHI.

Eight residue trials were conducted in strawberries in the USA. Residues in strawberries at the 0-day PHI were 0.10, 0.30, 0.68, 0.91, 1.1, 1.5, 1.6, and 2.0 mg/kg.

The Meeting noted that the USA GAP is the same for all berry fruit (except grapes) and considered a group maximum residue level. To consider a group maximum residue level, residues in individual crops should be similar (e.g., medians should not differ by more than 5×). The Meeting agreed to estimate a maximum residue level for the group Berry fruit (except grapes). In deciding whether to combine the datasets for blueberries, raspberries and strawberries for use in the statistical calculator or to only utilize the data from the commodity with the highest residues, the Meeting agreed not to combine the data sets (Kruskal-Wallis test). Therefore, recommendations on berry fruit will be based on raspberries, as the commodity with the highest residues. Based on the data set for raspberries, the Meeting estimated a maximum residue level of 10 mg/kg for Berries and other small fruits, except grapes, together with an STMR of 2.2 mg/kg. The Meeting withdrew its previous maximum residue level recommendations of 0.5 mg/kg for raspberries, red, black and 2 mg/kg for strawberry.

*Assorted tropical and sub-tropical fruits - inedible peel**Avocado*

Cyprodinil is registered in the USA for use in avocado at a GAP of 4×0.37 kg ai/ha, with a 0-day PHI.

Six trials were conducted in avocados in the USA. Residues in avocados at the 0-day PHI were 0.08, 0.18, 0.23, 0.30, 0.35, and 0.60 mg/kg.

The Meeting estimated a maximum residue level of 1 mg/kg for avocados, along with an STMR of 0.265 mg/kg.

Kiwifruit

Cyprodinil is registered in the USA for use in kiwifruit at a GAP of 2×0.53 kg ai/ha, with a 0-day PHI.

Three residue trials were conducted in kiwifruit in the USA. Residues in kiwifruit at the 0-day PHI were 0.61, 0.99, and 1.1 mg/kg.

The Meeting determined that there were insufficient data for the estimation of a maximum residue level in kiwifruit.

Litchi (lychee)

Cyprodinil is registered in the USA for use in litchi at a GAP of 4×0.37 kg ai/ha, with a 0-day PHI.

One residue trial was conducted in litchi in the USA. Residues in litchi at the 0-day PHI were 1.3 mg/kg.

The Meeting determined that there were insufficient data for estimation of a maximum residue level in litchi.

*Brassica vegetables**Cabbages, Head*

Cyprodinil is registered in the USA for use in brassica vegetables at a GAP of 4×0.37 kg ai/ha, with a 7-day PHI.

Six trials were conducted in cabbage in the USA. Residues in cabbages (with wrapper leaves) at a PHI of 6–8 days were < 0.02, 0.02 (s), 0.02, 0.04, 0.19, and 0.36 mg/kg, where (s) indicates a result scaled to account for application rates outside $\pm 25\%$ of GAP. Residues in cabbages (without wrapper leaves) were < 0.02 (5), and 0.08 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg for head cabbages, along with an STMR of 0.03 mg/kg.

Flowerhead Brassicas

Six trials were conducted in broccoli in the USA and Canada. Residues in broccoli at a PHI of 6–8 days were 0.02, 0.15, 0.20, 0.34, 0.43 and 1.1 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg for broccoli, along with an STMR of 0.27 mg/kg and agreed to extend the MRL and STMR to the subgroup Flowerhead brassicas.

Fruiting vegetables, Cucurbits

The 2003 JMPR estimated maximum residue levels of 0.2 mg/kg for both cucumber and summer squash, based on data matching Spanish and Italian GAPs of 4×0.038 kg ai/hL with a 7-day PHI, and 3×0.30 kg ai/ha with a 7-day PHI respectively.

The Meeting received residue data from the USA in melon, cucumber and summer squash.

Cyprodinil is registered in the USA for use in fruiting vegetables, other than cucurbits at a GAP of 4×0.37 kg ai/ha, with a 1-day PHI.

Five residue trials were conducted in melons in the USA. Residues in melons at the 1-day PHI were 0.05, 0.06, 0.10, 0.17 and 0.33 mg/kg.

Seven residue trials were conducted in cucumber in the USA. Residues in cucumber at the 1-day PHI were 0.04, 0.05, 0.09 (2), 0.11, 0.15, and 0.24 mg/kg.

Five residue trials were conducted summer squash in the USA. Residues in summer squash at the 1-day PHI were 0.02, 0.03, 0.07 (2), and 0.09 mg/kg.

The Meeting noted that the USA GAP is for all cucurbit fruiting vegetables, and considered a group maximum residue level. To consider a group maximum residue level, residues in individual crops should be similar (e.g., medians should not differ by more than 5 $\times$). The Meeting agreed to estimate a maximum residue level for the group Fruiting vegetables, Cucurbits. In deciding whether to combine the datasets for melons, cucumbers and summer squash for use in the statistical calculator or to only utilize the data from the commodity with the highest residues, the Meeting recognized the similarity of the datasets (confirmed by the Kruskal-Wallis test), and decided to combine the datasets.

Combines residues were: 0.02, 0.03, 0.04, 0.05 (2), 0.06, 0.07 (2), 0.09 (3), 0.10, 0.11, 0.15, 0.17, 0.24, and 0.33 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg for Fruiting vegetables, Cucurbits, together with an STMR of 0.09 mg/kg. The Meeting withdrew the previous maximum residue level recommendations of 0.2 mg/kg for cucumber and summer squash.

Fruiting vegetables, other than Cucurbits

The 2003 JMPR estimated a maximum residue level of 0.2 mg/kg for eggplant, based on data matching the Italian GAP of 3×0.30 kg ai/ha, with a 7-day PHI, and the Spanish GAP of 3×0.038 kg ai/hL, with a 7-day PHI. Based on a combined data set from three European GAPs (Italy: 3×0.30 kg ai/ha, with a 7-day PHI, Spain: 3×0.038 kg ai/hL, with a 7-day PHI, and Switzerland: 0.30 kg ai/ha, with a 3-day PHI), the 2003 JMPR estimated a maximum residue level of 0.5 mg/kg for tomatoes. The 2003 JMPR estimated a maximum residue level of 0.5 mg/kg for peppers, sweet, based on data matching the Italian GAP of 3×300 g ai/ha, with a 7-day PHI, and the Spanish GAP of 3×38 g ai/hL, with a 7-day PHI.

The Meeting received residue data from the USA and Canada in tomatoes, sweet peppers and chili peppers. Both field and greenhouse trial data were supplied for all three crops.

Cyprodinil is registered in the USA for use in fruiting vegetables, other than cucurbits, at a GAP of 4×0.37 kg ai/ha, with a 0-day PHI.

Eleven residue trials were conducted in sweet pepper in the USA and Canada. Residues in sweet pepper at the 0-day PHI were 0.04, 0.10, 0.13, 0.15, 0.19, 0.21 (GH), 0.23, 0.23 (G), 0.25, 0.27 (GH), and 0.68 mg/kg. 'GH' indicates a trial conducted in a greenhouse, all other trials were conducted in the field.

Five trials were conducted in chili pepper in the USA. Residues in chili pepper at the 0-day PHI were 0.20, 0.27, 0.28, 0.59 (GH), and 0.67 mg/kg.

Sixteen trials were conducted in tomatoes in the USA. Residues in tomatoes at the 0-day PHI were 0.02, 0.03 (GH), 0.06, 0.09, 0.11, 0.13, 0.14 (2), 0.16, 0.17 (GH), 0.20, 0.22 (GH), 0.24, 0.26, 0.30, and 0.32 (GH) mg/kg.

A series of residue trials in fruiting vegetables (eggplant, sweet pepper and tomato), was considered by the 2003 JMPR. Most of the trials were conducted in greenhouse crops, and in accordance with a GAP of 3×0.38 kg ai/ha applications, with a 7-day PHI. The majority were conducted as decline trials and have data for the USA PHI of 0 days. The application rates from the 2003 trials are within $\pm 25\%$ of the USA GAP (4×0.37 kg ai/ha).

At a PHI of 0 days, residues of cyprodinil in greenhouse grown eggplant from trials from Italy and Spain relevant to USA GAP were 0.07, 0.14, and 0.23 (2) mg/kg.

At a PHI of 0 days, residues of cyprodinil in greenhouse grown tomato from trials from Greece, Italy, Spain, Switzerland and the UK, relevant to USA GAP were 0.08, 0.12, 0.13, 0.20, 0.21 (2), 0.22 (3), 0.23, 0.25 (3), 0.36, 0.41 mg/kg.

At a PHI of 0 days, residues of cyprodinil in field and greenhouse grown sweet pepper from Spanish and Italian trials relevant to USA GAP were 0.02, 0.26 (G), 0.27, 0.41 (GH), 0.73 (GH), 1.0 (GH), and 1.2 (GH) mg/kg. (GH) indicates a result from a greenhouse trial.

The Meeting agreed to combine the datasets for the USA (field and greenhouse) and European (greenhouse) to give a larger dataset for the purposes of estimation of dietary parameters and a maximum residue level for fruiting vegetables, other than cucurbits.

Residues in field and greenhouse grown tomatoes from trials carried out in the USA, Greece, Italy, Spain, Switzerland and the UK relevant to USA GAP were 0.02, 0.03 (G), 0.06, 0.08 (G), 0.09, 0.11, 0.12 (GH), 0.13, 0.13 (GH), 0.14 (2), 0.16, 0.17 (G), 0.20, 0.20 (GH), 0.21 (GH) (2), 0.22 (GH) (4), 0.23 (GH), 0.24, 0.25 (GH) (3), 0.26, 0.30, 0.32 (GH), 0.36 (GH), 0.41 (GH) mg/kg.

Residues in field and greenhouse grown sweet pepper from trials carried out in the USA, Spain and Italy relevant to USA GAP were 0.02, 0.04, 0.10, 0.13, 0.15, 0.19, 0.21 (GH), 0.23, 0.23 (GH), 0.25, 0.26 (GH), 0.27, 0.27 (GH), 0.41 (GH), 0.68, 0.73 (GH), 1.0 (GH), and 1.2 (GH) mg/kg.

The Meeting considered that the USA GAP is for all fruiting vegetables, other than cucurbits, except mushroom and sweet corn, and considered a group maximum residue level. To consider a group MRL, residues in individual crops should be similar (e.g. medians should not differ by more than 5×). The Meeting agreed to estimate a maximum residue level for the group fruiting vegetables, other than cucurbits, except mushroom and sweet corn. In deciding whether to combine the datasets for sweet peppers, chili peppers, tomatoes and eggplants for use in the statistical calculator or to only utilize the data from the commodity with the highest residues, the Meeting agreed not to combine the data sets (Kruskal-Wallis test). Therefore, recommendations on fruiting vegetables, other than cucurbits, except mushroom and sweet corn will be based on the 2003 data set for sweet peppers, as the commodity with the highest residues.

Based on the combined data set for sweet pepper, the Meeting estimated a maximum residue level of 2 mg/kg for fruiting vegetables, other than cucurbits, except sweet corn and mushrooms, together with an STMR of 0.24 mg/kg. The Meeting agreed to withdraw the previous maximum residue level recommendations of 0.2 mg/kg for eggplant, 0.5 mg/kg for tomatoes, and 0.5 mg/kg for peppers, sweet.

The Meeting noted that the residues in chili pepper and other commodities within the group of fruiting vegetables differed significantly. Using the default dehydration factor of 7 for peppers, the following data set was obtained for dried chili peppers: 1.4, 1.9, 2.0, 4.1, and 4.7 mg/kg. The Meeting estimated a maximum residue level of 9 mg/kg for dried chili peppers, together with an STMR-P of 2.0 mg/kg.

Brassica leafy vegetables

Cyprodinil is registered in the USA for use in brassica leafy vegetables (including mustard greens), at a GAP of 4×0.37 kg ai/ha, with a 7-day PHI.

Seven trials were conducted in mustard greens in the USA in accordance with GAP. Residues in mustard green leaves at the 7-day PHI were 0.23, 0.36, 0.36 (s), 0.37, 0.71, 5.4, and 8.0 mg/kg, where (s) indicates a result scaled to account for application rates outside $\pm 25\%$ of GAP.

The Meeting estimated a maximum residue level of 15 mg/kg for mustard greens, together with an STMR of 0.37 mg/kg. The Meeting agreed to extrapolate to estimate a maximum residue level of 15 mg/kg for brassica leafy vegetables.

Leafy vegetables, except brassica leafy vegetables

The 2003 JMPR estimated maximum residue levels of 10 mg/kg for lettuce, head and lettuce, leaf, based on data matching GAP for France (2×0.19 kg ai/ha, with a 14-day PHI) and Italy (3×0.26 kg ai/ha, with a 14-day PHI).

The Meeting received residue data from the USA and Canada in head lettuce, leaf lettuce, spinach, and watercress.

Cyprodinil is registered in the USA for use in leafy vegetables, other than brassica leafy vegetables, at a GAP of 4×0.37 kg ai/ha, with a 0-day PHI.

Eight trials were conducted in lettuce, head in accordance with the USA GAP. Residues in lettuce heads, with wrapper leaves at the 0-day PHI were 1.6, 2.0, 2.2, 2.3, 2.7, 2.9, 5.1, and 21 mg/kg. Residues in lettuce head with wrapper leaves removed were 0.07, 0.15, 0.31, 0.32, 0.63, 0.69, 1.6, and 3.2 mg/kg.

Six trials were conducted in leaf lettuce, in accordance with the USA GAP. Residues in lettuce leaves at the 0-day PHI were: 8.5, 10 (2), 11, 14, and 24 mg/kg.

Ten trials were conducted in spinach in accordance with the USA GAP. Residues in spinach at the 0-day PHI were 5.6, 6.1, 6.6, 8.3, 11 (2), 12, 13, 14, and 32 mg/kg.

One trial was conducted in watercress in accordance with the USA GAP. Residues in watercress at the 0-day PHI were 12 mg/kg.

The Meeting noted that the USA GAP is the same for all leafy vegetables other than brassica leafy vegetables and considered a group maximum residue level. To consider a group maximum residue level, residues in individual crops should be similar (e.g., medians should not differ by more than 5×). However, the Meeting agreed not to combine the data sets (Kruskal-Wallis test). TAs a result recommendations on leafy vegetables other than brassica leafy vegetables were based on the spinach dataset, as the commodity with the highest residues. Based on the dataset for spinach, the Meeting estimated a maximum residue level of 50 mg/kg for leafy vegetables, except brassica leafy vegetables, together with an STMR of 11 mg/kg. The Meeting agreed to withdraw the previous maximum residue level recommendations of 10 mg/kg for lettuce, head and lettuce, leaf.

Legume vegetables

The 2003 JMPR estimated a maximum residue level of 0.5 mg/kg for beans (in pods), except broad bean and soya bean, based on data matching the GAPs of Spain (3×0.038 kg ai/hL, with a 14-day PHI) and (2×0.38 kg ai/ha, with a 14-day PHI).

The Meeting received residue data from the USA in common beans (snap beans, pods and succulent seed) and lima beans (succulent shelled seeds).

Cyprodinil is registered in the USA for use in beans (succulent), including chickpea, lupin, kidney, lima, mung, navy, pinto, snap, wax, and broad bean, asparagus bean and blackeyed pea, with a GAP of 4×0.37 kg ai/ha, with a 7-day PHI.

Eight trials were conducted in common beans (pods and succulent seeds) in accordance with the USA GAP. Residues in pod and seed samples at the 7-day PHI were 0.10, 0.12, 0.13, 0.16, 0.17, 0.18, 0.23, and 0.49 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg in beans, except broad bean and soya bean (green pods and immature seeds), together with an STMR of 0.165 mg/kg. The Meeting agreed to withdraw the previous maximum residue level recommendation of 0.5 mg/kg for beans, except broad bean and soya bean (green pods and immature seeds).

Six trials were conducted in lima beans (seeds without pods) in accordance with the USA GAP. Residues in succulent seeds at the 7-day PHI were < 0.02 (3), 0.02, 0.03 and 0.04 mg/kg.

The Meeting estimated a maximum residue level of 0.06 mg/kg for beans, shelled, together with an STMR of 0.02 mg/kg.

Beans (dry)

Cyprodinil is registered in the USA for use in beans (dry) at a GAP of 4×0.37 kg ai/ha, with a 7-day PHI.

Nine trials in beans (dry) were conducted in accordance with the USA GAP. Residues in beans at the 7-day PHI were < 0.02 , 0.02 (3), 0.03, 0.04 (3), and 0.15 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg for beans, dry, together with an STMR of 0.03 mg/kg.

Carrots

Cyprodinil is registered in the USA for use in carrots at a GAP of 4×0.37 kg ai/ha, with a 7-day PHI.

Ten trials in carrots were conducted in the USA and Canada in accordance with the USA GAP. Residues in carrots at the 7-day PHI were: 0.02, 0.05 (2), 0.06 (s), 0.08 (s) 0.10, 0.12, 0.18,

0.39, and 0.40 mg/kg, where (s) indicates a result scaled to account for application rates outside $\pm 25\%$ of GAP.

The Meeting estimated a maximum residue level of 0.7 mg/kg for carrots, together with an STMR of 0.09 mg/kg.

The Meeting noted that the US GAP for parsnips is the same as that for carrots, and agreed to extrapolate the residue data for carrots and estimated a maximum residue level of 0.7 mg/kg for parsnips, together with an STMR of 0.09 mg/kg.

Radish

Cyprodinil is registered in the USA for use in radish at a GAP of 2×0.37 kg ai/ha, with a 7-day PHI.

Five trials in radish were conducted in accordance with the USA GAP. Residues in radish roots at the 7-day PHI were < 0.01 (3), 0.03, and 0.14 mg/kg.

Residues in radish tops at the 7-day PHI were 0.13, 0.17, 0.40, 0.45, and 1.3 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for radish, together with an STMR of 0.01 mg/kg.

The Meeting agreed that residues of cyprodinil arising in radish tops would be covered by the proposed maximum residue level of 15 mg/kg for brassica leafy vegetables.

Herbs

Cyprodinil is registered in the USA for use in herbs at a GAP of 4×0.37 kg ai/ha, with a 7-day PHI.

Three trials in basil were conducted in accordance with the USA GAP. Residues in fresh basil leaves at the 7-day PHI were 1.5, 1.7 and 2.1 mg/kg. Residues in dried basil leaves at the 7-day PHI were 8.8 mg/kg.

Three trials in chives were conducted in accordance with the USA GAP. Residues in fresh chives at the 7-day PHI were 0.62, 1.0, and 1.1 mg/kg. Residues in dried chives at the 7-day PHI were 2.9 mg/kg.

Four trials in parsley were conducted in accordance with the USA GAP. Residues in fresh parsley at the 7-day PHI were 2.9, 3.0, 7.1, and 16 mg/kg. Residues in dried parsley at the 7-day PHI were 20 (2), 30, and 112 mg/kg.

The Meeting noted that the USA GAP is for all herbs and considered a group maximum residue level. To consider a group maximum residue level, residues in individual crops should be similar (e.g., medians should not differ by more than $5\times$). The Meeting agreed to estimate a maximum residue level for the group herbs. In deciding whether to combine the datasets for basil, chives and parsley for use in the statistical calculator, or to only utilize the data from the commodity with the highest residues, the Meeting agreed not to combine the data sets (Kruskal-Wallis test). Therefore, recommendations on herbs were based on parsley, as the commodity with the highest residues. Based on the data set for fresh parsley, the Meeting estimated a maximum residue level of 40 mg/kg for herbs, together with an STMR of 5.05 mg/kg.

The Meeting estimated a maximum residue level of 300 mg/kg for dried herbs except hops, dry, based on the data set for dried parsley, together with an STMR of 25 mg/kg.

Processing studies

A processing study for lemons was evaluated by the current Meeting; however as the residue data set for lemons was insufficient for the estimation of a maximum residue level or STMR, STMR-P values for citrus processed products were not estimated.

Some processing data for tomatoes was generated as part of the residue trial in tomatoes provided to the Meeting. Processing studies for apples, barley, grapes, plums, tomatoes and wheat

were considered by the 2003 JMPR. The studies in apples and tomatoes are relevant to the crops being considered by the current Meeting. Processing factors are tabulated below.

RAC	Processed product	PF
Apples	Wet pomace	3.5
	Juice	0.03
Tomatoes	Juice	0.17
	Purée	0.52
	Paste	0.86, 2.3

The processing factors were applied to the STMRs for the raw commodities to produce the following STMR-P values: wet apple pomace 1.8 mg/kg; apple juice 0.015 mg/kg; tomato juice 0.036 mg/kg; tomato purée 0.11 mg/kg; and tomato paste 0.48 mg/kg.

Residues in animal commodities

Farm animal dietary burden

Dietary burden calculations incorporating all commodities considered by the current and 2003 Meetings for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6. The calculations are made according to the livestock diets of the USA/Canada, the European Union, Australia and Japan as laid out in the OECD table.

	US/CAN		EU		AU		Japan	
	Max.	Mean	Max.	Mean	Max.	Mean	Max.	Mean
Beef cattle	0.91	0.37	13.9	1.8	5.8	1.4	0.46	0.46
Dairy cattle	1.7	0.87	13.5	1.4	23.3^a	1.8^b	0.26	0.26
Poultry – broiler	0.49	0.49	0.80	0.54	0.12	0.12	0.066	0.066
Poultry – layer	0.49	0.49	4.1^c	0.76^d	0.12	0.12	-	-

^a Highest maximum dairy cattle dietary burden suitable for HR and MRL estimates for mammalian milk

^b Highest mean dairy cattle dietary burden suitable for STMR estimates for mammalian milk

^c Highest maximum poultry dietary burden suitable for HR and MRL estimates for poultry meat and eggs

^d Highest mean poultry dietary burden suitable for STMR estimates for poultry meat and eggs

Animal commodity maximum residue levels

Mammals

A feeding study on lactating dairy cattle was considered by the 2003 JMPR.

Lactating Holstein dairy cows were dosed daily by gelatin capsule with cyprodinil at the equivalent of 5, 15 and 50 ppm in the dry-weight diet for 28 consecutive days. Milk was collected throughout and on days 28, 29, and 30, a cow from each dosing group was slaughtered for tissue collection. Cyprodinil residues were not detected (LOQ 0.01 mg/kg) in the milk (days 0, 1, 3, 7, 14, and 21), kidney, or fat of cows from the highest dose group (50 ppm), nor in milk (day 26) or muscle from any dose groups. Cyprodinil was present in liver (highest residue 0.013 mg/kg) from the highest dose group but not from the other groups.

The 2003 JMPR estimated a maximum residue level of 0.0004* mg/kg (F) for milk, together with an STMR of 0 mg/kg, based on a maximum dietary burden for dairy cattle of 8.2 ppm, and a mean dietary burden of 0.53 ppm.

The highest dietary burden for dairy cattle is for Australia (max. dietary burden of 23.3 ppm and mean dietary burden of 1.8 ppm). The Meeting noted that no residues of cyprodinil were quantified in milk above the LOQ (0.01 mg/kg) at feeding levels up to 50 ppm in cattle. The Meeting concluded that the existing maximum residue level and STMR for milk remain appropriate.

The 2003 JMPR estimated maximum residue levels of 0.01* mg/kg (fat) and STMRs of 0 mg/kg for meat (from mammals other than marine mammals), and edible offal (mammalian). These limits were based on a maximum dietary burden of 8.2 ppm, and a mean dietary burden of 0.53 ppm.

As for dairy cattle, the highest dietary burdens for calculation of meat MRLs are 23.3 ppm (max.) and 1.8 ppm (mean), considering all the use patterns evaluated by the 2003 JMPR and the present Meeting. Given that no residues of cyprodinil were found above the LOQ in muscle or fat of cattle at a feeding level of 50 ppm, the Meeting considers that the existing maximum residue level for meat (from mammals other than marine mammals), and the STMR values remain appropriate. No residues were found above the LOQ in kidney even at the highest dose of 50 ppm. In liver, no residues were found above the LOQ in liver at feeding levels of 5 and 15 ppm, while at 50 ppm, low residues up to 0.013 mg/kg were found. The Meeting estimated a maximum residue level of 0.01 mg/kg for edible offal (mammalian), together with an STMR of 0 mg/kg. The Meeting agreed to withdraw the previous recommendation of 0.01* mg/kg for edible offal (mammalian).

Poultry

A feeding study in poultry was not presented to the 2003 JMPR or to the present Meeting.

The 2003 JMPR estimated maximum residue levels of 0.01* mg/kg for eggs and poultry, edible offal of, and 0.01* mg/kg (fat) for poultry meat and STMRs of 0 mg/kg. These limits were based on a maximum dietary burden of 2.6 ppm and a mean dietary burden of 0.50 ppm, and consideration of the laying hen metabolism study.

Based on the use patterns considered by the 2003 JMPR and the present Meeting, the Meeting noted that the highest dietary burden for poultry (both for meat and egg producing birds) was the EU diet, with a maximum dietary burden of 4.1 ppm and a mean dietary burden of 0.76 ppm.

As noted by the 2003 JMPR, cyprodinil parent compound was not detected in poultry tissues in the laying hen metabolism study (except in kidney at 0.001 mg/kg), even at feeding levels of 215 and 226 ppm. Cyprodinil was detected in eggs at 0.002-0.011 mg/kg from birds dosed at 215 and 226 ppm. Given that these feeding levels are around 50 times the maximum dietary burden of 4.1 ppm estimated for poultry, the Meeting considers that the existing maximum residue levels, and STMR values for poultry commodities remain appropriate.

RECOMMENDATIONS

CCN	Commodity name	Recommended maximum residue level, mg/kg		STMR (P), mg/kg
		New	Previous

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Dietary Intakes (IEDIs) of cyprodinil were calculated for the 13 GEMS/food cluster diets using STMRs/STMR-Ps estimated by the current Meeting and by the 2003 JMPR. The ADI is 0–0.03 mg/kg bw and the calculated IEDIs were 5–40% of the maximum ADI (0.03 mg/kg bw). The Meeting concluded that the long-term intakes of residues of cyprodinil,

resulting from the uses considered by the current Meeting and by the 2003 JMPR, are unlikely to present a public health concern.

Short-term intake

The 2003 JMPR decided that an ARfD was unnecessary and concluded that the short-term intake of cyprodinil is unlikely to present a public health concern.

DICAMBA (240)

First draft prepared by Dr. Yukiko Yamada, Ministry of Agriculture, Forestry and Fisheries, Tokyo, Japan

EXPLANATION

Dicamba, a systemic broad-spectrum herbicide, was first evaluated by the 2010 JMPR which estimated an ADI of 0–0.3 mg/kg bw and ARfD of 0.5 mg/kg bw, and recommended the following residue definitions for plant commodities:

Definition of the residue for plant commodities (for compliance with the MRL): *Dicamba*

Definition of the residue (for estimation of dietary intake) for plant commodities: *Sum of dicamba and 5-OH dicamba expressed as dicamba*

Definition of the residue for animal commodities (for compliance with the MRL and for estimation of dietary intake): *Sum of dicamba and DCSA.*

Based on the above residue definition, the 2010 Meeting also recommended maximum residue levels for 21 commodities. These maximum residue levels were adopted as Codex MRLs at the Codex Alimentarius Commission in 2011 (REP 11/CAC, Appendix III, Part 2).

The 2010 JMPR received information on metabolism, method of analysis, storage stability, supervised residue trials and processing studies on soya beans. However, supervised trials were conducted in the USA with PHI of 7 days while the approved US label at that time indicated PHI of 14 days. Since no trials matched the GAP, the Meeting could not estimate a maximum residue level for soya bean (dry).

The label of one formulation, relevant to the trials, was since revised and approved with new PHI of 7 days matching that of the supervised trials. New US GAP allows two different applications: application of 0.56 kg ai/ha as a broadcast made to the soil surface approximately 14 days prior to planting and application of 1.12 kg ai/ha applied 7 days prior to harvest. The maximum total application rate per season is 2.24 kg ai/ha.

In the supervised trials on soya beans provided to the 2010 Meeting, pre-plant application of 0.56 kg ai/ha 14 days before planting and pre-harvest application of 2.24 kg ai/ha 7 days before harvest were made. The pre-harvest application rate was two times the GAP rate. The 2011 Meeting decided to apply the concept of proportionality to the residues from these trials to recommend a maximum residue level.

The Forty-fifth Session of the Codex Committee on Pesticide Residues in 2013 considered the Principles and Guidance for Application of the Proportionality Concept to Estimation of Maximum Residue Limits for Pesticides and agreed to forward the document to the 36th Session of the Commission for adoption and inclusion in the Procedural Manual as an Annex to the Risk Analysis Principles Applied by the Codex Committee on Pesticide Residues. It agreed that desiccants should be excluded from the application of the proportionality concept (REP 13/PR, paras 93 and 98, Annex VIII). The 36th Codex Alimentarius Commission adopted the proposed amendments to the Procedural Manual as above.

The current Meeting received information on new supervised trials on soya beans following the US GAP and analytical methods used for the determination of dicamba and related compounds in the new supervised trials on soya beans

RESIDUE ANALYSIS

Analytical Methods

The 2010 JMPR reviewed a number of analytical methods, mostly employing GC-ECD with GC-MS for confirmation, developed for the determination of dicamba, 5-OH dicamba and 3,6-dichloro-2-hydroxybenzoic acid (DCSA) in plant and animal commodities. Many of these methods developed for plant commodities were applicable to analysis of soya beans (dry).

An analytical method used to determine dicamba, 5-OH dicamba and DCSA arising in newly conducted supervised residue trials on soya beans was provided to the current Meeting. The method is summarized in Table 1 and its details are given below.

Table 1 Summary of analytical method for the determination of residues

Method No. Reference	Matrix tested	Analytes	Method	Limit of Quantitation
BASF Analytical Method No. D0902, Saha, M. (2009) *	Soya bean	Dicamba 5-OH dicamba DCSA	LC-MS/MS	0.01 mg/kg for each analyte, except for 0.05 mg/kg for each analyte in forage and hay (2010 Supervised Field Trials only)

*Validity of the method was tested on corn matrices in the cited separately performed study.

The soya bean samples were homogenized using a Retsch ultra centrifugal milling with liquid nitrogen cooling. The forage and hay samples were processed using a Stephan floor chopper with dry ice. All samples were stored frozen in plastic bags until analysis.

Residues in soya bean homogenate were extracted by hydrolysis in 1N HCl at 90 °C, cooling to room temperature, centrifugation and filtration. The filtrate was diluted with water and an aliquot of the extract was cleaned-up by liquid-liquid partitioning with hexane:ethyl acetate (1:1, v/v) and the organic phase was evaporated to dryness. Residues in dried organic phase were re-dissolved in methanol-water (1:9, v/v) and analysed by LC-MS/MS. MS/MS detection in the negative ionization mode was used to monitor ion transitions from m/z 219→175 for dicamba; m/z 235→155 for 5-OH-dicamba; and m/z 205→161 for DCSA.

For the analysis of the forage and hay samples from the 2010 growing season, a hexane partition was added prior to the hexane:ethyl acetate partition. This additional clean-up step was used due to matrix interferences. Other minor modifications were also made to the method but none of them had significant influence to analytical results.

This method was validated for dicamba, 5-OH dicamba and DCSA in soya bean matrices at the fortification concentration range between 0.01 and 10 mg/kg, in conjunction with the field sample analyses obtained in 2010 and 2012 growing seasons. The results of validation are summarized in Table 2.

The mean recoveries at all fortification levels were 73–100%, within an acceptable range for the three analytes in soya bean seeds with the relative standard deviation well below 20%. On the other hand, the mean recoveries of these three analytes in soya bean forage and hay were mostly between 70 and 109% with the relative standard deviation below 20% except that occasionally at the fortification level of 0.01 mg/kg, the recoveries were lower than 70% and the relative standard deviation around 20% were observed in 2010.

The limit of quantitation (LOQ) of this method is 0.01 mg/kg for the determination of dicamba, 5-OH dicamba and DCSA in soya bean seeds, forage and hay. However, the LOQ was 0.05 mg/kg for these analytes in soya bean forage or hay in the analyses performed in 2010.

Table 2. Recoveries of dicamba, 5-OH dicamba and DCSA in soya bean matrices by the method No.D0902

Soya bean matrix	Analyte	Fortification level (mg/kg)	N	Recoveries (%)	Mean (%)	RSD (%)
Seeds (2010 season)	Dicamba	0.01	6	78, 79, 90, 101, 110, 90	91	13

An asterisk (*) denotes that the result is the mean of duplicate or triplicate analyses of the same fortification sample.

USE PATTERNS

The authorized use on soya beans in the USA is summarized in Table 3.

Table3 Registered uses of dicamba on soya bean (dry) in the USA

Crop	Country	Formulation (g/kg or g/L and type)	F/G/P ^a	Application			PHI (days)
				Method	No. per crop season	min. - max. kg ai/ha per applic. ^b	
Soya bean (dry)	USA	480SL	F	Spray*	1 (pre-plant)	0.14–0.56	NA
					1 (pre-harvest)**	0.28–1.12	7
					Total 2	(2.24/season)	-

^a F = outdoor or field use, G = glasshouse, P = protected

^b Information given on active ingredient referring to dicamba only

NA = not applicable

* Aerial spray is also allowed.

** After soya bean pods have reached mature brown colour and at least 75% leaf drop has occurred. Do not feed soya bean fodder and hay following a pre-harvest application.

The label permits grazing after the pre-plant application while use of soya bean plants for grazing is not a common practice unless good harvest is not expected for some reasons such as natural disasters. The label prohibits feeding the plant materials after pre-harvest application.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The information on new supervised field trials of dicamba on soya beans, conducted in the USA in 2010 and 2012, were received and summarized in Table 4.

All trials were conducted outdoor. Application rates were reported as dicamba acid equivalents expressed in kg ai/ha. Residue concentrations were reported for dicamba, 5-OH dicamba and DCSA expressed in mg dicamba equivalents/kg. Residue concentrations are recorded unadjusted for recoveries or for residue values in control samples. Where duplicate samples were taken from a single plot, individual results are reported, and the calculated average concentration (in parentheses) is used for the estimation of maximum residue level. Where trials were conducted in the same location, with the same or similar varieties, similar formulations or different salt types, and at the same or similar timing, they are not regarded as independent and the highest residues from these trials were used for estimating a maximum residue level and STMR. Although trials included control plots, no control data are recorded in the tables below unless residues in control samples significantly exceeded the LOQ.

Total residues were calculated by summing up the concentrations of dicamba and 5-OH dicamba expressed in mg dicamba equivalents/kg. Residue concentrations found to be below the limit of quantitation (LOQ) or the limit of detection (LOD) were reported as < LOQ or < LOD respectively. Where the concentration of dicamba or 5-OH dicamba was < LOQ, they were regarded to be at the LOQ and where it was < LOD, they are regarded to be 0 for calculation.

Residues from the trials conducted according to maximum GAP and used for the estimation of maximum residues and STMR/HR are underlined.

Pulses

Soya bean

The approved use of dicamba in soya bean consists of two different applications: application of up to 0.56 kg ai/ha as a broadcast made to the soil surface approximately 14 days prior to planting, and/or up to 1.12 kg ai/ha applied 7 days prior to harvest. If both pre-plant and pre-harvest applications are used in one season, the maximum seasonal use rate must not exceed 2.24 kg ai/ha. Soya bean plants are susceptible to dicamba.

2010 Season (bridging trials)

Field trial data were generated for dicamba from four bridging trials (equivalent of 12 tests) on soya bean conducted in EPA Region 5 (Iowa, Minnesota, Nebraska, and South Dakota; one trial each) during the 2010 growing season.

For each trial, one untreated control plot and three “side-by-side” treated plots comparing three different soluble concentrate (SL) formulations of dicamba were established. The formulations tested were: a diglycolamine (DGA) salt of dicamba (480 g ai/L SL); a diethylenetriamine (DETA) salt of dicamba (480 g ai/L SL); and an N,N-bis (3-aminopropyl)-methylamine (BAPMA) salt of dicamba (600 g ai/L SL).

The treated plots received one broadcast application of the designated dicamba formulation to the soil targeting 28 days before planting at 0.56 kg ai/ha and one pre-harvest application targeting 7 days before the harvest of mature soya bean seed at 1.12 kg ai/ha, for a seasonal total of 1.7 kg ai/ha. The actual total application rate was 1.63–1.73 kg ai/ha/season. The applications were made using ground equipment in approximately 181–211 l/ha of water. An adjuvant was included in the spray mixture (0.25% v/v non-ionic spreader/sticker/surfactant of a minimum 80% active ingredient) together with ammonium sulfate liquid fertilizer (2% w/v).

From each untreated plot, single forage and hay (forage dried to less than 20% moisture) samples were collected at the BBCH 16 growth stage (vegetative, 6th trifoliate leaf unfolded), and a single sample of seed was collected at maturity (BBCH89). From each treated plot, duplicate forage and hay samples were collected at the BBCH 16 growth stage, 66–78 days after treatment (37–50 days after planting), and duplicate samples of seed were collected at maturity (BBCH89), 7 days after the second (last) application.

The soya bean samples were stored frozen (<-10 °C) for maximum of 872 days (29 months) for seed, 957 days (31 months) for forage, and 962 days (32 months) for hay from sample collection to extraction for analysis.

The residues of dicamba and its metabolites 5-OH-dicamba and DCSA in/on soya bean samples were quantitated by LC-MS/MS using BASF analytical method D0902. Acceptable concurrent method validation data for soya bean matrices were obtained for each analyte. In this study, the validated LOQ for residues of dicamba, 5-OH dicamba, and DCSA was 0.01 mg/kg in/on soya bean seed (dry) samples and 0.05 mg/kg in/on soya bean forage and hay samples. Apparent residues of dicamba (each analyte) were < LOQ in/on all untreated control soya bean seed, forage and hay samples. Concurrent analysis of untreated soya bean samples (seed, forage and hay) fortified with a mixture of dicamba, 5-OH-dicamba and DCSA at 0.01, 0.05, 0.1, 1 or 10 mg/kg, resulted in acceptable range of recovery of 70–120% at the stated LOQs with some isolated exceptions.

After only preplant application of three different SL formulations of dicamba, residues of dicamba were below the limit of quantitation of 0.05 mg/kg in all soya bean forage and hay samples harvested at a growth stage targeting BBCH 16.

After one pre-plant and one pre-harvest applications using the different salt types, residues measured in the seed (dry) samples were primarily the parent herbicide and mostly relatively low (< 0.1 mg/kg). However, several samples had significant residues but not in a particular pattern. These residues in the seed suggest that the pod containing the seed may have begun to split allowing residues to contact the seed. Another possibility for the significant residues is contact of the seed with the outer surface of the pods during shelling.

2012 Season

Eight field trials on soya bean were conducted during the 2012 growing season in EPA Region 2 (one trial each in New Jersey and North Carolina), Region 4 (Louisiana, one trial) and Region 5 (Illinois and Wisconsin, one trial each; Iowa, three trials). Each trial location consisted of one untreated and one treated plot. The treated plot received one broadcast pre-plant application of dicamba (a diglycolamine (DGA) salt of dicamba, 480 g dicamba acid equivalents/L SL) at the rate targeting

0.56 kg ai/ha to the soil targeting 28 days prior to planting, followed by one late-season, broadcast foliar application targeting 1.12 kg ai/ha, 7 days prior to harvest of mature seed. The actual total application rate was 1.66–1.74 kg ai/ha/season. The applications were made using ground equipment in approximately 181–219 l/ha of water with the same adjuvant as in 2010 and 2 % w/v ammonium sulfate.

From each untreated plot, single forage and hay (forage dried to less than 20% moisture) samples were collected at the BBCH 16 growth stage, and a single sample of seed was collected at maturity (BBCH89). From each treated plot, duplicate forage and hay samples were collected at the BBCH 16 growth stage, 62–88 days after treatment (33–60 days after planting); and duplicate samples of seed were collected at maturity (BBCH 89), 6 or 7 days after the last application. In one trial (Guthrie, IA), seed samples were harvested at 0, 3, 11 and 14 days after the last application, in addition to the 7 day PHI, to examine residue decline.

The soya bean samples were stored frozen from harvest to extraction, for 88–205 days (2.9 to 6.9 months). Samples were analysed within 6 days of extraction. Adequate storage stability data are available to support the storage conditions and durations for the samples in the subject study.

Soya bean samples (seed, forage and hay) were analysed for residues of dicamba and the metabolites 5-OH-dicamba and DCSA using a modified version of BASF Analytical Method No. D0902. The LOQ for each matrix was 0.01 mg/kg for these three analytes. The limit of detection (LOD) was set at 20% of the LOQ, or 0.002 mg/kg. Apparent residues of dicamba and the metabolites were < LOQ in/on all untreated control soya bean seed, forage and hay samples.

Individual procedural recoveries of dicamba, DCSA and 5-OH-dicamba from soya bean seed, forage and hay samples were within 70–120%. Mean recoveries of each analyte across all soya bean matrices and fortification levels at 0.01 and 1.0 mg/kg ranged from 80 to 103% (4–15% RSD).

After one broadcast preplant plus one late-season pre-harvest application of dicamba 480 g ai/l SL, residues of parent dicamba in soya bean seed (dry) harvested at maturity, 6 or 7 days after the last application, ranged from < 0.01 mg/kg to 0.60 mg/kg and the metabolites 5-OH dicamba and DCSA, were < 0.01 mg/kg in/on the 16 treated soya bean seed (dry) samples in this study.

Data from the residue decline site indicate that dicamba residues in soya bean seed generally declined with increasing pre-harvest intervals.

Residues of dicamba, 5-OH dicamba and DCSA were determined and reported individually. Dicamba concentrations were used for estimating a maximum residue level of dicamba in/on soya bean (dry) and the sum of dicamba and 5-OH dicamba expressed as dicamba was calculated and used for exposure assessment. Where the concentration of 5-OH dicamba was below the LOQ, the value of LOQ was used for the calculation of total concentration. However, where the concentration of 5-OH dicamba was below the LOD, its concentration was assumed to be zero.

The dicamba concentrations used for estimating a maximum residue level of dicamba in/on soya bean (dry) are underlined and the sum of dicamba and 5-OH dicamba used for estimating STMR for exposure assessment are double-underlined in the following Table.

^a Expressed in mg dicamba equivalents/kg. Average values in parentheses.

^b Sum of dicamba and 5-OH dicamba expressed as dicamba.

DALT= days after the last application

dbp = days before planting

dbh = days before harvest

Animal feed stuffs

Soya bean forage and hay

Soya bean forage and hay samples were collected before the second application was made. Therefore, residues in these commodities came from pre-plant application.

FATE OF RESIDUES IN STORAGE AND PROCESSING

The 2010 JMPR received and reviewed information on processing of soya bean to oil. The summary of processing studies on soya bean is transcribed below.

Table 4Summary of processing studies

Processed Product	Processing factor	
	Dicamba	Total residues
Soya bean		
Meal	0.35	0.36
Hulls	3.9	3.8
Grain dust	676	669
Refined oil	< 0.019	< 0.036

APPRAISAL

Dicamba, a systemic broad-spectrum herbicide, was first evaluated by the 2010 JMPR which estimated an ADI of 0–0.3 mg/kg bw and ARfD of 0.5 mg/kg bw, and recommended the following residue definitions for plant commodities:

Definition of the residue for plant commodities (for compliance with the MRL): *Dicamba*

Definition of the residue for plant commodities (for estimation of dietary intake): *Sum of dicamba and 5-OH dicamba expressed as dicamba*

Definition of the residue for animal commodities (for compliance with the MRL and for estimation of dietary intake): *Sum of dicamba and DCSA expressed as dicamba*

The 2010 Meeting reviewed metabolism, method of analysis, storage stability, supervised residue trials and processing studies of dicamba in soya beans. However, as no supervised trials matched US GAP, the Meeting could not estimate a maximum residue level for soya bean (dry). The 2011 Meeting decided to apply the concept of proportionality to the residues from these trials to recommend a maximum residue level.

The Forty-fifth Session of the Codex Committee on Pesticide Residues in 2013 agreed to the Principles and Guidance for Application of the Proportionality Concept to Estimation of Maximum Residue Limits for Pesticides and further agreed that desiccants should be excluded from the application of the proportionality concept.

The current Meeting received information on new supervised trials on soya beans following the US GAP and analytical methods used for the determination of dicamba and related compounds in the new supervised trials on soya beans.

Method of analysis

The current Meeting received information on the analytical method used for the determination of dicamba, 5-OH dicamba and 3,6-dichloro-2-hydroxybenzoic acid (DCSA) arising in soya bean seeds, forage and hay in newly conducted supervised residue trials. The method analysed these compounds using LC-MS/MS, monitoring ion transitions from m/z 219→175 for dicamba; m/z 235→155 for 5-OH-dicamba; and m/z 205→161 for DCSA.

The method was found suitable for the determination of the three analytes in soya bean seeds, forage and hay with mean recoveries in the acceptable range of 70–110% at the fortification levels between 0.01 and 10 mg/kg.

The limit of quantitation (LOQ) is 0.01 mg/kg for the determination of dicamba, 5-OH dicamba and DCSA in soya bean seeds, forage and hay, except that this LOQ was not achievable in forage or hay for the 2010 season analysis.

Results of supervised residue trials on crops

Soya bean (dry)

A total of twelve supervised residue trials were conducted in the USA in 2010 and 2012.

The approved use of dicamba in soya bean in the USA consists of two different applications: application of up to 0.56 kg ai/ha as a broadcast application made approximately 14 days prior to planting, and/or up to 1.12 kg ai/ha applied to soya bean plants after soya bean pods have reached mature brown color and at least 75% leaf drop has occurred with a PHI of 7 days. If both pre-plant and pre-harvest applications are used in one season, the maximum seasonal use rate must not exceed 2.24 kg ai/ha. After a pre-harvest application soya bean fodder and hay must not be fed to animals.

After one pre-plant and one pre-harvest applications using the three different salt types, residues in the seed (dry) samples were primarily the parent compound and mostly relatively low (< 0.1 mg/kg). However, residue concentrations vary hugely, due possibly to the split of pods causing seeds to come into contact with dicamba itself or dicamba residue on the outer surface of pods. Since all the trials approximated normal agricultural practices, the Meeting decided to use these trial results in estimating a maximum residue level. No significant difference or pattern was observed among the trials using these different formulations.

Residues of dicamba in soya bean (dry) from those trials matching the GAP of the USA were, in rank order (n=12): < 0.01 (2), 0.01, 0.02, 0.025 (2), 0.035, 0.06, 0.12, 0.545, 5.4 and 5.6 mg/kg.

The Meeting estimated a maximum residue level of 10 mg/kg to replace the previous recommendation of 5 mg/kg. For the purpose of calculating animal dietary burden, the Meeting estimated a median residue of 0.03 mg/kg.

Corresponding total residues (dicamba and 5-OH dicamba) of dicamba were (n=12): < 0.01, < 0.02, 0.02 (2), 0.025, 0.03, 0.035, 0.06, 0.13, 0.555, 5.635 and 6.06 mg/kg.

The Meeting estimated an STMR of 0.033 mg/kg.

Soya bean forage and hay

Soya bean forage and hay samples were collected before the second application was made to avoid abscission. Therefore, residues in these commodities came from a pre-plant application only. The US label prohibits the use of fodder or hay after a pre-harvest application.

The residues from the pre-plant application were expected to be very low as shown in the trials (mostly < 0.05 mg/kg and in one trial 0.06 mg/kg for dicamba) and, as such, residues in soya bean forage and hay from only pre-plant application would not have impacted on the livestock dietary burden. Therefore, the Meeting confirmed the decision of the 2010 and 2011 JMPR that there was no need for estimating a maximum residue level, median residue or highest residue for soya bean fodder and hay.

Fate of residues during processing

The 2010 JMPR received and reviewed information on processing of soya bean seed to oil and meal.

Processed Product	Processing factor		STMR/STMR-P
	Dicamba	Total residues	
Soya bean			0.033
Refined oil	< 0.019	< 0.036	0.001

As there is no concentration of dicamba and 5-OH dicamba observed in refined oil, the estimation of a maximum residue level is not necessary for this commodity.

On the basis of the processing factor of 0.35 for dicamba only, a median residue of 0.0105 mg/kg was calculated for soya bean meal, which may be used as a livestock feed item.

Residue concentration was observed in soya bean hulls and grain dust which may also be used as animal feeds. The processing factors of dicamba only, calculated for these commodities, were 3.9 and 676, respectively. From these factors, median residues in soya bean hulls and grain dust for the estimation of animal burden were calculated to be 0.117 and 20.3 mg/kg, respectively.

Residues in animal commodities

Soya beans and processed soya bean products may be fed to dairy cattle, beef cattle, broilers and layers. The maximum and mean dietary burdens were calculated using the highest residues and median residues of dicamba in commodities for which maximum residue levels were recommended by the 2010 JMPR and current JMPR and their processed products on a basis of the OECD Animal Feeding Table.

Residues of 5-OH dicamba was not included in the calculation of animal dietary burden as its concentrations in animal feeding items were very low and the feeding study with 5-OH dicamba resulted in very low uptake (< 0.01 mg/kg) of 5-OH dicamba into tissues, milk or blood of cattle at a dose equivalent to 59 ppm in the diet.

The resulting maximum and mean dietary burdens to be used for estimating maximum residue levels for commodities of animal origin (both mammals and poultry) were identical to those of the 2010 and 2011 JMPR.

The Meeting concluded that there was no need to re-evaluate maximum residue levels, STMRs or HRs for commodities of animal origin.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant commodities (for compliance with the MRL): *Dicamba*.

Definition of the residue for plant commodities (for estimation of dietary intake): *Sum of dicamba and 5-OH dicamba expressed as dicamba*.

Definition of the residue for animal commodities (for compliance with MRLs and for estimation of dietary intake): *Dicamba and 3,6-dichlorosalicylic acid (DCSA) expressed as dicamba*.

Residue is not fat-soluble.

Commodity		Recommended MRL, mg/kg		STMR/STMR-P mg/kg	HR/HR-P mg/kg
CCN	Name	New	Previous

	Soya bean (dry)			0.03	
	Soya bean meal			0.0105	
	Soya bean hull	-		0.117	-
	Soya bean grain dust	-		20.3	-

^a residues of dicamba only.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Dietary Intakes (IEDIs) of dicamba were calculated for the 13 GEMS/Food cluster diets using STMRs and STMRPs estimated by the 2010 and current Meeting (see Annex 3 of the 2013 Report). The ADI is 0–0.3 mg/kg bw and the calculated IEDIs were 0–1% of the maximum ADI. The Meeting concluded that the long-term intake of residues of dicamba resulting from the uses considered by the current JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short-Term Intakes (IESTI) of dicamba were calculated for soya bean and its processed commodity using STMRs/STMR-Ps estimated by the current Meeting (see Annex 4 of the 2013 Report). The ARfD is 0.5 mg/kg and the calculated IESTIs were 0% of the ARfD. The Meeting concluded that the short-term intake of residues of dicamba, when used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

DIFENOCONAZOLE (224)

The first draft was prepared by Professor Mi-Gyung Lee, Andong National University Republic of Korea

EXPLANATION

Difenoconazole was first evaluated by the JMPR in 2007 for toxicology when an ADI of 0–0.01 mg/kg bw and an ARfD of 0.3 mg/kg bw were established. In 2007 and 2010, the JMPR evaluated the compound for residues and recommended numerous maximum residue levels. The compound was listed by the Forty-fourth Session of the CCPR for residue evaluation for additional maximum residue levels by the 2013 JMPR.

The residue is defined, for compliance with the MRL and for estimation of dietary intake for plant commodities, as parent *difenoconazole*. For animal commodities for compliance with the MRL and for estimation of dietary intake, it is defined as *sum of difenoconazole and 1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1,2,4-triazol)-1-yl-ethanol (CGA 205375), expressed as difenoconazole*. The residue is fat soluble.

The current Meeting received supervised residue trial data for oranges, grapefruit, lemons, mandarin, tangerines, apples, pears, grapes, bulb onion, spring onion, head cabbage, broccoli, melons, gherkin, summer squash, sweet pepper, chili pepper, tomato and potatoes. The government of Republic of Korea provided residue trial data for Japanese persimmon and ginseng. Processing studies on oranges, apples, grapes, tomato, potato and ginseng were also provided. The Forty-fourth Session of the CCPR requested the 2013 JMPR to re-evaluate the ginseng processing studies evaluated in 2010, in accordance with the new classification on the processed products, i.e., dried ginseng (including red ginseng) and ginseng extracts.

RESIDUE ANALYSIS

Analytical methods

The manufacture provided information for analytical methods (REM 147.08 and AG-575B) used for analysis of parent difenoconazole in plant matrices.

Method REM 147.08 was considered by the 2007 and 2010 JMPR. The method was used for the analysis of citrus fruits, grapes, onions, brassica vegetable, cucurbits and potatoes. LOQs of the method by LC-MS/MS determination were 0.01 mg/kg in the all matrices and the procedural recoveries by matrix were in the range of 80–106% at various fortification levels.

Method AG-575B is one of the updated versions of AG-575. AG-575 and AG-575A (another updated version of AG-575) were considered by 2007 and 2010 JMPR. The method AG-575B was used for the analysis of apples, pears, peppers and tomatoes. LOQs in all matrices by GC-NPD determination were 0.01 mg/kg. The procedural recoveries by matrix were in the range of 98–109% at various fortification levels.

LOQs were 0.01 mg/kg in all matrices.

For potato and the processed products, recoveries from method validation were included.

In addition, the manufacturer provided information on analytical methods, Meth-160 and Meth-160, Revision #2. After minor modifications, the methods were used for analyzing triazole metabolites 1, 2, 4-triazole (T), triazole alanine (TA), and triazole acetic acid (TAA) in the same substrates subjected to difenoconazole analysis.

The triazole metabolites were extracted from 5.0 grams of sample with 60 mL of methanol:water (80:20, v/v) [Orange oil samples were first diluted with hexane then extracted twice with methanol:water (80:20, v/v), first with 60 mL, then with 30 mL. Extracts were combined and brought to a final volume of 100 mL with methanol:water (80:20, v/v)]. Individual 1.0 mL aliquots of each extract were processed separately through solid phase extraction (SPE) cleanup and/or derivatization steps, which were specific for each analyte. The TAA aliquot was purified through a C-18 SPE cartridge, then derivatized using HCl/butanol esterification. The TA aliquot underwent two derivatizations directly (bypassing a Bond Elut Certify II SPE cartridge cleanup step in order to capture conjugated residues of TA); the first was an esterification using HCl/butanol and the second was an acylation using HFBA (heptafluorobutyric anhydride). The T aliquot did not undergo further cleanup and was directly derivatized with dansyl chloride to produce the dansyl derivative of 1,2,4-triazole. The derivative was partitioned into ethyl acetate which was evaporated to dryness, then re-dissolved in 2.5 mL of acetonitrile:water (30:70, v/v). The TA and TAA derivatized extracts were evaporated to dryness as well, then brought to a final volume of 2.5 mL in acetonitrile:water (30:70, v/v). All three derivatized extracts were submitted to HPLC for individual analysis. Determination and quantitation of derivatives of 1,2,4-triazole, triazole alanine and triazole acetic acid were conducted using HPLC employing mass spectrometric (MS/MS) detection. LOQs for all analytes were 0.01 mg/kg. The procedural recoveries for the metabolites in all substrates were in the range of 70–115% at fortification levels of 0.1–2.0 mg/kg.

The metabolite, triazole alanine in apple, pear, peppers and tomato was analysed by including a Bond Elut Certify II SPE cartridge cleanup step prior to derivatization. As the cleanup removes any conjugated triazole alanine, additional analysis was again conducted without the SPE cartridge cleanup step. The results had no discrepancies in the data of triazole alanine between with or without cleanup procedure.

Table 2 Procedural recovery results and LOQs for triazole metabolites in various crops using Meth-160

Sample	Analyte	Range of fortification, mg/kg	No.	Range of recoveries, %	Mean recovery, % ± SD
Oranges	1,2,4-Triazole	0.01-0.50	16	74-79	87±7.3

For potato and the processed products, recoveries from method validation were included.

LOQs were 0.01 mg/kg in all matrices, with the exception of triazole alanine (TA) in potato tubers (0.02 mg/kg).

Meth-160 and Meth-160 Revision #2 were used in pome fruits; Meth-160, in peppers and tomato; Meth-160 Revision #2, in the other crops. Both Meth-160 and Meth-160 Revision #2 were modified and then applied.

Analytical methods of difenoconazole residues for ginseng and the processed products were similar to the methods considered by the JMPR in 2010, other than a change in volume of elution solvents on the florisil column. Analytical method used for fresh ginseng was changed to the method used for dried ginseng. LOQs for difenoconazole based on GC-ECD are 0.003 mg/kg for fresh ginseng and 0.007 mg/kg for the other substrates. Concurrent recoveries were 86–113% at the fortification levels of 0.003–1.0 mg/kg.

Persimmon, Japanese was ground with a blender after removing seeds and stalk. These samples were individually packed in polyethylene bags and stored at -20 °C until analysis. Difenoconazole residues were extracted using acetone and then the extract was partitioned with dichloromethane. The residue concentration was determined with GC-ECD. LOQ of difenoconazole was 0.02 mg/kg and concurrent recoveries of the compound were 88–107% at fortification levels of 0.02–2.0 mg/kg.

Table 3 Recovery results of difenoconazole in ginseng and Japanese persimmon

Matrix	Range of fortification, mg/kg	Mean recovery, % ± SD (n=5)
Ginseng	0.003	86 ± 2 ^a , 94 ± 4 ^b

	1.0	102 ± 3
	2.0	97 ± 6, 104 ± 7

^{a, b} In each case, five replicates were run.

Stability of residues in stored analytical samples

Information provided for the 2007 JMPR indicated that difenoconazole residues were stable at approximately -20 °C for 1 year in some commodity, but for 2 years in most commodities: banana, cotton seed, cotton seed meal, cotton seed oil, lettuce, potatoes, soya beans, tomatoes, wheat forage, wheat grain and wheat straw. In animal tissues and milk, difenoconazole and metabolite CGA 205375 were also stable at or below -18 °C for approximately 10 months. Difenoconazole residues in ginseng and the processed products were stable for 135 days when stored at or below -20 °C (2010 JMPR).

Stability test data for triazole metabolites (T, TA, TAA) were not provided for the Meeting.

Samples from the trials were stored at ca. -15 or -20 °C until analysis of difenoconazole for the following periods: 5 months in citrus fruits and grape, 8 months in apple and pear, 9 months in onions,

tomato and potato, 11 months in peppers, head cabbage and broccoli, 6 months in cucurbits. For analysis of triazole metabolites, the samples were stored for maximum 12 months under the same frozen conditions.

For ginseng and Japanese persimmon, stability was tested by analysing difenoconazole residues in spiked samples in parallel run when residue in field treated sample was analysed. The untreated samples were spiked at the time of sampling of the treated crops. The spiked and trial samples were kept under the same storage condition, at or below -20 °C.

Table 4 Storage stability of difenoconazole in ginseng and Japanese persimmon

Matrix	Fortification level, mg/kg	Days of storage, stored at ca. -20°C	Remaining, % Mean $\pm$ SD, n=5
Ginseng	0.03	17	107 $\pm$ 4
	0.2	24	89 $\pm$ 5
Dried ginseng	0.07	31	104 $\pm$ 1
	0.2	21	102 $\pm$ 4
Red ginseng	0.07	30	112 $\pm$ 2
	0.2	23	99 $\pm$ 1
Dried ginseng ethanol extract	0.07	20	94 $\pm$ 2
	1.0	27	103 $\pm$ 2
Dried ginseng water extract	0.07	10	101 $\pm$ 1
	1.0	28	95 $\pm$ 2
Red ginseng ethanol extract	0.07	4	97 $\pm$ 2
	0.5	24	104 $\pm$ 5
Red ginseng water extract	0.07	28	106 $\pm$ 3
	0.5	18	100 $\pm$ 3
Persimmon, Japanese	0.2	51, 37	107 $\pm$ 8, 95 $\pm$ 5

USE PATTERN

Difenoconazole is a broad-spectrum fungicide used for disease control in various crops. The registered uses on crops which were submitted for evaluation by the 2013 JMPR are summarized in Table 5.

Table 5 Registered uses of difenoconazole on crops submitted for evaluation

Crop	Country	Form., %, w/v	Method	Application					PHI, days
				Rate, kg ai/ha	Rate, kg ai/hL	No.	Interval days	Total/season, kg ai/ha	
Citrus fruits	USA	EC 250	Foliar, G, A	0.09-0.14		(4)	7-21	0.56	0
Pome fruits	USA	EC 250	Foliar, G, A	0.078		(5)	7 – 10 ^a	0.37	14
Persimmon, Japanese	Rep. of Korea	WP 10 w/w	Foliar, G		0.0054	5	10		7
Grapes	USA	EC 250	Foliar, G, A	0.09-0.13		(4)	10-21 ^a	0.52	7
Bulb vegetables (onion bulb, garlic, shallot)	USA	EC 250	Foliar, G, A, C	0.09-0.13		(4)	7-10 ^a	0.52	7
Bulb vegetables (spring onion)	USA	EC 250	Foliar, G, A, C	0.09-0.13		(3)	7-10 ^a	0.38	7
Brassica (Cole) leafy vegetables (head cabbage, broccoli, Brussels sprouts)	USA	EC 250	Foliar, G, A, C	0.09-0.13		(4)	7-10 ^a	0.52	1
Fruiting vegetables (melons, cucumber, summer squash)	USA	EC 250	Foliar, G, A, C	0.09-0.13		(4)	7-10 ^a	0.52	0
Fruiting vegetables (tomato, peppers)	USA	EC 250	Foliar, G, A, C	0.078-0.13		(4)	7-14 ^a	0.52	0
Potato	USA	EC 250	Foliar,	0.078-		(4)	7-14 ^a	0.52	14

Crop	Country	Form., %, w/v	Method	Application					PHI, days
				Rate, kg ai/ha	Rate, kg ai/hL	No.	Interval days	Total/season, kg ai/ha	
			G, A, C	0.13					
Potato	USA	FS 360	Post-harvest: in line aq. spray	3.5 g ai/t		1			
Ginseng	Rep. of Korea	SC 11.3 w/w	Foliar, G		0.0030	4	10		7
	Rep. of Korea	SC 10 w/w	Foliar, G		0.0054	5	10		14

For only citrus fruits, there is a recommendation for use of adjuvant in label of EC 250 formulation. For grapes, bulb vegetables, brassica vegetables, fruiting vegetables and potato (for pre-harvest treatment), there is a recommendation for use of adjuvant in the label of SC formulation 11.4%, w/w. In pome fruits, there is no recommendation for adjuvant in any labels.

In the USA, EC 250 formulation is registered for grapes except Concord, Concord seedless and Thomcord.

Potatoes: flowable concentrate for seed treatment (36%, w/v) was used as a post-harvest spray for the control of certain post-harvest rots caused by Silver scurf (*Helminthosporum solani*) and *Fusarium* species; tubers should be tumbling as they are treated; use T-jet controlled droplet applicator^a (CDA) or similar application system; do not use on seed potatoes or on other seed pieces.

^a No more than 2 sequential applications before alternating to another fungicide with a different mode of action

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials for difenoconazole on the following crops.

Crop group	Commodity	Table No.
Citrus fruits	Orange, mandarin, tangerine	6
	Grapefruit	7
	Lemon	8
Pome fruits	Apple	9
	Pear	10
	Persimmon, Japanese	11
Berries and other small fruits	Grapes	12
Bulb vegetables	Onion, Bulb	13
	Spring onion	14
Brassica (cole or cabbage) vegetables, Head cabbages,	Cabbages, Head	15
Flowerhead cabbages	Broccoli	16
Fruiting vegetables, Cucurbits	Melons (Cantaloupe)	17
	Gherkin	18
	Squash, Summer	19
Fruiting vegetables, other than Cucurbits	Tomato	20
	Peppers, Sweet and Chili	21
Root and tuber vegetables	Potato	22
	Ginseng	23

Most residue trials were carried out in the USA according to GLP principles. Some trials had not been performed in compliance with GLP principles.

In handling duplicate samples, if two field samples were taken or results of two replicate plots were submitted, the mean value was calculated. From two trials carried out side-by-side, the higher residue was chosen.

Residue information from the USA trials included analytical results for triazole metabolites, 1, 2, 4-triazole, triazole alanine and triazole acetic acid. Triazole alanine was detected in field treated samples of most crops, up to maximum 1.5 mg/kg in head cabbage. In control samples, magnitudes of concentration of triazole alanine were nearly equivalent or less than residue concentrations determined in field treated samples.

Citrus fruits

Residue trials on citrus fruits were conducted in California, Florida and Texas in 2007 (oranges—nine trials; mandarins—two trials; tangerines one trial; grapefruits—six trials and lemons—five trials). Difenoconazole EC 250 formulation (250 g/L) was applied to citrus fruits as foliar applications four times at a rate of 0.14–0.15 kg ai/ha with 7 day intervals. Application volumes were between 95 and 935 L/ha for the concentrate sprays and 945 and 3742 L/ha for the dilute cover sprays, including NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v) in the spray solution.

Two replicate samples of mature fruit were collected on the last day of application. In the decline trials, samples were collected at 0, 3, 7 and 10 days after last application (DLA).

Table 6 Difenoconazole and metabolite residues in orange, mandarin and tangerine from supervised trials performed in the USA with EC 250 (Report No.: T004712-06)

Pome fruits

Apples and pears

Residue trials on apples and pears were conducted in California, Colorado, Idaho, Illinois, Michigan, New York, Oregon, Pennsylvania, Virginia and Washington in 2004. Difenoconazole EC 250 formulation was applied to apples (13 trials) and pears (six trials) as a foliar application five times at a rate of 0.072–0.081 kg ai/ha with 7 day intervals. Application volumes were between 94 and 935 L/ha for the concentrate sprays and between 945 and 3742 L/ha for the dilute cover sprays, non-ionic surfactant (0.125%, v/v) was included in the spray solutions. There is no recommendation for adjuvant for pome fruits in any label of difenoconazole in the USA.

After the last application, duplicate samples of mature fruit were collected 12–16 days for apples and 13–15 days for pears. In the decline trials, samples were collected at 0, 5, 9 or 10, 14 and 19 days after last application.

Persimmon, Japanese

Six residue trials were carried out on Japanese persimmon in the Republic of Korea in 2011 (3 trials) and 2012 (3 trials). The trial plots received five foliar applications of WP 10 formulation (% w/w) at a rate of 0.0054 kg ai/hL with 10 day intervals. In all trials, persimmon was harvested 0, 1, 3, 7, 14 and 21 days following the final application. The seeds and stalk of the fruit were removed prior to grinding, the samples were packed in plastic bags and stored at -20°C. Residue analyses were performed within 51 days after sampling.

In three trials conducted in 2011, five applications were made on the same dates. Likewise, in three trials of 2012, dates of five applications were the same. All six trials were performed with the same variety on different farms located within approximately 10-20 km, using the same hand sprayer with one head nozzle. All residue analyses were made in one laboratory, with four analytical replicates by the same analytical method.

WP 10 (% w/w) formulation was applied.

^{a, b} All trials were conducted with the same variety on different farms located within approximately 10-20 km. Three trials of each year were performed at the same dates of application, thus the three trials were not considered as independent.

Berries and other small fruits

Grapes

Twelve residue trials on grapes were conducted in California, New York, Oregon, Pennsylvania and Washington in 2007. Difenoconazole EC 250 formulation was applied to grapes as a foliar application four times at a rate of 0.13 kg ai/ha with 7 day intervals. Treatments were made in varying post foliar spray volumes ranging from about 93 to 930 L/ha, using NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v).

Duplicate samples of mature grapes were collected 6–7 days after the last application. In the decline trials, samples were collected at 0, 3, 5, 7 and 14 days after last application.

^a The trial was not selected as use of EC 250 formulation is not permitted for Concord variety.

^b The trials were conducted with the same variety at the same dates of application under the same weather conditions, using different soil and irrigation type (flood and drip) and different sprayer (airblast, tractor). These trials were not considered independent.

Bulb onions

Onion, Bulb

Eight residue trials on bulb onion were conducted in California, Colorado, Idaho, Illinois, New York, Texas and Washington in 2006. Difenoconazole EC 250 was applied to bulb onions as broadcast foliar spray applications four times at a rate of 0.13 kg ai/ha with 7 day intervals. Treatments were made in varying spray volumes ranging from about 60 to 300 L/ha application, using NIS + Silwet or Kinetic non-ionic surfactant (0.1%, v/v).

Duplicate samples of onion bulbs were collected 7 days after the last application. In the decline trials, samples were collected at 0, 3, 5, 7 and 9 days after last application.

Spring onion

Three residue trials on spring onion were conducted in California, Georgia and Texas in 2006. Difenoconazole EC 250 was applied to spring onions as foliar broadcast spray applications three times at rates of 0.13 kg ai/ha with 7 day intervals. Treatments were made in varying post foliar spray volumes ranging from about 160 to 300 L/ha application, using NIS + Silwet or Kinetic non-ionic surfactant (0.1%, v/v).

Duplicate samples of onions (whole plant) were collected 6 or 7 days after the last application. In the decline trial, samples were collected at 0, 3, 5, 7 and 9 days after last application.

Brassica (cole or cabbage) vegetables, Head cabbages, Flowerhead brassicas

Cabbages, Head

Six residue trials on head cabbage were conducted in California, Florida, North Carolina, New York, Texas and Wisconsin in 2006. Difenoconazole EC 250 was applied to head cabbage as foliar broadcast spray applications four times at a rate of 0.12-0.13 kg ai/ha with 7 day intervals. Treatments were made with varying spray volumes ranging from about 19 to 190 L/ha of, using NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v).

Duplicate samples of mature cabbages were collected 1 and 7 days after the last application. In the decline trials, samples were collected at 0, 1, 3, 5, 7 and 9 days after last application.

^a Residue concentration for head cabbage with wrapper leaves is indicated with normal letter. For head cabbage without wrapper leaves and wrapper leaves, the residue concentrations are indicated with italic letter and on the dot line, respectively.

^b The LOQ for TA is 0.02 mg/kg for this sample.

Broccoli

Six residue trials on broccoli were conducted in California, Texas and Washington in 2006. Difenoconazole EC 250 was applied to broccoli as foliar broadcast spray applications four times at a rate of 0.13 kg ai/ha with 7 day intervals. Treatments were made with varying spray volumes ranging from about 190 to 380 L/ha, using NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v).

Duplicate samples of mature broccoli were collected 1 and 7 days after the last application. In the decline trial, samples were collected at 0, 1, 3, 5, 7 and 9 days after last application.

^a Analysed portion was head and stem of broccoli.

Fruiting vegetables, Cucurbits

Melons

Six residue trials on cantaloupe were conducted in California, Georgia, Illinois and Texas in 2006. Difenoconazole EC 250 was applied to melons as post over the top broadcast spray applications four times at a rate of 0.12–0.13 kg ai/ha with 7 day intervals. Treatments were made in varying spray volumes ranging from about 27 to 290 L/ha, using NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v).

Melon (whole fruit) samples were collected 0 and 7 days after the last application. In one trial, samples were taken at PHIs of 4 and 7 days due to excessive rain on 0 day. In the decline trial, samples were collected at 0, 1, 3, 5, 7 and 9 days after last application.

Gherkin

Six residue trials on gherkins were carried out in Florida, Georgia, Michigan, North Carolina, Texas and Wisconsin during 2006 and 2007. Difenoconazole EC 250 was applied to gherkins as foliar broadcast spray applications four times at a rate of 0.13 kg ai/ha with 7 day intervals. Treatments were

made in varying spray volumes ranging from about 19 to 290 L/ha application, using NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v).

The fruit samples were collected 0 and 7 days after the last application. In the decline trial, samples were collected at 0, 1, 3, 5, 7 and 9 days after last application.

Squash, Summer

Five residue trials were conducted on summer squash (courgette) in California, Florida, Illinois, New York and South Carolina) during 2006 and 2007.

Difenoconazole EC 250 was applied to summer squash as post over the top broadcast spray applications four times at a rate of 0.13–0.14 kg ai/ha with 7 day intervals. The spray volumes were about 25–464 L/ha including NIS + Silwet or Kinetic non-ionic surfactant (0.125%, v/v). The fruit samples were collected 0 and 7 days after the last application. In the decline trial, samples were collected at 0, 1, 3, 5, 7 and 9 days after last application.

Fruiting vegetables, other than Cucurbits

Tomato

Eleven residue trials were carried out on tomato in California, Florida, New York, Ohio, and South Carolina in 2004.

Difenoconazole EC 250 was applied to tomatoes as foliar broadcast spray four times at a rate of 0.12–0.13 kg ai/ha. The intervals between applications were 7 days and all treatments were made at spray volumes ranging from about 19 to 334 L/ha, using non-ionic surfactant (0.125%, v/v). Fruit samples were collected on the last day of application, further, 6–8 days after the last application. In the decline trial, samples were collected at 0, 1, 4, 7 and 9 days after last application.

Peppers (Sweet and Chili)

Residue trials were conducted on sweet peppers and chili peppers in California, Florida, Illinois, North Carolina and Texas in 2004.

Difenoconazole EC 250 was applied to sweet peppers (6 trials) and chili peppers (3 trials) as foliar broadcast spray four times at a rate of 0.12–0.14 kg ai/ha. The intervals between applications were 7 days and all treatments were made at spray volumes ranging from about 27 to 493 L/ha using non-ionic surfactant (0.125%, v/v). The fruit samples were collected on the last day of application, further, 7 days after the last application. In the decline trials, samples were collected at 0, 1, 4, 7 and 9 days after last application.

Root and tuber vegetables

Potato (post-harvest treatment)

Potatoes were obtained from a commercial grower received a post-harvest treatment using difenoconazole FS 360 formulation (g/L). For each trial, information on potato source (soil properties, maintenance fertilizers and pesticides, some harvest/storage) was provided. In one trial, modification after harvest (washing and air-drying the day before post-harvest treatment) was reported. Until post-harvest treatment, the potato tubers were kept in on-site storage for approximately one to four months at 6 to 14 °C.

Difenoconazole solution was applied once to potatoes (five trials, conducted in Idaho, Maine, Ontario, Washington and Wisconsin) as a post-harvest treatment at a rate of 3.4–3.8 g ai/t tubers. The applications were made with a tank mixture containing also azoxystrobin (SC 250) and fludioxonil (SC 230), each at a rate of 4.5 g ai/t tubers. The spray was directed to tubers falling from a conveyor belt or moving along a roller table. The post-harvest treated tubers (approximately 14 tubers) were

collected within 0 day after the test substance had dried. At the Ontario site (trial ON14), tubers were cut in half, retaining half as the sample.

In one trial (ID19), the following additional treatments were also included to evaluate residue levels from different application methods:

Spray directed to tubers placed on a flat surface close together, allowed to dry, turned over, and sprayed again (surface/stationary).

Spray directed to tubers placed close together inside a spray chamber, allowed to dry, turned over, and sprayed again (spray chamber).

Spray directed to tubers placed on a brush table that rolled the potatoes under the spray (brush table).

At the following three sites, additional treated samples were collected for storage study. After the post-harvest treatment and the test substance had dried, tubers were placed in typical potato storage:

Trial ID19: 30 and 231 days at 6 °C, 95% RH

Trial ON14: 14, 31 and 59 days at 3–5 °C, 95% RH

Trial WA32: 13, 32, and 61 days at 5–10 °C.

Until analysis, all samples were kept frozen at below -17 °C in site facilities and at ca. -20 °C in the analytical lab. In all control samples, difenoconazole was < 0.01 mg/kg.

^a As application equipment, backpack CO₂ sprayer (WA32 trial), conveyor belt with backpack CO₂ sprayer (WI19 trial), CDA applicator with diaphragm pump (ME04 trial), CO₂ sprayer in rolling table chamber (On14) and conveyor belt with backpack CO₂ sprayer (ID19 trial) were used.

Ginseng

There was a request for the re-estimation of maximum residue levels for processed ginseng products as a change in grouping for the processed products was made during the 2011 CCPR Session. The 2010 JMPR recommended maximum residue levels for fresh ginseng and the products, based on the residue levels from five trials conducted in the Republic of Korea in 2009. For the present JMPR evaluation, the country additionally provided data from two trials (Study No. 09072-944 and 09072-945). The new trials were conducted in 2010 at the sites of the two trials that were carried out in 2009 and evaluated by JMPR in 2010.

Ready to harvest ginseng, 5 years in qage, was treated four times with a difenoconazole SC 10 formulation (% w/w) at a rate of 0.0054 kg ai/hL (10 mL of a formulation with 10% ai in 20 litre of water) with 10 day intervals. Fresh ginseng was harvested 14 days after the last application.

Trials conducted in 2009 were evaluated by the 2010 JMPR.

^a *Panax ginseng* C.A. Mey. (Violet-stem variant)

^b GAP for SC 10 (% w/w)

^c GAP for SC 10.7 (% w/w) as of 2009. Currently, the formulation composition is 11.3 (% w/w).

^d SC 10.7 formulation was used only in the one trial, according to the registered usage.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In processing

The Meeting received information on the fate of difenoconazole residues during the processing of oranges, apples, grapes, tomatoes, potatoes and ginseng.

Oranges (juice, oil and dried pulp)

Orange trees were treated four times with difenoconazole EC 250 by foliar cover spray applications at rates of 0.14 kg ai/ha (total rate 0.56 kg ai/ha) and at an exaggerated rate of 5× (total rate 2.8 kg ai/ha) in one residue trial (Trial No. E15FL078041) conducted in Florida in 2007. Composite samples (~200 kg) of mature fruit were collected on day 0, after the last application, and used for processing of oranges into fresh juice, citrus oil and dried pulp simulating normal commercial processing practices.

Oranges were batch tub washed. Approximately 2.75 kg of oranges per batch were abraded to scarify the flavedo for oil recovery. The scarified fruit was weighed and retained for juice processing.

The collected oil-water emulsion was screened and the scarified flavedo was set aside for later addition to the shredded peel. The first run oil-water emulsion was processed through a cream separator and centrifuge to separate the oil. The free oil was removed and frozen. The residual emulsion was centrifuged, and recovered oil was added to the oil collected the previously. The entire volume of oil collected was placed in frozen storage.

An aliquot of the scarified oranges was transferred to the juice extractor to recover the juice from the peel. The collected juice was screened to remove vesicular membranes, seed, segment membranes and peel fragments.

The peel from a juice extractor was shredded and combined with the scarified flavedo from the scarification process and with rag (the stringy axis and white fibrous membrane) and seeds from the juice finisher extraction process to generate wet peel. Lime was added to the wet peel and mixed. The limed peel was pressed. The wet peel pulp was dried to below 10% moisture and then the dried pulp was milled.

Apples (juice and wet pomace)

Apples were treated five times with difenoconazole EC 250 by foliar cover spray applications with a rate of 0.075–0.078 kg ai/ha (total rate 0.38 kg ai/ha) in two residue trials (Trial No. 5A-FR-04-5190 and WF-FR-04-5199) conducted in New York and Washington in 2004. An exaggerated rate of 5× (total rate 0.19 kg ai/ha) was also applied in the each trial. Composite samples (~ 60 kg) of mature fruit were collected 14–18 days after the last application.

Processing of apples into wet pomace and fresh juice was performed under processing conditions simulating commercial practices. Unwashed apples were washed and reduced to crushed apple pulp. The crushed apple pulp was heated with low steam and treated with enzyme. The enzyme treated pulp was pressed and wet pomace and fresh juice was collected.

Grapes (raisin and juice)

Grapes were treated four times with difenoconazole EC 250 by foliar broadcast spray applications with a rate of 0.13 kg ai/ha (total rate 0.52 kg ai/ha) in two residue trials (Trial No. E03NY078021 and W32CA078023) conducted in California in 2007. Exaggerated rates of 3 $\times$ (total rate 1.6 kg ai/ha) and 5 $\times$ (total rate 2.6 kg ai/ha) were also applied. Composite samples (~ 45 kg) of mature fruit were collected approximately 7 days after the final application. Processing of grapes into juice and raisins was performed under processing conditions that simulated commercial practice.

^a Processing factors were not derived due to use of Concord variety.

Tomato (paste and puree)

Tomatoes were treated four times with difenoconazole EC 250 by post foliar broadcast spray applications with a rate of 0.12–0.13 kg ai/ha (total rate 0.50–0.52 kg ai/ha) in two residue trials (Trial No. WC-FR-04-5222 and WD-FR-04-5225) conducted in California in 2007. Exaggerated rates of 5× (total rate 0.63–0.65 kg ai/ha) were also applied. Composite samples (~ 135 kg) of mature fruit were collected either on day 0, after the spray was completely dry (WD-FR-04-5225) or at 7 days after the final application (WC-FR-04-5222). Processing of tomatoes into paste and puree was performed according to commercial processing practices.

As a first step, tomatoes were washed by the washing system consisted of two sets of washing flumes/spray washers. The washed tomatoes were crushed by a grinder and pumped into the hot break system to be heated to 91–92 °C. Peel and seeds (wet pomace) were removed from the crush, producing tomato juice. Concentration of juice to puree was done using a vacuum evaporator until Natural Tomato Soluble Solids (NTSS) of puree reaches to the target NTSS of 8–16%. Puree transferred to the vacuum kettle evaporator was condensed to paste until the paste reaches the target NTSS, of 24–35%.

Potatoes (wet peel, flake and chip)

A processing study was conducted on treated tubers from one residue trial (Trial No. ID19, Idaho, USA). Potatoes were treated post-harvest with a spray application directed to tubers falling from a conveyor belt. The applications were made with a spray solution containing difenoconazole, fludioxonil and azoxystrobin at a rate of 3.5–3.6, 4.5 and 4.5 g ai/t tubers, respectively. Bulk tuber samples (~ 113 kg) were collected after the test substance had dried (0 day) and used for processing. Processing was conducted according to commercial processing practices.

Potato tubers were washed and representative samples were removed and returned to storage for chip processing. The remaining tubers were steam peeled and scrubbed. The peel was collected, and the peeled tubers were hand trimmed as necessary. The trimmings were added to the collected peel and both were hydraulically pressed to produce the wet peel sample, which was placed in frozen storage.

The peeled tubers were sliced into slabs, washed in cold water, and pre-cooked at 70 to 77 °C for 20 minutes in a steam-jacketed kettle. The pre-cooked tuber slabs were cooled to less than 32 °C for approximately 20 minutes and then steam-cooked at 94 to 100 °C for 40 to 42 minutes. The cooked tuber slabs were mashed in a grinder and mixed with an emulsion of pre-weighed food additives. The cooked mash was dried into a thin sheet, which was broken into large flakes by hand and then fed into a press for milling into potato flakes. After drying on a fluidized bed-dryer, to remove excess moisture, the potato flake samples were placed into frozen storage.

The tubers retained for chips were removed from storage. The tubers were peeled, trimmed and cut into thin slice. The slices were placed in a tub of hot water to remove free starch, drained, and then fried at 163 to 191 °C for approximately 120 seconds. The fried chips were drained, salted and placed in frozen storage for later analysis.

Ginseng (dried-, red ginseng, the extracts)

Ginseng was treated four times with SC 10 formulation (% w/w) at a rate of 0.0054 kg ai/hL at 10 day intervals. The fresh ginseng was then harvested at 14-day PHI. Two processing studies (Study No. 09072-944 and 09072-945) were conducted in 2010, in the same manner with the method described in 2010 JMPR evaluation.

Briefly, washed ginseng (RAC, ginseng treated with tap water to remove soil particles) was dried in hot air to produce dried ginseng (water content, 8.0% and 9.6% in each study). The washed ginseng was steamed, dried in hot air, and dried again under sunlight to produce red ginseng (water content, 9.0% and 12.1% in each study).

Ethanol or water extracts of the dried and red ginseng were made by refluxing with ethanol (70%) or with water. The solvents were evaporated until the sugar content in the extract reached 65 or 72 °Brix. Water content in the dried extracted product was as follows: in two studies each, 38.5%, 40.2% in ethanol extract of dried ginseng, 48.5%, 36.8% in water extract of dried ginseng, 38.2%, 37.2% in ethanol extract of red ginseng and 53.4%, 35.9 % in water extract of red ginseng.

^a Bold letter value refers to Pf derived by the present Meeting. The others came from the previous JMPR reports.

^b For ginseng, the 2010 JMPR derived only one Pf, 3.3 for dried ginseng, due to an uncertainty of the dataset.

APPRAISAL

Difenoconazole was first evaluated by the JMPR in 2007 for toxicology when an ADI of 0–0.01 mg/kg bw and an ARfD of 0.3 mg/kg bw were established. In 2007 and 2010, the JMPR evaluated for residues and recommended numerous maximum residue levels. The compound was listed by the Forty-fourth Session of the CCPR for residue evaluation for additional MRLs by the JMPR in 2013.

The residue is defined, for plant commodities, as parent difenoconazole for compliance with the MRL and for estimation of dietary intake. For animal commodities, it is defined as sum of difenoconazole and 1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1,2,4-triazol)-1-yl-ethanol (CGA 205375), expressed as difenoconazole, for compliance with the MRL and for estimation of dietary intake. The residue is fat soluble.

The present Meeting received residue trial information on citrus fruits, pome fruits, grapes, Japanese persimmon, bulb vegetables, brassica vegetables, fruiting vegetables, ginseng and post-harvest treated potato. Further, processing studies on oranges, apples, grapes, tomatoes, potatoes and ginseng were provided. According to a request from the Forty-fourth Session of the CCPR, the Meeting re-evaluated the ginseng processing studies evaluated in 2010 to estimate MRLs complying with the new classification for processed products.

Methods of analysis

The analytical methods used for the determination of difenoconazole in samples from supervised trials, had already considered by the JMPR in 2007 and 2010. The methods are based on LC-MS/MS and GC-NPD determination and the limits of quantitation were 0.01 mg/kg. The validity of the analytical results was supported by validation data on representative crops and results of concurrent recovery studies.

The methods used for ginseng and the processed products were also considered by the 2010 JMPR. The limits of quantitation for difenoconazole based on GC-ECD were between 0.003 and 0.007 mg/kg and concurrent recoveries ranged between 86% and 113%.

Difenoconazole in Japanese persimmon were extracted with acetone and partitioned with dichloromethane. The LOQ by GC-ECD determination was 0.02 mg/kg and concurrent recoveries ranged from between 88% and 107%.

The Meeting additionally received information on analytical methods used for the determination of triazole metabolites 1, 2, 4-triazole, triazole alanine and triazole acetic acid residues in the same plant commodity samples from the supervised trials. The methods involved extraction with organic solvents, SPE clean-up and/or derivatization steps, partition with ethyl acetate and

determination by LC-MS/MS. The limits of quantitation for all metabolites were 0.01 mg/kg and procedural recoveries ranged from 70% to 115%.

Stability of residues in stored analytical samples

The 2007 JMPR concluded that difenoconazole was stable for 2 years in most plant commodities when deep frozen. This covered the stability of difenoconazole in samples from the supervised trials. New data on ginseng and Japanese persimmon were provided. The storage stability tests were conducted simultaneously with storage of field trial sample for 4–31 days in ginseng and the products and for 51 days in Japanese persimmon. The results indicated that residues in the samples were stable during the storage period.

Results of supervised residue trials on crops

Citrus fruits

Difenoconazole is registered in the USA for use on citrus fruits at a GAP of 4×0.14 kg ai/ha (total seasonal rate of 0.56 kg ai/ha), 7 day interval and a PHI of 0 days. Residue trials on citrus fruits were conducted in the USA, matching the critical GAP. Residue concentrations of difenoconazole in citrus fruit, determined on a whole fruit basis, were: 0.11, 0.13, 0.13, 0.14, 0.15, 0.15, 0.23, 0.26 and 0.37 mg/kg in oranges (n=9); 0.17, 0.38 mg/kg in mandarin (n=2); 0.49 mg/kg in tangerine (n=1); 0.075, 0.09, 0.11, 0.13, 0.18 and 0.18 mg/kg in grapefruit (n=6); 0.09, 0.16, 0.17, 0.19 and 0.24 mg/kg in lemons (n=5).

The Meeting noted that as the GAP in USA was for citrus fruits and that the medians of data sets for oranges, mandarins, grapefruits and lemons differed by less than 5-fold, agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, given a Kruskal-Wallis H-test indicated that the residue populations were not different, it was agreed to combine the results to give a data set of: 0.075, 0.09, 0.09, 0.11, 0.11, 0.13, 0.13, 0.13, 0.14, 0.15, 0.15, 0.16, 0.17, 0.17, 0.18, 0.18, 0.19, 0.23, 0.24, 0.26, 0.37, 0.38 and 0.49 mg/kg (n=23) for citrus.

The Meeting agreed to estimate a maximum residue level of 0.6 mg/kg, an STMR of 0.16 mg/kg and an HR of 0.49 mg/kg for whole citrus fruits.

Pome fruits

Difenoconazole is registered in the USA for use on pome fruits at a GAP of 5×0.078 kg ai/ha (total seasonal rate of 0.37 kg ai/ha), 7 day intervals and a PHI of 14 days. Residue trials on apple and pear were conducted in the USA and complied with the US GAP.

Residues in apples were (n=13): 0.02, 0.07, 0.07, 0.08, 0.13, 0.16, 0.21, 0.25, 0.28, 0.37, 0.38, 0.39 and 0.47 mg/kg.

Residues in pears were (n=6): 0.07, 0.12, 0.12, 0.14, 0.19 and 0.27 mg/kg.

A national use pattern in the Republic of Korea permits up to five foliar applications of difenoconazole WP 10 (% w/w) on Japanese persimmon at a rate of 0.0054 kg ai/L with 10 day intervals and a PHI of 7 days. Six trials were conducted in the Republic of Korea in 2011 (3) and 2012 (3) matching the critical GAP.

However, all trials were conducted with the same variety. In each year, three trials were performed at the same dates of application and under the same weather conditions, thus the trials were not considered as independent. As a result the Meeting considered that for this evaluation, only two residue values (0.37, 0.43 mg/kg) were available. In addition, the GAP differed from that of the US GAP for pome fruits. Consequently, the persimmon residue values could not be combined with residues from apple and pear.

The Meeting noted that the GAP in USA was for pome fruits and that the medians of the apple and pear data sets differed by less than 5-fold and agreed to consider a group maximum residue

level. In deciding on the data set to use for estimating a group maximum residue level, since a Mann-Whitney U-test indicated that the residue populations for apple and pear were not different it was agreed to combine the results to give a data set of: 0.02, 0.07 (3), 0.08, 0.12 (2), 0.13, 0.14, 0.16, 0.19, 0.21, 0.25, 0.27, 0.28, 0.37, 0.38, 0.39 and 0.47 mg/kg (n=19) for pome fruits group.

The Meeting estimated a maximum residue level of 0.8 mg/kg, an STMR of 0.16 mg/kg and an HR of 0.47 mg/kg for pome fruits. The Meeting withdrew its previous recommendation of 0.5 mg/kg for pome fruits.

Grapes

A national use pattern in the USA permits up to four foliar applications of difenoconazole EC 250 (250 g/L) on grapes at a rate of 0.13 kg ai/ha (total seasonal rate of 0.52 kg ai/ha) with 10 days interval and a PHI of 7 days. Twelve trials conducted in the USA matched the critical GAP, of which two trials were not considered independent as they were carried out on the same variety at a nearby location (experiencing the same weather conditions) and shared the same dates of application. In addition, one trial was excluded as it was carried out with a grape variety for which use was not allowed.

Residues in grapes were (n=10): 0.11, 0.17, 0.19, 0.23, 0.40, 0.64, 0.65, 0.67, 1.3 and 1.5 mg/kg.

The 2007 JMPR estimated a maximum residue level of 0.1 mg/kg for grapes, based on residue trials conducted in southern Europe matching Italian GAP (four applications to grape vines with a spray concentration of 0.005 kg ai/hL with a PHI of 21 days).

As the US use pattern is considered the more critical GAP than the Italian GAP, the Meeting recommended a maximum residue level of 3 mg/kg, an STMR of 0.52 mg/kg and an HR of 1.5 mg/kg for grapes, using residue data from the USA. The Meeting withdrew its previous recommendation of 0.1 mg/kg for grapes.

Bulb vegetables

Onion, bulb

A national use pattern in the USA permits up to four foliar applications of difenoconazole EC 250 (250 g/L) on bulb onions at a rate of 0.13 kg ai/ha (total seasonal rate of 0.52 kg ai/ha), with a 7 day interval and a PHI of 7 days.

Residues in onion, bulb were (n=8): < 0.01 (3), 0.01, 0.02, 0.02, 0.03 and 0.07 mg/kg.

Based on the residue values, the Meeting estimated a maximum residue level of 0.1 mg/kg, an STMR of 0.015 mg/kg and an HR of 0.07 mg/kg for onion, bulb.

Spring onion

A national use pattern in the USA permits up to three foliar applications of difenoconazole EC 250 (250 g/L) on green onions including spring onions at a rate of 0.13 kg ai/ha (total seasonal rate of 0.38 kg ai/ha), with 7 days interval and a PHI of 7 days. Three trials conducted in the USA matched the critical GAP.

Residues in whole spring onion were (n=3): 2.3, 2.8 and 3.8 mg/kg.

The Meeting estimated a maximum residue level of 9 mg/kg, an STMR of 2.8 mg/kg and an HR of 3.8 mg/kg for spring onions.

Brassica (cole or cabbage) vegetables, Head cabbages, Flowerhead cabbages

A national use pattern in the USA permits up to four foliar applications of difenoconazole EC 250 (250 g/L) on Brassica (cole) leafy vegetables at a rate of 0.13 kg ai/ha (total seasonal rate of

0.52 kg ai/ha) with 7 days interval and a PHI of 1 day. Six trials on head cabbage and broccoli each were conducted in the USA according to the critical US GAP.

Residues in head cabbage with wrapper leaves were (n=6): 0.09, 0.30, 0.34, 0.46, 0.94 and 1.3 mg/kg.

Residues in broccoli (head and stem) were (n=6): 0.15, 0.32, 0.32, 0.35, 0.37 and 0.53 mg/kg.

Based on GAPs of various European countries, the 2007 JMPR recommended a maximum residue level of 0.2 mg/kg for Brussels sprouts, head cabbage and cauliflowers, respectively, and 0.5 mg/kg for broccoli. As the USA GAP allows a shorter PHI (1 day) than the European GAP, the Meeting decided to use the US trials for maximum residue level estimation.

The Meeting noted that the GAP in USA was for Brassica vegetables and that the medians of the two data sets differed by less than 5-fold and agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, since a Mann-Whitney U-test indicated that the residue populations for head cabbage and broccoli were not different, it was agreed to combine the results to give a data set of: 0.09, 0.15, 0.3, 0.32, 0.32, 0.34, 0.35, 0.37, 0.46, 0.53, 0.94 and 1.3 mg/kg (n=12) for Brassica (cole or cabbage) vegetables, Head cabbages, Flowerhead cabbages.

The Meeting estimated a maximum residue level of 2 mg/kg, an STMR of 0.35 mg/kg and an HR of 1.3 mg/kg for the crop group, Brassica (cole or cabbage) vegetables, Head cabbages, Flowerhead cabbages. The meeting withdrew its previous recommendations for Brussels sprouts, Head cabbage and Cauliflowers of 0.2 mg/kg and for Broccoli of 0.5 mg/kg.

Fruiting vegetables, Cucurbits

Melons

A national use pattern in the USA permits up to four foliar applications of difenoconazole EC 250 (250 g/L) on cucurbit vegetables at a rate of 0.13 kg ai/ha (total seasonal rate of 0.52 kg ai/ha), 7 day interval and a PHI of 0 days. Six trials on cantaloupe conducted in the USA were provided for this Meeting. Five trials were performed according to the US critical GAP, however in one trial the harvest was made 4 days after the last application.

Residues in whole melon were (n=5): 0.06, 0.08, 0.14, 0.19 and 0.35 mg/kg.

The Meeting estimated a maximum residue level 0.7 mg/kg, an STMR of 0.14 mg/kg and an HR of 0.35 mg/kg for melons, except watermelon.

Cucumber, summer squash

A national use pattern in the USA permits up to four foliar applications of difenoconazole EC 250 (250 g/L) on cucurbit vegetables at a rate of 0.13 kg ai/ha (total seasonal rate of 0.52 kg ai/ha), 7 day interval and a PHI of 0 days. Six trials on gherkins and five trials on summer squash were provided to the Meeting. The trials were conducted in the USA complied with the critical US GAP.

Residues in gherkin were (n=6): < 0.01, 0.01, 0.03, 0.04, 0.04 and 0.15 mg/kg.

Residues in summer squash were (n=5): < 0.01, 0.02, 0.05, 0.06 and 0.06 mg/kg.

The Meeting noted that the GAP in USA is for fruiting vegetables, cucurbits with edible peel and that the medians of the two data sets differed by less than 5-fold and agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, since a Mann-Whitney U-test indicated that the residue populations for gherkin and summer squash were not different it was agreed to combine the results to give a data set of < 0.01, < 0.01, 0.01, 0.02, 0.03, 0.04, 0.04, 0.05, 0.06, 0.06 and 0.15 mg/kg (n=11) for fruiting vegetable, cucurbits with edible peel.

The Meeting estimated a maximum residue level of 0.2 mg/kg, an STMR of 0.04 mg/kg and an HR of 0.15 mg/kg for fruiting vegetables, cucurbits with edible peel (cucumber, gherkin and summer squash).

Fruiting vegetables, other than Cucurbits

A national use pattern in the USA permits up to four foliar applications of difenoconazole EC 250 (250 g/L) on fruiting vegetables (tomatoes and peppers) at a rate of 0.13 kg ai/ha (total seasonal rate of 0.52 kg ai/ha), 7 day interval and a PHI of 0 days. Trials conducted in the USA (11 trials for tomatoes, six trials for sweet peppers, three trials for chili pepper) were provided to the current Meeting. The trials were performed according to the critical US GAP.

Residues in tomato were (n=11): 0.01, 0.10, 0.11, 0.11, 0.14, 0.15, 0.16, 0.26, 0.27, 0.39 and 0.39 mg/kg.

Residues in sweet pepper were (n=6): 0.06, 0.10, 0.11, 0.14, 0.14 and 0.18 mg/kg.

Residues in chili pepper were (n=3): 0.10, 0.16 and 0.26 mg/kg.

Residue data for sweet pepper and chili pepper was combined for mutual support. Further, the Meeting noted that the GAP in USA was for fruiting vegetable other than cucurbits and that the medians of the two data sets differed by less than 5-fold and agreed to consider a group maximum residue level. In deciding on the data set to use for estimating a group maximum residue level, as a Mann-Whitney U-test indicated that the residue populations for tomatoes and peppers were similar, it was agreed to combine the results to give a data set of 0.01, 0.06, 0.10(3), 0.11 (3), 0.14 (3), 0.15, 0.16, 0.16, 0.18, 0.26, 0.26, 0.27, 0.39 and 0.39 mg/kg (n=20) for fruiting vegetables other than cucurbits.

The 2007 JMPR recommended a maximum residue level of 0.5 mg/kg for tomato from eleven trials conducted on tomatoes in Europe (France, Greece, the UK, Spain) matching the Italian GAP (2 applications at 0.13 kg ai/ha with a PHI of 7 days). However, the GAP of the USA was considered to be the critical GAP.

Therefore, based on the combined dataset on tomato and peppers from the US trials the Meeting estimated a maximum residue level of 0.6 mg/kg, an STMR of 0.14 mg/kg and an HR of 0.39 mg/kg for fruiting vegetables other than cucurbits except sweet corn and mushrooms. The Meeting withdrew its previous recommendation for tomatoes of 0.5 mg/kg.

Furthermore, the Meeting estimated a maximum residue level of 5 mg/kg, an STMR of 1.1 mg/kg and an HR of 1.8 mg/kg for chili peppers dried.

Potato (post-harvest treatment)

A national use pattern in the USA permits a single post-harvest application of difenoconazole to potatoes at a rate of 3.19 g ai/t tubers with in an line aqueous spray application using T-jet controlled droplet applicator (CDA) or similar application system. The US GAP does not specify a withholding period.

Residue trials on potatoes involving post-harvest application were conducted at five sites in different regions of the USA. In the trials, difenoconazole FS 360 (360 g/L) was applied once to potatoes as a post-harvest treatment at a rate of 3.5–3.8 g ai/t tubers, spraying directly to tubers falling from a conveyor belt or moving along a roller table. Post-harvest treated tubers were then collected on the day of treatment (0 day) once the test substance had dried. In decline studies, tubers were stored for up to 231 days in typical storage conditions of 5–10 °C.

At one site, potato tubers were cut at the field site. At another one site, in addition to a conveyor belt treatment, three additional application methods (surface, spray chamber and brush table) were utilized. The two methods using surface spraying and spray chamber did not comply with US GAP.

Therefore, in total five trials matching US GAP were available for use in estimating a maximum residue level.

In the USA, a pre-harvest application using difenoconazole formulation is also authorized on potatoes. No residue was detected in pre-treatment samples.

Residues in potatoes from post-harvest treatment (n=5): 0.61, 0.87, 1.2, 1.3 and 1.9 mg/kg.

The Meeting estimated a maximum residue level of 4 mg/kg, an STMR of 1.2 mg/kg and an HR of 1.9 mg/kg for post-harvest treated potato. The Meeting withdrew its previous recommendation of 0.02 mg/kg for potato that had been based on the residues resulting from pre-harvest treatment.

Ginseng

The maximum GAP in the Republic of Korea allows five applications of difenoconazole SC 10 (% w/w) on ginseng at a rate of 0.0054 kg ai/hL, with a 10 day interval and a PHI of 14 days.

Two trials, using ready to harvest ginseng plantations (5 years old), were conducted in the Republic of Korea, complying with the maximum GAP. The resulting residues were: 0.030 and 0.044 mg/kg.

Of five trials evaluated by the 2010 JMPR, four trials matched the maximum GAP of the Republic of Korea. Thus the residues were (n=6): 0.006, 0.017, < 0.02, < 0.02, 0.030 and 0.044 mg/kg.

The Meeting estimated a maximum residue level 0.08 mg/kg, an STMR of 0.02 mg/kg and an HR of 0.044 mg/kg for ginseng. The Meeting withdrew its previous recommendation of 0.5 mg/kg for ginseng.

Animal feed

Residue information on animal feeds was not provided to the current Meeting.

Fate of residues during processing

The Meeting received information on the fate of difenoconazole residues during the processing of oranges, apples, grapes, tomatoes, potatoes and ginseng. The following table summarizes processing factors, STMR-Ps and HR-Ps estimated by the Meeting.

Raw agricultural commodity	Processed commodity	Pf (best estimate)	RAC STMR/HR	STMR-P/HR-P
Citrus	Citrus juice	< 0.01	0.16	0.002
	Citrus oil	47		7.5
	Citrus dry pulp	4.0		0.64
Pome fruit	Apple juice	0.03	0.16	0.005
	Apple pomace, wet	9.5		1.5
Grape	Raisin	2.1	0.52/1.5	1.1/3.2
	Juice	0.46		0.24
Tomatoes	Paste	1.6	0.14	0.22
	Puree	0.57		0.08
Potato	Flakes	< 0.024	1.2	0.029
	Chips	0.073		0.088
	Peel, wet	3.2		3.8
Ginseng	Dried including red ginseng	2.6	0.02/0.044	0.052/0.11
	Extracts	7.0	-	0.14

For dried grapes (raisin), the Meeting estimated a maximum residue level of 6 mg/kg, based on the processing factor of 2.1 for raisins and the maximum residue level of 3 mg/kg for grapes.

The Meeting re-calculated a processing factor for dried ginseng including processing study results for red ginseng, for a processing factor of 2.6. Based on the processing factor of 2.6 and a maximum residue level of 0.08 mg/kg for the ginseng raw commodity, the Meeting recommended a maximum residue level of 0.2 mg/kg for ginseng, dried including red ginseng. For ginseng extracts, applying the calculated processing factor of 7.0, a maximum residue level of 0.6 mg/kg was estimated.

Residues in animal commodities

Estimated dietary burdens of farm animals

Dietary burden calculations for beef cattle and dairy cattle and poultry are provided below. The dietary burdens were estimated using the OECD diets listed in Appendix IX of the 2009 edition of the FAO Manual.

Potential feed items include: almond hulls, apple pomace, bean forage, cabbages, head, carrot culls, citrus dried pulp, grape pomace, dry, pea vines, potato culls, potato process waste (wet peel), rape seed fodder, rape seed meal, soya bean seed, sugar beet leaves or tops, sunflower seed meal, wheat straw and fodder.

The Japanese animal diet contained only soya bean seed and rape seed meal of those commodities for which the JMPR estimated highest and median residues. The residues in the two commodities resulted in an animal dietary burden of less than 0.01 ppm on dry matter basis, therefore those values are not included in the summary table.

	Livestock dietary burden, difenoconazole, ppm of dry matter diet					
	US-Canada		EU		Australia	
	max	mean	max	mean	max	mean
Beef cattle	12.56	11.42	17.88 ^a	15.30 ^b	11.39	10.80
Dairy cattle	4.87	4.36	14.91 ^c	12.37 ^d	11.31	10.71
Poultry, broilers	0.01	0.01	0.96	0.61	0.01	0.01
Poultry, layers	0.01	0.01	1.89 ^e	1.11 ^f	0.01	0.01

^a Highest maximum beef or dairy cattle dietary burden suitable for maximum residue level estimates for mammalian meat and edible offal

^b Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat and edible offal

^c Highest maximum dairy cattle dietary burden suitable for maximum residue level estimates for milk

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for milk

^e Highest maximum broiler or layer poultry dietary burden suitable for maximum residue level estimates for poultry meat, edible offal and eggs

^f Highest mean broiler or layer poultry dietary burden suitable for STMR estimates for poultry meat, edible offal and eggs

Estimated residues in animal commodities

For MRL estimation, the residues in the animal commodities are the sum of difenoconazole and CGA 205375 (1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1, 2, 4-triazol)-1-yl-ethanol)) expressed as difenoconazole.

Cattle

The 2007 JMPR evaluated two animal transfer studies carried out with Holstein dairy cows administering difenoconazole at 1, 3, 10 ppm (study 1) or 1, 5, 15 ppm (study 2) in the dry-weight diet for 29–30 consecutive days. The Meeting concluded that the two feeding studies were generally in good agreement of transfer factors. Thus, the present Meeting used the study with the 5 and 15 ppm feeding levels as most closely bracketing the dietary burdens.

For maximum residue level estimation, the high residues in the tissues were calculated by interpolating the maximum dietary burden of 17.88 ppm (in 2010 it was 2.42 ppm) between the

relevant feeding levels (5 and 15 ppm) from the dairy cow feeding study and using the highest tissue concentrations from individual animals within those feeding groups.

The STMR values for the tissues were calculated by taking the STMR dietary burden of 15.30 ppm between the relevant feeding levels (5 and 15 ppm) from the dairy cow feeding study and using mean residue of the three animals.

The following table shows the expected residues in animal commodities.

	Feed level (ppm) for milk residues	Residues (mg/kg) in milk	Feed level (ppm) for tissue residues	Residues (mg/kg) in			
				Muscle	Liver	Kidney	Fat
Maximum residue level beef or dairy cattle							
Feeding study ^a	5	< 0.005	5	0.012	0.29	0.046	0.058
	15	0.013	15	0.058	0.80	0.14	0.16
Dietary burden and residue estimate	14.91	0.013	17.88	0.071	0.95	0.17	0.19
STMR beef or dairy cattle							
Feeding study ^b	5	< 0.005	5	0.012	0.25	0.043	0.046
	15	0.013	15	0.046	0.70	0.13	0.14
Dietary burden and residue estimate	12.37	0.011	15.30	0.047	0.71	0.13	0.14

^a Highest residues for tissues and mean residue for milk

^b Mean residues for tissues and milk

For muscle, the residues arising from dietary burdens of 17.88 ppm and 15.30 ppm were 0.071 mg/kg and 0.047 mg/kg, respectively. In fat, the residues arising from dietary burdens of 17.88 ppm and 15.30 ppm were 0.19 mg/kg and 0.14 mg/kg, respectively.

The residues in milk were 0.013 mg/kg and 0.011 mg/kg from dietary burdens of 14.91 ppm and 12.37 ppm, respectively.

For liver, the residues arising from dietary burdens of 17.38 ppm and 15.30 ppm were 0.95 mg/kg and 0.71 mg/kg, respectively. In kidney, the residues arising from dietary burdens of 17.88 ppm and 15.30 ppm were 0.17 mg/kg and 0.13 mg/kg.

The Meeting estimated a maximum residue level for difenoconazole in mammalian fat of 0.2 mg/kg. STMR and HR values for mammalian muscle and fat were estimated as 0.047 and 0.071 mg/kg in muscle, 0.14 and 0.19 mg/kg in fat, respectively.

For milk, the Meeting estimated a maximum residue level of 0.02 mg/kg and an STMR value of 0.011 mg/kg. Information on fat distribution in milk was not available.

The Meeting estimated a maximum residue level, an STMR value and an HR value for difenoconazole in mammalian edible offal of 1.5, 0.71 and 0.95 mg/kg, respectively, reflecting residues in liver of higher residue level.

The Meeting withdrew its previous recommendations on commodities of mammalian origin and milks.

Poultry

The 2007 JMPR evaluated a transfer study carried out with laying white leghorn hens. Four groups of 15 laying hens were fed rations treated with difenoconazole at 0.3, 1, 3 and 10 ppm for 28 consecutive days. Eggs were collected on 10 occasions for analysis (days 0 before treatment, 1, 3, 6, 9, 13, 16, 20, and 23). Poultry tissue and egg samples from the 0.3 ppm feeding group were not analysed because residues were at or below LOQ (< 0.01 mg/kg) in the 1 ppm feeding group. For poultry tissue, residues in 1 ppm feeding level were also not analysed as the residues in 3 and 10 ppm feeding levels were at or below LOQ (< 0.01 mg/kg).

	Feed level (ppm) for egg residues	Residues (mg/kg) in egg	Feed level (ppm) for tissue residues	Residues (mg/kg) in			
				Muscle	Liver	Skin	Fat
Maximum residue level broiler or laying hen							
Feeding study ^a	1	< 0.01	3	< 0.01	< 0.01	< 0.01	< 0.01
	3	0.046	10	< 0.01	< 0.01	< 0.01	< 0.01
Dietary burden and residue estimate	1.89	0.026	1.89	< 0.01	< 0.01	< 0.01	< 0.01
STMR broiler or laying hen							
Feeding study ^b	1	< 0.01	3	< 0.01	< 0.01	< 0.01	< 0.01
	3	0.032	10	< 0.01	< 0.01	< 0.01	< 0.01
Dietary burden and residue estimate	1.11	0.011	1.11	< 0.01	< 0.01	< 0.01	< 0.01

^a Highest residues for tissues and mean residues for egg

^b Mean residues for tissues and mean residues for egg

For poultry tissues, residues arising from the maximum dietary burden of 1.89 ppm were below LOQ (0.01 mg/kg). The Meeting confirmed the maximum residue level recommendation of < 0.01 mg/kg for poultry tissues (fat, edible offal). Further, the Meeting estimated an STMR value and an HR value, 0.001 mg/kg and 0.002 mg/kg, respectively, for the tissues (muscle, fat and edible offal).

For eggs, residues arising from dietary burdens of 1.89 ppm and 1.11 ppm were 0.026 mg/kg and 0.011 mg/kg. The Meeting estimated a maximum residue level of 0.03 mg/kg and an STMR value 0.011 mg/kg and an HR value of 0.026 mg/kg for eggs. The Meeting withdrew its previous recommendation for eggs of 0.01* mg/kg.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue concentrations listed below are suitable for establishing MRLs and for assessing IEDIs and IESTIs.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for plant commodities: *difenoconazole*.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for animal commodities: *sum of difenoconazole and 1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1,2,4-triazol)-1-yl-ethanol*, expressed as *difenoconazole*.

The residue is fat-soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The ADI for difenoconazole is 0–0.01 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for difenoconazole were estimated for the 13 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the previous and present JMPR. The results are shown in Annex 3 of the 2013 JMPR Report. The IEDIs ranged 4–60% of the maximum ADI. The Meeting concluded that the long-term intake of residues of difenoconazole from uses considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The ARfD for difenoconazole is 0.3 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for difenoconazole were calculated for the food commodities for which STMRs or HRs were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2013 JMPR Report. The IESTIs varied from 0–30% of the ARfD for children and 0–20% for the general population.

The Meeting concluded that the short-term intake of residues of difenoconazole from other uses that have been considered by the present Meeting is unlikely to present a public health concern.

DIQUAT (031)

The first draft was prepared by Dr Dugald MacLachlan, Australian Government Department of Agriculture, Fisheries and Forestry

EXPLANATION

Diquat is an herbicide used in a variety of crops and was first reviewed by the 1970 JMPR. Diquat was scheduled at the Forty-fourth Session of the CCPR (2012) for periodic re-evaluation of toxicology and residues by the 2013 JMPR.

Diquat is a non-selective contact herbicide; the major use of which is for pre-harvest desiccation of a variety of crops. It is rapidly absorbed by green plant tissue and interacts with the photosynthetic process to produce compounds that destroy plant cells. It is inactivated on contact with soil and not taken up by plant roots. As a general herbicide diquat is used to control weeds before planting, before or just after crop emergence, and as a directed spray between the rows of established crops.

IDENTITY

Common name	Diquat
Chemical name	
IUPAC:	6,7 dihydrodipyrido[1,2-a:2',1'-c]pyrazinediium dibromide
CAS:	6,7-dihydrodipyrido[1,2-a:2',1'-c]pyrazinediium (8 & 9 CI)
CAS number:	2764-72-9 (diquat); 85-00-7 (diquat dibromide)
CIPAC Code:	55 (diquat); 55.303 (diquat dibromide)
Molecular formula:	C ₁₂ H ₁₂ N ₂ Br ₂ (diquat)
Molecular mass	344.05 (diquat), 184.2 (diquat ion)

Structural formula:

**Formulations**

Formulations	Active ingredient content
SL diquat	150–240 g ai/L
SL diquat and paraquat mixtures	45–135 g ai/L

Specifications

Specifications for diquat have been developed by FAO (2008).

PHYSICAL AND CHEMICAL PROPERTIES

Pure diquat dibromide as the monohydrate

Property	Results (method)	Reference
Appearance	Pure diquat dibromide is a yellow crystalline solid with no known characteristic odour	Wollerton, 1987; PP901/0024
Melting point	325 °C with decomposition	Wollerton, 1987; PP901/0024
Relative density	1.61 g/cm	Wollerton, 1987; PP901/0024
Vapour pressure	less than 10^{-8} kPa at 25 °C	Wollerton, 1987; PP901/0024
Henry's Law constant	An absolute value for Henry's Law Constant (H) cannot be calculated since pure diquat dibromide has no measurable vapour pressure. The value of H is estimated to be less than 5×10^{-12} Pa/m ³ /mol.	
Solubility in water including effect of pH	712 g/L at pH 5.2 (buffered water) 718 g/L at pH 7.2 (buffered water) 713 g/L at pH 9.2 (buffered water)	Wollerton, 1987; PP901/0024
Solubility in organic solvents (at 20 °C)	Methanol 25 g/L Acetone < 0.1 g/L Dichloromethane < 0.1 g/L Toluene < 0.1 g/L Ethyl acetate < 0.1 g/L Hexane < 0.1 g/L	Wollerton, 1987; PP901/0024
Partition coefficient n-octanol/water	log P _{ow} -4.6	Wollerton, 1987; PP901/0024
Hydrolysis	The hydrolysis of diquat was studied in the dark in sterile, aqueous buffered solutions at pH 4, pH 7 and pH 9 at 50 °C for 5 days. Diquat was shown to be hydrolytically stable under all the conditions tested in this study.	Dixon and Alderman, 2012; PP901_10823
Photolysis	The photolysis of diquat was investigated in sterile natural water under continuous irradiation from a xenon arc lamp simulating natural sunlight. Diquat was rapidly degraded, with only 15.8% parent compound remaining after 3 days irradiation. Degradation followed first-order kinetics with an estimated half-life of 31 hours (equivalent to 6.5 days of Tokyo spring sunshine, or 2 days summer sunlight at a latitude of 50 °N).	Oliver and Webb, 2005; PP901_1892
Dissociation constant	Not measureable	Wollerton, 1987; PP901/0024

Technical grade material

Property	Results (method)	Reference
Physical state, colour, and odour	Dark brown clear liquid with earthy odour	Wollerton, 1987; PP901/0024

Property	Results (method)	Reference
Density at 25 °C	1.26 g/cm ³	Wollerton, 1987; PP901/0024
pH at 20 °C	6.68	Wollerton, 1987; PP901/0024
Surface tension at 20 °C	41.0 mN/m	Wollerton, 1987PP901/0024

METABOLISM AND ENVIRONMENTAL FATE

Metabolites are given various abbreviations and code numbers in the studies. Structures and abbreviations and codes are shown below.

Degradation compounds from metabolism of diquat in plants, animals, soil, or water

Compound Name	Structure	Found in:
TOPPS 1,2,3,4-tetrahydro-1-oxopyrido (1,2-a) pyrazin-5-ium ion R032245		Livestock, plants
Diquat monopyrindone SYN546442 R34908		Livestock, crops
Diquat dipyrindone R030740		Livestock, crops
1-hydroxy-3,4-dihydro-1H-pyrido[1,2-a]pyrazine-2-carboxylic acid		Photolysis
1,4-dihydro-pyrido[1,2-a]pyrazin-5-ylum		Photolysis
3,4-dihydro-pyrido[1,2-a]pyrazin-5-ylum		Photolysis

Compound Name	Structure	Found in:
Picolinic acid		Livestock, crops
Picolinamide		Livestock, crops

The identification of residue components in the animal and plant metabolism studies was achieved using authentic standards of the compounds involved.

Animal metabolism

The Meeting received studies on the metabolism of diquat in rats, lactating goats and laying hens. The metabolism of only low levels of radioactivity are found in plant parts such as tubers that are not directly exposed to the spray in plants and animals was investigated using [^{14}C] diquat bromide. The structural formula and the positions of the ^{14}C label are shown below. The studies on rats were evaluated by the WHO Core Assessment Group.

*Label positions of diquat: marked as **

Ring-labelled diquat

Bridge-labelled diquat

Lactating goat

Wickstead and Lowrie (2012 PP901_10848) studied the metabolism of diquat in a lactating goat (53.5–58 kg bw; 2 kg milk/d) that was dosed orally via gelatin capsule once a day with ring labelled [^{14}C] diquat dibromide just after the morning milking for 7 consecutive days at the equivalent of 90 ppm in the feed (feed consumption 2.2 kg DM/d). Milk was collected twice daily and urine and faeces were collected daily. The goat was sacrificed approximately 12 h after the administration of the final dose and tissues taken post-mortem for quantification and analysis of radioactivity.

The radioactive residue in liquid samples was determined by direct liquid scintillation counting. Solid samples were homogenised frozen and the radioactive residue determined by combustion analysis followed by liquid scintillation counting. Milk, liver, kidney, composite muscle (forequarter, hindquarter and tenderloin in the ratio 4:4:1) and subcutaneous fat, sub-samples of were extracted three times (four times for fat) with 10% trichloroacetic acid. The resulting extracts were then further fractionated and subjected to chromatographic analysis by HPLC-MS/MS with concurrent radiodetection for identification/characterisation and quantification, respectively. The day 6 urine sample was analysed directly by LC-MS to provide further understanding of the biotransformation pathway.

The total recovery of dosed radioactivity was 97% with the majority of the radioactivity excreted in the faeces (84%) and only low levels (0.8%) in the urine. Approximately 12% remained in the gastrointestinal tract contents.

TRR in milk samples increased during the dosing period and reached a maximum of 0.015 mg equiv/kg in the milk collected at 156 hours (Day 7 pm) after the start of dosing. The large difference in TRR levels for samples collected at the morning and afternoon milkings is indicative of rapid elimination.

Figure 1 Radioactive residue in milk following dosing of a lactating goat once daily, equivalent to 90 ppm in the feed, for 7 consecutive days + morning samples, ● evening samples

Subsamples of day-4 to day-7 milk were separated by centrifugation into cream and skimmed milk; the fraction of cream residue to skimmed milk residue was between 0.57 and 0.67 in all samples suggesting the residues do not selectively partition into lipids.

Radioactive residues in tissues were low and ranged from 0.003 mg equiv/kg in the omental fat to 0.079 mg equiv/kg in the kidneys. Good extractability was achieved for the milk and muscle samples with greater than 90% TRR recovered in extracts. Extractability of radioactive residues from kidney and fat was approximately 80%TRR while the extractability from liver was slightly lower at 64% TRR.

The identified metabolites in the tissue, milk and urine samples are summarised in Table 1.

Table 1 Identification of radioactivity in goat tissue, milk and urine

Matrix	Milk	Liver	Kidney	Muscle	Subcutaneous Fat	Urine
TRR (mg equiv/kg)	0.012	0.052	0.079	0.010	0.016	—
			%TRR			
Extracted	94	64	83	91	80	

Matrix	Milk	Liver	Kidney	Muscle	Subcutaneous Fat	Urine
Diquat dipyrindone	82	33	29	46	20	16
Diquat monopyridone	ND	13	21	13	ND	19
Diquat	ND	22	4.3	ND	3.5	19
Unextracted	6.2	36	17	9.1	20	—

ND = not detected

The radioactivity remaining in liver and kidney after extraction with 10% trichloroacetic acid was further investigated using molecular weight/size exclusion filtration following treatment of the debris with sodium dodecyl sulphate. In liver, 9.2% TRR (0.005 mg equiv/kg) was characterised as having a molecular weight of < 3 kDa and a further 9.8% TRR (0.005 mg equiv/kg) > 3 kDa. In kidney, 1.2% TRR (0.001 mg equiv/kg) was characterised as < 3 kDa and a further 2.5% TRR (0.002 mg equiv/kg) > 3 kDa.

Laying hens

The metabolism of diquat in laying hens was studied by Leahey and Hemingway (1973, PP901/0464). Doses of ^{14}C -bridge labelled diquat were applied to the hen feed pellets and were administered orally once daily. Three experiments were carried out in this study, as follows:

Experiment 1

One hen was given a single oral dose of [^{14}C] diquat at a rate equivalent to 4–5 ppm in the diet and excreta collected for 3 days post dosing. Expired air was collected for 4 hours on day 1 and 7 hours on day 2 by drawing the air through ethanolamine traps.

Experiment 2

One hen was given five daily oral doses of [^{14}C] diquat at a rate equivalent to 4–5 ppm in the diet. Excreta and eggs were collected daily. The hen was sacrificed 7 days after the final dose, and samples of meat, fat, liver, kidney and lungs collected.

Experiment 3

One hen was given 14 daily oral doses of [^{14}C] diquat at a rate equivalent to 0.4–0.5 ppm in the diet. Excreta and eggs were collected daily. The hen was sacrificed 4 hours after the final dose, and samples of meat, fat, liver, kidney and blood collected.

TRR levels in the samples were determined by oxidative combustion followed by liquid scintillation counting (LSC) or by direct liquid scintillation counting. Dose feed pellets were analysed 1 and 28 days after treatment with [^{14}C] diquat. Pellets were extracted with water followed by 1 N HCl, and the combined extracts analysed by paper chromatography and by isotope dilution. Faeces samples were extracted by boiling with 2 M HCl, and the extracts analysed by paper chromatography against reference standards and by isotope dilution for diquat, diquat monopyridone and TOPPS. Fat was dissolved in a xylene solution for analysis by LSC. All other tissues were dried and analysed by sample oxidation. Eggs were separated into yolk and albumen. The egg yolks from experiments 2 and 3 were extracted by refluxing with 2 M HCl. Diquat, diquat monopyridone and TOPPS were isolated and analysed by isotope dilution.

The majority of the administered residue was rapidly excreted in hens. Extremely low residues of diquat or its metabolites were found in the tissues and eggs of poultry after continuous oral dosing with diquat.

In Experiment 1 after 3 days, 98% of dose was recovered in the excreta with almost none recovered in expired air traps.

In Experiment 2 after 8 days, 94% of dose was recovered in the excreta, most of which was unchanged diquat. The residue levels in eggs during and after dosing are shown in Figure 2. One week

after the final dose, very low radioactive residues were found in the tissues, indicating that neither diquat nor its metabolites accumulate in the hen. TRR in egg yolks from days 5 and 6 comprised 36–39% diquat, 54–61% diquat monopyridone and 6–7% TOPPS.

Figure 2 Radioactive residues in eggs following dosing of hens once daily, equivalent to 4–5 ppm in the feed, for 5 consecutive days

Table 2 Radioactive residues in hen tissues following oral administration of [^{14}C] diquat to a laying hen for 5 consecutive days at 4–5 ppm in the diet

Sacrifice time	TRR (mg equiv/kg)				
	Muscle	Fat	Liver	Kidney	Lung
5 days dosing + 7 days depletion)	< 0.0001	0.0008	0.0004	0.0035	0.0008

Residues in excreta were profiled. During the dosing period, unchanged diquat accounted for 75–80% of the excreted radioactivity. TOPPS (2%) and diquat dipyrindone (4%) were also detected.

In Experiment 3 very low TRR were detected in the egg albumen (0.00001–0.00012 mg equiv/kg) and yolk (0.0002–0.0032 mg equiv/kg) of eggs collected throughout the 14 day dosing period. Very low TRR were found in the tissues collected 4 hours after the final dose.

Figure 3 Radioactive residues in eggs following dosing of hens once daily, equivalent to 0.4–0.5 ppm in the feed, for 14 consecutive days (outlier at day 8 white 0.00012 mg equiv/kg and yolk 0.0032 mg equiv/kg not plotted)

The extractability of radioactivity from treated feed pellets declined with time after preparation and may have accounted in part for the unexpected decline in TRR for eggs. Yolk from day 9 + 10 eggs contained 26% diquat, yolks from day 7 contained 85% diquat monopyridone and egg yolks from day 11 contained 10% TOPPS.

Table 3 Radioactive residues in hen tissues following oral administration of [^{14}C] diquat to a laying hen for 14 consecutive days at 0.4–0.5 ppm in the diet

Sacrifice time	TRR (mg equiv/kg)					
	Muscle	Fat	Liver	Kidney	Lung	Blood
Day 14 (14 days dosing)	0.00019	0.00010	0.00042	0.00045	0.00016	0.00043

A later study French and Leahey (1988, RJ0622B Fujie 1988 addendum PP901/0470) also investigated the metabolism and distribution of [^{14}C] diquat in laying hens. Three laying hens were each given daily doses of ^{14}C -ring labelled diquat by oral gavage for 4 days at 2.4 mg/kg bodyweight/day equivalent to 32 ppm in the diet. Excreta and eggs were collected daily. The hens were sacrificed 18 hours after the last dose, and samples of liver, kidney, muscle and fat collected. Samples were stored at -18°C prior to analysis. TRR levels in the samples were determined by combustion followed by liquid scintillation counting (LSC) or by direct liquid scintillation counting (egg whites, extracts). Pooled tissue samples were extracted with acetonitrile. After solvent extraction, liver and kidney samples were subjected to a second extraction with 2 M HCl under reflux. Residues in liver and kidney extracts were characterized using HPLC and TLC against reference standards, and by isotope dilution.

Table 4 Radioactive residues in eggs and tissues following oral administration of [^{14}C] diquat to hens for 4 consecutive days at 32 ppm in the diet

Matrix	Radioactive residue (mg equiv/kg)
Egg yolk (day 2 ^a)	< 0.001
Egg white (day 2 ^a)	0.004
Liver	0.030–0.045
Kidney	0.042–0.058

Matrix	Radioactive residue (mg equiv/kg)
Muscle (leg and breast)	0.003
Fat (abdominal and subcutaneous)	0.004

^a All hens laid eggs at day 2 only

Radioactive residues in the muscle, fat and eggs were all < 0.01 mg/kg and were not analysed further. For liver, 76% of the radioactive residue was extracted with acetonitrile/water, and a further 22% TRR was extracted with 2 M HCl, total extracted 97%. The residue comprised mainly diquat, with small amounts of TOPPS, diquat monopyridone and diquat dipyrindone being identified. For kidney, 70% TRR was extracted with acetonitrile/water, and a further 28% TRR extracted with 2M HCl, total 98%. The residue in kidney was shown to comprise diquat and diquat monopyridone in similar amounts together with small amounts of TOPPS and diquat dipyrindone.

Table 5 Identification of the radioactive residues in liver and kidney following oral administration of [¹⁴C] diquat to hens for 4 consecutive days at 32 ppm in the diet

Unidentified in acetonitrile/water extract	27	37
Unidentified in 2 M HCl extract	13	24
Unextracted	2.6	1.9

In an additional study, Hughes and Leahey (1975, PP901/0461) studied the absorption, metabolism and distribution of incurred residues of [¹⁴C] diquat in laying hens. ¹⁴C-ring labelled diquat was sprayed onto mature barley plants at a rate equivalent to 1.1 kg ai/ha. After 4 days, the barley plants were harvested and the dried grain powdered and pelleted for dosing. One laying hen (hen 1) was given a single oral dose of treated grain pellets. A further two laying hens (hens 2 and 3) were each given 11 consecutive daily doses of treated grain pellets at a rate equivalent to 1–1.5 ppm in the diet. Excreta and eggs were collected daily. Hen 2 was sacrificed 7 days after the final dose and hen 3 was sacrificed 4 hours after the final dose. At sacrifice, samples of heart, liver, kidney, lungs, muscle and fat were collected.

TRR levels in the samples were determined by oxidative combustion followed by LSC or by direct liquid scintillation counting (diluted egg yolk and albumen, extracts). Samples of the pelleted barley grain were extracted by refluxing with 2 N HCl, and the extracts analysed for diquat and its photoproducts by paper chromatography against reference standards and by isotope dilution. Faeces samples from hen 1 and hen 2 (day 10) were extracted by refluxing with 2 N HCl, and the activity in the extract determined by LSC. The hen 2 (day 10) sample was analysed by paper chromatography against reference standards and by isotope dilution. Faeces samples from hens 2 and 3 were analysed by combustion. Egg yolk (hen 2, day 8) was extracted with ethyl acetate, and the extract analysed by LSC to determine the amount of radioactivity associated with fat. The egg yolk residue was purified by washing with 1 N HCl, 1 N NaHCO₃ and water, and combusted to determine the amount of radioactivity associated with protein.

The majority of the administered dose was excreted in the faeces. The transfer of residues to eggs and tissues was very low following repeated daily oral dosing. The maximum residues found in eggs albumen and yolk was 0.0006 and 0.0039 mg equiv/kg respectively. Residue levels in tissues were very low, with the highest residues being found in kidney (0.014 mg equiv/kg) and liver (0.0046 mg equiv/kg) at 4 hours after the final dose).

Unidentified photoproducts	59	49
Unextracted	15	27

Analysis of the faeces from hen 2 (day 10) showed that the composition of the radioactivity in the faeces was fairly similar to the composition of the dose.

Radioactive residues in the egg albumen were very low and as a result no attempt was made to characterise the residue. The yolks from hen 2 (days 10, 11 and 13) were analysed. Diquat, TOPPS and diquat monopyridone were found to account for only a small part of the residue in egg yolk. The majority of the residue in egg yolk was found to be associated with fats and protein. This is in contrast to the study (French and Leahey, 1988; Report RJ0622B) where hens were dosed with [^{14}C] diquat only where diquat, TOPPS and diquat monopyridone accounted for almost all the radioactive residue in eggs.

Metabolic pathways in animals

Diquat is poorly absorbed following oral ingestion and is largely excreted in the faeces; residues in tissues, milk and eggs are low.

In the ruminant dosed with [^{14}C] diquat at the equivalent of 90 ppm in the diet for a period of 7 consecutive days and terminated 12 hours after the final dose, the recovery of ^{14}C was 97%. The majority of the radioactivity was found in the faeces and only 0.8% in the urine. Radioactive residues milk and tissues were low. In liver, diquat (22%), diquat monopyridone (13%) and diquat dipyrindone (33%) were the major components of the ^{14}C residue. In kidney the major components were diquat (4.3%), diquat monopyridone (21%), and diquat dipyrindone (29%). In milk the radioactive residue comprised almost entirely diquat dipyrindone. Radioactive residues in muscle and fat were very low comprising of diquat dipyrindone (20–46% TRR). Diquat represented 3.5% TRR in fat but was not found in muscle. In muscle diquat monopyridone represented 13% TRR and was not found in the fat sample.

In poultry dosed with diquat at 32 ppm in the diet for 4 days, the residues in eggs and tissues were low. The radioactive residue in liver was characterised as mainly diquat (48%), with small quantities of diquat monopyridone (3.9%), diquat dipyrindone (3.1%) and TOPPS (1.8%), also present. The radioactive residue in kidney was mainly comprised of diquat (12%) and diquat monopyridone (15%). Small quantities of diquat dipyrindone (6.6%) and TOPPS (3.9%) and were also present.

The metabolism of diquat in ruminants and laying hens is adequately understood. In both goats and hens diquat is oxidised to form diquat monopyridone and diquat dipyrindone. TOPPS is found as a minor metabolite in hens but was not detected in studies of the metabolism of diquat by goats or rats.

Figure 4 Proposed metabolic pathway for diquat in livestock (ruminant and poultry)

Plant metabolism

For weed control, diquat is applied either pre-emergent or inter row. On contact with the soil, diquat is strongly adsorbed by clay minerals and organic matter, reducing the availability of the chemical for degradation and uptake by plant roots. It is unlikely that soil residues will be taken up by the crops. Additionally diquat is used pre-harvest for crop desiccation with application at a time when plants are entering senescence and little diquat is expected to be translocated.

The metabolism of diquat in plants was studied in tomatoes (pre-emergent application) and in potatoes and rape plants (pre-harvest desiccation). Each study utilised ring-labelled diquat (as the dibromide salt).

Tomatoes

Derz (2012, A1412A_10298) studied the metabolism of diquat in tomatoes (var “Vitella”) following a single pre-emergence application to soil for the control of weeds. A single pre-emergence application at a nominal application rate of 1.0 kg diquat/ha (spray volume 300 L/ha) of an SL formulation was made to sandy loam soil into which tomato seeds had previously been sown. The tomato plants were maintained in a container in a glasshouse until maturity. Mature fruits, immature fruits, leaves and stems were harvested 112 days after application and were separately homogenised and radioactivity determined by combustion/LSC. TRR were 0.002 mg equiv/kg in tomato leaves and < 0.001 mg equiv/kg in mature fruits and due to the low levels were not analysed further.

The low levels detected in mature fruits and in leaves suggest that uptake of residues from soil into crops is negligible.

Potatoes

The metabolism of diquat in potato plants (var Belana”) following a desiccant use pattern was studied by Derz (2012 A1412A_10304). A single foliar application of an SL formulation of [¹⁴C] diquat dibromide was made to potato plants at growth stage BBCH 44–48 and at an application rate of 0.97 kg ai/ha in a spray volume of 400 L/ha. The potato plants were grown outdoors in a sandy loam soil and the tubers and haulm harvested 10 days and 20 days after application. Tubers were gently

wiped to remove the adhering soil, were washed with water and then peeled. After peeling, the potato flesh was washed again and the radioactivity in all wash solutions determined by LSC. The tuber flesh and skins were separately homogenised in a frozen state and the radioactivity determined by combustion/LSC.

The wash solutions were not analysed further since the radioactive residue present was determined to be extremely low, i.e., 0.0003 mg equiv/kg potato.

TRRs in tuber flesh were 0.029 and 0.032 mg equiv/kg for the samples taken after 10 and 20 days after application respectively. TRRs in tuber skins harvested after 10 and 20 days amounted to 0.044 and 0.039 mg equiv/kg, respectively. Sub-samples of tuber flesh and skins were extracted under reflux with water/sulphuric acid. Aliquots of the water / sulphuric acid extracts were centrifuged, adjusted to pH 9 and subjected to solid phase extraction.

The total extractability for all samples was very high with > 95% TRR extracted by a single water/sulphuric acid reflux. The levels of radioactivity that remained unextracted were low in all samples ($\leq 4.7\%$ TRR; ≤ 0.002 mg equiv/kg) and were not investigated further.

The principal component of the residue in the extracts was parent diquat representing $\geq 71.7\%$ TRR. No postulated metabolites of diquat were detected. A minor unassigned metabolite was observed during TLC analysis but only in potato flesh from the samples harvested 10 days after treatment and at very low levels, corresponding to 0.5% TRR (< 0.001 mg equiv/kg). No individual fraction contained $> 9.0\%$ TRR (0.003 mg equiv/kg).

The extracted radioactivity was analysed by chromatography. The identified components for tuber flesh and skins at each sampling interval are summarised in Table 11.

Table 11 Identification of radioactivity in potato tubers

	flesh		skins	
Days after application	10	20	10	20

^a mg equiv/kg calculated directly from radioactivity extracted, radioactivity in the debris and specific activity.

^b Unassigned components which chromatographed away from the origin in 1D-TLC. In the 10 day sample this comprises of a single discrete component.

^c Polar material on origin of the radio-chromatogram using 1D-TLC.

^d The remainder comprises diffuse areas of radioactivity within the chromatogram which cannot be assigned to discrete radioactive components.

^e Extractable residues in 2–3 fractions per harvest timepoint that were not analysed and produced during processing that were too low for analysis. No single fraction comprised $> 9.0\%$ TRR (> 0.003 mg equiv/kg) in either harvest timepoint.

^f Radioactivity remaining in the debris after the water/sulphuric acid reflux extraction procedure.

^g The net cumulative incremental losses or gains during analysis, calculated as 100%—sum of all components.

The presence of diquat in tubers suggests translocation occurs though the levels are low.

Oilseed Rape

Derz (2012, A1412A_10305) also studied the metabolism of diquat in oilseed rape plants following use of diquat for pre-harvest crop desiccation. An SL formulation of [¹⁴C] diquat was applied as a single foliar application to oilseed rape plants (var “Belinda”) at growth stage BBCH 80–87 at an

application rate of 0.58 kg ai/ha and in a spray volume of 300 L/ha. The rape plants were grown outdoors in a sandy loam soil and the seed, pods and foliage were harvested 5 days after application. The seeds were homogenised in a frozen state to a powder and the radioactive residue determined by combustion/LSC. A sub-sample of seed was extracted sequentially once with hexane, using a Soxhlet-extractor, to remove the oil and then the remaining meal twice with water / sulphuric acid under reflux. Aliquots of the combined water / sulphuric acid extracts were centrifuged, adjusted to pH 9 and subjected twice to solid phase extraction (SPE) procedures.

TRR in the oilseed rape seed was 0.97 mg equiv/kg. Extractability was high with 82% TRR extracted from the seed. Significant radioactive residues were only extracted into the water/sulphuric acid extracts (82% TRR), while the initial hexane which contained the oil fraction only extracted 0.3% TRR.

The principal component of the residue in the meal, after extraction of the oil with hexane, was parent diquat representing 48% TRR. Diquat metabolites TOPPS and diquat monopyridone were observed at low levels corresponding to 7.8 and 2.0% TRR respectively. Minor unassigned components were observed representing in total 3.9% TRR (0.038 mg equiv/kg) but no individual component accounted for > 2% TRR (0.019 mg equiv/kg).

Unextracted radioactivity amounted to 17.9% TRR. A sub-sample of post-extraction solids was subjected sequentially to further extraction with acetonitrile/water (80/20), diluted acid and a surfactant solution. Each separate treatment step released radioactivity representing $\leq 2.0\%$ TRR and in total only a further 3.5% TRR was extracted leaving 10.1% TRR (0.098 mg equiv/kg) which was not investigated further.

The principal component of the residue in the meal after extraction of the oil was parent diquat with two diquat metabolites, TOPPS and diquat monopyridone, observed at low levels.

Table 12 Summary of total radioactive residues and extractability in rape seed treated with [^{14}C] diquat dibromide

Metabolic Pathways in Crops

For weed control use, diquat is applied pre-emergent or as an inter-row spray; in this use diquat will inevitably reach the soil. There is no deliberate application to crop plants, and accidental application is avoided so far as possible by careful spraying and/or the use of shielded sprayers. There is effectively no direct application to plants. Once on the soil, diquat is strongly adsorbed by clay minerals and organic matter and largely unavailable for metabolism by soil organisms or uptake by plant roots. It is not expected that there would be any residues in crop commodities following weed control use of diquat.

In the tomato metabolism study where [^{14}C] diquat was applied to the soil as a single pre-emergent application, radioactive residues in leaves and mature fruits were very low, 0.002 and < 0.001 mg equiv/kg respectively.

Where diquat is used for desiccation of crops, the residues found in commodities that are not exposed to the spray (i.e. tubers) show only low levels of parent diquat with no degradation products were observed. Where direct spray could result in application to the commodity, other metabolites/degradates, i.e. TOPPS and diquat monopyridone are also found albeit at low levels (< 7.8% and 2.0% TRR respectively). The proposed transformation pathway for diquat following desiccation use is shown in Figure 5.

Figure 5 Proposed metabolic pathway for diquat in plants following pre-harvest desiccation use

Confined rotational crop studies

A confined rotational crop study was conducted on a sandy loam soil treated at 1.12 kg ai/ha with ^{14}C ring-labelled diquat (Lee 1989 PP901/0451). After intervals of 30, 120, and 365 days, carrots (var

Imperator), lettuce (var “Parris Island Romaine”) and wheat (var “Anza”) were planted and grown under greenhouse conditions to maturity. Plant samples were harvested at immature and mature stages for analysis. In most cases, the TRR in the mature plant were below the LOD (< 0.008 mg equiv/kg). The TRR was above the LOD in the carrot leaf at 365-days post- treatment (0.017 mg equiv/kg) and the wheat straw at 120- and 365-days post-treatment (0.022 and 0.024 mg equiv/kg, respectively). It is likely the radioactive residue in these plants, identified as parent diquat, is due to contamination with soil though not all the residues were removed with rinsing. Immature plants contained TRRs above LOD (0.035–0.090 mg equiv/kg) but these residues were not characterized since the immature plants are not a typical raw agricultural commodity. The bulk of the radioactivity was contained in the soil, mostly in the 0–7.6 cm soil depth (TRR 0.13–1.15 mg equiv/kg) with little observed in the 7.6–15 cm soil cores (0–0.047 mg equiv/kg).

Crops grown in soil containing [^{14}C] diquat showed negligible uptake of radioactivity. As such, crops grown in rotation with diquat-treated crops are not expected to contain residues of diquat or diquat degradation products.

Field Crop Rotational Studies

No field crop rotational studies were made available to the meeting. However, no residues are expected in rotational crops.

Environmental fate in soil

Route of Degradation in Soil

Aerobic degradation in soil

The rate and route of degradation of [^{14}C] diquat was investigated in four soils under aerobic conditions by Dixon (2012, PP901_10824). [^{14}C] Diquat was applied at a nominal rate equivalent to a single application of 0.54 kg ai/ha. The soil samples were incubated under aerobic conditions in the laboratory and maintained under moist, dark conditions at 20 °C for up to 120 days. Extraction was sequentially using calcium chloride solution, sulphuric acid (6 M) and finally water and acetone solutions. Additional samples for each soil type were incubated up to 364 days and the volatile radioactivity recovered in the liquid traps quantified to investigate the potential for further mineralisation to $^{14}\text{CO}_2$ beyond the normal study duration.

The mean total recoveries of radioactivity for the 0 to 120 DAT soil samples were between 93 and 103% of applied radioactivity (AR). The total extracted was high throughout the incubation period (from 97 to 99% AR at 0 DAT and 96 to 101% AR at 120 DAT). Of the extraction solutions, minimal radioactivity was extracted using calcium chloride solutions ($\leq 0.3\%$ extracted at 0 DAT).

Levels of parent compound decreased slowly over the incubation period from initial values of 96% to be 86–98% AR at 120 DAT. In addition to parent, four minor metabolites were present at levels $< 5\%$ AR; diquat monopyridone and three unknown compounds.

The unextracted radioactivity remained constant throughout the 120 DAT incubation period for the Gartenacker loam and 18 Acre sandy clay loam soils, ranging from 0.4 to 3.2% AR. Unextracted radioactivity at 7 days in the Marsillargues silty clay and North Dakota sandy clay loam soils were 9.5 and 8.1% AR, respectively, declining thereafter. Limited degradation to volatile products was observed with levels of $^{14}\text{CO}_2$ in traps totalling $< 5\%$ AR by the end of the study 36 DAT.

The rate of degradation was estimated using single first-order (SFO) kinetics. The DT_{50} values obtained are presented in Table 14.

Table 14 Summary of DT_{50} for diquat in the various culture systems at 10 mg diquat/L

Soil	DT_{50} (days)	Chi^2	r^2

Gartenacker (Switzerland, loam)	662	0.81	0.9109
18 Acres (UK, sandy clay loam)	> 1000 ^a	1.46	0.0702
Marsillargues (France, silty clay)	> 1000 ^a	4.16	0.0034
North Dakota (USA, sandy clay loam)	> 1000 ^a	3.05	0.0017

^a Although there was a small amount of degradation, calculated DT₅₀ values could not be differentiated from zero using SFO kinetics and therefore a default of 1000 days is proposed.

A number of studies assessed the degradation of diquat by soil bacteria and fungi and to enhance the understanding of the intrinsic biodegradability of diquat (Ricketts, 1997 PP901/0876; Kuet *et al.*, 2001a PP901/1321; Kuet and Pinheiro, 2001 PP901/0741; Kuet *et al.*, 2001b PP901/1244). The studies used a range of techniques including isolated soil bacterial cultures, aqueous soil extracts, isolated soil fungal species and a soil yeast culture (*Lipomyces starkeyi*). Diquat is rapidly and extensively degraded by soil micro-organisms, normally found in soil pore water, in the absence of soil, to give a small number of non-volatile degradation products (not identified), with mineralisation to CO₂. The DT₅₀ for degradation in soil solution is rapid at < 1 week.

Addition of clay minerals to the bacterial test system proportionately decreased the rate of diquat degradation, and ¹⁴CO₂ evolution, until the point when virtually all the diquat had adsorbed onto the clay, when degradation apparently ceased. This finding confirms that sorbed diquat is not available to biological degradation processes.

Mônego (2006, PP901/1977) studied the rate of degradation of [¹⁴C] diquat in four viable Brazilian soils: Argissolo Vermelho from Eldorado do Sul (sandy clay loam), Latossolo Vermelho from Nova Prata (clay), Neossolo from Osório (sand) and Gleissolo from Viamão (sandy loam) under aerobic laboratory conditions. The test was performed at 20 °C in the dark under aerobic conditions with soil moisture content at 40% of the maximum water holding capacity (MWHC). Diquat was applied to the soils at the rate of 0.5 kg ai/ha. The dissipation half-lives were calculated using nonlinear first-order regression and are summarised in Table 15.

Table 15 Dissipation half-lives (DT₅₀) for diquat in four soils from Brazil

Soil	k	Half-life (days)
Argissolo (sandy clay loam),	0.00071	976
Latossolo (clay)	0.00239	290
Neossolo (sand)	0.00148	468
Gleissolo (sandy loam)	0.00122	568
Mean		576

Diquat dissipation proceeded slowly in each soil. Unchanged diquat accounted for an average of 99%, 101%, 104% and 99% at day 0 to 86%, 77%, 80% and 83% at day 119 for Argissolo, Latossolo, Neossolo and Gleissolo soils, respectively. Other than diquat, only a single minor compound was detected in Argissolo, Neossolo and Gleissolo soils but accounted for less than 2.8% of the applied radioactivity at the end of the study.

The soil dissipation of diquat occurs at a very slow rate and is dependent on the equilibrium between sorbed and dissolved phases.

Aerobic degradation of TOPPS

Dixon and Dove (2012, CGA130327 10007) investigated the rate of degradation of [¹⁴C]-TOPPS in four soils under aerobic conditions. [¹⁴C]-TOPPS was applied at a nominal rate equivalent to a single application rate of 0.15 kg ai/ha. The microbial biomass at the end of the incubation period (120 DAT) was in the range 1.6 to 2.7% of organic carbon indicating that the soil supported a viable microbial population. The soil samples were maintained under moist, dark aerobic conditions at 20 °C for up to 120 days.

Levels of TOPPS decreased over the incubation period from initial values of 93–94% to 3.8–46% AR (Gartenacker and Marsillargues) and from 94–95% to 82–85% AR (18 Acres and White Swan). Limited mineralisation to $^{14}\text{CO}_2$ was observed in 18 Acres and White Swan soils, with maximum levels reaching 2.2% AR by the 120 DAT timepoint. However, significant levels of $^{14}\text{CO}_2$ were formed during the incubation period for Gartenacker and Marsillargues soils, with levels reaching 53 and 46% AR at 120 DAT, respectively, indicating that mineralisation is potentially a major route of degradation.

The TOPPS degradation data were modelled to obtain DT_{50} and DT_{90} values using SFO kinetics as listed in the table (Patterson 2012 CGA130327_10009). DT_{50} values range from 28 to 757 days with a geometric mean of 224 days.

Table 16 Dissipation half-lives for TOPPS in soil

Soil	DT_{50} (days)	DT_{90} (days)
18 Acres	750	> 1000
Gartenacker	27.8	92.4
Marsillargues	159	529
White Swan	757	> 1000

Anaerobic degradation

A number of studies have investigated the long-term dissipation of diquat in field soils (Wilkinson 1980 PP148/0662; Gowman *et al.*, 1980 PP148/0576; Cole *et al.*, 1986 PP148/0014; Dyson and Chapman 1986 PP901/0017). Dissipation of diquat was monitored following application of either a single dose of diquat at exaggerated application rates (UK and USA), or of repeat annual doses of diquat applied at normal field application rates (USA). These long-term studies indicate that the DT_{50} for the total diquat residue was in the range 10–20 years in the UK and 1–4 years in the USA.

Monitoring studies on diquat residues in soil after long-term treatment of various crops with diquat showed that soil residues were considerably lower than the 'theoretical' maximum that would be anticipated on the basis of the amount of diquat known to have been applied and assuming no degradation (Devine 2004, PP901/1604).

Surveys on sites using diquat as a desiccant in various crops were also carried out in Europe (Anderson and Earl 1996, PP901/0522). In a series of 39 trials, diquat residues were determined in a variety of soils 184–280 days after a single application of diquat in an SL formulation as a desiccant to a variety of crops (potatoes, oilseed rape, peas and sunflowers) at rates up to 1 kg ai/ha. The amount of diquat reaching the soil was substantially below the theoretical deposition rate based on the amount of diquat applied. The average loss of applied diquat by degradation on the plant and soil between application and sowing of the following crop was 75%. German trials (on potatoes, oilseed rape and fodder peas, treated at 0.5–0.6 kg ai/ha) showed a loss of diquat 268 days after application of 45–75%. Following application at rates of 0.5–1.0 kg ai/ha, the increases in diquat soil residues the following spring were less than 0.11 mg/kg and averaged only 0.03 mg/kg in the top 30 cm of soil.

Diquat in soil adsorbs strongly to clay materials, and is not bioavailable leading to persistence in soils. However, when released into solution diquat is available for microbial degradation. Diquat degrades very slowly in standard aerobic soil studies. Mineralisation to form CO_2 was demonstrated with the extent varying between soils. Diquat is persistent in the environment.

Soil photolysis

The photolysis of diquat was investigated on both dry and moist soil surfaces of one soil, Gartenacker (Switzerland, loam) by Dixon and Gilbert (2012, PP901_10832). Ring-labelled [^{14}C] diquat was applied at a rate equivalent to 0.54 kg ai/ha, to thin layers of either dry or moist soil in individual photolysis vessels. The treated soils were maintained at about 20 °C and continuously irradiated using light from a xenon arc lamp filtered to provide a spectral distribution close to natural sunlight, with a

mean light intensity of 24.3 W/m^2 for periods up to the equivalent of approximately 30 days summer sunlight.

The mean mass balance ranged from 97 to 101% for the irradiated samples and from 98 to 101% for the dark controls.

Dry layer tests

Only slight degradation occurred in the light and dark dry soil samples. Two minor degradation products, TOPPS and diquat monopyridone, were observed in the irradiated samples, individually accounting up to 0.9% AR.

Moist layer tests

Degradation was more significant in the light moist soil samples with only a small degree of degradation occurring in the dark moist soil samples. The major photolytic degradation product was TOPPS which reached a maximum of 9.9% AR after 30 days. Diquat monopyridone was also detected but was generally present at levels $< 1\%$ AR. A number of other minor degradation products were also detected. Unknown SP-1, present at between 5.2 and 5.4% after 30 days, was found to be composed of two components by TLC. The maximum level of either single component was 4.0% AR. Volatile radioactivity, confirmed as CO_2 , resulted mainly from irradiation of moist soil with levels of $^{14}\text{CO}_2$ reaching 7.2% AR by 30 DAT.

The maximum levels of unextracted residues were observed under light and moist conditions and were present up to a level of 3.1% AR after the 30-day incubation period.

In soil exposed to light, the main degradation pathway involved oxidation to diquat monopyridone and TOPPS. In dark samples, only oxidation to diquat monopyridone was observed. There was also photodegradation to a number of minor unknowns under moist light conditions. There was a small amount of mineralization to carbon dioxide.

The rate of degradation was estimated using single first-order (SFO) kinetics. Under the experimental conditions, photolytic DT_{50} values in dry soil and in moist soil were 237 and 37 days respectively (equivalent summer days for Europe and North America at latitudes 30° and 50°N). Degradation in the dark controls was significantly slower with DT_{50} for the dry and moist soils being 857 and > 1000 days, respectively.

Soil photolysis is not expected to be a significant route of diquat degradation.

Aqueous Photolysis

Oliver and Webb (2005, PP901/1892) studied the photolysis of diquat in sterile natural water (Middle Row Pond). Solutions containing $10 \mu\text{g } [^{14}\text{C}] \text{ diquat/mL}$ were continuously irradiated using light from a xenon arc lamp filtered to give a spectral distribution close to that of natural sunlight. The samples were maintained at 25°C and were irradiated for periods up to the equivalent of approximately 15 days Tokyo spring sunlight (equivalent to approximately 5 days of summer sunlight at latitude of 50°N).

The mean mass balance (across all samples) was 94% of the applied radioactivity. Diquat was rapidly degraded accounting for 16% AR after 3 days of continuous irradiation. The photo-degradation of diquat followed first-order kinetics with an estimated half-life of 31 hours under continuous irradiation, equivalent to approximately 6.5 days of Tokyo spring sunlight (or approximately 2 days of summer sunlight at a latitude of 50°N).

A number of photo-degradates were formed (> 8 HPLC peaks in samples at 2 and 3 days of irradiation). The most significant identified metabolite formed was TOPPS, reaching a level of 23% AR at 15 days irradiation. Traces of diquat monopyridone were also detected (maximum 4.3% AR after 3 days). A mixture of 1,4 dihydropyrido[1,2a]pyrazin-5-ylum and 3,4 dihydropyrido[1,2a]pyrazin-5-ylum was detected by LC-MS/MS analysis although levels were not determined. The majority of the remainder consisted of a polar component (representing a maximum

of 12% AR after 2 days of irradiation) identified as 1-hydroxy-3,4-dihydro-1H-pyrido[1,2-a]pyrazine-2-carboxylic acid. Trapped volatiles ($^{14}\text{CO}_2$) accounted for up to 3.8% AR during the irradiation period. No significant degradation was apparent in the dark controls indicating that the degradation in irradiated samples was the result of photodegradation only.

Aqueous photolysis of diquat is expected to be a significant route of degradation under environmental conditions.

RESIDUE ANALYSIS

Analytical methods

The analysis of diquat is complicated by its polar nature and similarity in properties to paraquat. Several different analytical methods have been reported for the analysis of residues of both compounds in plant materials, animal tissues, milk and eggs. Early methods used in field trials generally involve extraction of residues by reflux with sulphuric acid with clean-up on cation exchange columns. Detection was initially achieved spectrophotometrically following reduction with alkaline dithionite or sodium borohydride. In more recent methods, the diquat recovered from the cation exchange column is subjected to HPLC with NPD or UV detection. In the case of animal commodities, trichloroacetic acid is sometimes used in place of sulphuric acid for the extraction step.

The efficiency of the acid extraction step has been demonstrated during the metabolism studies where the majority of the total radioactive residue (TRR) was recovered in the aqueous acid extracts.

The most recent advance in methods has been the use of LC-MS/MS which allows for the clean-up steps to be omitted.

A brief description of the methods used in the residue trials is given in Table 17.

Table 17 Summary of major analytical methods used for the determination of diquat and metabolites in various matrices

Method/reference	Matrix	Extraction	Clean-up	Detection, LOQ
PPRAM 1	Plant commodities	Reflux 0.5 M H_2SO_4	Filter extract, percolate through cation exchange column, wash 2.5% NH_4Cl , elute saturated NH_4Cl . A portion is reduced with alkaline sodium dithionite.	Spectrophotometric detection, 350–450 nm LOQ 0.1–0.5 mg/kg
PPRAM 005/RAM 005	Plant commodities	<u>Oil seeds:</u> Remove oil by extracting with hexane. Then proceed as for other crops. <u>Other crops:</u> Reflux 0.5 M H_2SO_4	Filter extract, percolate through cation exchange column, wash 2.5% NH_4Cl , elute saturated NH_4Cl . A portion is reduced with alkaline sodium dithionite.	Spectrophotometric detection, 350–450 nm LOQ 0.05–0.1 mg/kg
RM5/RM5.5	Plant commodities	Reflux 18 N H_2SO_4	Filter extract, percolate through cation exchange column, wash 2.5% NH_4Cl , elute saturated NH_4Cl . A portion is reduced with alkaline sodium dithionite.	Spectrophotometric detection, 350–450 nm LOQ 0.02–0.05 mg/kg
RM5C	Plant commodities	Reflux 18 N H_2SO_4	Filter extract, percolate through cation exchange column, wash 2.5% NH_4Cl , elute saturated NH_4Cl . A portion is reduced with sodium borohydride.	GC-NPD LOQ 0.02 mg/kg
PPRAM 007	Liquid	Mix with cation	Place resin in a column and	Spectrophotometric detection

Method/reference	Matrix	Extraction	Clean-up	Detection, LOQ
	commodities (milk, water)	exchange resin and roll for 2 hours, decant the liquid and wash the resin 3× with deionised water	wash 2.5% NH ₄ Cl, elute saturated NH ₄ Cl. A portion is reduced with alkaline sodium dithionite.	(350–450 nm) LOQ 0.001–0.01 mg/kg
RAM 252 RAM 252/01 RAM 252/02	Plant commodities	Reflux 0.55 to 1 N H ₂ SO ₄ depending on matrix	Precipitation with EDTA may be used prior to clean-up using cation exchange. Filter extract, percolate through cation exchange column, sequentially wash with deionised water, 2 M HCl and 2.5% NH ₄ Cl. Elute using saturated NH ₄ Cl. A portion is reduced with alkaline sodium dithionite. If using HPLC, clean-up using C18 SPE cartridge	Spectrophotometric detection 350–450 nm (RAM 252) 2 nd derivative spectrophotometric detection (RAM 252/01) HPLC-UV 310 nm (RAM 252/02) LOQ 0.02–10 mg/kg
RAM272	Plant commodities	Reflux 0.55 to 1N H ₂ SO ₄ depending on matrix	<u>For oilseeds:</u> precipitation with EDTA is required prior to clean-up using cation exchange. <u>For all crops:</u> Filter extract, percolate through cation exchange column, sequentially wash with deionised water, 2M HCl and 2.5% NH ₄ Cl. Elute using saturated NH ₄ Cl. Clean-up the eluate on a preconditioned SPE cartridge.	Reversed-phase ion-pair HPLC-UV (310 nm) LOQ 0.01–0.05 mg/kg.
POPIT MET.021 Rev00	Citrus	Reflux 1 M H ₂ SO ₄	Filter extract, adjust to 100 mL. An aliquot is derivatised using potassium ferricyanide/NaOH and partitioned against CH ₂ Cl ₂ . The organic phase is evaporated and redissolved in CH ₃ CN/H ₂ O (1:1).	LC-MS/MS LOQ 0.02 mg/kg
GRM012.03A	Plant commodities	<u>Oilseeds:</u> Reflux 1M H ₂ SO ₄ <u>Other:</u> Reflux 1M H ₂ SO ₄ + octan-2-ol	Centrifuge if required. Aliquots (0.01 µL) are diluted with ammonium formate (250 mM) and CH ₃ CN.	LC-MS/MS LOQ 0.01 mg/kg
RM5B	Animal commodities	Reflux 18 N H ₂ SO ₄	<u>Fat:</u> Partition against hexane. <u>All samples:</u> Filter extract, percolate through cation exchange column, wash with H ₂ O, 2.5% NH ₄ Cl, elute saturated NH ₄ Cl. A portion is reduced with sodium borohydride.	GC-NPD LOQ 0.02 mg/kg
PPRAM 7	Animal commodities	Homogenise in ten times the volume CCl ₃ COOH (10%), centrifuge. Retain the liquid. Resuspend the pellet in CCl ₃ COOH (10%) and	Percolate through cation exchange column. Sequentially wash with H ₂ O, 2 N HCl, H ₂ O, 2.5% NH ₄ Cl, H ₂ O. Elute saturated NH ₄ Cl. A portion is reduced with alkaline sodium dithionite.	Spectrophotometric detection (350–450 nm) LOQ 0.01 mg/kg

		centrifuge retaining the liquid.		
GRM012.02A	Animal commodities	Homogenise in ten times the volume CCl ₃ COOH (10%)	Centrifuge, aliquots (75 μ L) are diluted with ammonium formate (250 mM) and CH ₃ CN.	LC-MS/MS LOQ 0.005 mg/kg

Plant materials

PPRAM 1 (developed for paraquat and extended to diquat, PP148/0910, PP148/0972, PP148/0349, PP901/0478)

Samples are extracted by reflux in dilute (0.5 M) sulphuric acid solution to which a small amount of octan-2-ol is added (about 1:500 v/v). The filtered digest is percolated through a column of cation-exchange resin. The column is washed with aqueous ammonium chloride (2.5%) to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. A portion of the eluate is treated with alkaline sodium dithionite (0.2% w/v in 0.3 M NaOH) to reduce diquat to a free radical. Light absorption of the radical is measured spectrophotometrically between 350 and 450 nm. The absorption is compared to a reference solution prepared from saturated ammonium chloride and sodium dithionite. The spectra must be measured within 5 minutes of adding the dithionite. The LOQ was 0.01–0.05 mg/kg for diquat in crop matrices, depending on the crop.

Table 18 Recovery data for the determination of diquat obtained during carrot residue analysis (PP901/0636)

Matrix	Fortification Level (mg/kg)	Recovery (%)	n	Mean (%)	RSD (%)
Carrot	0.10	97, 78, 82	3	86	12
Lettuce	0.50	75, 102, 75	3	84	19
Onion	0.10	74, 99, 76	3	83	17

Residue Analytical Method PPRAM 005/RAM 005(PP901/0230, PP901/0220)

For oil seeds: a preliminary hexane extraction is performed to remove oil before the acid extraction. All commodities: Samples are extracted by reflux in dilute (0.5 M) sulphuric acid solution. The filtered digest is neutralised and percolated through a column of cation-exchange resin. The column is washed with aqueous ammonium chloride (2.5%) to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. A portion of the eluate is treated with alkaline sodium dithionite (0.2%w/v in 0.3 M NaOH) to reduce diquat to a free radical. Light absorption of the radical is measured spectrophotometrically (350–450 nm). The LOQ was 0.01–0.1 mg/kg for diquat in crop matrices, depending on the crop.

Residue Analytical Method RM-5 (PP901/0594)

Samples are extracted by reflux in concentrated (18 N) sulphuric acid solution for 15 minutes. A small volume of octan-2-ol may be added to reduce foaming. Filter the digest. For oily crops, extract the filtered digest three times with benzene, retaining the aqueous phase. The filtered digest/aqueous phase is neutralised using 50% NaOH, EDTA (1 g) is added and the solution adjusted to pH 9 (10 M NaOH) and percolated through a column of cation-exchange resin. The column is washed with aqueous ammonium chloride (2.5%) to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. In method versions RM-5 and RM-5-5, a portion of the eluate is treated with alkaline sodium dithionite to reduce diquat to a free radical. Light absorption of the radical is measured spectrophotometrically (350–450 nm).

In method version RM-5C, reduction with dithionite was replaced by reduction with sodium borohydride and determination of the reduced diquat product was by GC-NPD in place of spectrophotometry.

The LOQ of the method was 0.02 mg/kg for diquat in crop matrices.

Residue Analytical Method PPRAM 007 (PP901/1005)

Aliquots of milk or water are mixed with cation-exchange resin by rolling for 2 hours. After allowing the resin to settle, the milk or water is decanted away from the resin and the resin washed three times with deionised water. The resin is then packed into a burette and the water allowed to percolate through. The resin column is washed with aqueous ammonium chloride (2.5%) to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. A portion of the eluate is treated with alkaline sodium dithionite to reduce diquat to a free radical. Light absorption of the radical is measured spectrophotometrically (350–450 nm). The LOQ of the method was reported to be 0.001 to 0.01 mg/kg for diquat in liquid matrices, depending on the sample volume used, however no data to support the LOQ was supplied.

Residue Analytical Method RAM 252 (PP901/0589)

Samples are extracted by reflux in dilute (0.55–1 M, depending on sample type) sulphuric acid solution. The filtered digest is neutralised using NaOH and percolated through a column of cation-exchange resin. For some crops an additional clean-up i.e. required where 5% (w/v) EDTA solution is added after the neutralisation step and the solution filtered prior to loading onto the cation exchange column. The column is washed with deionised water, hydrochloric acid (2 M), aqueous ammonium chloride (2.5%) and deionised water to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. A portion of the eluate is treated with alkaline sodium dithionite to reduce diquat to a free radical. Light absorption of the radical is measured using a scanning spectrophotometer in second-derivative mode (350–450 nm). Oilseeds may be analysed directly as whole, seeds or extracted with hexane and the cake and oil (from evaporation of the hexane extract) determined separately. The LOQ of the method ranged from 0.01 mg/kg to 10 mg/kg, depending on the matrix.

In an extension to the method (RAM 252/02) the sample is cleaned up using a C₁₈ SPE cartridge prior to analysis using HPLC-UV.

Residue Analytical Method RAM 272 (PP901/0226, PP901/0225)

Crop samples are extracted by reflux in dilute (0.55–1 M, depending on sample type) sulphuric acid solution. The filtered digest is neutralised and percolated through a column of cation-exchange resin. The column is washed with deionised water, hydrochloric acid (2 M), aqueous ammonium chloride (2.5%) and deionised water to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. An additional clean-up step using precipitation with EDTA is required prior to ion-exchange clean-up for oilseed crops. A portion (10 mL) of the eluate from the resin column is transferred to a pre-conditioned SPE cartridge (C₁₈) and eluted, collecting a portion of the second 5 mL for final determination. The analytical standards are cleaned-up in the same way to remove interferences arising from ammonium chloride. Diquat residues in the clean-up extracts are

determined using reversed-phase ion-pair HPLC with UV detection (310 nm). The LOQ of the method ranged from 0.01 to 0.05 mg/kg, depending on the matrix.

Residue Analytical Method POPIT MET.021.Rev00 (PP148/3146)

Diquat is extracted from crop samples by reflux in dilute (1 M) sulphuric acid solution. After cooling, the extract is filtered and adjusted to a volume of 100 mL before an aliquot of the extract solution is derivatized with potassium ferricyanide/sodium hydroxide. The resulting solution is partitioned against dichloromethane. The organic phase is evaporated and redissolved in acetonitrile:water (1:1, v / v) for quantification by liquid chromatography with mass-selective triple-quadrupole mass-spectrometric detection (LC-MS/MS). The LOQ of the method was 0.02 mg/kg.

Table 25 Recovery data for the determination of diquat using method POPIT MET.021.Rev00 (PP148/3146)

Residue Analytical Method GRM012.03A (PP901/0478, PP901/2096)

Samples are extracted by reflux in dilute sulphuric acid solution (3.75% v/v). Octan-2-ol may be added to reduce foaming. Extracts are centrifuged (if required) and aliquots (100 µL=0.01 g) are diluted with aqueous ammonium formate (250 mM) and acetonitrile. Final determination is by LC-MS/MS, primary 183–157 m/z and confirmatory 183–130 m/z transition data. The detector response was linear for solution concentrations ranging from 0.000005 to 0.005 µg/mL corresponding to sample concentrations of 0.005 to 0.16 mg/kg (r^2 1.000). Sample extracts (3.75% v/v H₂SO₄) were stable for at least 15 days when stored at < 7 °C. Final extracts (CH₃CN: pH 3.7 aqueous ammonium formate buffer 30:70 v/v) were stable for at least 8 days when stored at < 7 °C. Stock solutions of diquat in water were stable for at least 51 days when stored at < 7 °C. No significant enhancement or suppression of MS/MS response was detected for the matrices in Table 26. The LOQ of the method is 0.01 mg/kg for diquat in crop matrices.

It was noted that diquat absorbs strongly to glass and it is imperative to use disposable polypropylene labware (not Teflon). LC systems should be fitted with PEEK tubing rather than stainless steel to avoid Teflon or derivatized the glass silanols using trimethylsilane.

In addition, a range of methods have been published in the scientific literature for the analysis of diquat in various crops that are similar to those reported above (Worobey 1993; Chichila and Walters 1991; Chichila and Gilvydis 1993; Aramendía *et al.*, 2006; King 1978; Calderbank and Yuen 1966; Tadeo *et al.*, 2000).

An LC-MS/MS method has been developed by Kolberg *et al.*, (2012). Homogenised samples (10 g for potato and 5 g for barley, pulses and other dry commodities are weighed into 50 mL centrifuge tubes and 100 µL of a 10 µg/mL internal standard mixture added. For the dry commodities, water (10 mL) is added and the slurry was allowed to stand for 10 min to allow the water to thoroughly wet the sample. Then 10 mL of extraction solution (MeOH (50%) + HCl 0.1 M in H₂O (50%)) is added and the mixture shaken for 2 min followed by heating at 80 °C in a water bath for 15 min after which the extracts are shaken vigorously and then cooled prior to centrifugation for 5 min at 4000 rpm. An aliquot is filtered through a syringe filter (0.45 µm) and analysed directly by LC-MS/MS (m/z 183/157). LOQs were 0.006 mg/kg for diquat in potatoes and barley. Mean recoveries in three different laboratories were 94 to 120% (n=5).

RESIDUES IN FOOD OF ANIMAL ORIGIN

Residue Analytical Method RM-5B

Samples are extracted by reflux in concentrated (18 N) sulphuric acid solution. Fat samples are initially cleaned-up by hexane partition. For all sample types, the filtered digest is then percolated through a column of cation-exchange resin. The column is washed with water and aqueous ammonium chloride (one-tenth saturated) to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. Diquat is reduced with sodium borohydride and determination of the reduced diquat product is by GC-NPD. The LOQ of the method is 0.02 mg/kg for diquat in animal matrices.

^a Possibly double-fortified

Residue Analytical Method PPRAM 7 (PP901/1005)

Tissue samples (10–20 g) are homogenised in ten times the volume of trichloroacetic acid (10%). The homogenates are centrifuged and then the supernatant liquid decanted and retained. The precipitate is re-suspended in trichloroacetic acid (10%, 50 mL) and centrifuged again, decanting the supernatant and combining with the first. The de-proteinised extracts are then percolated through a column of cation-exchange resin. The column is washed with water, hydrochloric acid (2 N), water, aqueous ammonium chloride (2.5%) and water again to remove co-extractives. Diquat is then eluted with saturated ammonium chloride solution. A portion of the eluate is treated with alkaline sodium dithionite to reduce diquat to a free radical. Light absorption of the radical is measured colourimetrically (350–450 nm). The LOQ of the method was 0.01 mg/kg for diquat in animal tissues.

Residue Analytical Method GRM012.02A (PP148/3006)

Samples are extracted by homogenisation in 10% w/v aqueous trichloroacetic acid. Extracts are centrifuged and aliquots (75 µL=0.005 g) are diluted with ammonium formate (250 mM) and acetonitrile (CH₃CN: pH 3.7 aqueous ammonium formate buffer 30:70 v/v). Final determination is by LC-MS/MS. The detector response was linear for the range 0.000025–0.015 µg/mL. No significant matrix effects were observed. Primary extracts were stable for at least 14 days when stored at < 7 °C. Final extracts were stable for at least 7 days under the same storage conditions. The LOQ of the method is 0.005 mg/kg for diquat in milk, eggs, muscle tissue, liver, kidney, fat and blood.

Extraction of residues from incurred residue samples

Potatoes

In the metabolism study employing a similar extraction procedure as analytical methods PPRAM 1, PPRAM005, RAM 252 and GRM012.03A (with the exception that the water content of the samples were not taken into consideration), the extractability of the radioactive residues from both potato flesh and skin was very high (> 95% TRR). Diquat was the only significant component present in the extracted material. The extraction using reflux with sulphuric acid/water is suitable for use in analytical methods for determining diquat.

Rape seed

In the metabolism study, the first water/sulphuric acid reflux extraction recovered approximately 70% TRR. Diquat accounted for 48% of the TRR.

Milk and tissues

The metabolism study utilised three sequential extractions (four for fat) with 10% trichloroacetic acid. The extraction procedure extracted 94% of radioactivity in milk with diquat accounting for 82% of the radioactivity. In tissues ≥ 80% of the radioactivity was extracted with the exception of liver which was lower at 63%. In tissues diquat was 20 to 46% of the radioactive residue. The extraction procedure is suitable for use in analytical methods and has been employed in PPRAM7 and GRM012.02A.

Chicken liver

A sub-sample of composited chicken liver from metabolism study was used for the radio-validation of method RM-5B-1. Extraction of diquat involves reflux with 18 N H₂SO₄. Diquat measured using method RM-5B-1 was 0.012 and 0.013 mg/kg. Recoveries for samples spiked at 0.05 and 0.1 mg/kg were 80 and 85% respectively. The metabolism study reported diquat level in liver to be 0.022 mg/kg which is similar to the values measured using method RM-5B-1 after correction for recovery (0.015–0.016 mg/kg).

Applicability of multi-residue methods

Incorporation of diquat into multiresidue screen is unlikely as extraction from crops generally requires reflux in an acid solution.

Stability of residues in stored analytical samples

The freezer storage stability of diquat in fortified plant, animal tissues, milk and eggs samples was studied. Residues were generally stable for the duration of the studies.

Stability of residues in plant products

Langridge (2007) studied the stability of diquat in spinach, wheat grain, oilseed rape seed, lentil, orange, potato and wheat straw under freezer storage conditions for up to 24 months. These include representatives of the four crop types, predominantly water-, oil-, protein- and starch-containing materials. Crop samples (10 g of spinach, wheat grain, oilseed rape seed, lentil, whole orange, potato and wheat straw) were separately weighed into polypropylene extraction vessels and fortified with known amounts of a standard solution of diquat in water at a target rate of 0.2 mg/kg. The fortified samples were sealed (after allowing any solvent to evaporate) and gently shaken to distribute the analyte before being stored in a temperature monitored freezer at < -18 °C. Method GRM012.03A was used to determine diquat in the crop commodities.

There was no significant decrease (> 30% as compared to the initial value) in the observed residues of diquat in spinach, wheat grain, oilseed rape seed, lentil, whole orange, potato and wheat straw when stored deep frozen at < -18 °C for a period of at least 24 months.

Table 29 Storage stability results for samples spiked with diquat at 0.2 mg/kg.

USE PATTERNS

Diquat is a non-volatile herbicide with two principal modes of use:

desiccant use as a harvest aid

weed-control use, before planting or around and between the rows of established crops.

Diquat is fast-acting and effectiveness varies with weed species; repeat applications may be necessary on certain perennial weeds while annual weeds are generally destroyed with one application.

Table 30 presents a summary of relevant GAP. The table is divided into two parts, desiccation uses where diquat is applied deliberately and directly to the target crop and weed-control uses where diquat is applied to weed plants and is not allowed to come into contact with the crop plants.

Table 30 Selected registered uses of diquat (SL formulations)

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

Diquat is a non-selective herbicide that is highly active against growing weeds. The Meeting received information on supervised field trials for diquat on the following crops or crop groups:

Commodity	Table No.
Citrus fruit	Table 32
Pome fruit	Table 33
Strawberries	Table 34
Banana	Table 35
Tomato	Table 36
Pulses	Tables 38–45
Carrots	Table 46
Potato	Tables 47–48
Rape seed	Tables 49–50
Sunflowers	Table 51
Coffee (beverage seeds)	Table 52
Animal feed	Tables 53–56

Trials were generally well documented with laboratory and field reports; trials from the 1980s followed the standards of those times. Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Control samples are indicated in the summary tables with a "c". Unless stated otherwise, residue data are recorded unadjusted for recovery.

Residues and application rates have generally been rounded to two significant figures or, for residues near the LOQ, to one significant figure. Residue values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. Those results included in the evaluation are underlined.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Most trial designs used non-replicated plots. Most field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Table 31 Summary of sprayers, plot sizes and field sample sizes in the supervised trials

Crop	Location	Year	Sprayer	Plot size	Sample size	Sample to analysis interval (days)
Orange	Brazil	1987-2003	CO ₂ backpack sprayer	4×15 m ² to 100 m ²	Not reported to 3 kg	294-346 d

Potato	Austria, France	2009	Backpack sprayer	17×3 m ² - 25×3 m ²	> 2kg	< 7 months
Potato	UK, France, Austria	2010	Backpack sprayer	10×3 m ² - 30×3 m ²	> 2.4kg	< 3 months

Crop	Location	Year	Sprayer	Plot size	Sample size	Sample to analysis interval (days)
Potato	France, Italy, Spain	2009	Backpack sprayer	17×3 m ² - 10×6 m ²	> 2kg	< 3 months
Potato	France, Italy, Spain	2010	Backpack sprayer	Not reported - 20×2.25 m ²	> 2kg	< 6 months
Potato	USA	1994	Backpack sprayer	3×15 m ² - 4×37 m ²	Not reported	196-260 d
Rape	Austria, France, Italy	2009	Backpack sprayer	20×6 m ²	> 0.5kg	< 365 d
Rape	Austria	2009	Backpack sprayer	17×3 m ² - 80×3 m ²	> 0.5kg	< 365 d
Rape	Spain, France, Italy	2010	Backpack sprayer	10×3 m ² - 10×6 m ²	> 0.5kg	< 185 d
Rape	USA	2009-2010	Backpack sprayer, tractor mounted sprayer, bicycle sprayer	8.2×12.2 m ² to 136×26 m ²		< 789 d
Sunflower	France	1993-1994	Backpack sprayer			< 266 d
Sunflower	France	2004	Backpack sprayer			< 76 d

Where duplicate field samples from an unreplicated plot were taken at each sampling time and were analysed separately, the mean of the two analytical results was taken as the best estimate of the residues in the plot and only the means are recorded in the tables. Similarly where samples were collected from replicate plots the mean result is reported (see general consideration JMPR 2010).

Citrus fruits

Two trials in 1988 and 1989 were conducted using diquat formulated as a soluble concentrate (SL). Applications were made close to commercial harvest of the citrus fruit, as appropriate for weed control. Orange fruit were sampled 14 days after application. Sample size and storage conditions were not reported.

Pome fruits

Twelve supervised residue trials with diquat on apples were conducted in Europe between 1998 and 2010. In these trials, diquat was formulated as an SL formulation applied once at a rate of 1.0 kg ai/ha to the area around the base of the trees, well away from the fruit. All applications included an appropriate locally-typical adjuvant (wetter) at the recommended rate. In four trials from 1998–1999,

applications were made late in the growing season, at the time of harvest (0-day PHI). In eight trials from 2010, applications were made early in the growing season of the apples, as appropriate for weed control. Consequently, PHIs ranged from 0 to 171 days. Mature apple fruit were sampled at normal commercial harvest (BBCH growth stages 85–89) and stored frozen until analysis. Samples of apples were stored for a maximum of 215 days. Residues of diquat in apple samples were determined using methods RAM 272/02 or GRM012.03A.

Strawberry

Three supervised trials were carried out on protected strawberries during 2000 in the UK. In each trial one application of an SL formulation was made at a rate of 0.85 to 0.92 kg ai/ha at BBCH 57–60.

Samples of strawberries were taken at normal harvest 47 to 50 days after the application and were stored frozen for up to one month prior to analysis. Residues of diquat in strawberries were determined by ion-pair high performance liquid chromatography using method RAM 272/02.

^a Applications pre-flowering and used a spray shield

Banana

Eight supervised trials were conducted on bananas during 1992 and 1993, three in Costa Rica, three in Guatemala and two in Ecuador. Trials in Costa Rica and Guatemala consisted of two plots, one receiving three applications of diquat a SL formulation at a rate of 0.6 kg ai/ha and the other receiving two applications of a formulation also containing paraquat at a rate of 0.15 kg diquat/ha, at intervals of 29 to 33 days. The trials in Ecuador also consisted of two plots, both treated three times at intervals of 28 days at rates of either 0.2 or 0.4 kg ai/ha. The three trials conducted in Guatemala included an adjuvant “Agral” in each application and the two trials in Ecuador included “Agral 90” in each application according to local practice. Applications were sprayed directly to the soil around the plants according to commercial practices. Samples of mature banana bunches were collected immediately after the spray dried and also after 3 days for the trials in Costa Rica and Ecuador. On sampling, bananas were washed by immersion in water for 5–10 minutes according to local practices. All samples were stored frozen until analysis. Residues of diquat in banana samples were determined using method RAM 005/01.

Tomato

Eight supervised residue trials were conducted in Europe during 2009 and 2010 where diquat was applied for weed control between the rows of tomato plants (inter-row application). In the trials, diquat as a SL formulation was applied once at a rate of 0.8 kg ai/ha. All applications included an appropriate adjuvant (wetter) at the recommended rate. Four of the trials contained additional plots treated with diquat pre-emergence with tomatoes sampled at normal commercial harvest 92 to 118 days after application. Samples of tomatoes were stored frozen for a maximum of 8 months. Tomato samples were analysed for residues of diquat using method GRM012.03A.

Pulses

Beans, dry

Eight supervised trials were conducted on dried beans without pods (field and fodder beans) in Germany during 1984 and 1985. Each trial received a single application of a diquat SL formulation at 0.6 kg ai/ha. Mature beans were collected from 3 to 13 days after treatment. The seeds were separated from the pods and samples were frozen until analysis. Storage periods ranged up to 243 days (8 months). Residues of diquat were determined using method PPRAM 5. Mean procedural recoveries were 59–64% for samples fortified at 0.1–0.2 mg/kg. The data are not suitable for estimating maximum residue levels.

^a PH Pre-harvest

Eight supervised trials were conducted in the USA in 1994 where diquat SL formulation was applied to mature bean plants as a desiccant 4 days prior to harvest of bean seeds. Dry bean samples were taken by hand or mechanically and maintained frozen until analysis. The maximum period of storage was 338 days. Samples were analysed for residues of diquat using method RAM 252/01.

Peas, dry

Seventeen supervised trials on dry peas were conducted in Europe from 1981 to 1992. One trial was carried out in France, seven in Germany, five in Denmark and four in the UK. A single application of an SL formulation of diquat was applied to dry pea plants 4 to 14 days prior to harvest. Mature peas were collected and the seeds were separated from the pods. Seeds, haulm and pods were analysed for residues of diquat using method PPRAM 5 or PPRAM 5A. Samples were stored frozen at about – 20 °C prior to analysis. The maximum period of frozen storage was reported as 508 days (16 months). Mean procedural recoveries for the 1981 France trials were approximately 61% for samples fortified at 0.5 mg/kg. The data from the 1981 trials are not suitable for estimating maximum residue levels.

Six supervised trials were conducted in the USA in 1994. Diquat was applied as a single application of an SL formulation at 0.42 kg ai/ha. Diquat applications were made to mature pea plants as a desiccant, 4 days prior to harvest of pea seeds. Dry pea samples were taken by hand or mechanically and maintained frozen at –20 °C until analysis. The maximum period of storage was 356 days. Samples were analysed for residues of diquat using method RAM 252/01.

Lentils, dry

Fourteen trials on lentils were conducted in Canada and the USA. All trials received one application of diquat as an SL formulation at 0.4 or 0.42 kg ai/ha for broadcast application or 0.55 kg ai/ha for aerial applications. In some trials, a separate plot was treated with 2× application rates. Samples of lentil seeds were collected mechanically or by hand and stored frozen until analysis. The maximum period of frozen storage was about 12 months, though storage duration was not reported for study CRR114. Residues of diquat on lentil seeds from trials in the US were analysed using method RAM 252/01 while PPRAM 5A (modified as method 107) was used for the Canadian trials. Field trial reports were not available and analytical recoveries for the 1989 Canadian trials were 52–71%, mean 60% and, as such, the trials are not suitable for estimation of maximum residue levels. The description of the 1982 field trials was not adequate and there were no reports for the analytical phase. The trials are not suitable for use in maximum residue estimation.

Soya beans, dry

Four supervised trials on soya beans using diquat as a desiccant were conducted in Europe (France) during 1985 and 1994. Samples were maintained at -20 °C for periods up to 246 days, though the storage interval was not included in report R 2-FP. Diquat residues were determined by analytical method PPRAM 5 or RAM 252/01.

^a Calculated residue (from separate oil and meal determinations)

Seven supervised trials using diquat as a desiccant on soya beans were conducted in various locations in the US in 1987. Samples were maintained in freezers at -20 °C for periods up to 136 days until analysis. Diquat residues were determined by analytical method RM-5C.

Carrots

Six supervised trials on carrots were conducted in Germany during 1983–1984. An SG formulation of diquat and paraquat was applied two or three times at rates of 0.71 to 0.98 kg ai/ha. Applications were made inter-row for the control of weeds. An additional trial on carrots was conducted in Italy during 1993 where a single application of an SL formulation of diquat was made between the crop rows at 0.8 kg ai/ha. Samples were stored frozen for up to 256 days. Residues of diquat from the trials in Germany were analysed using method PPRAM 1A or PPRAM 1B and in the Italy trial using method RAM 005/01.

Table 46 Residues in carrots (directed inter-row application for weed control). Trials at Lüneburg Germany 1983, Freisbach Germany 1984 and Lombardo Italy 1993 used spray shields.

Potatoes

Sixteen supervised residue trials were conducted on potatoes in Europe during 2009 and 2010. An SL formulation of diquat was applied once at a rate of 1.0 kg ai/ha. A wide range of potato types was used in these trials from early-maturing to late-maturing varieties. Samples of potatoes were stored for a maximum of 8 months. Potato samples were analysed for residues of diquat using method GRM012.03A.

Eight supervised trials using diquat as a desiccant for potatoes were conducted in various locations in the US in 1994. Potato tubers were collected 7 days after the last application. Samples were maintained in freezers at –20 °C from 196 to 260 days prior to extraction. Diquat residues were determined using analytical method RAM 252/01.

Sunflowers

Ten trials on sunflowers were conducted in France using diquat as a desiccant or harvest aid. All treated plots received one application of diquat as an SL formulations at the rate of 0.6 kg ai/ha. Sunflower heads were collected 5 to 7 days after treatment and either shelled by hand or threshed by combine. Samples were stored frozen for 7 months prior to analysis. Sunflower seeds were fractioned into oil and cake components, analysing each component separately and calculating residues in the seed using weight ratios of oil to cake, which were roughly 40% to 60%, respectively. Residues of diquat from the 1993 and 1994 trials were analysed using methods RAM 005/01 and method RAM 252/01, respectively. Residues of diquat in the 2004 trials were analysed using RAM 252/02 and RAM 272/02.

Table 51 Residues of diquat in sunflower seed (pre-harvest desiccation) (residue levels reported for sunflower seeds were calculated from residues in oil and cake and the weight ratios of the components in each sample analysed)

Animal feed stuffs

Legume Animal Feeds

Diquat is used as a desiccant in the following crops and is applied shortly before harvest to dry the plants and facilitate harvest therefore, in addition to seeds, the derived animal feed commodities are straw and hay.

FATE OF RESIDUES IN STORAGE AND PROCESSING

Data are available to demonstrate the stability of diquat under conditions more extreme than those encountered in commercial food processing. Residue analytical methods for diquat in crops extract diquat from crop matrices by reflux in aqueous acid. At these concentrations of acid used pHs are low (< 0) and reflux temperatures are above 100 °C. Under these conditions there was no evidence of

degradation with acceptable mean recovery efficiencies obtained for diquat. Diquat is hydrolytically stable under conditions of extreme acidity and elevated temperature that might be encountered in commercial food processes.

The effect of processing on the level of diquat-derived residues was also investigated for soya beans to oil and rape seed to oil.

As a measure for the transfer of residues into processed products, a processing factor was used, which is defined as

$$PF = \frac{\text{Total residue in processed product (mg/kg}^{-1}\text{)}}{\text{Total residue in raw agricultural commodity (mg/kg}^{-1}\text{)}}$$

A concentration of residues takes place when $PF > 1$.

Soya beans

One application of diquat was made to soya beans (*var* Asgrow 2187) at a rate of 2.8 kg ai/ha seven days before normal commercial harvest. At harvest, samples of treated and untreated seed were collected and transported frozen to the processing facility. The beans were dried in a forced-air oven to achieve the optimal moisture content for hull removal (10%). The conditioned beans were cracked and the hulls removed by aspiration. After hulling the kernels were pre-heated to 74 °C and flaked by rolling to a thickness of 0.2–0.3 mm. Flaked kernels were solvent extracted using hot (63 °C) hexane for six cycles (3 hours). After draining the solvent, the flakes were dried using warm air for a further 4 hours to produce solvent-extracted meal. The miscella (oil and hexane mixture) was separated by evaporation, during which the crude oil reaches 85 °C temperature. Crude oil was sampled and the hexane discarded. Crude oil was refined by mixing crude oil with sodium hydroxide for 90 minutes at 20–24 °C and 20 minutes at 63–67 °C. After allowing to settle for an hour at 60–65 °C, the oil was refrigerated for at least 12 hours before the refined oil was decanted and filtered. The fraction remaining is the soapstock. Refined oil and soapstock were sampled.

The balance study achieved overall diquat mass balances of 141 and 131% for oil production. Residues and processing factors are presented in Table 57.

Rape seed

A processing study was performed for rape seed. Two residue trials on rape were conducted in northern France and the United Kingdom during 2011. One application of diquat was made to rape at

a rate of 2.0 kg ai/ha five days before normal commercial harvest. Rape seed was processed into refined oil. Two balance and two follow-up design tests were conducted, one balance study and one follow-up study on seed from each field trial. The process was representative of commercial oilseed rape processing.

Seed with non-optimal moisture content was dried until the optimal moisture content for pressing (6–10%) was achieved. The conditioned seed was cleaned manually using a sieve to remove parts of coarse stalks and weed seeds to produce cleaned seed. The rape seed was crushed to break the testa (seed coat) and flakes sampled. A screw press was used to separate the seed into a liquid phase (crude oil) and a solid phase (press cake). If required (depending on the pressing qualities of the seed), a heated press head was used. Crude oil and press cake were sampled. The press cake for solvent extraction was transferred to a small technical extraction plant. The first extraction step used n-hexane circulated through the press cake for about 2 hours at approximately 60 °C. After the circulation time, the solvent-oil-mixture (miscella) was pumped into a distillation vessel and after distillation, the extracted oil and the distilled n-hexane was transferred back to the press cake for a second extraction step. Fresh n-hexane was added and a second extraction performed under the same conditions as the first extraction. A second distillation was conducted as above, after which the remaining solvent was removed from the oil by rotary evaporation at 80 °C. Solvent-extracted oil and solvent-extracted meal were sampled. Before refining, crude oil (from screw pressing) from each sample was mixed with the corresponding solvent-extracted oil. The combined oil was sampled and then filtered. Refining of the crude oil included hydration, desliming (degumming), neutralisation, washing, drying, bleaching, filtration and deodorization steps, after which the refined oil was sampled. On completion of processing, samples were frozen immediately and stored below -18 °C.

Two balance and two follow-up processing studies were conducted where oilseed rape plants were treated with diquat and the harvested seeds processed by industrial processes into rape-seed oil. The procedures used closely mimicked industrial oil production processes. Good mass balances of diquat were achieved. Residues in processed commodities were reduced from those in raw rape seed, with processing factors from 0.17 to 0.76 in solvent-extracted meal and < 0.01 to < 0.03 in refined oil. Residues in by-products were also reduced from those in raw rape seed, with processing factors of 0.23 and 0.82 in press cake, 0.63 and 0.61 in crude oil and < 0.01 and < 0.03 in solvent-extracted oil. Only in waste (course plant debris and weed seeds) did residues increase, to 20 and 41 mg/kg in the two studies.

Residues of diquat (ion) were measured using method GRM012.03A. From receipt at the analytical facility, except for sample preparation and the removal of a sub-sample for analysis, the samples were stored frozen at or below -18 °C. Samples were stored frozen for a maximum period of 223 days from sampling to analysis and residues in the processed products are deemed to be stable over the storage period.

The balance study achieved overall diquat mass balances of 141 and 131% for oil production. The residues and processing factors found in the processed samples are presented in Table 58.

Sunflower

No formal processing studies have been carried out for sunflower seeds. However, in ten supervised trials where diquat was applied as a desiccant or harvest aid, oil was extracted from seeds and residues were determined in the separated oil and cake fractions. All residues of diquat in the oil were below the LOQ (< 0.05 mg/kg). Residues of diquat concentrated in sunflower cake by a mean factor of 1.2. Residues did not concentrate in the oil.

Livestock feeding studies

Dairy cow feeding study

The transfer of diquat residues from feed to tissues and milk of dairy cows was studied using incurred residues (Edwards *et al.*, 1976). A 2-hectare field of grass was sprayed with diquat at 4 kg ai/ha. The treated grass was harvested after 4 days of sunny, dry and warm weather and processed to grass nuts.

Levels of diquat in the grass nuts were 209 ppm after production and before study start and showed no decline in concentration during storage under ambient conditions.

Lactating cows (Friesian, 3 to 7 years, 394 to 559 kg, three per dose rate) were fed diets containing fresh grass and a mixture of treated (209 ppm diquat) and untreated grass. Mean daily feed consumption during the exposure period was 9.9 kg DM fresh grass and 8.8–9.1, 8.1–9.1, 9.0–9.1 and 5.3–7.6 kg grass nuts/cow for groups 1, 2, 3 and 4 respectively. Mean daily milk yield during the exposure period was 7 to 18 kg/cow/day. Based on mean daily feed consumption, the exposure was equivalent to 18, 50 and 84 ppm in the feed. Cows were milked twice daily and morning milk combined with milk from previous evening and three samples retained per week (Monday, Wednesday and Friday). Two cows per dose group were sacrificed after 30 days of dosing and samples of liver, kidney, fat and muscle (cardiac, pectoral and adductor) collected. The actual interval between last dosing and sacrifice was not reported. The remaining cow per dose group was fed untreated grass nuts and sacrificed after a further seven days.

Samples of feed and tissues were stored frozen for up to 4 weeks prior to analysis while milk samples were stored frozen for a maximum of 1 week. Feed samples (pelleted grass) were analysed for diquat using the analytical method PPRAM-5 to confirm the dose level of diquat in the feed. Milk samples were analysed for diquat using analytical method PPRAM-7 while samples of liver, kidney, fat and muscle were analysed for diquat using the analytical method TBM/3 (method adapted to determine diquat by monitoring the absorption at 379 nm).

There were no residues of diquat at or above the LOQ (0.001 mg/kg) in any of the milk samples from any of the dose groups, throughout the duration of the study. There were no residues of diquat at or above the LOQ (0.01 mg/kg) in any of the tissue samples (liver, kidney, fat and muscle) from any of the dose groups, throughout the duration of the study.

Table 60 Diquat residues in bovine milk and tissues

Matrix	18 ppm	50 ppm	84 ppm

Laying hen feeding study

A transfer study was conducted in White Leghorn chickens (1.70–1.82 kg bw, 28 weeks old) where laying hens were fed for 21 or 28 days on diets containing 1, 5 or 10 ppm diquat in the feed (Lai *et al.*, 1977). Each group were fed with basal feed treated with a known amount of diquat dibromide monohydrate. The dose level for each group was adjusted by mixing treated and untreated feed to obtain concentrations of diquat in feed on a dry weight basis of 1.0, 5.0 and 10 ppm. Mean daily food consumption during dosing period was 116–128 g/hen/day for the control group and 117–125, 112–141 and 109–140 g/hen/day for the 1, 5 and 10 ppm feed level groups respectively. The efficiency of egg production was not affected by the dosing with mean egg production during dosing period of 89–96% for the control group and 86–98%, 90–98% and 91–99% for the 1, 5 and 10 ppm feed level groups respectively. Eggs were collected daily and retained for analysis from days 1, 7, 14, 21, 28 and also day 35 (after a depuration period of 7 days). Eggs from each dose group were pooled for each day of sampling. Ten chickens from each group (excluding control Group 1) were sacrificed after 21 days and 28 days of treatment and after 7 days of depuration (study day 35). Samples of liver, muscle, heart, gizzard, skin and fat were collected from all sacrificed animals. The period of storage prior to analysis was not reported.

No residues of diquat were detected (< 0.005 mg/kg) in any of the egg, fat, muscle, liver or heart samples. With the exception of a residue of 0.006 mg/kg at the highest treatment rate on day 21, no detectable residues (< 0.005 mg/kg) were found in any of the chicken skin samples. Residues in gizzard reached a maximum of 0.019 mg/kg at day 21 in the birds dosed at the equivalent of 10 ppm,

were 0.018 mg/kg at day 28, declined during depuration to < 0.005 mg/kg, though a residue of 0.006 mg/kg remained in the 5 ppm group.

APPRAISAL

Diquat is a non-selective contact herbicide with uses on many crops. Diquat has been evaluated several times by the JMPR with the initial evaluation in 1970 and the latest in 1994. Diquat was scheduled at the Forty-fourth Session of the CCPR (2012) for periodic re-evaluation of toxicology and residues by the 2013 JMPR.

The Meeting received information on the metabolism of diquat in animals, on crops, methods of residue analysis, freezer storage stability, GAP information, supervised residue trials, fate of residue during storage and processing, and livestock feeding studies.

Diquat is 6,7-dihydrodipyrido[1,2-a:2',1'-c]pyrazinediium dibromide.

Metabolites referred to in the appraisal are addressed by their common names:

Diquat monopyridone

Diquat dipyridone

TOPPS

Animal metabolism

Metabolism of diquat in goats and hens involves formation of diquat dipyridone and diquat monopyridone. TRR are expressed in terms of diquat ion.

In a study where a lactating goat was orally treated once daily for 7 consecutive days with ring labelled [¹⁴C]-diquat at a dose equivalent to 90 ppm in the feed, approximately 97% of the administered dose was recovered with the majority in the excreta (84% faeces, < 1% urine) or gastrointestinal tract (12%). The radioactivity in the tissues ranged from 0.003 in fat to 0.079 mg equiv/kg in kidney. TRR values in milk were up to 0.015 mg equiv/kg during the dosing period with

levels not reaching a plateau after seven days of dosing. Major components of the ^{14}C residues were unchanged diquat ion (liver 22% TRR), diquat dipyrindone (kidney 29% TRR, liver 33% TRR, muscle 46% TRR, fat 20% TRR, milk 82% TRR) and diquat monopyridone (kidney 21% TRR, liver 13% TRR, muscle 13% TRR).

Laying hens were orally treated once daily in experiments where a single hen received a single dose at 4-5 ppm, five daily doses at 4-5 ppm or 14 doses daily doses at 0.4-0.5 ppm. By three days after administering the last dose the majority (> 94%) of the dose was recovered in the excreta. Radioactivity in tissues of hens dosed at 0.4-0.5 ppm ranged from 0.00010 mg equiv/kg in fat to 0.00045 mg equiv/kg in kidney. The ^{14}C levels in egg whites and yolks reached a plateau of 0.00003 and 0.00014 mg equiv/kg respectively by seven days of dosing. Yolk from day 9+10 eggs contained diquat ion (26% TRR), yolks from day 7 contained diquat monopyridone (85% TRR) and egg yolks from day 11 contained TOPPS (10% TRR).

In another study laying hens were each given daily doses of ^{14}C -ring labelled diquat by oral gavage for 4 days at the equivalent of 32 ppm in the diet. At sacrifice 18 hours after the last dose, radioactive residues in the muscle, fat and eggs were all < 0.01 mg equiv/kg. Levels of radioactivity in liver and kidney were 0.045 and 0.058 mg equiv/kg respectively with unchanged diquat (liver 48% TRR, kidney 12% TRR) and diquat monopyridone (liver 3.9% TRR, kidney 15% TRR) the main residue components. Minor components identified were TOPPS (liver 1.8% TRR, kidney 3.9% TRR) and diquat dipyrindone (liver 3.1% TRR, kidney 6.6% TRR).

In an additional study laying hens fed a diet containing powdered grain harvested from barley plants treated with [^{14}C]-diquat, the dose was equivalent to 1 to 1.5 ppm in the feed for 11 consecutive days with hens sacrificed 4 hours or 7 days after the last exposure. The major components of the ^{14}C in the grain were diquat ion (17% TRR) and TOPPS (8.7% TRR). Most of the administered dose was recovered in the excreta (84-89%) with less than 0.1% recovered in eggs. Radioactive residues in egg white reached a plateau by day 5 of dosing with a maximum level of 0.0006 mg equiv/kg while egg yolk reached a plateau by day 8 with a maximum residue of 0.0039 mg equiv/kg. In tissues at sacrifice 4 hours after last exposure, ^{14}C residues were highest in kidney (0.014 mg equiv/kg) and much lower in muscle and fat at 0.0009 and 0.0022 mg equiv/kg respectively. Diquat ion was a minor component of the ^{14}C residues in egg yolk at 0.9% TRR with TOPPS and diquat monopyridone present at 3.5 and 3.0% TRR respectively.

Metabolism in laboratory animals (rat) was summarized and evaluated by the WHO panel of the JMPR in the present meeting. The metabolism of diquat in ruminants and laying hens is adequately understood. In both goats and hens diquat is oxidised to form diquat monopyridone and diquat dipyrindone. TOPPS is found as a minor metabolite (< 10% TRR) in hens but was not detected in studies of the metabolism of diquat by goats or rats.

Plant metabolism

Diquat is used for two different situations:

Directed sprays for weed control (crop not intentionally treated)

Use as a crop desiccant to facilitate crop harvest (crop treated)

Plant metabolism studies were conducted with diquat to investigate these two situations.

Application prior to crop emergence

A single application of ^{14}C -diquat was made to soil into which tomato seeds had been sown prior to emergence. Residues in mature fruit and leaves harvested 112 days after application were < 0.001 and 0.002 mg equiv/kg respectively and were not analysed further.

Crop desiccation

The use of diquat as a pre-harvest desiccant was investigated in potato and rape following foliar spray application to the crop. Since the plants are senescent at the time of application or die quickly after application, metabolism is essentially stopped and translocation from the treated parts of the crops

into other plant parts such as seeds and roots is reduced. Following use as a crop desiccant, diquat ion was the major component of the ^{14}C residue in the skin and flesh of potato tubers accounting for more than 70% of TRR with no other individual component comprising more than 10% TRR. The major component in rape seed harvested from crops, following pre-harvest desiccation, was diquat ion at 48% TRR with smaller amounts of TOPPS (7.8% TRR) and diquat monopyridone (2.0% TRR).

The metabolism of diquat by plants is well understood. Following directed application to weeds using shielded sprayers there is minimal contact of the crop with diquat. A portion of the spray will reach the soil, but as described later, diquat is strongly absorbed by soil components such that it is largely unavailable for uptake by plant roots.

Following use as a pre-harvest desiccant, diquat ion is the major component of the ^{14}C residue in those parts exposed to direct sprays with TOPPS and diquat monopyridone present as minor components. Only low levels of radioactivity are found in plant parts such as potato tubers that are not directly exposed to the spray (< 0.05 mg equiv/kg).

Environmental fate

The Meeting received information on soil aerobic metabolism, soil photolysis and aqueous hydrolysis properties of [^{14}C]-diquat. Studies were also received on the behaviour of [^{14}C]-diquat in a rotational crop situation.

Diquat residues are persistent in soils, however residues in soil are strongly bound to soil components and not available for uptake by plants. As such, residues in soil should not contribute significantly to the residues in succeeding crops.

In soil incubation studies under aerobic conditions in the dark, diquat disappeared with a half-life that was > 290 days. In the absence of soil, diquat was rapidly and extensively degraded by soil micro-organisms normally found in soil pore water to give a small number of non-volatile degradation products (not identified) with mineralisation to CO_2 . The DT₅₀ for degradation in solutions of soil micro-organisms is rapid at < 1 week. Addition of clay to these solutions essentially stopped further degradation confirming that sorbed diquat is not available for biological degradation.

The degradation product TOPPS is also persistent in soils. Studies on the aerobic soil degradation of the diquat metabolite TOPPS estimated DT₅₀ values for degradation of 28 to 757 days.

Soil photolysis has negligible effect on degradation. In a study with application of ^{14}C -diquat on the surface of a sterilised loam soil, the DT₅₀s for photolytic degradation on dry and wet soil were 237 and 37 days respectively.

In a study of aqueous photolysis the DT₅₀ for degradation was 31 hours. The major degradation product was TOPPS with smaller amounts of diquat monopyridone and 1-hydroxy-3,4-dihydro-1H-pyrido[1,2-a]pyrazine-2-carboxylic acid formed.

In a confined rotational crop study with wheat, lettuce and carrot, a plot of sandy loam soil was treated with [^{14}C]-diquat at the equivalent of 1.1 kg ai/ha and crops sown 30, 120 and 365 days. At normal commercial harvest, crops grown in soil containing ^{14}C -diquat showed negligible uptake of radioactivity (TRR up to 0.02 mg equiv/kg). Residues above the LOD of 0.008 mg equiv/kg could have been due to contamination with adhering soil. Crops grown in rotation with diquat-treated crops are not expected to contain residues of diquat ion or diquat degradation products. Diquat residues in soil should contribute little to residue levels in rotational crops.

Methods of analysis

The Meeting received description and validation data for analytical methods for residue analysis of diquat in various plant and animal commodities. Early methods used in field trials generally involved extraction of residues by reflux with sulphuric acid with clean-up on cation exchange columns. Following reduction of diquat ion with alkaline dithionite or sodium borohydride, detection was initially achieved spectrophotometrically (350–450 nm). In more recent methods the diquat ion recovered from the cation exchange column is subjected to HPLC-UV or GC-NPD for quantitation. In

the case of animal commodities, trichloroacetic acid is sometimes used in place of sulphuric acid for the extraction step. LOQs were in the range 0.01 to 0.1 mg/kg.

The most recent advance in methods has been the use of LC-MS/MS which allows for the clean-up steps to be omitted with LOQs of 0.005 mg/kg for animal commodities, 0.006 mg/kg for potato and barley and 0.02 mg/kg for citrus.

The efficiency of the acid extraction step has been demonstrated during the metabolism studies where the majority of the total radioactive residue (TRR) was recovered in the acid extracts.

Multi-residue methods are currently not validated for diquat.

Stability of pesticide residues in stored analytical samples

The Meeting received information on the stability of diquat in samples of commodities from crops stored frozen.

Diquat is stable for at least 24 months in homogenised samples of spinach, wheat grain, wheat straw, rape seed, lentils, orange fruit and potato tubers fortified with diquat and stored frozen.

The periods of demonstrated stability cover the frozen storage intervals used in the residue studies.

Definition of the residue

In metabolism studies of diquat in goats and hens diquat ion was a significant component of the residue in hen (48% TRR liver; 12% TRR kidney) and goat (22% TRR liver; 4.3% TRR kidney) tissues. Other major components were diquat monopyridone (13% TRR liver; 13% muscle) and diquat dipyrindone (33% TRR liver; 29% kidney; 20-46% muscle and fat; > 80% milk) with small amounts of TOPPS (1.8% liver; 3.9% kidney) formed in hens. Radioactivity in egg yolks comprised mostly diquat monopyridine (up to 85% TRR) and diquat ion (up to 26% TRR) with smaller amounts of TOPPS (up to 10%TRR).

The major components of the residue in livestock are diquat ion, diquat monopyridone and diquat dipyrindone and should be considered for inclusion in the residue definition for compliance with MRLs and estimation of dietary intake in animal commodities. However, at realistic livestock exposures no residues of diquat ion, diquat monopyridone or diquat dipyrindone are expected. Additionally, current analytical methods for tissues have only been validated for determination of residues of diquat. Noting the above, the Meeting considered diquat ion to be a suitable as a residue definition for compliance with MRLs and estimation of dietary intake for animal commodities.

The log P_{ow} for diquat is -4.6 suggesting diquat residues are not fat soluble. There was only a small difference in residue levels in muscle and fat confirming diquat ion does not preferentially partition into fat and that the residue should not be classed as fat soluble. The Meeting decided that residues of diquat are not fat soluble.

Diquat is used on crops for two different situations:

Directed sprays or pre-emergent application for weed control (crop not intentionally treated)

Use as a crop desiccant to facilitate crop harvest (crop treated)

No residues are expected in situations where crops are not directly sprayed (directed sprays for weed control, pre-emergent or pre-sowing applications). The conclusion is supported by the results of confined crop rotation studies where soil residues were not taken up by crops.

Following use as a crop desiccant, diquat ion was the major component of the residue in flesh and skins of potato tubers and in rape seeds accounting for more than 70% of TRR in potatoes and 48% TRR in rape seeds. TOPPS was also detected in rape seed but represented less than 10% of the TRR. In plants, the majority of diquat-related residues in crops are accounted for in the previous residue definition; diquat ion.

Based on the above the Meeting confirmed the previous residue definition for compliance with MRLs and estimation of dietary intake for plant commodities.

Definition of the residue for compliance with MRL and estimation of dietary intake (animal and plant commodities): *diquat ion*

The residue is not fat soluble.

Results of supervised residue trials on crops

The Meeting received supervised residue trial data for diquat on citrus fruits, pome fruits, strawberries, banana, tomato, pulses, carrots, potatoes, rape, sunflower and coffee as well as for some animal feed commodities.

As no data were available for alfalfa fodder, barley, maize, oats, rice, sorghum and wheat the Meeting agreed to withdraw previous recommendations for these commodities.

A range of uses for diquat involve the application to weeds growing under trees in a variety of countries. The Meeting noted the results of soil aerobic metabolism and confined rotational crop studies that show that diquat in soil is not available for plant uptake. As application to weeds growing under trees is not expected to result in residues in harvested commodities the Meeting decided to evaluate the use on tree crops together, using the data on the crops supplied as mutual support for recommendations for those commodities with approved use-patterns. Diquat is approved for weed control in citrus fruit (Brazil, Costa Rica, Dominican Republic), pome fruit (Slovakia), banana/plantain (Belize, Costa Rica, Dominican Republic, El Salvador, Guatemala, Nicaragua, Panama), cashews (Dominican Republic), coffee (Belize, Brazil, Costa Rica, Dominican Republic, El Salvador, Guatemala, Nicaragua, Panama), stone fruit (Slovakia) and also apple and other fruit trees (Canada, USA).

Tree crops (application to weeds)

Field trials involving citrus orchards where diquat was applied to weeds were conducted in Brazil and were available to the Meeting.

The GAP for citrus in Brazil is application directed to weeds at 0.5 kg ai/ha with a PHI of 14 days. In the trials matching this GAP diquat residues in ranked order were (n=3): < 0.01 (2), < 0.02 mg/kg. Residues in trials on citrus that utilized rates higher than permitted in Brazil were < 0.01 (2) mg/kg.

Field trials involving apples were conducted in Europe were made available to the Meeting. The GAP for apples in Slovakia is application directed to weeds at 1.0 kg ai/ha with a PHI not specified (unnecessary). In twelve trials matching this GAP and with PHIs ranging from 0 to 171 days residues were (n=12): < 0.01 (10), < 0.05 (2) mg/kg.

Diquat is permitted to be used for weed control in banana plantations in various countries of central America (Belize, Costa Rica, Dominican Republic, El Salvador, Guatemala, Nicaragua, Panama) with an application rate of 0.6 kg ai/ha and no PHI required. In six trials from Costa Rica, Ecuador and Guatemala that matched GAP residues were < 0.05 mg/kg.

Diquat is approved in a range of Central and South American countries for weed control in coffee plantations including Belize, Brazil, Costa Rica, Dominican Republic, El Salvador, Guatemala, Nicaragua and Panama with maximum application rate of 0.5–0.6 kg ai/ha and a PHI typically 0 days. In trials from Costa Rica and Guatemala residues in coffee beans were < 0.05 (6) mg/kg.

The Meeting concluded that residues of diquat are not expected in harvested commodities from tree crops when application is to the weeds. The Meeting considered an LOQ of 0.02 mg/kg achievable and decided to estimate an STMR of 0 mg/kg, an HR of 0 mg/kg and a maximum residue level of 0.02 (*) mg/kg for citrus fruit, pome fruit, banana and coffee beans and to extrapolate the values to cashew apple (including cajou), cashew nuts and stone fruit.

*Berries and other small fruit (application to weeds)**Strawberries*

Trials were available from the UK. The GAP for strawberry in Sweden is a single application to weeds at 0.5 kg ai/ha before flowering or after harvest (use of spray shield) with no PHI required.

Residues in three trials from the UK at > 1.4 times the GAP of Sweden were: < 0.05 (3) mg/kg.

The Meeting utilized trials approximating the GAP of Sweden to estimate a maximum residue level for strawberries. Noting the exaggerated rates used in the three trials, the long interval between application and harvest and the requirement for a physical barrier when spraying, the Meeting estimated a maximum residue level of 0.05 * mg/kg, an STMR of 0 mg/kg and an HR of 0 mg/kg for strawberries.

Fruiting vegetables other than Cucurbits

Diquat is permitted to be used for weed control in row crops (includes tomatoes) in Spain with an application rate of 0.45 kg ai/ha and using spray protectors or shields, PHI 15 days.

Only one trial utilized a spray screen. The application rate was 2 times the GAP of Spain and residues were < 0.01 mg/kg. In another seven trials where the application rate was 2 times the maximum application rate of Spain and that did not use a spray shield the residues were also < 0.01 (7) mg/kg. The Meeting considered there is no expectation of residues above the LOQ for tomatoes and agreed to extrapolate the conclusion to fruiting vegetables other than cucurbits except sweet corn and fungi.

The Meeting estimated a maximum residue level of 0.01* mg/kg, an STMR of 0 mg/kg and an HR of 0 mg/kg for fruiting vegetables, other than cucurbits (except sweetcorn, fungi and mushrooms).

Pulses (pre-harvest desiccation)

Residue data from trials in common beans were made available from Germany and the USA for pre-harvest desiccation. The use pattern in Germany is 0.6 kg ai/ha with a PHI of 5 days. Analytical recoveries reported for trials from Germany on beans were low making the trials unsuitable for estimating maximum residue levels. The use pattern in Canada is for pre-harvest desiccation of beans at up to 0.41 kg ai/ha for ground application and 0.55 kg ai/ha for aerial application with a PHI of 4 days. In eight trials conducted in the USA approximating Canadian GAP residues were < 0.05 (8) mg/kg. The Meeting estimated an STMR of 0.05 mg/kg and a maximum residue level of 0.05* mg/kg for beans, dry replacing the previous recommendation of 0.2 mg/kg.

In Canada, diquat is permitted for pre-harvest desiccation of peas at up to 0.41 kg ai/ha for ground application and 0.55 kg ai/ha for aerial application with a PHI of 4 days. In five trials conducted in the USA approximating Canada GAP residues were: 0.05, 0.05, 0.09, 0.11 and 0.56 mg/kg. The Meeting considered five trials insufficient to estimate a maximum residue level for peas dry.

Pre-harvest desiccation sprays are permitted in Slovakia on peas at up to 0.8 kg ai/ha with a PHI of 6 days. In nine trials conducted in Europe, residues following a pre-harvest desiccation application at 0.6 kg ai/ha and after a 6 day PHI were: 0.03, 0.04, 0.04, 0.04, 0.05, 0.05, 0.06, 0.10, 0.15 mg/kg. The Meeting estimated an STMR of 0.05 mg/kg and a maximum residue level of 0.3 mg/kg for peas, dry confirming the previous recommendation.

In Canada, pre-harvest desiccation sprays are permitted in lentils at up to 0.41 kg ai/ha for ground application and 0.55 kg ai/ha for aerial application with a PHI of 4 days. In three trials conducted in USA with application at 0.42 kg ai/ha residues were < 0.05, 0.13 and 0.54 mg/kg at 4 days after application. The Meeting considered three trials insufficient to estimate a maximum residue level for diquat in lentils and withdrew its previous recommendation of 0.2 mg/kg.

In Canada, pre-harvest desiccation sprays are permitted in soya beans at up to 0.56 kg ai/ha with a PHI of 4 days. In seven trials conducted in USA at 0.56 kg ai/ha residues were < 0.01, 0.02, 0.03, 0.03, 0.04, 0.09, 0.16 mg/kg in samples harvested 7 to 10 days after application. The Meeting noted there was little decline in residues between 4 and 10 days and decided to use the data to estimate an STMR of 0.03 mg/kg and a maximum residue level of 0.3 mg/kg for soya beans (dry) replacing its previous recommendation of 0.2 mg/kg.

Carrots (directed application for weed control)

In Spain diquat is approved for general weed control in row crops including carrots (GAP: 0.45 kg ai/ha using spray protectors, PHI 15 days). In three trials in Germany and Italy that used spray shields and with application rates that were two times GAP of Spain residues were: 0.01, < 0.02, < 0.02 mg/kg.

The Meeting considered three trials insufficient to estimate a maximum residue level for carrots.

Potato (pre-harvest desiccation)

Diquat is approved for pre-harvest desiccation of potato crops in various countries. Pre-harvest desiccation use-patterns approved in various countries include Austria (GAP: 0.5 kg ai/ha, PHI 10 days), Brazil (GAP 0.5 kg ai/ha, PHI 7 days), Canada (GAP 2×0.84 kg ai/ha, PHI 0 days), Germany (GAP: 1 kg ai/ha, PHI 10 days), the Netherlands (GAP: 0.8 kg ai/ha, max 2 sprays and 1 kg ai/ha per crop, PHI 0 days), Spain (GAP: 0.8 kg ai/ha, PHI 15 days), the UK (GAP: 1.0 kg ai/ha, max 2 sprays and 1 kg ai/ha per crop, PHI 0 days or 14 days if storing potatoes) and the USA (GAP: 0.56 kg ai/ha, PHI 7 days).

In trials in Europe approximating the GAP of the UK residues were: < 0.01 (10), 0.01, 0.01, 0.01, 0.01, 0.02, 0.02 mg/kg.

In trials conducted according to the GAP of USA residues were: < 0.05 (6), 0.06, 0.06 mg/kg.

Using the residue data from the USA, the Meeting estimated an STMR of 0.05 mg/kg, an HR of 0.06 mg/kg and a maximum residue level of 0.1 mg/kg for potato replacing the previous recommendation of 0.05 mg/kg.

Rape seed, (pre-harvest desiccation)

Diquat is approved for pre-harvest desiccation of oilseed rape in Austria (GAP: 0.6 kg ai/ha, PHI 5 days), Canada (GAP: 0.41 kg ai/ha, PHI 14 days), Germany (GAP: 0.6 kg ai/ha, PHI 5 days), the UK (GAP: 0.6 kg ai/ha, PHI 7-10 days) and the USA (GAP: 0.56 kg ai/ha, PHI 7 days).

Residues in rape seeds from trials conducted in Europe approximating German GAP were (n=12): 0.02, 0.03, 0.03, 0.05, 0.06, 0.07, 0.08, 0.10, 0.12, 0.22, 0.27, 0.33, 0.38, 0.42, 0.44, 0.45 mg/kg.

In trials approximating GAP in the USA total residues in rape seeds were (n=9): 0.06, 0.24, 0.30, 0.30, 0.46, 0.48, 0.52, 0.72, 0.82 mg/kg.

The Meeting considered the trials from the USA would lead to the higher maximum residue level and estimated an STMR of 0.49 mg/kg and a maximum residue level of 1.5 mg/kg for rape seed replacing its previous recommendation of 2 mg/kg.

Sunflower seed (pre-harvest desiccation)

Diquat is approved for pre-harvest desiccation of sunflowers in Canada (GAP: 0.41 kg ai/ha, PHI 15 days) and Slovakia (GAP: 0.6 kg ai/ha, PHI 6 days). Residues in trials from France approximating Slovakian GAP were (n=13): < 0.05, 0.06, 0.07, 0.08, 0.09, 0.10, 0.11, 0.11, 0.15, 0.19, 0.41, 0.46, 0.54 mg/kg.

The Meeting estimated an STMR of 0.11 mg/kg and a maximum residue level of 0.9 mg/kg for sunflower seed replacing its previous recommendation of 1 mg/kg.

Animal feeds

Pea fodder (pre-harvest desiccation)

Residue levels occurring in pea straw were evaluated. In four trials conducted in the UK approximating GAPs in Austria (0.6 kg ai/ha, PHI 5 days) and France (0.6 kg ai/ha, PHI 4 days) residues in pea straw were 3.6, 14, 18, 25 mg/kg all on an as received basis. The Meeting estimated median and highest residues of 16 and 25 mg/kg on an as received basis for residues of diquat in pea straw.

The Meeting estimated a median residue of 16 mg/kg, a highest residue of 25 mg/kg (both on an as received basis) and a maximum residue level of 50 mg/kg for pea fodder (on a dry weight basis).

The Meeting received two trials conducted in France that measured residues in soya bean forage. The meeting considered two trials insufficient to make recommends for soya bean forage.

Fate of residues during processing

The Meeting received information on the fate of incurred residues of diquat during the processing of soya bean, oilseed rape/canola and sunflower seeds. Studies of the hydrolysis of diquat under a range of conditions showed diquat is stable.

Summary of selected processing factors for diquat

Raw commodity	Processed commodity	Individual PF	Best estimate PF	STMR _{RAC} (mg/kg)	STMR _{RAC} × PF (mg/kg)
Soya bean	Hulls	2.6 3.6	3.1	0.03	0.093
	Meal	0.7 1.0	0.85		0.0255
	Oil	< 0.04 < 0.07	< 0.055		< 0.00165
Rape/canola	Meal	0.17 0.20 0.58 0.76	0.39	0.49	0.19
	Oil	< 0.01 < 0.01 < 0.03 < 0.03	< 0.02		< 0.0098
Sunflower seed	Oil	< 0.1 < 0.1 < 0.1 < 0.5 < 0.6 < 0.6 < 0.7 < 0.8 < 0.8 < 1	< 0.6	0.11	< 0.066
	Cake	1 1 1.2 1.2 1.2 1.2 1.3 1.3 1.3 1.3	1.2		0.132

Residues are not expected in oils obtained from treated crops.

Residues in animal commodities

Farm animal feeding studies

The Meeting received information on the residue levels arising in tissues and milk when dairy cows were fed a diet containing incurred residues of diquat at dietary levels of 18, 50 and 84 ppm for 30 consecutive days. There were no residues of diquat at or above the LOQ (0.001 mg/kg) in any of the milk samples from any of the dose groups, throughout the duration of the study. There were no residues of diquat at or above the LOQ (0.01 mg/kg) in any of the tissue samples (liver, kidney, fat and muscle) from any of the dose groups.

The Meeting also received information on the residue levels arising in tissues and eggs, when laying hens were fed a diet containing diquat at total dietary levels of 1, 5 and 10 ppm diquat for 21 or 28 consecutive days. No residues of diquat above the LOQ (< 0.01 mg/kg) were found in any of the egg, fat, muscle, skin, liver or heart samples.

Animal commodity maximum residue levels

Dietary burden calculations for beef cattle and dairy cattle and poultry are provided below. The dietary burdens were estimated using the OECD diets listed in Appendix IX of the 2009 edition of the FAO Manual.

Summary of livestock dietary burden (ppm of dry matter diet)

	US-Canada		EU		Australia		Japan	
	max	mean	Max	Mean	max	Mean	max	Mean
Beef cattle	0.12	0.09	7.3	4.7	28 ^a	18 ^c	0.09	0.09
Dairy cattle	2.9	1.9	8.7	5.6	20 ^b	13 ^d	0.09	0.09
Poultry Broiler	0.06	0.06	0.11	0.10	0.08	0.08	0.04	0.04
Poultry Layer	0.06	0.06	2.9 ^e	1.9 ^{f g}	0.08	0.08	0.05	0.05

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian meat

^b Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

^c Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat.

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs.

^f Highest mean poultry dietary burden suitable for STMR estimates for poultry meat.

^g Highest mean poultry dietary burden suitable for STMR estimates for poultry eggs.

Animal commodity maximum residue levels

The Meeting concluded that at the maximum estimated dietary burdens for cattle of 28 ppm and 2.9 ppm for poultry no residues are expected in tissues, milk and eggs.

The Meeting estimated HR and STMR values of 0 for milk, muscle, edible offal and fat. The Meeting estimated the following maximum residue levels: milk 0.001* mg/kg; meat (mammalian except marine mammals) 0.01* mg/kg and edible offal 0.01* mg/kg to replace its previous recommendations of: milk 0.01 mg/kg; meat (mammalian except marine mammals) 0.05 mg/kg and edible offal 0.05 mg/kg.

For poultry no residues are expected. The Meeting estimated the following maximum residue levels for poultry commodities: poultry meat 0.01* mg/kg; poultry edible offal 0.01* mg/kg and eggs 0.01* mg/kg to replace its previous recommendations of: eggs 0.05 mg/kg; poultry meat 0.05 mg/kg and poultry edible offal 0.05 mg/kg.

The Meeting estimated the following STMR values: poultry meat 0 mg/kg; poultry fat 0 mg/kg; poultry edible offal 0 mg/kg and eggs 0 mg/kg.

RECOMMENDATIONS

On the basis of the data obtained from supervised residue trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with MRL and for estimation of dietary intake (for animal and plant commodities):

Definition of the residue for compliance with MRL and estimation of dietary intake (for animal and plant commodities): *Diquat ion*.

The residue is not fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The WHO Panel of the 2013 JMPR established an Acceptable Daily Intake (ADI) of 0–0.006 mg/kg bw for diquat.

The evaluation of diquat resulted in recommendations for MRLs and STMR values for 30 raw and processed commodities. Where data on consumption were available for the listed food commodities, dietary intakes were calculated for the 13 GEMS/Food Consumption Cluster Diets. The results are shown in Annex 3 of the 2013 JMPR Report.

The IEDIs in the thirteen Cluster Diets, based on the estimated STMRs were 0–4% of the maximum ADI (0.006 mg/kg bw). The Meeting concluded that the long-term intake of residues of diquat from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The WHO Panel of the 2013 JMPR established an Acute Reference Dose (ARfD) of 0.8 mg/kg bw for diquat. The IESTIs represented 0% of the ARfD of 0.8 mg/kg bw.

The Meeting concluded that the short-term intake of residues of diquat resulting from uses that have been considered by the JMPR is unlikely to present a public health concern.

DITHIANON (180)

The first draft was prepared by Dr U Banasiak, Delegate for Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

The fungicide dithianon was first evaluated by the JMPR in 1992 (T, R). The compound was evaluated for toxicology by the 2010 JMPR within the periodic review programme of the CCPR. The periodic review for residues was scheduled at the 39th Session of the CCPR for the 2012 JMPR but postponed to be evaluated by the 2013 Meeting.

The Meeting received information from the manufacturer on physical and chemical properties, metabolism studies on plants and animals, analytical methods, supervised residue trials data, processing studies as well as use pattern.

IDENTITY

Common name: Dithianon

Chemical name:

IUPAC: 5,10-Dihydro-5,10-dioxonaphtho-[2,3-beta]-1,4-dithiine-2,3-dicarbonitrile

CA: 5,10-Dihydro-5,10-dioxonaphtho[2,3-beta]-1,4-dithi-in-2,3-dicarbonitrile

CAS number: 3347-22-6

CIPAC number: 153

Molecular formula: C₁₄H₄N₂O₂S₂

Structural formula:

Molecular mass: 296.3

Minimum purity: active substance (ai) manufactured 930 g/kg

Formulations

Dithianon is available in numerous commercial formulations in different formulation types (SC, WDG, WP) in many countries.

PHYSICAL AND CHEMICAL PROPERTIES

Dithianon, the pure and the technical grade active ingredient are thermally stable solids. The compound is poorly soluble in water and hexane and soluble in toluene, dichloromethane and acetone. It hydrolyses rapidly under neutral or alkaline conditions, is not explosive, not self-igniting and does not burn. The physical and chemical properties of dithianon are shown in detail in Table 1 (ai = pure active ingredient, TC = technical material, purity in percent (%)).

METABOLISM AND ENVIRONMENTAL FATE

The metabolism and distribution of dithianon in plants and animals was investigated using the [5,6,9,10-]¹⁴C-labelled compound or, in some studies, a [5,6,9,10-]¹³C/¹⁴C-labelled compound.

* Denotes position(s) of carbon-¹³ label and position(s) of carbon-¹⁴ label

Chemical names, structures and code names of metabolites and degradation products of dithianon are summarized in Table 2.

M216F020	glucuronic acid conjugate of 1,4-dihydroxynaphthalene	

Animal metabolism

The metabolism of dithianon has been studied in laboratory rats, goats and hens.

Rats

Rat metabolism studies were evaluated by the WHO Core Assessment Group of the 2010 JMPR. A summary of the rat metabolism is given below:

At tested doses of 10 and 50 mg/kg bw, orally administered dithianon was about 40–50% absorbed in rats. The majority of the administered dose was recovered in Faeces (64.0–72.2%) and in urine (26.7–31.4%). Dithianon was extensively metabolized according to the following key transformation steps: oxidation of the sulphur atoms, cleavage of the dithiine ring, reduction of the 1,4-naphthoquinone moiety and further glucuronidation, as well as substitution of the carbonitrile moieties by amino and carboxy groups. The only metabolite in rat urine at a level greater than 2% was M216F020 (glucuronic acid conjugate of 1,4-dihydroxynaphthalene).

Lactating goats

The fate of dithianon in lactating goats was investigated by Cheng (1990, DT-440-006 and 1992 DT-440-008) and Webb and Richardson (1994, DT-440-011).

Study 1 [Cheng 1990, DT-440-006; Cheng 1992, DT-440-008]

One lactating goat each was dosed by capsule at a daily nominal rate of 6 mg (equiv. to 2.5 mg/kg feed) and 60 mg ¹⁴C-dithianon (equiv. to 28 mg/kg feed) for five days. One animal was assigned as control. Milk, urine and faeces were sampled during the course of the study and liver, kidney, muscles and fat were obtained after the end of the experiment.

Solid matrices were homogenized under frozen conditions followed by sample combustion. Faeces were homogenized with deionized H₂O, whereas the liquid samples (urine, blood, bile, milk and cage wash) were homogenized without any additional additives and finally combusted. Radioactivity was determined using liquid scintillation counter (LSC).

Each matrix was blended with a mixture of chloroform, methanol and with a buffer of either 0.1 M potassium phosphate (pH 5) or 0.1 M ammonium acetate (pH 5). The volume ratios of solvents were depending on the matrix adjusted and sample was blended again. The mixture was centrifuged and the resulting layers were transferred to separate containers. The extraction was repeated on the remaining solid. The chloroform fractions of the tissues were rotary-evaporated to dryness; and the residue was partitioned between hexane and acetonitrile. The aqueous/methanol and organic-soluble

fractions were concentrated before analysis. After extraction, the remaining solid was dried, and aliquots were combusted to obtain material balances of radioactivity for each examined sample.

Extracted ^{14}C -dithianon from the goat milk, bile, excreta and tissues were subjected to high-performance liquid chromatography (HPLC) and thin-layer chromatography (TLC) to determine the metabolite profiles. Urine was hydrolysed using aryl sulfatase and β -glucuronidase and analysed by HPLC and TLC techniques. The total radioactive residues (TRR) in mg/kg and% of the total applied radioactivity (TAR) in goat tissue and milk after administration of ^{14}C -radiolabelled dithianon are shown in Tables 3 and 4.

The nature of radioactive residues in lactating goat dosed with 60 mg radiolabeled ^{14}C -dithianon/day was investigated by separation of radioactive residues into organo-soluble (non-polar), aqueous/methanol-soluble (polar) and non-extracted (bound/conjugated) fractions.

The results are shown in Tables 5 and 6 as well as were described below:

In liver, several radioactive components were detected by HPLC analysis. The concentration of each component was low, with the highest being 0.02 mg/kg for the polar (aqueous-soluble component A-4). TLC analysis of the organic-soluble extract revealed several components. One component (accounted 0.96% of TRR) was presumably identified as parent dithianon.

In kidney, several radioactive components were detected by HPLC analysis. The highest concentrations were detected in the aqueous-soluble extract and were identified as A-2 (0.03 mg/kg) and A-3 (0.03 mg/kg), respectively. One component was identified as dithianon (2.32% of TRR in the kidney sample).

In milk, several radioactive components were detected by HPLC analysis and all had radioactive concentrations less than 0.01 mg/kg. A component in the organic-soluble extract was identified as dithianon and accounted for 8.2% of TRR in the milk sample.

HPLC analysis of bile indicated the presence of several radioactive components. The major components were identified as A-2, A-3, A-4, and A-5. The percentage of the samples radioactivity that these components constituted ranged from 12.1% to 30.8%. Dithianon accounted for 2.19% of the TRR in the bile sample.

In Faeces, several radioactive residue components were detected by analysis of the aqueous-soluble and the organic-soluble extracts. All components constituted less than 5% of TRR. Dithianon accounted for 3.27% of TRR in Faeces sample.

HPLC analysis of urine indicated the presence of two major radioactive components, identified as A-2 and A-3. Each component constituted 21.1% and 37.0% of TRR, respectively. A minor component was identified as dithianon (1.7% of TRR).

Study 2 [Webb and Richardson, 1994, DT-440-011]

One lactating goat was dosed by capsule at a daily nominal rate of 60 mg $^{13}\text{C}/^{14}\text{C}$ -dithianon (equivalent to 25 mg/kg feed) for 5 consecutive days. Animals were sacrificed 6 hours post dose 5. The radiochemical purity was determined to be > 97% over the dosing period. The carbon-13 isotope abundance was 42.6%. Milk, urine and Faeces were sampled during the course of the study and liver, kidney, muscles and fat were obtained after the end of the experiment. Solid matrices were analysed by means of sample combustion. Radioactivity in liquid samples was measured by liquid scintillation counters (LSC). The results for TRR and of TAR are shown in Tables 8 and 9.

Different extraction approaches were used in order to extract radioactive material from the different matrices:

Liver and kidney were extracted via methanol and chloroform and partitioned by KCl into chloroform, aqueous and methanol/water phases. The chloroform fraction was dried and partitioned into hexane and acetonitrile phases. The volume of the methanol/water phase was reduced; the methanol was removed and radioactive substances were extracted using ethyl-acetate. The acetonitrile and ethyl acetate phases were combined and concentrated (representing the organic phase).

The extraction of muscle samples was done using chloroform/methanol following an aqueous KCl partitioning into a chloroform, methanol/water and final aqueous phase.

Fat was extracted with dichloromethane. The revealed extract was dried and partitioned into an acetonitrile and a hexane phase.

After extraction, the samples of liver and kidney were treated with enzymes (pepsin, glucuronidase, sulfatase and pancreatin), acid and/or alkali hydrolysis to release the non-extracted radioactivity. Aliquots of the hydrolysate and remaining pellet were analysed by combustion and/or LSC. Liquid samples were analysed by a number of TLC and HPLC systems.

The distribution of TRR in tissues (as results of the solvent extraction) and in milk is summarized in Table 10. Solvent extraction of tissues afforded between 27.3% (0.043 mg/kg) and 49.1% (0.077 mg/kg) of the ^{14}C -residues in liver (total residue 0.157 mg/kg), 40.6% (0.193 mg/kg) of the ^{14}C -residues in kidney (total residue 0.475 mg/kg), 20% (0.003 mg/kg) of the ^{14}C -residues in muscle (total residue 0.013 mg/kg), 26.1% (0.019 mg/kg) of the ^{14}C -residues in fat (total residue 0.074 mg/kg) and 78.39% (0.012 mg/kg, 96 h sample) of the ^{14}C -residues in whole milk (total residue between 0.003 and 0.018 mg/kg). Non-extracted residues accounted for 72.7% (0.114 mg/kg) of the liver residue, 59.4% (0.282 mg/kg) of the kidney residues, 80% (0.01 mg/kg) of the muscle residue, 73.9% (0.055 mg/kg) of the fat residue and 21.7% (0.003 mg/kg) of the milk residue (96–102 h value).

^a Acetone, cyclohexane, dichloromethane

Chromatography of the extracted radioactivity revealed metabolites with a wide range of polarity. HPLC analysis proved to be the most efficient in terms of resolution of components. Comparison of the organic and aqueous phases using HPLC reverse phase system indicated that there were some similarities in the metabolite profiles for liver, kidney, urine and bile however the profiles were very complex, containing numerous metabolites (> 20 compounds in the organic phase and > 6 compounds in the aqueous phase). The quantitation of such complex mixtures was difficult due to the low concentration of radioactive residues and the incomplete resolution of all components, no single metabolite in these extracts was > 0.05 mg/kg. No parent was present in the extracts and none of the metabolites were identified. The metabolites did not appear to match any of the reference chemicals. No chromatographic profiling of the muscle, fat or milk extracts was carried out because of the low concentrations of metabolites.

The enzymatic hydrolysis of the PES was carried out as follows: After solvent extraction, unreleased radioactivity present in liver was partly solubilized by treatment with pepsin, (25% of the unextracted radioactivity) or base (NaOH, up to 67%). Pancreatin treatment of the residuum from base solubilisation afforded 52% of the remaining radioactivity. Base treatment solubilised 49% of the unextracted radioactivity in the RRR of kidney. Incubation in pH 7.5 buffer of the residuum from base solubilisation afforded 49% of the remaining radioactivity. Chromatographic profiles of the solubilised radioactivity were obtained but it was not possible to identify any of the components. No metabolic pathway can be directly derived since none of the metabolites being present could be identified.

In this study, a further experiment to demonstrate the reactivity of dithianon with nucleophiles (commonly thiols in the form of proteins and peptides such as glutathione) was undertaken *in vitro*. Glutathione and N-acetylcysteine were shown to react very quickly with dithianon when incubated in pH 6.5 buffers at 37 °C without the intermediacy of facilitating enzymes such as glutathione transferase. This experiment indicated that the reaction of dithianon with glutathione and protein thiol groups *in vivo* will be virtually instantaneous. Thus, the metabolism of dithianon was likely to have been initiated by the opening of the dithiine ring by endogenous thiols (e.g. glutathione). The reaction with protein thiol groups accounts for the high levels of unextracted radioactivity found in the tissues. Following the ring opening reaction, further biotransformation via, for example, the glutathione pathway will have produced the very complex metabolite mixtures seen during the chromatographic analysis of the tissue extracts and the analysis of urine and bile.

Laying hens

The absorption, distribution, excretion of dithianon in laying hens was studied by Cheng (1990, 1992).

Cheng, 1990, DT-440-005; Cheng, 1992, DT-440-007

Two groups of laying hens, five hens per group, were treated orally once daily for 5 consecutive days with gelatin capsules containing the test substance. Animals were sacrificed 6 hours after the last dose. One group of hens was treated at a nominal dose level of 0.36 mg/day and the other group was treated at a nominal dose level of 3.6 mg/day. A third group of 5 hens served as the control group and was treated with empty capsules. The doses of dithianon were equivalent to a nominal dose rate of 3 and 30 mg/kg in the feed based on a projected average feed consumption of 120 g per hen per day. The actual doses of dithianon administered were 0.396 mg/day and 3.99 mg/day, respectively, equivalent to 3.57 mg/kg and 38.7 mg/kg in the feed.

Excreta from each group were collected daily. Eggs were collected twice daily (am and pm) during the dosing period. The 'pm-eggs' were refrigerated and added to the 'am-collections' the following morning. The eggs were separated into yolks and whites, which were stored separately. All samples were pooled according to day, sample matrix and subset, and then weighed. Approximately 6 hours after administration of the last dose, the animals were sacrificed. A sample of heparinized blood

was taken from each animal. Tissue samples [skin adhering to fat, breast muscle, thigh muscle, kidneys (both), liver, fat (abdominal)] and gastrointestinal (GI) tract, GI tract contents, and shelled eggs in oviduct (if present) were collected. Blood was refrigerated until analysis; all other samples were stored at or below 0 °C.

All measurements of radioactivity in liquid samples were analysed directly by LSC. Radioactivity in solid samples was determined by combustion followed by LSC. Tissue samples (kidney, liver, thigh muscle, breast muscle, and abdominal fat, skin with fat and GI tract) were homogenized while frozen, and triplicate aliquots were weighed for combustion. Excreta samples were homogenized with water (1:1 w/v), and triplicate aliquots were weighed for combustion. Triplicate aliquots of blood samples were weighed for combustion. Egg white and egg yolk were homogenized separately, and triplicate aliquots were weighed for LSC. Post-extracted solid samples were combusted prior to analysis by LSC.

Tissues, egg yolk, blood, and excreta from chickens (high dose group; 38.7 mg/kg feed) were extracted for metabolite profiling. Extraction procedures were carried out with a mixture of chloroform, methanol and water. The chloroform-soluble fraction was separated from the methanol:water fraction and each was concentrated to dryness. The organo-soluble (chloroform) residue was reconstituted in hexane and re-extracted with acetonitrile. The hexane and acetonitrile fractions were separated for radioanalysis. The water soluble fraction (methanol:water) residue was reconstituted in water. The extracted ^{14}C residues were analysed by TLC and high performance liquid chromatography (HPLC). Fractions of the HPLC eluate were collected, and each was analysed directly by LSC.

As shown in Table 11, following oral administration of ^{14}C -dithianon to laying hens, the overall recoveries of radioactivity were approximately 93.9% and 94.6% of the total applied radioactivity (TAR) for the low and high dose groups, respectively. The elimination rate of radioactivity in excreta was rapid and constant. Approximately 90% of TAR was eliminated in excreta by 6 hours after the last dose. The majority of the radioactivity was in excreta (approximately 90% TAR), GI tract contents (3.4% to 4.8% TAR), GI tract (0.6% TAR), liver (0.03% TAR), and kidneys (0.02% TAR). All of the eggs together contained less than 0.01% of the dose administered, most of which was retained in the yolk.

Table 11 Material balance after administration of ^{14}C -dithianon to laying hens (DT-440-005)

^a Sac day 4: eggs in the oviduct taken about 6 hours after sacrifice

^b TRR values for egg yolk and white combined

The extraction procedure served to characterize the radioactivity in each sample as organo-soluble (non-polar), aqueous : methanol-soluble (polar), and non-extracted residues. The distribution of radioactivity in eggs, tissues and excreta from the high dose group is summarized in Table 13. The results for partitioning of the chloroform-soluble residues between hexane and acetonitrile are presented in Table 14 for egg yolks, skin with fat, liver and kidney. Acetonitrile-hexane partitioning of the chloroform-soluble residues in muscle, abdominal fat, blood and excreta was not performed.

Table 13 TRR extracted in eggs, tissues and excreta of laying hens after dosing with ¹⁴C-dithianon, equivalent to 38.7 mg/kg in the feed (DT-440-007)

Matrix	TRR ^a , mg/kg	Chloroform TRR, mg/kg (%)	Aqua methanol TRR, mg/kg (%)	ERR ^b TRR, mg/kg (%)	PES ^c TRR, mg/kg (%)	Recovery ^d TRR, mg/kg (%)
Egg yolks (last day)	0.078	0.010 (12.4)	0.027 (34.5)	0.037 (46.9)	0.042 (53.5)	0.079 (101)
Muscle	0.022	0.003 (12.6)	0.012 (55.7)	0.015 (68.3)	0.008 (35.0)	0.023 (103)
Skin with fat	0.041	0.004 (10.8)	0.027 (64.8)	0.031 (75.6)	0.011 (27.7)	0.042 (103)
Liver	0.186	0.029 (15.6)	0.105 (56.5)	0.134 (72.1)	0.046 (24.7)	0.180 (97)
Kidney	0.378	0.025 (6.6)	0.254 (67.1)	0.279 (73.7)	0.126 (33.3)	0.405 (107)
Blood	0.275	0.013 (4.73)	0.103 (37.6)	0.116 (42.3)	0.162 (58.8)	0.278 101
Excreta, pool (last day)	20.1	1.81 (8.99)	13.7 (68.0)	15.48 (77.0)	7.14 (35.5)	22.6 (113)

^a TRR values measured directly by combustion and LSC

^b ERR: Extracted radioactive residue (sum of chloroform and methanol: water extracts)

^c PES: Post-extraction solids remaining after extraction

^d Sum of TRR in all extracts and PES

Table 14 Distribution of ^{14}C -dithianon-derived chloroform-soluble tissue residues between hexane and acetonitrile (DT-440-007)

Matrix	TRR ^a , mg/kg	Chloroform-soluble TRR, mg/kg (%)	Hexane-soluble TRR, mg/kg (%)	Acetonitrile-soluble TRR, mg/kg (%)
Egg yolks (last day)	0.078	0.010 (12.4)	0.008 (9.9)	0.002 (2.5)
Skin with fat	0.041	0.004 (9.8)	0.002 (4.9)	0.002 (4.9)
Liver	0.186	0.029 (15.6)	0.012 (6.5)	0.016 (8.6)
Kidney	0.378	0.025 (6.6)	0.012 (3.3)	0.012 (3.3)

^a TRR values measured directly by combustion and LSC

The findings of the characterization of metabolites (components) are summarized in Table 15 for liver, kidney, skin with fat and egg yolk. Additionally, for all matrices including blood and excreta the results are described as follows:
