n.d. = Not detected

In Bedfordshire soil incubated at 10 °C, the total ^{14}C recovery (based on the Day 0 dose) from this soil averaged 97.9%. Extracted radio-label decreased from 99.2% on Day 0 to 6.4% after 30 days. The PES reached a maximum of 39.6% and evolution of $^{14}CO_2$ reached 52.4% by Day 30. Negligible quantities of ^{14}C (< 1%) were detected in the volatile organic compounds traps.

[^{14}C]Flonicamid incubated in UK soils at 20 °C declined rapidly from 95% on Day 0 to 0.5% of the applied radioactivity (AR) by Day 14 (Bedfordshire soil) or to 1.5% by Day 7 and non-detectable at Day 14 (Birmingham soil). TFNA rose to a maximum of 19.2–30.6% by Day 1, and then dropped to non-detectable levels by Day 7. TFNA-OH rose to a maximum of 12.1–21.3% by Day 2/3 and declined to non-detectable levels by Day 7. TFNG-AM rose to a maximum of 7.8–9.7% by Day 0.33 and declined to less than 1.0% by Day 3 (Bedfordshire soil) or non-detectable levels by Day 7 (Birmingham soil). Minor metabolites TFNA-AM and TFNG were detected at levels $\leqslant$ 3.7% between Day 0.33 and Day 14. Minor polar components were observed in the HPLC chromatograms at Days 1–14. All polar components were $\leqslant$ 2.2% AR.

In Speyer 2.1 soil, a similar trend was observed where flonicamid decreased from 96.8% of the AD at Day 0 to less than 1% by Day 14. TFNA rose to a maximum of 12.2% by Day 3 then dropped to less than 0.5% of the AD at Day 14. TFNA-OH rose to a maximum of 17.6% by Day 7 and declined to 1.0% of the AD at Day 14. TFNG-AM rose to a maximum of 10.2% by Day 2 and dropped to less than 1% of the applied dose at Day 14. TFNA-AM rose to a maximum of 7.6% at Day 7 and then declined to less than 0.5% by Day 14. Minor metabolite TFNG was detected at levels below 4% between Day 0.33 and Day 14. Several minor polar components were observed in the HPLC chromatograms at Days 2–14. All polar components were less than 7.1% of the applied dose.

In Bedfordshire soil incubated at 10 °C parent flonicamid decreased from 96.3% AR at Day 0 to 1.7% by Day 14 (Table 33). TFNA rose to a maximum of 24.3% by Day 3, and then dropped to less than 2% by Day 14. TFNA-OH rose to a maximum of 32.7% by Day 7 and declined to 16.1% at Day 14. TFNG-AM rose to a maximum of 8.1% by Day 0.67 and dropped to less than 1% by Day 14. Minor metabolites TFNA-AM and TFNG were detected at levels below 6% between Day 0.33 and Day 14. Minor polar components were observed in the HPLC chromatograms at Days 2–14. All polar components were less than 2.3% of the administered dose.

The DT_{50} and DT_{90} values were calculated for each soil set. First-order kinetics were observed for all soils. For the soils incubated at 20 °C the DT_{50} and DT_{90} values ranged from 0.7 to 1.8 days and 2.3 to 6.0 days, respectively. The DT_{50} value was 2.4 days and the DT_{90} value was 7.9 days for the soil incubated at 10 °C. The most rapid degradation kinetics were observed for the Bedfordshire soil and the Birmingham soil at 20 °C. The DT_{50} and DT_{90} values for each soil set are shown in Table 34.

Table 34 Aerobic degradation of flonicamid in soil incubated at 20 °C and 10 °C

Soil		Incubation	DT_{50}	DT_{90}	
Type	Origin	temperature	[days]	[days]	r^2
Loamy sand	Bedfordshire	20 °C	0.7	2.3	0.9898
Sandy loam	Birmingham		0.7	2.4	0.9890
Sand	Speyer 2.1		1.8	6.0	0.9989
Loamy sand	Bedfordshire	10 °C	2.4	7.9	0.9721

TFNA, TFNA-OH and TFNG-AM were the major degradates in all soils over the course of the study which peaked at levels of 12.2 to 30.6%, 12.1 to 32.7% and 7.8 to 10.2% respectively, of the applied radioactivity. Minor degradates TFNG and TFNA-AM were detected at less than 7.7% AR at all sampling points over the course of the study. All of the degradates were metabolised and mineralised to carbon dioxide and immobilised as soil-bound residue.

Soil photolysis

The photochemical degradation of [pyridyl-^{14}C]flonicamid (specific activity 9.08 MBq/mg) was investigated in a loamy sand soil (pH 7.2, 0.98% organic matter, origin Madison, Ohio, USA) under laboratory conditions.

Ten grams (10 g) of dried soil was weighed into each photolysis vessel, made of clear glass, to a depth of approximately 3 mm. The fortification solution of [^{14}C]flonicamid (ca. 50 µL) was added onto the soil surface of each sample jar at a rate of approximately 0.1 mg eq/kg (0.1 µg/g) by means of a syringe. A total of 16 dark control and 16 light exposed samples were prepared. Two additional sample vessels were prepared for each treatment condition at an exaggerated rate (4×) for use in metabolite isolation as required. The temperature of the light-exposed and dark control samples was maintained at 20 ± 1 °C throughout the study. The light exposed and dark control samples were analysed at 0, 1, 3, 7, 9, 11 and 15 days after fortification.

Whilst volatile radioactivity was not trapped, based on the overall recoveries, good material balance was achieved, precluding the requirement for volatile traps.

[^{14}C]Flonicamid decreased from 99.0% of the applied radioactivity (AR) on Day 0 to 59.5% AR after 15 days continuous illumination. Concurrently, the metabolite TFNG-AM was detected in Day 1 sample extracts at 2.9% AR and increased to 29.5% AR by Day 15. TFNA-AM and TFNG were also detected as minor metabolites in the illuminated soils, reaching maximum concentrations of 5.0% (Day 11 and Day 15) and 2.0% AR (Day 15), respectively.

In the dark controls flonicamid decreased from 99.0% of the AR on Day 0 to 80.4% AR after 15 days dark storage. The metabolite TFNG-AM was detected in Day 1 sample extracts at 1.2% AR and increased to 13.8% AR by Day 15 samples. TFNA-AM and TFNG were detected as minor metabolites reaching maximum concentrations of 2.8% (Day 9 and Day 15) and 2.0% AR (Day 15), respectively. The mass balance and ^{14}C distribution of radioactivity from the photochemical degradation of [^{14}C]flonicamid on soil is shown in Table 35.

[a] (% ^{14}C in designated fractions) × (% extracted)

Recovery = Extracted plus bound residues

Values are average of duplicate samples

The degradation of flonicamid appears to have followed first order kinetics. A linear regression analysis was performed on the data generated by the HPLC analyses of the samples. The resultant DT_{50} values were 22.4 days for the exposed samples (correlation coefficient (R^2) = 0.9729) and 53.3 days (R^2 = 0.9589) for the dark control samples (Table 36).

Table 36 Calculated values of the DT_{50} from the soil photolysis of flonicamid

	DT_{50} [days]	R^2
Loamy sand (Madison, Ohio, USA)		
exposed	22.4	0.9729
dark controls	53.3	0.9589

Residues in succeeding crops

Confined rotational crop

Flonicamid, radio-labelled at the 3 position of the pyridine ring (specific activity: 9.08 MBq/mg), formulated as a wettable granule (WG) was applied twice to loamy sand soil at a rate equivalent to 100 g ai/ha at an interval of two weeks. Soils were allowed to age under greenhouse conditions after treatment and prior to planting. After the appropriate plant-back intervals (PBIs) of 30, 120 or 360 days, the rotational crops, representative of the root vegetable (carrot), small grain (wheat), and leafy vegetable (lettuce) crop groups, were planted.

The crop samples of lettuce, carrot and wheat (forage, straw, chaff and grain) were homogenised with dry ice and analysed for total ^{14}C residues by combustion analysis. The PES were also analysed by combustion analysis. The TRR combustion data for crop samples are summarized in Table 37.

Table 37 Distribution of TRR levels of harvested crops

The homogenized tissue samples were extracted three times with acetonitrile/water 40:60 v/v (0.1% phosphoric acid). Each extract was centrifuged or vacuum filtered. The PES was allowed to air dry and then was subjected to combustion analysis. The solvent extracts were pooled then reduced to a small volume by rotary evaporation under reduced pressure. If sufficient residue was detected in the extract or the PES, additional analysis was conducted by HPLC-LSC to characterize the nature of the ^{14}C residue present.

TRRs in all raw agricultural commodities (RACs) declined with prolonged PBIs such that, at the 120-day PBI, no further characterization/identification of the TRRs was performed for immature and mature lettuce and mature carrot roots due to the low total radioactivity. Further to this, at the 360-day PBI, none of the TRRs from any of the crop parts were further subjected to characterization/identification as these were too low.

Overall, extraction of the TRRs with organic solvents released greater than 55% of the TRRs. In most commodities, only small amounts of flonicamid and TFNA-OH were detected with TFNG and TFNG-AM identified as major metabolites. In wheat grain, TFNA was also observed as a major metabolite while in wheat forage, TFNA and TFNA-OH accounted for greater than 10% of the TRRs. TFNA-AM was the only predominant metabolite in mature carrot root.

Field rotational crop

At each of the six field trials conducted in the US, three applications of flonicamid 50WG were made to the primary crop (cotton) at the maximum rate of 0.1 kg ai/ha at 7 ± 1 day intervals, resulting in a total seasonal application rate of approximately 0.31 kg ai/ha. Following harvest of the treated cotton, the rotational crops, wheat (four sites) and turnips (two sites), were planted at 30 and 60 days following the last application. The wheat and turnip samples were taken for analysis at normal maturity for each crop matrix.

Aliquots of homogenised samples were extracted twice with acetonitrile:water (50/50, v/v). Concentrated HCl was added to the combined extracts prior to being filtered and partitioned with ethyl acetate (twice). The combined ethyl acetate extract was evaporated just to dryness and residues taken up in acetonitrile:water (30/70, v/v) and analysed by LC-MS/MS. For wheat straw, an additional SPE clean-up step using a C_{18} cartridge before the partitioning with ethyl acetate was inserted.

Table 39 Maximum residues in rotated crop samples 30 and 60 days following the last application of Flonicamid 50WG to cotton

	Plant back interval [days]	Flonicamid [mg/kg]	TFNG [mg/kg]	TFNA [mg/kg]	TFNA-AM [mg/kg]

n.d. = Not detected

LOD = 0.005 mg eq/kg

No quantifiable residues of flonicamid or its metabolites TFNG, TFNA, and TFNA-AM were detected in any crop matrix in any rotational crop planted at either 30 or 60 days after the last application of flonicamid to the primary crop of cotton.

RESIDUE ANALYSIS

Analytical Methods

The Meeting received descriptions and validation data for analytical methods for residues of flonicamid and its metabolites TFNA-AM, TFNA and TFNG in plant commodities and flonicamid, TFNA-AM, TFNA, TFNG and OH-TFNA-AM in animal commodities. All residue analytical methods rely on LC-MS/ MS. Typical LOQs achieved for plant and animal commodities fall in the range of 0.01–0.02 mg/kg. The LOQs for milk and animal products (liver, kidney, muscle, eggs) were 0.01 mg/kg for each analyte. Methods have been subjected to independent laboratory validation. The methods described briefly below have been used for the analysis of the samples generated during the supervised field trials, processing studies and storage stability investigations.

Table 40 Characterization of Enforcement Analytical Methods for Plant and Animal Commodities

Method ID	Method Type	Detector	Analytes	LOQ/analyte	Matrices	Report

Plant Commodities

Method P-3561M

Residues of flonicamid and its metabolites TFNG, TFNA and TFNA-AM were extracted twice with acetonitrile/deionised water (1/1, v/v). After centrifugation, the extracts were combined and evaporated until dryness. The sample extract was then acidified and filtered. In the case of wheat straw, the sample extract underwent clean-up using a C_{18} SPE column eluted with acetonitrile/deionised water (1/4, v/v). The eluate (in the case of wheat straw sample) or the filtrate (in the case of potato tuber or peach sample) was liquid-liquid partitioned twice in ethyl acetate. The ethyl acetate layer was evaporated to near dryness and diluted in acetonitrile/deionised water (3/7, v/v) before quantification by HPLC-MS/MS.

The method underwent successful inter-laboratory validation by EN-CAS laboratories using cottonseed. Average recoveries of flonicamid, TFNG, TFNA and TFNA-AM ranged from 70–110% with RSD of $\leqslant$ 16%, demonstrating good reproducibility.

Method P-3822

The HPLC-MS/MS method P3822 quantifies residues of flonicamid and its metabolites TFNG, TFNA and TFNA-AM in raw agricultural commodities and processed commodities. The extraction and clean-up steps of method P-3822 are very similar to those of P-3561M, however; for oily crop samples (e.g. cotton matrices and potato chips), an additional hexane partition step and acidification is included before filtration.

The method underwent successful inter-laboratory validation by EN-CAS laboratories using the same commodities. Average recoveries of flonicamid, TFNG, TFNA and TFNA-AM ranged from 70–110% with RSD of $\leqslant$ 16% (with the exception of pepper/TFNG at 0.1 mg/kg where the RSD was 33%), demonstrating overall good reproducibility.

AGR/MOA/IKI220-1 v.1

Flonicamid and its major metabolites were extracted with a mixture of acetonitrile/water/acetic acid (60/40/0.1, v/v/v), followed by a washing with hexane (except for potato) and a clean-up using a C_{18} phase SPE cartridge (except for potato and lemon), and followed by a liquid/liquid partition with ethyl acetate. After evaporation to dryness, the residues of flonicamid and its major metabolites were dissolved in a mixture of acetonitrile/water (30/70, v/v) prior to analysis by HPLC-MS/MS using two mass transitions. For oil-seed rape, the TFNA results were confirmed by the use of another liquid chromatographic column.

The method underwent successful inter-laboratory validation by Eurofins laboratories using the same commodities. Average recoveries of flonicamid, TFNG, TFNA and TFNA-AM ranged from 70–110% with RSD of $\leqslant$ 20%, demonstrating good reproducibility.

AATM-R-165

Residues of flonicamid and its metabolites were extracted by shaking with acetonitrile:water (1:1). The extract was then decanted and the extraction was repeated with acetonitrile. An aliquot of the combined acetonitrile extracts was diluted with water, filtered and analysed by ultra performance liquid chromatography (UPLC) with positive-ion electrospray ionization (ESI) tandem mass spectrometry (MS/MS). Quantitation of the analytes was achieved by comparison with mixed external standards of flonicamid and its metabolites.

Due to the nature of the cottonseed oil samples, the method was modified such that cottonseed oil was dissolved in hexane and then partitioned with acetonitrile. An aliquot of the acetonitrile layer was taken and diluted with water and analysed.

Determination of Residues of IKI-220 and its Metabolites TFNG, TFNA and TFNA-AM in Various Crops—Validation of the Method"

This method was used for the freezer storage stability study A-22-00-03 whereby residues of flonicamid and its metabolites TFNG, TFNA and TFNA-AM were extracted with methanol. After filtration, the sample solution was washed with n-hexane, concentrated and then cleaned-up on a C_{18} SPE cartridge. The eluate was evaporated to dryness and methylated with diazomethane/diethylether. After concentration, the residues were liquid-liquid partitioned twice in ethyl acetate. The ethyl acetate layer was filtered through anhydrous sodium sulphate and evaporated to dryness. The residues were purified on a Florisil SPE cartridge and reconstituted in acetone prior to analysis by GC/MSD.

Animal Commodities

Method 842993

Residues of flonicamid and its metabolites TFNA, TFNA-AM, OH-TFNA-AM and TFNG in milk samples were extracted twice with ethanol/water (4/4, v/v). The sample extracts were combined and evaporated to dryness prior to liquid-liquid partitioning twice with hexane. The aqueous phase was evaporated to dryness and the residue was dissolved in water/acetonitrile/trifluoroacetic acid (90/10/0.1, v/v/v) prior to HPLC-MS/MS analysis.

Method 844743

Bovine and Poultry Tissues

Residues of flonicamid and its metabolites TFNA, TFNA-AM, OH-TFNA-AM and TFNG were extracted twice with acetonitrile/water (8/2, v/v). After addition of silicon anti foaming agent to the combined extracts of each tissue/egg sample, the solution was evaporated to dryness. The residue was then dissolved in methanol/water/acetic acid (2000/500/15, v/v/v) prior to liquid-liquid partitioning twice with hexane. The aqueous phase was evaporated to dryness and the residue was dissolved in water/acetonitrile/trifluoroacetic acid (90/10/0.1, v/v/v) prior to clean-up using gel permeation chromatography (GPC). The eluate was evaporated to dryness and redissolved in methanol/water (1/9, v/v) and subject to HPLC-MS/MS analysis.

Eggs

Residues of flonicamid and its metabolites TFNA, TFNA-AM, OH-TFNA-AM and TFNG in egg samples were extracted with acetonitrile/water (8:2; v/v) and the suspension was treated at 60 °C for 1 h. After denaturisation, the process was repeated. The extracts were subsequently combined and partitioned by a liquid-liquid extraction with cyclohexane. The acetonitrile/water phase was evaporated to dryness and the residue was dissolved in methanol/water/acetic acid (2000:500:15; v/v/v) followed by clean-up using GPC. The eluate was evaporated to dryness and the residue was re-dissolved with 30% acetonitrile in water prior to analysis using HPLC-MS/MS.

The method underwent successful inter-laboratory validation by FMC Princeton Environmental Sciences Laboratory using poultry eggs. Average recoveries of flonicamid, TFNG, TFNA and TFNA-AM ranged from 77–108% with RSD of $\leqslant$ 21%, demonstrating good reproducibility.

AGR/MOA/IKI-5

Residues of flonicamid and its metabolite TFNA-AM in samples of bovine, muscle, fat, liver, milk and eggs were extracted with acidified acetonitrile/water (80/20, v/v). All the contents of the dispersive SPE citrate extraction tube were added to the extracts and shaken vigorously by hand, vortexed and centrifuged. The supernatant was evaporated to dryness and residues were dissolved in acetonitrile/ water (10/90, v/v) and filtered (liver only) prior to analysis by HPLC-MS/MS.

The method underwent successful inter-laboratory validation by PTRL Europe using the same commodities. Average recoveries of flonicamid and TFNA-AM were within the range of 70–110% with RSD of $\leqslant$ 20%, demonstrating good reproducibility.

P-3580

While the Meeting did not receive a description of the method P-3580 titled `Radio-validation of Goat Muscle Treated with $^{14}$C-Radio-labelled IKI-220 (F1785) Insecticide and method Validation of Residue Methodology for IKI-220 (F1785) and its Major Metabolites in/on Cow Muscle, Kidney and Liver`, the results of the ILV performed by ADPEN Laboratories was provided, and the method was subsequently renumbered to P-3581. Average recoveries of flonicamid and its metabolites TFNA, TFNA-AM, OH-TFNA-AM and TFNG in bovine muscle were within the range of 82–110% with RSD of $\leq$ 17%, demonstrating good reproducibility.

Validation data for the methods described above are available from specific method validation studies or from residue studies where specific method validation recovery experiments were performed separately from routine sample analysis. These method recovery data, for plant and animal commodities are summarized in Table 41.

Table 41 Method recovery data of flonicamid and metabolites in plants and animal products

Stability of residues in stored analytical samples

Information was received on the freezer storage stability of flonicamid and its metabolites in plant commodities. The storage stability of flonicamid and its metabolites TFNA, TFNA-AM and TFNG are described as follows. The results are shown in Table 42.

Wheat (grain, forage, straw, bran, middling, germ), cottonseed (seed, hulls, meal, refined oil), spinach, potato tuber, apple juice and tomato

Report: P-3570

Study No. 178CSS02R1

Method: P-3561

Description: Untreated control samples were fortified with flonicamid and its metabolites TFNA, TFNA-AM and TFNG at a concentration of 0.5 mg/kg per analyte and then frozen below –17 °C. Samples were analysed immediately after fortification (0 day) and after storage intervals up to 2 years (23 months). At each interval, three stored samples were analysed, with one or more procedural recovery samples (control samples spiked just before analysis at 0.5 mg/kg).

Apples, potatoes, wheat grain and wheat straw

Report: Not assigned

Study No. A-22-00-03

Method: "Determination of Residues of IKI-220 and its Metabolites TFNG, TFNA and TFNA-AM in Various Crops—Validation of the Method"

Description: Untreated control samples were fortified with flonicamid and its metabolites TFNA, TFNA-AM and TFNG at a concentration of 0.1 mg/kg per analyte for apple, potato and wheat grain and 0.2 mg/kg for wheat straw and then frozen below–17 °C. Samples were analysed immediately after fortification (0 day) and after storage intervals up to 18 months. At each interval, two stored samples were analysed, with one or more procedural recovery samples (control samples spiked just before analysis).

USE PATTERN

The insecticide flonicamid is registered in Canada, the United States, Slovenia, Cyprus and Australia for control of various insects on a variety of crops. The information available to the Meeting on registered uses on various fruits, vegetables, tree nuts, oilseeds, dried hops, mint and tea is summarized in Table 44. The manufacturer submitted labels for all flonicamid uses.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials for flonicamid uses that produced residues on the following commodities:

Commodity	Group	Table No.
Apples	FP Pome fruits	45
Pears		46
Peaches	FS Stone fruits	47
Cherries		48
Plums		49
Strawberries	FB Berries and small fruits	50
Broccoli	VB Brassica vegetables	51

Commodity	Group	Table No.
Cabbage		52
Cucumber	VC Fruiting vegetables, Cucurbits	53
Melon		54
Summer squash		55
Tomatoes	VO Fruiting vegetables, other than Cucurbits	56
Bell peppers		57
Non-bell peppers		58
Head lettuce	VL Leafy vegetables (including Brassica leafy vegetables)	59
Leaf lettuce		60
Spinach		61
Radish leaves		62
Mustard greens		63
Potato	VR Root and tuber vegetables	64
Carrot		65
Radish		66
Celery	VS Stem and petioles	67
Wheat	Cereal grains	68
Barley		69
Almonds	TN Tree nuts	70
Pecans		71
Pistachios		72
Rape seed	SO Oilseed	73
Cotton seed		74
Mint	HH Herbs	75
Hops	DH Dried herbs	76
Tea	DT Teas	77
Wheat forage and straw	AS Straw, fodder and forage of cereal grains and grasses	78
Barley forage and straw		79
Alfalfa		80
Almond hulls		81
Cottonseed gin trash		82

In the residue supervised trials tables, where two samples were taken from a single plot, the average value is reported (individual sample results in parentheses). Where results from separate plots with distinguishing characteristics such as different formulations, varieties or treatment schedules were reported, results are listed for each plot. In these cases, the higher residue has been used for calculation purposes. Dates of duration of residue sample storage before analysis were provided.

Residue values from the trials conducted according to the maximum GAP have been used for the estimation of maximum residue levels. Those results included in the calculations by the OECD MRL-calculator are underlined.

Pome fruits

Apple

Twelve independent trials were conducted on apples in the US between 1968 and 1995. In all trials, three foliar spray applications of a WG formulation were made with a re-treatment interval of 7 days. Apples were harvested 14–21 days after last treatment (DALT).

In Australia. fourteen independent trials were conducted on between 1983 and 2009. In all trials, three foliar spray applications of a WG formulation were made with a re-treatment interval of 7 days and apples were harvested 21 DALT.

The analytical method P-3568 (based on method P-3561M) was used to analyse samples collected from the US trials while method AATM-R-165 was used to analyse the samples from the Australian trials. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 35 days for the Australian trials and 297 days (ca. 10 months) for the US trials Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 45.

Pear

Six independent trials were conducted on pears in the US between 1962 and 1996. In all trials, three foliar spray applications of a WG formulation were made with a re-treatment interval of 7 days. Pears were harvested 14–21 DALT.

The analytical method P-3568 (based on method P-3561M) was used to analyse the samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 329 days (ca. 11 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 46.

Berries and other small fruits

Strawberry

Eight independent trials were conducted on strawberries in the US in 2008. In all trials, three foliar spray applications of a SG formulation were made with a re-treatment interval of 6–8 days. Strawberries were harvested 14 DALT.

The analytical method P-3561M was used to analyse the samples. The LOQ was determined to be 0.02 mg/kg/analyte.

The maximum period of sample storage at –20 °C was 498 days (ca. 17 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 50.

Fruiting vegetables, cucurbits

Cucumber

Six independent trials were conducted on field cucumbers in the US during the 2001 growing season. In all trials, three foliar spray applications of a WG formulation were made at 0.10 kg ai/ha with a re-treatment interval of 6–7 days. Cucumbers were harvested 0 DALT. Four independent trials were conducted on greenhouse cucumbers in Canada and the US during the 2008 and 2009 growing seasons. In each of the greenhouse trials, one of the plots was treated with two foliar spray applications of a SG formulation at 0.15 kg ai/ha with a re-treatment interval of 6–7 days. The other plot was treated twice via syringe to the rock wool cubes in which the plants were grown. Application rates were determined using an average plant density of 2.4 plants per square meter, regardless of the actual density in the respective trials. The nominal rate was 0.15 kg ai/ha per application for a total range of 0.30 kg ai/ha per season. In all trials, cucumbers were harvested 0 DALT.

Two independent trials were also conducted on field cucumbers in Australia during the 2011 and 2012 growing seasons. In both trials, three foliar spray applications of a WG formulation were made at 0.10 kg ai/ha or 0.20 kg ai/ha with a re-treatment interval of 7 days. Cucumbers were harvested 0, 1, 3 and 7 DALT.

For the North American trials, the analytical method P-3561M was used to analyse all samples. The LOQ for the field cucumbers was determined to be 0.025 mg/kg/analyte while the LOQ for greenhouse cucumbers was 0.02 mg/kg/analyte. In Australia, the analytical method AATM-R-165 was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 340 days (ca. 11.5 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 53.

[a] Mean of four duplicate samples

N/A = Not applicable as treatment was made via syringe to the growth media

Melons

Six independent trials were conducted on melons in the USA during the 2003 growing season. In all trials, three foliar spray applications of a WG formulation were made with a re-treatment interval of 7 days. Melons were harvested 0 DALT.

The analytical method P-3561M was used to analyse samples. The LOQ was determined to be 0.01 mg/kg/analyte. On average, for all the trials, 12 fruits were sampled from each control and treated plot. In trials 5, 11, 13 and 17, fruits were quartered and each quarter was placed in a plastic bag and stored in a freezer. In Trial 14, melons were cut and 1/8th of each melon was placed into plastic bags. In Trial 15, the study only reported that fruits were placed into plastic bags. Trials 1 through 4, 6 through 10, 12 and 16 were conducted on cucumbers or summer squash.

Five independent trials were conducted on rockmelons (cantaloupe) in Australia during the 2010, 2011 and 2012 growing seasons. In all trials, three foliar spray applications of a WG

formulation were made at 0.10 kg ai/ha or 0.20 kg ai/ha with a re-treatment interval of 7 days and DALTs of 0, 1, 3 and 7 days.

The analytical method AATM-R-165 was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte. Five commercially mature fruit weighing > 7 kg were collected by hand from five plants per plot and placed in labelled specimen bags. No specimens were collected from the buffer areas of each plot. Sampling was conducted after the spray solution had dried at the 0-day DALT. Any soil adhering to the fruit was removed by brushing not washing. Gloves were worn and changed between treatments. All specimens were double bagged and labelled in accordance with the specimen list defined in the study plan. No information was provided as to whether the melons were cut prior to bagging.

A total of thirteen independent trials were conducted in Southern Europe (France, Italy and Spain) on field and greenhouse-grown melons during the 2003, 2004 and 2011 growing seasons. In the trials conducted during 2003 and 2004, three foliar spray applications of a WG formulation were made at 0.08 kg ai/ha with re-treatment intervals of 4–10 days. In the trials conducted in 2011, three foliar spray applications of a WG formulation were made at 0.05 kg ai/ha with a re-treatment interval of 7 days. In all trials, melons were harvested 0, 1, 2, 3 and/or 7 DALT.

For the 2003 and 2004 trials, the analytical method was based on the method A22-00-02 and adapted to melon peel by changing the C_{18} clean-up. For the 2011 trials, the LC-MS/MS method AGR/MOA/IKI220-1 was used to analyse all samples. For both methods, the LOQ was determined to be 0.01 mg/kg/analyte for each peel and pulp. In general, each harvested fruit was cut in minimum of two slices. From each retained slice, the peel was separated from the pulp.

In total, the maximum period of sample storage at –20 °C was up to 340 days (11.5 months). Storage stability data on water content commodities show that residues are stable for at least 23 months. The results are summarized in Table 54.

Table 54 Residues of Flonicamid in Whole Melons Following Foliar Spray with a 50 WG Formulation of Flonicamid in North American Regions, Australia and Southern EU

The experimental weight percentage ratio between peel and pulp was reported to be:

[a] 38.1% for peel and 61.9% for pulp

[b] 50.5% for peel and 49.5% for pulp

[c] 31.1 % for peel and 68.9% for pulpl

[d] 38.9 % for peel and 61.7% for pulp

[e] 41.6% for peel and 58.4% for pulp

Squash

Five independent trials were conducted on summer squash in the US during the 2001 growing season. In all trials, three foliar spray applications of a WG formulation were made with a re-treatment interval of 6–7 days. Squash was harvested 0 DALT.

The analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

Three independent trials were also conducted on pumpkin in Australia during the 2010 and 2012 growing seasons. In all trials, three foliar spray applications of a WG formulation were made at 0.10 kg ai/ha or 0.20 kg ai/ha with a re-treatment interval of 7 days. Pumpkins were harvested 0, 1, 3 and 7 DALT.

The analytical method AATM-R-165 was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The Meeting also received four independent trials conducted on pumpkin in Hungary during the 2012 growing season. In all trials, two foliar spray applications of a WG formulation were made at 0.08 kg ai/ha with a re-treatment interval of 7 days. Pumpkins were harvested 0, 1, 3 and 7 DALT.

The analytical method SOP R 700 FEJ2 was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C for all trials was up to 351 days (12 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 55.

Tomatoes

Twenty-six independent trials were conducted on field tomatoes in the US between 2001 and 2010. For 12 of the trials, three foliar spray applications of a WG formulation were made at 0.10 kg ai/ha with re-treatment intervals of 6–12 days. Fourteen additional independent trials on field tomatoes were conducted in the US between 2010 and 2011 where two foliar spray applications of a SG formulation were made at 0.15 kg ai/ha with 6–8 day retreatment intervals. Three independent trials were conducted on greenhouse tomatoes in Canada and the US between 2010 and 2011 where two

foliar sprays of a SG formulation were made at 0.15 kg ai/ha with 6–7 day retreatment intervals, In all trials, tomatoes were harvested 0 DALT.

The analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 382 days (19 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 56.

[a] The last applications made at each site were on the same day and the varieties were the same, rendering the trials dependent

[b] The last applications made at each site were 19 days apart, therefore, trials were considered independent

[c] The last applications made at each site were 5 days apart, and varieties were not sufficiently different to render the trials independent

[d] The last applications made at each site were 8 days apart, and the tomato variety H3155 could not be identified, therefore, trials were considered dependent

[e] The last applications made at each site were 9 days apart, and varieties were not sufficiently different to render the trials independent

[f] The last applications were made on the same day and varieties were not sufficiently different to render the trials independent.

Bell peppers

Six independent trials were conducted on field bell peppers in the US in 2001 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–7 days. Bell peppers were harvested 0 DALT.

The analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 382 days (19 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 59.

Leafy vegetables (including Brassica leafy vegetables)

Head lettuce

Six independent trials were conducted on head lettuce in the US in 2002 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–8 days. Head lettuce was harvested 0 DALT.

Method P-3575, a modified version of analytical method P-3561, was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 147 days (ca. 5 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 59.

Leaf lettuce

Six independent trials were conducted on leaf lettuce in the US in 2002 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–7 days. Leaf lettuce was harvested 0 DALT. Side-by-side trials were also conducted in 2003 on Cos lettuce to compare the WG formulation to the SG formulation (with and without surfactant). The same use pattern was applied as that of the six trials.

A modified version of analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 172 days (ca. 6 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 60.

Spinach

Six independent trials were conducted on spinach in the US in 2001 and 2002 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–9 days. Plants were harvested 0 DALT.

Method P-3575, a modified version of analytical method P-3561M, was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 131 days (ca 4 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 61.

Radish leaves

Five independent trials were conducted on radish leaves in the US in 2003 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–9 days. Leaves were harvested 2 DALT.

The analytical method P-3561M was used to analyse all samples of radish roots and radish tops. The LOQ for radish leaves was determined to be 0.05 mg/kg/analyte.

The maximum period of sample storage at –20 °C was 517 days (ca. 17 months) for radish leaves. Concurrent storage stability data show that the residues are stable for up to 464 days (ca. 15 months). The results are summarized in Table 62.

Root and tuber vegetables

Potato tubers

Sixteen independent trials were conducted on potatoes in the US in 2001 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–8 days. Potato tubers were harvested 0 DALT.

In Australia, four independent trials were conducted in 2010 and 2012 where two foliar spray applications of a WG formulation were made at 0.08 kg ai/ha or 0.16 kg ai/ha with 7–9 day re-treatment intervals. Potato tubers were harvested 14 DALT.

The analytical method P-3561M was used to analyse all samples collected from the US trials while method AATM-R-165 was used for the Australian trials. For both methods, the LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 315 days (ca 11 months). Storage stability data on high starch content commodities show that the residues are stable for at least 23 months. The results are summarized in Tables 64.

Carrot roots

Eight independent trials were conducted on carrots in the US in 2003 where three foliar spray applications of a WG formulation with re-treatment intervals of 6–8 days. Carrot roots were harvested 6–8 DALT.

The analytical method P-3561M was used to analyse all samples. The LOQ of flonicamid was determined to be 0.02 mg/kg while the LOQ for all metabolites was determined to be 0.05 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 462 days (ca 15 months). Storage stability data on high starch content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 65.

[a] The last applications at each trial site were made 21 days apart, rendering the trials independent.

Celery

Six independent trials were conducted on celery in the US between 2001 and 2002 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 5–8 days. Celery was harvested 0 DALT. Celery stalks were cut at the soil level using hand clippers. Damaged leaves were removed when necessary.

A modified version of analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 198 days (ca. 7 months). Storage stability data on water content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 67.

Cereal grains

Wheat

The Meeting received information on fifteen independent trials on wheat in Northern and Southern EU between 2000 and 2001 with two foliar spray applications of a WG formulation and a re-treatment intervals of 16–28 days. Wheat grain was harvested 21–30 DALT.

The GC-MS analytical method A-22-00-02 was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte for grain.

The maximum period of sample storage at –20 °C was up to 433 days (ca. 15 months). Storage stability data on high starch content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 68.

Note: All trials identified with the same letter were considered dependent as they were conducted at the same location, the last applications were made on the same day at both sites and varieties were not determined to be sufficiently different

Barley

Eight independent trials were conducted on wheat in Germany and Denmark between 2011 and 2012 where a single foliar spray application of a WG formulation was made at 0.07 kg ai/ha. Barley grain was harvested 30–39 DALT.

The LC-MS/MS analytical method AGR/MOA/IKI220-1was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte for grain.

The maximum period of sample storage at –20 °C was up to 111 days (ca. 4 months). Storage stability data on high starch content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 69.

Tree Nuts

Almonds

Five independent trials were conducted on almonds in the US between 1996 and 2008 where three foliar spray applications of a SG formulation were made with re-treatment intervals of 6–8 days. Almonds were harvested 39–42 DALT.

A modified version of analytical method P-3822 was used to analyse all almond nutmeat samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 196 days (ca. 7 months). Storage stability data on oil content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 70.

Pistachios

Two independent trials were conducted on pistachios in the US in 2014 where three foliar spray applications of a SG formulation were made with re-treatment intervals of 6–7 days. Pistachios were harvested 40 DALT.

Analytical method P-3822 was used to analyse all samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 24 days. As pistachio samples were analysed within 30 days of sampling, freezer storage stability information was not required. The results are summarized in Table 72.

Rape seed

Eight independent trials were conducted on canola in the US in 2007 where three foliar spray applications of a SG formulation were made with re-treatment intervals of 6–8 days. Canola seeds were harvested 6–8 DALT.

Analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.02 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 755 days (ca. 25 months). Concurrent storage stability data on canola seed showed that the residues of flonicamid and its associated metabolites are stable for 735 days (ca. 24 months). The results are summarized in Table 73.

Cotton

Twelve independent trials were conducted on cotton in the US in 2001 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–9 days. Seeds were collected 29–32 DALT, dried and cleaned followed by a stick extraction to remove the gin trash. The lint cotton was saw ginned to remove the majority of the lint from the cottonseed.

In Australia, ten independent trials were conducted on cotton in 2012 where one or two foliar spray applications were made at 0.10 kg ai/ha or 0.20 kg ai/ha at re-treatment intervals of 14–15 days. Cotton was picked from bolls 7–43 DALT and ginned to separate the fuzz (undelinted).

Method P-3567, a modified version of analytical method P-3561M was used to analyse all samples collected from the US trials while method AATM-R-165 was used to analyse all samples from the Australian trials. The LOQ was determined to be 0.02 mg/kg/analyte for P-3567. For method AATM-R-165, the LOQ was 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 470 days (ca. 16 months). Storage stability data on oil content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 74.

Mint

Three independent trials were conducted on fresh mint in the US in 2011 where three foliar spray applications of a SG formulation were made with re-treatment intervals of 13–15 days. Mint leaves were harvested 7 DALT.

Analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.02 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 372 days (ca. 12 months). Concurrent storage stability data on mint tops show that the residues are stable for at least 364 days (ca. 12 months). The results are summarized in Table 75.

Dried hops

Four independent trials were conducted on hops in the US in 2003 and 2015 where three foliar spray applications of a WG or SG formulation were made with re-treatment intervals of 7–8 days. Green hop cones were sampled 9–11 DALT and dried to 8–10% moisture in a forced hot air dryer. Drying temperature was about 120–140 °F (49–64 °C).

The analytical methods P-3561M (2003 trial) or P-3822 (2015 trial) were used to analyse all samples. The LOQ for dried hop cones was determined to be 0.02 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 329 days (ca 11 months). Concurrent storage stability data on hops show that the residues are stable for at least 299 days (10 months). The results are summarized in Table 76.

Tea

Two independent trials were conducted on tea in Japan in 2001 where a single foliar spray application of a WG formulation was made. Leaves were harvested 7 DALT. On the day of harvest, leaves were processed according to standard procedure (steaming, cooling, primary drying and rolling, rolling, secondary drying and rolling, final drying and rolling and drying) prior to analysis

The analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.02 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 9 months. Storage stability data on various commodities show that the residues are stable for at least 23 months. The results are summarized in Table 77.

Animal feeds

Wheat forage and straw

Fifteen independent supervised trials were conducted in EU on wheat in 2000 and 2001, where two foliar spray applications of a WG formulation were made with re-treatment intervals of 16–21 days. Green forage (green plant, rest of plant) was sampled 0–7 DALT, stems and ears 14–21 DALT and straw 21–30 DALT.

The analytical methods A-22-02 was used to analyse all samples. The LOQ for green forage and straw was 0.02 mg/kg/analyte and 0.01 mg/kg/analyte for stems and ears.

The maximum period of sample storage at –20 °C was up to days (ca. 14 months). Storage stability data on starch content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 78.

Barley ears

Four independent supervised trials were conducted in Germany and Denmark on barley ears in 2012, where a single foliar spray application of a WG formulation was made at 0.07 kg ai/ha and where ears were sampled 0–22 DALT.

The LC-MS/MS analytical method AGR/MOA/IKI220-1was used to analyse all samples. The LOQ for green forage and straw was 0.01 mg/kg/analyte for ears.

The maximum period of sample storage at –20 °C was up to 111 days (ca. 4 months). Storage stability data on high starch content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 79.

[a] Reported in flonicamid equivalents.

Alfalfa forage, seed and hay

Four independent trials were conducted on alfalfa in the US in 2009 where two foliar spray applications of a SG formulation were made with re-treatment intervals of 7–8 days. Because alfalfa is harvested differently in California compared to the Pacific Northwest, sample collection times varied between these two regions. In the Idaho and Washington trials, seed samples were collected 13–14 DALT in the summer, and forage and hay samples were harvested the following year, 265–293 DALT.

Analytical method P-3561M was used to analyse all samples. The LOQ was determined to be 0.02 mg/kg/analyte.

The maximum period of sample storage at –20 °C was 432 days (ca. 14 months) for alfalfa seed, 490 days (ca. 16 months) for forage and 496 days (ca. 16 months) for hay. Concurrent storage stability data show that the residues of flonicamid and its metabolites are stable for 490 days in forage, 518 days in hay and 462 days in seed. The results are summarized in Table 80.

Almond Hulls

Five independent trials were conducted on almonds in the US between 1996 and 2008 where three foliar spray applications of a SG formulation were made with re-treatment intervals of 6–8 days. Almonds were harvested 39–42 DALT.

A modified version of analytical method P-3822 was used to analyse all almond nutmeat samples. The LOQ was determined to be 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 196 days (ca. 7 months). Storage stability data on oil content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 81.

Cotton seed by-products

Twelve independent trials were conducted on cotton in the US in 2001 where three foliar spray applications of a WG formulation were made with re-treatment intervals of 6–9 days. Seeds were collected 29–32 DALT, dried and cleaned followed by a stick extraction to remove the gin trash. The

lint cotton was saw ginned to remove the majority of the lint from the cottonseed while the ginned seed was saw delinted to remove most of the remaining linters.

In Australia, ten independent trials were conducted on cotton in 2012 where one or two foliar spray applications were made at 0.10 kg ai/ha or 0.20 kg ai/ha at re-treatment intervals of 14–15 days. Cotton was picked from bolls 7–43 DALT and ginned to separate the fuzzy seed and lint. The simulated gin trash consisted of ground parts of the cotton plant including bracts, stems, leaves, immature or mummified bolls, flowers and raw cotton.

Method P-3567, a modified version of analytical method P-3561M was used to analyse all samples collected from the US trials while method AATM-R-165 was used to analyse all samples from the Australian trials. The LOQ was determined to be 0.02 mg/kg/analyte for P-3567. For method AATM-R-165, the LOQ was 0.01 mg/kg/analyte.

The maximum period of sample storage at –20 °C was up to 470 days (ca. 16 months). Storage stability data on oil content commodities show that the residues are stable for at least 23 months. The results are summarized in Table 82.

FATE OF RESIDUES DURING PROCESSING

In processing-nature of residues

Hydrolysis of flonicamid, radio-labelled in the pyridine ring (specific activity 9.08 MBq/mg), at 1.0 mg ai/L, was investigated in aqueous buffer solutions (0.1 M sodium citrate-citric acid), at 90 °C and pH4 for 20 min (simulating pasteurisation), at 100 °C and pH 5 for 60 min (simulating baking, brewing and boiling), and at 120 °C and pH 6 for 20 min (simulating sterilisation).

Quantitative measurement of the radioactivity was carried out by LSC. Further analysis to quantify and identify the radio-labelled degradation products present in the test solutions was conducted using HPLC and TLC. Flonicamid was identified by HPLC co-chromatography with a certified standard. Selected samples were analysed by TLC to confirm the presence of flonicamid.

Table 83 Degradation of flonicamid under various hydrolysis conditions

Condition	Sampling Regime	Flonicamid [% AR]	Total Others [% AR]	Total Recovery [% AR]
pH 4, 90 °C	Heated	100.28	0.49	100.77
	Control	99.21	0.59	99.80
pH 5, 100 °C	Heated	96.87	0.98	97.85
	Control	97.19	0.57	97.76
pH 6, 120 °C	Heated	96.58	1.72	98.30

Condition	Sampling Regime	Flonicamid [% AR]	Total Others [% AR]	Total Recovery [% AR]
	Control	96.47	0.92	97.39

Overall good recovery of radioactivity was achieved for each of the processing conditions, ranging from 94.6 to 101.1% of the applied radioactivity (AR).

In all cases, flonicamid accounted for at least 96.5% of AR. Therefore, very limited degradation of flonicamid was observed in aqueous buffer solutions under all the conditions tested with no significant degradation product being formed.

In processing-effect on the residue level

The Meeting received information on the fate of flonicamid residues and its metabolites TFNA-AM, TFNA and TFNG during the processing of raw agricultural commodities (RAC) in apples to juice; peaches to canned peaches, juice, jam and puree; plums to dried prunes; tomatoes to paste; potatoes to chips and flakes; rape seed and cotton to refined oil and meal and mint to oil.

Processing of apples

One study was conducted in 2002 in Lyons, New York where apple trees were treated with three foliar spray applications, where the first two treatments were at 0.103 kg ai/ha and the third treatment was at 0.516 kg ai/ha, for a total of 0.722 kg ai/ha. The fruit was harvested 21 days after the last application and transported to the lab for processing into juice and pomace. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 84 and 93. To make juice and wet pomace, apples were ground in a hammer-mill. The resulting wet mash was loaded in one or more cloth stacks on the hydraulic press. The cloth stacks were pressed for 5 minutes at 2200–3000 psi to remove the apple juice. The wet pomace sample was then taken from the cloth stacks and bagged.

Processing of peaches

Four processing trials were conducted in 2001 in Italy (two), Spain and Southern France where peach trees were treated with two applications of a WG formulation at a rate of 0.07 kg ai/ha/application for a total of 0.140 kg ai/ha. The peaches were harvested 14 days following the last application and processed into canned peaches, juice, jam and puree. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 85 and 93. The information submitted on processing procedures is summarized as follows.

For each processed commodity, peaches were dipped in boiling water for a few minutes, peeled and stones removed.

Canned peaches

The fruits were cut in halves and placed in glass containers. Peaches were then covered with a 400 g/L sucrose solution. The containers were sealed and sterilized for 15 mins in a boiling water bath. The canned peaches were then cooled.

Juice

The fruits were cut into small pieces and weighed. The pulp was pressed through a sieve of 1 mm mesh size. The mixture was then centrifuged at 7500 rpm and filtered through a filter paper. The final volume of juice and sucrose content was measured and reported. Juice was transferred into a glass container, which was sealed and sterilized for 15 mins at 100 °C.

Jam

The fruits were cut in small pieces and weighed. A syrup solution was prepared by adding 50 mL of water to the same weight of sucrose as the quantity of peaches involved. The solution was cooked until complete dissolution of sucrose. The peaches were added to the syrup and cooked a few minutes before crushing. Pectin and citric acid were added to the mixture, corresponding to 0.5% and 0.6% in weight of sucrose added, respectively. The mixture was pressed through a sieve and the jam was cooked and controlled for sucrose concentration using a refractometer. Cooking was stopped as soon as 61% of sucrose concentration was achieved. The jam was transferred into a glass container, which was sealed and sterilized for 30 mins at 100 °C.

Purée

The fruits were cut into small pieces, weighed and transferred into a glass container. Sucrose was added equivalent to 10% of the weight of the peaches. The container was sealed and heated at 100 °C for 30 minutes. The syrup generated was removed and the volume was reported. The peaches were then crushed through a sieve. The weight of the resulting purée was reported and the sugar concentration was measured using a refractometer. The final sugar content was adjusted to 28% using sucrose. The purée was transferred into a glass container, which was sealed and sterilized for 15 min at 100 °C

Processing of plums

One processing trial was conducted in 1992 in Fairfield, California where plum trees were treated with three foliar spray applications where the first two treatments were at 0.103 kg ai/ha and the third treatment was at 0.516 kg ai/ha, for a total of 0.722 kg ai/ha. The fruit was harvested 14 days after the last application and dried. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 86 and 93. The information submitted on processing procedures is summarized as follows.

Dried prune

The plums were washed for five minutes in a tub of cold water. The washed plums were spread single layer on trays and dehydrated in a tray air dryer at 68–79 °C for 18–36 hours to reduce the moisture content to the desired range (19–29%).

Table 86 Residues of flonicamid in plums (RAC and processed fractions)

Processing of tomato

One study was conducted in 2001 in Davis, California where tomato plants were treated with three foliar spray applications where the first two treatments were at 0.102 kg ai/ha and the third treatment was at 0.506 kg ai/ha, for a total of 0.710 kg ai/ha. The fruit was harvested immediately after the last application and transported to the lab for processing into paste. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Table 93. The information submitted on processing procedures is summarized as follows.

Paste

The tomato fruit were batch rinsed using a high-pressure spray rinse at approximately 70–75 °C for 30 seconds per batch. The fruit was hand fed into the hammermill assembly of the Suntech Fruit Press for crushing. The crushed tomatoes were transferred to the Hubbert Steam Jacketed Kettle and rapidly heated to approximately 80–85 °C and held for 25–30 seconds. The hot break juice was hand fed into the Pulper Finisher for the separation of pomace and juice. The wet pomace recovered was pressed using the Suntech Fruit Press. The pressed wet pomace was discarded and the recovered press juice was returned to the finished juice.

The juice was then transferred to the Groen Vacuum Evaporator. The puree was removed from the evaporator when the desired Brix range was achieved. A portion of the puree was transferred to the 7.5 L Scrape Surface Vacuum Evaporator. The paste was removed from the evaporator when the desired Brix range was achieved. A portion of the paste was removed and 1% salt was added to adjust the Brix to the desired range of 24.0–30.0 °C. The paste was heated to 82–88 °C. The heated paste was packed in 3303 cans and sealed using the Dixie Electric Can Sealer. The sealed cans were then processed using an Open Atmospheric Water Bath Kettle for 15–20 minutes at 96–100 °C and then cooled under running tap water. A representative sample of the cooled canned puree was removed, packaged, labelled and placed in the freezer for the required sample fraction. The excess evaporated puree and paste was discarded.

Table 87 Residues of flonicamid in tomato (RAC and processed fractions)

Processing of potato

One study was conducted in 2001 in Ephrata, Washington where potato plants were treated with three foliar spray applications where the first two treatments were at 0.10 kg ai/ha and the third treatment was at 1.0 kg ai/ha, for a total of 1.22 kg ai/ha. The fruit was harvested immediately after the last application and transported to the lab for processing into chips and flakes. The results and the calculated processing factors (residue in processed commodity / residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 88 and 93. The information submitted on processing procedures is summarized as follows.

Chips

The potatoes are peeled for 25–35 seconds in batches using an abrasive peeler. A certain amount of peel is left on the tuber to produce a natural appearance to the finished product. The peel collected is weighed and discarded. The peeled potatoes are individually inspected and hand trimmed. The potatoes are cut using a restaurant style food cutter/slicer. The slices are placed in a tub of hot tap water to rinse the free starch from the surfaces of the slices. The slices are deep fried in a restaurant style deep fat fryer at approximately 163–191 °C for 60–90 seconds. Free oil is drained from the chips using a draining tray and salted by hand. The chips are inspected and undesirable chips are removed.

Flakes

Washed potatoes are sorted and scrubbed in batches using a restaurant style peeler fitted with a rubber scrubber for approximately 25–35 seconds. The peel is then hydraulically pressed to increase the solids content. Potatoes are then individually inspected, hand trimmed and cut into slabs using a restaurant style food cutter/slicer with a cutting blade set to approximately 1–1.3 cm. The potato slices are spray washed for approximately 30 seconds in cold water to rinse the free starch from the surface of the slices. The potato slices are precooked at approximately 70–77 °C for 202–22 minutes using a steam jacketed kettle and subsequently cooled down to less than 32 °C using cold running tap water in a 150 L steam jacketed kettle for 20–22 minutes. The cooled slices are steam cooked at 94–100 °C for 40–42 minutes using an atmospherically flowing steam batch style steam cooker and mashed using a restaurant style meat grinder without the grinding attachment. The mashed potatoes are placed in a bakery style mixer where an emulsion containing the additives are poured into the mashed potatoes and mixed for approximately 60 seconds. The potato mash is hand fed onto a laboratory single drum dryer where the potato mash is dried into a thin sheet. The dried potato sheet is broken into flakes. The large flakes are then hand fed into a hammermill for uniform sizing of the finished flakes. If moisture content of the potato flakes exceeds 9%, the flakes are dried on the fluidized bed dryer to less than or equal to 9% moisture.

The best estimates of the processing factors for parent residues (for MRL setting in case of residue increasing) and for the sum of flonicamid, TFNA-AM, TFNA AND TFNG (for dietary intake) are summarized in Table 93.

Rape seed

One study was conducted in 2007 in Prosser, Washington where rape seed plants were treated with three foliar spray applications of 0.30 kg ai/ha for a total of 0.90 kg ai/ha. The seeds were harvested 8 days following the last application and transported to the lab for processing into refined oil and meal. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Table 93. The information submitted on processing procedures is summarized as follows.

Refined Oil

Canola seeds were flaked in a flaking roll and flakes were heated to 85–100 °C and held for 10 to 15 minutes in the temperature range. Flakes were pressed (expelled) in an expeller to mechanically remove a portion of the crude oil. Residual crude oil remaining in the solid material (presscake) exiting the expeller was extracted with the hexane. The miscella (crude oil and hexane) was passed through a laboratory recovery unit to separate the crude oil and hexane. Crude oil was heated to 90–96 °C for hexane removal. Crude oil samples recovered from the expeller and solvent extraction were

filtered and combined. Percent free fatty acid (FFA) for the crude oil was determined. Crude canola oil was placed in a water bath and pre-treated with 85% phosphoric acid. Oil was mixed for 29–31 minutes at 40–45 °C. After the pre-treatment, an amount of 12°Baume sodium hydroxide was added to the oil. The samples were mixed for 19–21 minutes at 40–45 °C and then for 9–11 minutes at 65–70 °C. The neutralized oil was then centrifuged to separate the refined oil and soapstock. The refined oil was decanted and filtered. Soapstock was discarded. Resulting fraction of alkali refined oil was collected and frozen.

Meal

Presscake was placed in stainless steel batch extractors and submerged in 50–60 °C solvent (hexane). After 30 minutes, the hexane was drained and fresh hexane added to repeat the cycle two more times. The final two washes were for 15–30 minutes each. After the final draining, the extracted presscake (meal) was desolventized using warm air forced through the extracted presscake. Resulting fraction, canola meal was collected and placed into frozen storage.

Processing of cotton

Study 1: US

One processing trial was conducted in 2001 in Uvalde, Texas, where cotton was treated with three applications of a WG formulation where the first two treatments were made at a rate 0.10 kg ai/ha/application and the third treatment was made at a rate of 1.0 kg ai/ha/application for a total of 1.2 kg ai/ha. The undelinted cottonseed was harvested 30 days following the last application and processed into meal and oil. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 90 and 93. The information submitted on processing procedures is summarized as follows.

Cottonseed hulls

Cotton seed was dried and cleaned followed stick extraction to remove the gin trash. The lint cotton was saw ginned to remove 85–89% of the lint from the cottonseed. The ginned seed was saw delinted to remove most of the remaining linters. Approximately 3% of the lint remained with the seed. A mill was used to crack the seed and the hulls were removed from the kernels and sampled for analysis.

Cottonseed oil and meal

The kernels were dried to < 12% water, heated to 80–90 ºC for 30 minutes, and flaked, followed by passage through an expander extruder to form collets. The collets were submerged in hexane at 50–60 ºC for 30 minutes and washed twice with fresh hexane to remove the cottonseed oil. Residual hexane was removed from the meal fractions with warm air and the meal was sampled for analysis. Hexane was removed from the oil with a vacuum extractor, NaOH was added to precipitate the soap stock, the remaining hexane was removed and refined oil was sampled for analysis.

Study 2—Australia

One processing trial was conducted in 2012 in Narrabri, New South Wales, where cotton was treated with two applications of a WG formulation at a rate 0.10 kg ai/ha/application or 0.20 kg ai/ha/application for a total of 0.2 kg ai/ha or 0.4 kg ai/ha, respectively. The undelinted cottonseed was harvested 8, 15, 22, 29, 36, 43, 50 and 57 DALA and processed into meal and oil. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 91 and 93. The information submitted on processing procedures is summarized as follows.

Cottonseed hulls

The fuzzy seed was passed through a hand driven mechanical grinder to crack the hulls. The cracked fuzzy seed was sieved to separate the hulls from the unprocessed meal.

Cottonseed meal and oil

The unprocessed meal was placed in a small bolt apparatus which was screwed together to press the meal and extract the oil via pressure. Oil was collected during pressing from the drain hole on the apparatus using a syringe and collected in a plastic vial. The process was repeated until at least 1 m of oil was collected.

Mint

Two processing trials were conducted in 2011 in Moxee, Washington and Endeavour and Wisconsin. Mint was treated with three applications of a SG formulation at a rate 0.10 kg ai/ha/application for a total of 0.3 kg ai/ha. The mint tops were harvested 7 days following the last application and processed into oil. The results and the calculated processing factors (residue in processed commodity/residue in RAC) for MRL setting and dietary intake purposes are presented in Tables 92 and 93. No information was submitted on processing procedures.

The maximum storage intervals for mint oil was 368 days. Concurrent storage stability samples were fortified with flonicamid and its metabolites at 0.2 ppm soon after the receipt of the samples by the analytical laboratory. The storage stability samples were held in frozen storage under similar conditions to the field generated samples. After 334 days of freezer storage for mint oil, the storage stability samples were analysed for flonicamid. The recoveries for the mint

oil storage stability samples were in the ranges 43–46% (flonicamid), 42–49% (TFNA), 46–53% (TFNA-AM), and 42–45% (TFNG). Concurrent recoveries for spikes analysed along with these storage stability samples were 95% (flonicamid), 100% (TFNA), 81% (TFNA-AM), and 89% (TFNG). These data indicate that flonicamid and its metabolites undergo about 50% degradation in mint oil under the conditions which the samples were held between harvest and analysis. However, even when correcting for in-storage dissipation, residues of flonicamid and its metabolites do not concentrate in mint oil.

Residues in animal commodities

Dairy Cattle

One cattle feeding study was conducted where twelve dairy cows (Red Holstein and Simmentaler Fleckvieh, 4–9 years old, 550–770 kg bw) were divided into three groups. Animals were treated twice daily with a 1/1 mixture of flonicamid/TFNG by means of gelatin capsules and using a balling gun. Treatments were made after the morning and evening milking for 28 consecutive days. One group of three cows served as a control group The actual average doses administered were 0.086, 0.252 and 0.839 mg/kg bw. Based on the actual average daily feed intake of 20.1–25.1 kg/day (or 3.0–4.4 kg/day/100 kg bw) during the acclimation period, the actual dosing levels, constituting a 1/1 mixture of flonicamid/TFNG, were 2.50 mg, 6.89 mg and 23.69 mg/kg feed. All cows were sacrificed after 28 days of dosing, within 24 hours after the last dose.

Milk samples were collected on 15 selected days throughout the administration period. All milk samples were frozen at –20 ºC and analysed within 30 days after sampling. Therefore, storage stability data are not necessary. In contrast, all tissue samples were analysed within 12 months of collection. Freezer storage stability studies, conducted concurrently with the feeding studies, demonstrated that flonicamid, TFNA, TFNA-AM, OH-TFNA-AM and TFNG were stable for 374 days in all tissues except fat. For fat, flonicamid and its metabolites were demonstrated to be stable for 315 days.

All samples were analysed for residues of flonicamid, TFNA, TFNA-AM, OH-TFNA-AM and TFNG using validated analytical methods. In general, the samples were homogenised, extracted and the supernatant was purified by means of liquid-liquid partition or gel permeation chromatography. Some of the solid residues were further subjected to acid hydrolysis. The concentration of flonicamid and its metabolites in the purified extracts were determined by HPLC MS/MS. The LOQ for flonicamid and each of its metabolites in milk and fat is 0.01 mg/kg and for muscle the LOQ is 0.025 mg/kg while for liver and kidney the LOQ is dependent on the method used (0.01 or 0.025 mg/kg).

In milk, no quantifiable (< LOQ) residues of flonicamid, TFNG and TFNA were detected in any test group. For TFNA-AM, the average residues increased from < LOQ in the low dose group to 0.02 mg/kg in the mid dose group and to 0.08 mg/kg in the high dose group. OH-TFNA-AM average residues were ⩽ LOQ in the low and mid-dose groups and increased to 0.015 mg/kg in the high dose group.

In liver, TFNA-AM and OH-TFNA-AM were detected in the mid and high dose groups above the LOQ using two different analytical methods (FMC-P-3580 / RCC 844743) with different LOQ (0.025/0.01 mg/kg). TFNA-AM levels increased from less than LOQ in the low dose group to 0.039/0.015 mg/kg in the mid dose group and 0.113/0.053 mg/kg in the high dose group. OH-TFNA-AM levels increased from levels below LOQ (0.025/0.01 mg/kg) in the low dose group to levels slightly above the LOQ (< 0.025/0.010 mg/kg) in the mid dose group and 0.030/0.037 mg/kg in the high dose group.

In kidney, TFNA and TFNA-AM were detected in the medium and high dose groups above the LOQ using the same analytical methods as those used for kidney. OH-TFNA-AM and TFNG were only detected above the LOQ (0.025/0.01 mg/kg) in the high dose group. TFNA levels increased from levels below LOQ in the low dose group to 0.043/0.038 mg/kg in the mid dose group and 0.142/0.135 mg/kg in the high dose group. TFNA-AM levels increased from levels below LOQ in the low dose group to 0.031/0.023 mg/kg in the mid dose group and 0.105/0.088 mg/kg in the high dose group. OH-TFNA-AM levels increased from levels below LOQ in the low and mid dose group to 0.025/0.027 mg/kg in the high dose group. TFNG levels increased from levels below LOQ in the low and mid dose group to 0.010 mg/kg in the high dose group.

In muscle, only TFNA-AM was found. The level increased from below LOQ (0.025 mg/kg) in the low dose group to 0.027 mg/kg in the mid dose group and 0.088 mg/kg in the high dose group.

Similarly, only TFNA-AM was measurable in fat and only at the high dose level (0.015 mg/kg).

Poultry

Flonicamid and TFNG were dosed in a 1:1 mixture to 50, 22 week-old, laying hens (white leghorn hybrids) weighing on average 1.54 kg with an egg production of at least 0.8 eggs per day. The hens were randomly assigned to five groups, one of which served as control group. Each group was separated into three subgroups of three to four animals. After the acclimation period, the test substance was orally administered, once daily in the afternoon by means of gelatin capsules (after egg sampling). for 28 days. Based on the actual average daily feed intake of 0.108–0.116 kg/hen during the 4-week acclimation period, the actual dose levels were equivalent to average potential concentrations in the feed of 0.26, 2.51, 7.47 and 25.83 mg flonicamid/TFNG per kg feed.

Eggs were collected once daily and pooled per subgroup of three or four hens, resulting in three unique samples of eggs for each dose level. The egg pools were stored at –20 °C until analysis. The animals were sacrificed for tissue sampling the day after the last administration, 24 hours after the last dosing. Liver fat (composite of skin fat) and muscle were excised. Tissue samples were rinsed, weighed and labelled. Tissues were pooled per subgroup of three or four hens, homogenised and stored deep-frozen until analysis. Egg and tissue samples were stored for greater than 30 days. Freezer storage stability studies, conducted concurrently with the feeding studies, demonstrated that flonicamid, TFNA, TFNA-AM, OH-TFNA-AM and TFNG were stable for 8–10 months in eggs and tissues.

All samples were analysed for residues of flonicamid, TFNA, TFNA-AM, OH-TFNA-AM and TFNG using a validated analytical method. The samples were homogenised, extracted and the supernatant was purified by means of gel permeation chromatography. The concentration of flonicamid and its metabolites in the purified extracts were determined by MS/MS detection using HPLC for separation.

In eggs, no quantifiable (< LOQ) residues of TFNA, OH-TFNA-AM and TFNG were detected in any test group. For flonicamid, the average residues increased from < LOQ in the very low and low dose groups to 0.02 mg/kg in the mid dose group and to 0.08 mg/kg in the high

dose group. TFNA-AM average residues increased from < LOQ in the very low and low dose groups, to 0.27 mg/kg in the mid dose group and 0.95 mg/kg in the high dose group.

No quantifiable residues (< LOQ) of flonicamid, TFNA and TFNG were found in muscle in any treatment group. No quantifiable residues (< LOQ) of TFNA-AM was measurable in muscle at the very low dose group, but there appeared to be a dose response relationship at all other dose levels; 0.049 mg/kg in the low dose group, 0.168 mg/kg in the mid dose group and 0.654 mg/kg in the high dose group. OH-TFNA-AM was measurable only at the high dose level (0.014 mg/kg).

In liver and fat, no quantifiable residues (< LOQ) of flonicamid, TFNA, OH-TFNA-AM and TFNG were found at any dosing level. For liver, TFNA-AM residues increased from < 0.01 mg/kg (very low) to 0.054 mg/kg (low) to 0.166 mg/kg (mid) and 0.706 mg/kg (high) while for fat, TFNA-AM residues increased from 0.01 mg/kg (very low) to 0.022 mg/kg (low) to 0.062 mg/kg (mid) and 0.286 mg/kg (high).

Table 98 Residues in muscle, liver and fat following 28 days oral administration to laying hens

APPRAISAL

Flonicamid is a new insecticide for control of aphids and other sucking insects. It belongs to a new class of chemistry known as pyridinecarboxamide. At the Forty-sixth Session of the CCPR, flonicamid was scheduled for evaluation, for both toxicology and residues, as a new compound by the 2015 JMPR.

The Meeting received information on the metabolism of flonicamid in peaches, bell peppers, potatoes, wheat, lactating goats, laying hens and rotational crops, environmental fate, methods of residue analysis, freezer storage stability, GAP, supervised residue trials on various fruits, vegetables, tree nuts, oil seeds, dried hops, mint and tea, processing studies as well as livestock feeding studies.

In this document, the code names and chemical structures of the metabolites were as follows:

Flonicamid is *N*-cyanomethyl-4-(trifluoromethyl)nicotinamide (IUPAC).

Code Name	Structure	Chemical Name
Flonicamid IKI-220		N-cyanomethyl-4-(trifluoromethyl)nicotinamide
TFNA		4-trifluoromethylnicotinic acid
TFNA-AM		4-trifluoromethylnicotinamide
OH-TFNA-AM		6-hydroxy-4-trifluoromethylnicotinamide
TFNA-OH		6-hydroxy-4-trifluoromethylnicotinic acid
TFNG		N-(4-trifluoromethylnicotinoyl)glycine

TFNG-AM		N-(4-trifluoromethylnicotinoyl)glycinamide

Environmental fate in soil

The FAO Manual (FAO, 2009) explains the data requirements for studies of environmental fate. The focus should be on those aspects that are most relevant to MRL setting. For flonicamid, supervised residue trials were received for foliar spray on permanent crops and on annual crops. Therefore, according to the FAO manual, only studies on aerobic degradation, photolysis and rotational crops (confined, field) were evaluated.

Degradation

The route of degradation of [^{14}C]flonicamid in soil under aerobic conditions was investigated in a biologically active loamy sand soil collected from Madison, Ohio, USA and stored in a greenhouse. Flonicamid rapidly declined from 99.3% of the applied radioactivity (AR) at Day 0 to 2.3% by Day 30, resulting in a DT_{50} of 1 day and a DT_{90} of 3.4 days. TFNA and TFNA-OH were major components of the residue with TFNG, TFNG-AM and TFNA-AM all identified as minor metabolites.

The rate of aerobic degradation of [^{14}C]flonicamid, radiolabelled at the 3 position of the pyridine was investigated in three biologically active soils (sandy loam and sand at 10 °C and/or 20 °C)

For the soils incubated at 20 °C the DT_{50} and DT_{90} values for flonicamid ranged from 0.7 to 1.8 days and 2.3 to 6.0 days, respectively. For the soil incubated at 10 °C, the DT_{50} and DT_{90} values for flonicamid were 2.4 days and 7.9 days, respectively. TFNA, TFNA-OH and TFNG-AM were the major degradates in all soils over the course of the study. Minor degradates TFNG and TFNA-AM were detected at all sampling points over the course of the study. All of the degradates were metabolised and mineralised to carbon dioxide and immobilised as soil-bound residue.

Photolysis

The photochemical degradation of [pyridyl-^{14}C]flonicamid was investigated in a loamy sand under laboratory conditions.

[^{14}C]Flonicamid decreased to 60% of the applied radioactivity (AR) after 15 days of continuous illumination, resulting in a DT_{50} of 22 days. Concurrently, the major metabolite TFNG-AM was detected in Day 1 sample extracts and increased by Day 15. TFNA-AM and TFNG were also detected as minor metabolites in the illuminated soils, reaching maximum concentrations of 5% AR (Day 11 and Day 15) and 2% AR (Day 15), respectively.

In summary, based on the results of the environmental fate studies, flonicamid as well as its metabolites are likely to readily degrade and not persist in aerobic soil environments.

Plant metabolism

The metabolism of flonicamid was studied in peaches, bell peppers, potatoes and wheat.

Peach

Flonicamid, radiolabelled at the 3 position of the pyridine ring and formulated as a wettable granule, was applied twice to peach trees grown outdoor, with a 14-day re-treatment interval, at rates of 100 g ai/ha (low rate) or 500 g ai/ha (high rate) per application. Mature fruits and leaves were

harvested 21 days after the last treatment (DALA). Overall total radioactive residues (TRRs) in fruits at the low rate and the high rate were 0.10 mg eq/kg and 0.32 mg eq/kg, respectively, while in the leaves, TRRs followed the same trend, where residues were lower at the lower application rate (6.2 mg eq/kg) compared to those at the higher treatment rate (24 mg eq/kg).

The peaches were subjected to a surface wash using deionised water which removed very little radioactivity (≤ 15% TRRs), evidence of limited penetration. The majority of the TRRs were partitioned into the juice fraction (64–73% of the TRR) and to a lesser extent into the pulp (21% TRRs). While juice was not further extracted with organic solvents, extraction of the pulp with acetonitrile:water:phosphoric acid recovered 92% TRR. At both treatment rates, flonicamid (30–60% TRRs) and TFNA (17–49% TRRs) were the predominant residues in juice and pulp. All other metabolites, TFNG, TFNG-AM and TFNA- AM were ≤ 6% TRRs.

Bell pepper

A single application of flonicamid, radiolabelled at the 3 position of the pyridine ring, formulated as a 50% wettable granule formulation, was made to greenhouse grown bell pepper plants at 100 g ai/ha. Fruits and leaves were harvested 7 days and 14 days after treatment (DAT).

The TRRs in fruits decreased insignificantly from 0.17 mg eq/kg (7 DAT) to 0.11 mg eq/kg (14 DAT) while TRRs in leaves decreased from 2.2 mg eq/kg, when harvested 7 days after treatment to 1.4 mg eq/kg at 14 DAT.

The %TRR in the methanol:water surface wash for both leaves and fruits decreased as the corresponding extracted TRRs (61–81% TRRs) and those in the post-extraction solids (PES) increased with increasing DAT. This trend demonstrated the penetration of the radioactivity from the surface into the leaves and fruits.

Flonicamid and TFNG were the predominant residues in leaves (47–74% TRRs and 12–28% TRRs, respectively) while only flonicamid was the predominant residue in fruits (77–91% TRRs) at both harvest intervals. All identified metabolites (TFNA, TFNA-AM and TFNG-AM) were either not detected or were ≤ 12% TRRs.

Potato

Potato plants maintained outdoor were treated, either at the lower rate of 100 g ai/ha or the higher rate of 500 g ai/ha, with flonicamid radiolabelled at the 3 position of the pyridine ring and formulated as a 50% wettable powder. Both treatments were repeated at a two-week interval and potato tubers and foliage were harvested 14 days after the last application.

Overall TRRs in tubers at the low rate and the high rate were 0.11 mg eq/kg and 0.20 mg eq/kg, respectively, while those in mature foliage were higher than those in tubers; 1.5 mg eq/kg at the low rate and 7.7 mg eq/kg at the high rate. Considering the applications were made to the foliage of the potato plants, the presence of measurable TRRs in the tubers is evidence of translocation of the radioactivity from the foliage to the tubers. Furthermore, while the TRRs in tubers and foliage increased with increased application, the distribution of TRRs was relatively the same irrespective of the treatment rate.

Extraction of the potato tubers with ACN and ACN:water recovered up to 93% TRRs while extraction of potato foliage with ACN:water:acetic acid recovered up to 90% TRRs. Analysis of each of the extracted fractions of potato tubers and foliage from the low and high rate demonstrated that the major components of the residue, TFNA and TFNG, accounted for a significant portion of the TRRs. Moreover, TFNA accounted for 34% TRRs in tubers and 12–17% TRRs in foliage at both rates while TFNG accounted for 25–39% TRRs in tubers and 28–36% TRRs in leaves at both rates. The parent, flonicamid, accounted for 6–19% TRRs in potato tubers and 10–25% TRRs in foliage. Each of the other identified metabolites (TFNA conjugate, TFNG-AM, TFNA-AM, PM-1a, PM-1b and PM-3a) accounted for < 10% TRRs in tubers and in foliage. Overall, the general metabolic profile in foliage was similar to that in tubers.

Spring wheat

Spring wheat plants grown outdoor were treated with flonicamid, radiolabelled at the 3 position of the pyridine ring and formulated as a wettable powder, at a single application rate of 100 g ai/ha or 2 applications at 100 g ai/ha with a re-treatment interval of 7 days. Forage and hay were harvested 14 days and 42 days, respectively, after the single application. Approximately 95 days after the second treatment (200 g ai/ha/season), mature plants were harvested and separated into straw, chaff and grain.

Overall residues were lower in the wheat grain sample (2.6 mg eq/kg) than the straw (5.6 mg eq/kg) or chaff (6.6 mg eq/kg). The TRRs in the chaff were higher compared to straw potentially because of tissue size differences (higher surface area to weight ratio) assuming a uniform application. Further to this, considering the timing of application of the test material and the measurable TRRs in grain, chaff and straw at maturity, there appears to have been translocation of the radioactivity from the site of application to the mature plant parts.

Only forage and hay were analysed to elucidate the nature of the flonicamid residues. Extraction of these matrices with ACN:water:acetic acid recovered 96% TRRs. The analysis of forage and hay samples demonstrated that the nature and distribution of metabolites were similar in both matrices. The parent compound, flonicamid, and the TFNG metabolite represented the majority of the TRRs in both the forage (flonicamid: 43% TRRs; TFNG: 33% TRRs) and hay (flonicamid: 22%TRRs; TFNG: 53% TRRs). Metabolites TFNG-AM, TFNA and TFNA-AM were present at ≤ 13% TRRs.

In a second spring wheat metabolism study, plants grown outdoor were treated with flonicamid, radiolabelled at the 3 position of the pyridine ring and formulated as a wettable granule, at rates equivalent to 100 g ai/ha or 500 g ai/ha. The wheat plants were harvested 21 DAT and separated into straw (leaves and stem), chaff and grain (with hulls attached).

The TRRs in wheat straw, chaff and grain increased with increased application rate with the highest TRRs observed in chaff, followed by straw and grain, irrespective of the application rate. The distribution of TRRs was relatively the same irrespective of the treatment rate.

Similar to the first wheat metabolism study, extraction with ACN:water:acetic acid recovered 80–94%TRRs with flonicamid (24–50%TRRs) and TFNG (17–44% TRRs) representing the predominant residues at both treatment rates. All identified metabolites (TFNA, TFNG-AM, TFNA-AM and N-oxide TFNA AM) were either not detected or were each ≤ 10% TRR.

In summary, the Meeting determined that the degree of metabolism in all crops tested, following foliar application, was qualitatively similar, with the parent compound as the predominant residue. The major metabolic pathway of flonicamid in plants involved hydrolysis of the cyano group and the amide groups.

Rotational crops

In the confined rotational crop study, flonicamid, radiolabelled at the 3 position of the pyridine ring and formulated as a wettable granule was applied twice to loamy sand soil at a rate equivalent to 100 g ai/ha at an interval of two weeks. After the appropriate plant-back intervals (PBIs) of 30, 120 or 360 days, the rotational crops, representative of the root vegetable (carrot), small grain (wheat), and leafy vegetable (lettuce) crop groups, were planted.

TRRs in all raw agricultural commodities (RACs) declined with prolonged PBIs such that, at the 120-day PBI, no further characterization/identification of the TRRs was performed for immature and mature lettuce and mature carrot roots due to the low total radioactivity. Further to this, at the 360-day PBI, none of the TRRs from any of the crop parts were further subjected to characterization/identification as these were also too low.

Analysis of the harvested crop samples demonstrated very little uptake of ^{14}C-residues. Of the radioactivity taken up by plants, only limited amounts of flonicamid were detected (≤ 13% TRRs). TFNG and TFNG-AM were identified at > 10% TRRs in most RACs. In addition to

TFNG, other identified metabolites accounting for > 10% TRRs in wheat matrices and mature carrot root included TFNA-AM and TFNA-OH.

Conversely, in the field accumulation study, no quantifiable residues of flonicamid or its metabolites TFNG, TFNA, and TFNA-AM were detected in wheat (forage, straw and grain) and turnip (tops and roots) planted at either 30 or 60 days after the last application of flonicamid to the primary crop, cotton.

Based on the findings of the field crop rotation studies, the Meeting concluded that the uptake of quantifiable residues of flonicamid or its associated metabolites in secondary crops is unlikely.

Animal metabolism

Metabolism studies in rats reviewed by the 2015 JMPR and conducted using [^{14}C]flonicamid labelled at the 3-nicotinamide position, indicated that flonicamid was rapidly absorbed and quickly excreted. The majority of administered radioactivity was excreted in the urine and within the first 24 hours. There was no evidence of bioaccumulation following repeat doses. Distribution into the tissues was extensive with levels similar to blood concentrations; however, slightly higher concentrations were seen in the liver, kidneys, adrenals, thyroid and ovaries following single or repeat dosing and in the lungs following repeat dosing in males.

The main urinary residue was unchanged parent, followed by TFNA-AM, which was also the predominant metabolite in the faeces and bile. Other metabolites were TFNA in the faeces of low-dose animals, TFNA-AM N-oxide conjugate in the high-dose animals, TFNG-AM in the bile of high-dose animals and TFNG and TFNA-AM in the liver.

Metabolism studies were conducted in lactating goats where they were dosed orally once daily for 5 consecutive days with 3-pyridine-^{14}C-labelled flonicamid at a dose level equivalent to 10 ppm in feed. The major route of elimination of the radioactivity was via the urine which accounted for 49% of the administered dose (AD), while faeces accounted for up to 21% of the AD and milk accounted for 1% of the AD. Overall, the tissue burden was low, accounting for < 10% of the AD. The TRRs were highest in liver (1.2 mg eq/kg) followed by kidney (0.70 mg eq/kg), muscle (0.30–0.40 mg eq/kg) and fat (0.05–0.14 mg eq/kg).

Extraction of milk, using ethanol and ethanol:water recovered 97% TRRs and extraction of tissues and organs using ACN and ACN:water containing 1% acetic acid recovered greater than 42% TRRs. Flonicamid was rapidly metabolised in lactating goats, representing less than 6% TRRs in tissues and organs. TFNA-AM was the major component of the residue in organs (29% TRRs in liver, 31–41% TRRs in kidney), tissues (74% TRRs in fat, 42–50% TRRs in muscle) and milk (97% TRRs). The minor metabolites TFNA and 6-OH-TFNA-AM each accounted for ≤ 7% TRRs in liver, kidney, muscle and milk.

Leghorn laying hens were dosed orally once daily for 5 consecutive days with 3-pyridine-^{14}C-labelled flonicamid at a dose level equivalent to 10 ppm in feed. Approximately 91% of AD including 6% of AD from the gastrointestinal tract and its contents was recovered. Most of the AD (72%) was excreta-related. TRRs in egg white and egg yolk accounted for about 2.4% of AD (1.8% AD in egg white plus 0.6% AD in yolk). The tissue burden was low (< 6% of the AD) with highest concentrations of ^{14}C-residues found in kidney (1.4 mg eq/kg) followed by liver (1.2 mg eq/kg), muscle (evenly distributed between breast and thigh muscle; 1.0 mg eq/kg each), skin (0.70 mg eq/kg) and fat (0.15 mg eq/kg).

Extraction of eggs, tissues and organs with ACN and ACN:water containing 1% acetic acid recovered more than 81% TRR. Flonicamid accounted for only a very small percentage of the TRRs in eggs (2–4% TRRs), tissues (< 1% TRRs) and organs (< 0.5% TRRs). TFNA-AM was the predominant component of the residue in egg whites and egg yolks (≤ 96%TRRs), liver (93%TRRs), kidney (76%TRRs) and tissues (97%TRRs in both breast muscle and thigh muscle, 96%TRRs in skin and 95%TRRs in fat). Other metabolites identified in organs and tissues were

OH-TFNA-AM and TFNG-AM, however, neither of these accounted for greater than 5% of TRR.

The Meeting concluded that, in all species investigated, the total administered radioactivity was quickly and almost completely eliminated in excreta. The metabolic profiles differed quantitatively between the species, but qualitatively there were no major differences. The routes and products of metabolism in animals were consistent across the studies resulting from the hydrolysis of the cyano function to the amide function as well as ring hydroxylation. Moreover, TFNA-AM was the major component of the residue in all tissues, organs, milk and eggs of livestock animals.

While the overall metabolism in plants, livestock and rats is similar, the metabolism of flonicamid in animals is more extensive with hydrolysis of flonicamid to the major amide metabolite TFNA-AM.

Methods of analysis

The Meeting received descriptions and validation data for analytical methods for residues of flonicamid and its relevant metabolites TFNA-AM, TFNA and TFNG in plant commodities and for flonicamid, TFNA-AM, TFNA, TFNG and OH-TFNA-AM in animal commodities. Residue analytical methods rely on LC/MS-MS. Typical limits of quantitation (LOQs) achieved for plant commodities fell in the range of 0.01–0.02 mg/kg for each analyte. The LOQs for milk and animal products (liver, kidney, muscle and eggs) were 0.01 mg/kg for each analyte. Methods were successfully subjected to independent laboratory validation.

The acid version (addition of 1% formic acid to the acetonitrile extraction solvent) of the QuEChERS multi residue LC-MS/MS method was used for flonicamid, TFNA, TFNG and TFNA-AM in plant matrices with LOQs of 0.01 mg/kg for each analyte.

The Meeting determined that suitable methods are available for the analysis of flonicamid and its relevant metabolites in plant and animal commodities.

Stability of residues in stored analytical samples

The Meeting received storage stability studies under freezer conditions at –17 °C for flonicamid and its relevant metabolites TFNA-AM, TFNA and TFNG for the duration of the storage of 18 to 23 months in a wide range of raw and processed crop matrices, including high-water, high-starch and high-oil crops. The Meeting concluded that residues of flonicamid, TFNA-AM, TFNA and TFNG are stable for at least 18 months. Freezer storage stability studies were also conducted concurrently with several of the crop field trials, demonstrating similar results.

All milk samples from the feeding studies were frozen at –20 ºC and analysed within 30 days after sampling. Therefore, storage stability data are not necessary. In contrast, all tissue samples were analysed within 12 months of collection. Freezer storage stability studies, conducted concurrently with the feeding studies, demonstrated that flonicamid, TFNA, TFNA-AM, OH-TFNA-AM and TFNG were stable for 374 days in all tissues except fat. For fat, flonicamid and its metabolites were demonstrated to be stable for 315 days.

Definition of the residue

In primary crops, the parent compound represented the majority of the residue accounting for up to 61% TRRs in peach fruits, 91%TRRs in bell pepper fruits, 19% TRRs in potato and up to 50% TRRs in wheat forage, hay, straw, chaff and grain. Metabolites TFNA and TFNG were identified as predominant metabolites (> 10%TRRs) in all crop commodities. In the crop field trials, residues of TFNA and TFNG were measurable in all crops, the magnitude of which was crop-dependent. However, both the TFNA and TFNG were seen in the rat metabolism study and considered to be up to 10-fold less toxic than the parent flonicamid based on toxicity studies reviewed by the 2015 WHO.

In the field accumulation study no measurable residues of parent or any of its associated metabolites were observed in secondary crops.

In light of the above, the Meeting decided to define the residue for enforcement/monitoring and for risk assessment for plant commodities as parent only.

In the farm animal metabolism studies, the parent, flonicamid, was rapidly degraded in ruminants and poultry, accounting for ≤ 6% TRRs in all tissues, milk and eggs. Conversely, the metabolite TFNA-AM accounted for the majority of the radioactivity in goat tissues (29–74% TRRs) and milk (92–97%TRRs) and laying hen tissues (76–97% TRRs) and eggs (ca. 95%TRRs).

Similar findings were observed in the livestock feeding studies whereby flonicamid was present at very low levels in all animal commodities with the metabolite TFNA-AM representing the majority of the residues in tissues, milk and eggs. Therefore, TFNA-AM will be included in the residue definition for enforcement as a marker compound. Since the method of analysis is capable of analysing both flonicamid and TFNA-AM, the Meeting agreed to define the residue for enforcement/monitoring as flonicamid and TFNA-AM.

The log K_{ow} for flonicamid is 0.3. In the metabolism studies there was no evidence of the parent compound and TFNA-AM partitioning into fatty matrices (fat, milk and egg yolks) as the total residues were present at comparable concentrations in all livestock matrices. In the dairy cattle and poultry feeding studies, there was no evidence of the total residues of flonicamid and TFNA-AM sequestering into milk, eggs or fat. Therefore, the Meeting did not consider the residue fat soluble.

As TFNA-AM was the major component of the residue in all animal matrices in both the metabolism and feeding studies, the Meeting decided to define the residue for dietary risk assessment for animal commodities as parent and TFNA-AM.

Based on the above, the Meeting recommended that the residue definition for compliance with MRLs and estimation of dietary intake should be as follows:

Definition of the residue for compliance with MRL and estimation of dietary intake for plant commodities: *Flonicamid*

Definition of the residue for compliance with MRL and estimation of dietary intake for animal commodities: Flonicamid and the metabolite TFNA-AM, expressed as parent.

The residue is not fat soluble.

Results of supervised residue trials on crops

Pome fruits

Results from supervised field trials on apples and pears conducted in the US were provided to the Meeting, including apple and pear data from Australia.

A total of 16 independent supervised trials were conducted in the US on apples (12) and pears (4). The GAP in the US for pome fruits allows three applications at a maximum rate of 0.1 kg ai/ha with a PHI of 21 days.

Flonicamid residues from 12 apple trials matching the US GAP were: 0.02, 0.04 (3), 0.05 (4), 0.06, 0.07, 0.10 and 0.11 mg/kg.

Flonicamid residues from four pear trials matching the US GAP were: 0.01 (3) and 0.02 mg/kg.

A total of seven independent supervised trials were also conducted on apples in Australia according to the Australian GAP which allows three applications at a maximum rate of 0.01 kg ai/hL with a PHI of 21 days. Nine supervised trials were conducted on pears in Australia, however, in the absence of an Australian GAP, these trials were not considered.

Flonicamid residues from seven apple trials matching the Australia GAP were 0.09, 0.12 (2), 0.13, 0.15, 0.22 and 0.24 mg/kg.

The Meeting noted that in the US a group GAP for pome fruit exists and decided to explore the possibility of setting a group maximum residue level. As the supervised trials on apples conducted in Australia in accordance with the Australian GAP lead to the higher residues, the Meeting recommended that the group maximum residue level be based on the dataset from Australia.

Based on the Australian residue data for apples, the Meeting estimated a maximum residue level for pome fruits of 0.8 mg/kg and an STMR of 0.13 mg/kg.

Stone fruits

Results from supervised field trials on peaches, cherries and plums conducted in the US were provided to the Meeting.

A total of 19 independent supervised trials were conducted in the US on peaches (8), cherries (6) and plums (5) according to the US GAP on stone fruits which allows three applications at a maximum rate of 0.1 kg ai/ha with a 14-day PHI.

Residues of flonicamid from eight peach trials matching the US GAP for stone fruits were: 0.09 (2), 0.10, 0.13, 0.15, 0.22 (2) and 0.42 mg/kg.

Residues of flonicamid from six cherry trials matching the US GAP for stone fruits were: 0.26, 0.27 (2), 0.28 (2) and 0.36 mg/kg.

Residues of flonicamid from five plum trials matching the GAP for stone fruits were: 0.01, 0.02, 0.03 and 0.04 (2) mg/kg.

The Meeting noted that in the US a group GAP for stone fruits exists and decided to explore the possibility of setting a group maximum residue level. Since median residues among the representative commodities were not within a 5-fold range (0.14 mg/kg vs. 0.28 mg/kg vs. 0.03 mg/kg), the Meeting decided to estimate maximum residue levels for each subgroup based on the individual dataset for each representative commodity.

The Meeting estimated a maximum residue level of 0.9 mg/kg and an STMR of 0.28 mg/kg for cherries subgroup.

The Meeting estimated a maximum residue level of 0.7 mg/kg and an STMR of 0.14 mg/kg for peaches subgroup.

The Meeting estimated a maximum residue level of 0.1 mg/kg and an STMR of 0.03 mg/kg for plums subgroup.

Strawberries

Results from supervised field trials on strawberries conducted in the US were provided to the Meeting.

A total of eight independent supervised trials were conducted in the US on strawberries according to the US GAP for low growing berries, which allows three applications at a maximum rate of 0.1 kg ai/ha with a 0-day PHI.

Residues of flonicamid matching the US GAP were: 0.13, 0.19, 0.27, 0.33, 0.41, 0.47, 0.54 and 0.59 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.37 mg/kg for low growing berries.

Brassica (Cole or cabbage) vegetables, Head cabbages, Flowerhead brassicas

Results from supervised field trials on cabbage and broccoli conducted in the US were provided to the Meeting.

A total of 12 independent supervised trials were conducted in the US on broccoli (6) and cabbage (6) according to the US GAP on Brassica (Cole) Leafy Vegetables which allows three applications at a maximum rate of 0.1 kg ai/ha with a 0-day PHI.

Residues of flonicamid from six broccoli trials matching the US GAP for Brassica (Cole) leafy vegetables were: 0.250, 0.428, 0.432, 0.462, 0.499 and 0.553 mg/kg.

Residues of flonicamid from six trials on cabbage (with wrapper leaves) matching the US GAP for Brassica (Cole) Leafy Vegetables were: < 0.025, 0.025, 0.062, 0.205, 0.288 and 1.262 mg/kg.

Residues of flonicamid from six trials on cabbage (without wrapper leaves) matching the US GAP for Brassica (Cole) Leafy Vegetables were: < 0.025 (6) mg/kg.

The Meeting noted that in the US a group GAP for Brassica (Cole) leafy vegetables exists and decided to explore the possibility of setting a group maximum residue level. Since median residues among the representative crops were within a 5-fold range (0.45 mg/kg vs. 0.134 mg/kg) and the Mann-Whitney test indicated that the residues were not statistically different, the Meeting decided to estimate a group maximum residue level based on the following combined residues: < 0.025(7), 0.025, 0.062, 0.205, 0.288 and 1.262 mg/kg.

The Meeting estimated a maximum residue level of 2.0 mg/kg and an STMR of 0.358 mg/kg for Brassica (Cole or cabbage) vegetables, head cabbages and flowerhead Brassicas.

The Meeting estimated an STMR of 0.02 mg/kg for cabbage (without wrapper leaves).

Fruiting vegetables, Cucurbits

Supervised field trials on field- and greenhouse-grown melons conducted in Southern EU and on field-grown pumpkins conducted in Hungary were provided to the Meeting. However, only four trials on melons and four trials on pumpkins matched the critical GAP of Slovenia which allows three foliar spray applications of a WG formulation at 0.05 kg ai/ha with a re-treatment interval of 7 days and a PHI of 1 day. Therefore, in the absence of a sufficient number of trials matching the Slovenia critical GAP, these trials were not considered further.

A total of 17 independent supervised trials, conducted in the US on cucumber (6), melon (6) and summer squash (5) according to the US GAP on cucurbit vegetables, which allows three applications at a maximum rate of 0.1 kg ai/ha with a 0-day PHI, were provided to the Meeting. In addition, the Meeting received four greenhouse cucumber trials conducted in Canada and the US according to the US critical GAP which allows two foliar spray or soil applications at a maximum rate 0.15 kg ai/ha with a re-treatment interval of 6–7 days and a 0-day PHI.

Residues of flonicamid from six field cucumber trials matching the US GAP for cucurbit vegetables were: 0.04, 0.06 (3), 0.07 and 0.12 mg/kg.

Residues of flonicamid from six melon trials matching the US GAP for cucurbit vegetables were: 0.020, 0.03, 0.04, 0.05, 0.06 and 0.09 mg/kg.

Residues of flonicamid from five summer squash trials matching the US GAP for cucurbit vegetables were: 0.01, 0.03 (3) and 0.04 mg/kg.

Residues of flonicamid from the greenhouse cucumber trials matching the US GAP for the foliar spray application were: 0.05, 0.06, 0.14 and 0.54 mg/kg.

Residues of flonicamid from the greenhouse cucumber trials where the growth media was treated were: 0.09, 0.13, 0.16 and 0.20 mg/kg.

For greenhouse cucumbers, as there is an insufficient number of supervised trials conducted in accordance with the US critical GAP, the Meeting did not consider these trials further.

In addition to the US trials, the Meeting received 10 independent supervised field trials conducted in Australia on cucumbers (2), melons (5) and summer squash (3) according to the

Australian GAP on cucurbit vegetables which allows three applications at a maximum rate of 0.1 kg ai/ha with a 1-day PHI.

Residues of flonicamid from two field cucumber trials matching the Australian GAP for Cucurbit Vegetables were: 0.03 (2) mg/kg.

Residues of flonicamid from five melon trials matching the Australian GAP for Cucurbit Vegetables were: 0.03, 0.05 (2), 0.09 and 0.17 mg/kg.

Residues of flonicamid from three summer squash trials matching the Australian GAP for Cucurbit Vegetables were: 0.01, 0.04 and 0.08 mg/kg.

Since the use of flonicamid on the cucurbits crop group is registered in Australia, the residue decline trials demonstrated limited dissipation of flonicamid residues with increasing PHI and that there are an insufficient number of Australian trials at the critical GAP, the Meeting compared the US field trials against the Australian GAP and combined them as follows:

Residues of flonicamid in field cucumbers from eight trials were: 0.03 (2), 0.04, 0.06 (3), 0.07 and 0.12 mg/kg.

Residues of flonicamid in melons from 11 trials were: 0.02, 0.03(2), 0.04 (2), 0.05 (2), 0.06, 0.09 (2) and 0.17 mg/kg.

Residues of flonicamid in summer squash from eight trials were: 0.01 (2), 0.03 (3), 0.04 (2) and 0.08 mg/kg.

The median residues among the representative crops were within a 5-fold range (0.06 mg/kg vs. 0.05 vs 0.03 mg/kg) and the Kruskall-Wallis test indicated that the residues were not statistically different, therefore, the Meeting decided to combine the dataset as follows: 0.01 (2), 0.02, 0.03 (7), 0.04 (5), 0.05 (2) 0.06 (4), 0.07, 0.08, 0.09 (2), 0.12 and 0.17 mg/kg.

The Meeting estimated a maximum residue level for fruiting vegetables, cucurbits, of 0.2 mg/kg and an STMR of 0.04 mg/kg.

Fruiting vegetables, other than cucurbits

Results from supervised field trials on tomatoes, bell peppers and non-bell peppers were conducted in the US as well as supervised trials on greenhouse tomatoes conducted in Canada and the US were provided to the Meeting.

A total of 34 independent supervised trials were conducted in the US on field tomatoes (26), bell peppers (6) and non-bell peppers (2) according to the US GAP on fruiting vegetables, which allows three foliar spray applications of a WG formulation at a maximum rate of 0.1 kg ai/ha or two applications of a SG formulation at a maximum rate of 0.15 kg ai/ha. For both formulations, the crops may be harvested at a 0-day PHI.

Three additional trials were conducted in Canada and the US on greenhouse tomatoes where treatments were conducted according to the US GAP which allows two foliar spray applications at a maximum rate of 0.15 kg ai/ha with a 0-day PHI.

Only field tomato trials were conducted with both the WG and SG formulations, however, it was not clear which formulation resulted in the critical GAP:

Residues of flonicamid from 12 field tomato trials where the WG formulation was applied according to the US critical GAP for fruiting vegetables were: 0.03, 0.05, 0.06, 0.07, 0.08, 0.09 (3), 0.14, 0.15, 0.22 and 0.23 mg/kg.

Residues of flonicamid from 14 field tomato trials where the SG formulation was applied according to the US critical GAP for fruiting vegetables were: < 0.01, 0.05(2), 0.06, 0.07, 0.08, 0.10 (2), 0.11, 0.12 (2), 0.13, 0.15 and 0.19, mg/kg.

As highest residues in tomatoes were observed following treatment with the WG formulation, only these were considered when estimating the maximum residue level.

Residues of flonicamid from six bell pepper trials matching the US critical GAP for fruiting vegetables were: 0.06 (3), 0.10 and 0.11 (2) mg/kg.

Residues of flonicamid from two non-bell pepper trials matching the US critical GAP for fruiting vegetables, other than cucurbits were: 0.21 and 0.22 mg/kg.

As the GAP in the US is for the fruiting vegetables crop group, the median values from the trials conducted in the US on tomatoes, bell peppers and non-bell peppers were within 5-fold (0.09 mg/kg vs 0.08 mg/kg vs 0.21 mg/kg) and the Kruskall-Wallis test indicated that the residues from field trials were not statistically different, the Meeting decided to estimate a group maximum residue level. The residues in tomatoes, bell peppers and non-bell peppers were combined as follows: 0.03, 0.05, 0.06 (4), 0.07, 0.08, 0.09 (3), 0.10, 0.11 (2), 0.14, 0.15, 0.21, 0.22 (2) and 0.23 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.09 mg/kg for fruiting vegetables, other than cucurbits, excluding mushrooms and sweet corn.

Leafy vegetables

Leafy vegetables (excluding Brassica leafy vegetables)

Results from supervised field trials on head lettuce, leaf lettuce, spinach and radish leaves conducted in the US were provided to the Meeting.

A total of 18 independent supervised trials were conducted in the US on head lettuce (6), leaf lettuce (6) and spinach (6) according to the US GAP on leafy vegetables which allows three applications at a maximum rate of 0.1 kg ai/ha with a 0-day PHI.

A total of five independent supervised trials were conducted in the US on radish leaves according to the US GAP on root and tuber vegetables which allows three applications at a maximum rate of 0.1 kg ai/ha with a 3-day PHI.

Residues of flonicamid from six head lettuce (with wrapper leaves) trials matching the US GAP for leafy vegetables were: 0.39, 0.43, 0.49, 0.52, 0.58 and 0.62 mg/kg.

Residues of flonicamid from six trials on leaf lettuce matching the US GAP for leafy vegetables (except Brassica) were: 1.94, 2.18, 2.52, 2.67, 2.71, 3.06 and 3.11 mg/kg.

Side-by-side trials were conducted on cos lettuce comparing the WG formulation with the SG formulation with and without surfactant. These trials were not considered further in the estimation of the maximum residue level.

Residues of flonicamid from six trials on spinach matching the US GAP for leafy vegetables were: 4.82, 4.86, 5.71, 5.73, 6.59 and 6.97 mg/kg.

Residues of flonicamid from five trials on radish leaves matching the US GAP for root and tuber vegetables were: 0.21, 3.1, 5.4, 5.7 and 8.5 mg/kg.

As the GAP in the US is established for the leafy vegetables crop group, the Meeting decided to explore the possibility of setting a group MRL. The median residues in head lettuce, leaf lettuce and spinach, which are the representative commodities for this subgroup, differed by more than 5-fold (0.51 mg/kg vs 2.67 mg/kg vs 5.72 mg/kg). In addition, as the GAP for radish leaves differs from that of the other leafy vegetables, the Meeting decided to estimate maximum residue levels for each commodity based on the individual datasets without extrapolation to the entire subgroup.

The Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.51 mg/kg for head lettuce with wrapper leaves.

For leaf lettuce, the Meeting estimated a maximum residue level of 8 mg/kg and an STMR of 2.67 mg/kg

The Meeting estimated a maximum residue level of 20 mg/kg and an STMR of 5.72 mg/kg for spinach.

The Meeting estimated a maximum residue level of 20 mg/kg and an STMR of 8.50 mg/kg for radish leaves.

Brassica leafy vegetables

Results from supervised field trials on mustard greens conducted in the US were provided to the Meeting.

A total of eight independent supervised trials were conducted in the US on mustard greens according to the US GAP on Brassica (Cole) leafy vegetables which allows three applications at a maximum rate of 0.1 kg ai/ha with a 0-day PHI.

Residues of flonicamid from eight trials on mustard greens matching the US GAP for Brassica (Cole) leafy vegetables were: 2.04, 2.21, 3.96, 4.40, 4.78, 4.92, 6.87 and 8.31 mg/kg.

The Meeting estimated a maximum residue level of 15 mg/kg and an STMR of 8.31 mg/kg for the Brassica leafy vegetables subgroup.

Root and tuber vegetables

Results from supervised field trials on potatoes, carrots and radish roots conducted in the US and Australia (potatoes only) were provided to the Meeting.

A total of 23 independent supervised trials were conducted in the US on potatoes (16), carrots (2) and radishes (5) according to the critical GAP in the US which allows three applications at a maximum rate of 0.1 kg ai/ha with a 7-day PHI for potatoes and a 3-day PHI for carrots and radishes.

Residues of flonicamid from 16 potato trials matching the US GAP were: < 0.01 (15) and 0.015 mg/kg.

Residues of flonicamid from two carrot trials matching the US GAP were: 0.02 (2) mg/kg.

Residues of flonicamid from five radish trials matching the US GAP were: 0.02, 0.07, 0.10, 0.13 and 0.21 mg/kg.

The Meeting noted that in the US, group GAPs for root and tuber vegetables and tuberous and corm vegetables exist; however, as these GAPs are different for each crop group and there is an insufficient number of supervised residue trials provided for carrots, the Meeting decided to estimate individual maximum residue levels for potato and radish roots only.

For potatoes, the Meeting estimated a maximum residue level of 0.015 mg/kg and an STMR of 0.01 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.10 mg/kg for radish roots.

Celery

Results from supervised field trials on celery conducted in the US were provided to the Meeting.

A total of six independent supervised trials were conducted in the US on celery according to the US GAP for leafy vegetables, except Brassica vegetables, which includes the leaf petioles subgroup, and allows three applications at a maximum rate of 0.1 kg ai/ha with a 0 PHI.

Residues of flonicamid matching the US GAP were: 0.35, 0.43, 0.44, 0.45, 0.46, 0.93 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.45 mg/kg for celery.

Cereal grains

Results from supervised trials on wheat and barley conducted in Northern and Southern EU were provided to the meeting.

A total of 23 independent supervised trials were conducted in EU on wheat (15) and barley (8). The wheat trials were conducted according to the Slovenia GAP which allows two applications at a maximum rate of 0.07 kg ai/ha with a 28-day PHI.

As there is no GAP for barley, these trials were not considered further.

Residues of flonicamid in wheat grain matching the Slovenia GAP were: < 0.01 (11), 0.01, 0.02, 0.04 and 0.06 mg/kg.

The Meeting estimated a maximum residue level of 0.08 mg/kg and an STMR of 0.01 mg/kg for wheat.

Tree nuts

Results from supervised field trials on almonds, pecans and pistachios conducted in the US were provided to the Meeting.

A total of 12 independent supervised trials were conducted in the US on almonds (5), pecans (5) and pistachios (2) according to the US GAP which allows three applications at a maximum rate of 0.1 kg ai/ha with a 40-day PHI.

Residues of flonicamid in almond nutmeats matching the US GAP were: < 0.01 (5) mg/kg.

Residues of flonicamid in pecan nutmeats matching the US GAP were: < 0.01 (5) mg/kg.

Residues of flonicamid in pistachios matching the US GAP were 0.02 and 0.04 mg/kg.

As the Meeting could not conclude that there are no measurable residues in all tree nuts in the tree nut crop group and considering the insufficient number of supervised residue trials for pistachios, the Meeting agreed to estimate individual maximum residue levels for almonds and pecans at 0.01* mg/kg with an STMR of 0.01 mg/kg.

Oilseeds

Rape seed

Results from supervised field trials on rape seed conducted in the US were provided to the Meeting.

A total of nine independent supervised trials were conducted in the US on rape seed according to the US GAP which allows three applications at a maximum rate of 0.1 kg ai/ha with a 7-day PHI.

Residues of flonicamid matching the US GAP were: < 0.02, 0.02 (3), 0.04, 0.08, 0.09, 0.17 and 0.33 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg and an STMR of 0.04 mg/kg for rape seed.

Cotton seed

Results from supervised field trials on cotton conducted in the US and Australia were provided to the Meeting.

The GAP in the US is three applications at a maximum rate of 0.1 kg ai/ha with a 30-day PHI while the GAP in Australia is three applications at a maximum rate of 0.07 kg ai/ha with a 7-day PHI.

As the critical GAP is in Australia, only the Australian trials were considered.

Residues of flonicamid in cottonseed from eight independent supervised residue trials matching the Australian critical GAP were: 0.01 (2), 0.02, 0.04, 0.09, 0.13, 0.16 and 0.34 mg/kg.

The Meeting estimated a maximum residue level of 0.6 mg/kg and an STMR of 0.06 mg/kg for cottonseed.

Mint

Results from supervised field trials on fresh mint leaves conducted in the US were provided to the Meeting.

A total of three independent supervised trials were conducted in the US on mint according to the US GAP which allows three applications at a maximum rate of 0.1 kg ai/ha with a 7-day PHI.

Residues of flonicamid matching the US GAP were: 1.70, 1.92 and 2.36 mg/kg.

The Meeting estimated a maximum residue level of 6 mg/kg and an STMR of 1.92 mg/kg for mint.

Dried hops

Results from supervised field trials on dried hops conducted in the US were provided to the Meeting.

A total of four independent supervised trials were conducted in the US on dried hops according to the US GAP which allows three applications at a maximum rate of 0.1 kg ai/ha with a 10-day PHI.

Residues of flonicamid matching the US GAP were: 0.56, 1.15, 2.82 and 9.33 mg/kg.

The Meeting estimated a maximum residue level of 20 mg/kg and an STMR of 1.98 mg/kg for dried hops.

Teas

Results from supervised field trials on tea conducted in Japan were provided to the Meeting.

A total of two independent supervised trials were conducted in Japan on tea according to the Japanese GAP which allows one application at a maximum rate of 0.1 kg ai/ha with a 7-day PHI.

Residues of flonicamid in green tea leaves matching the Japanese GAP were: 15.7 and 20.1 mg/kg.

There is insufficient data for the Meeting to estimate a maximum residue level.

Animal feeds

Straw, fodder and forage of cereal grains and grasses including buckwheat fodder forage

Wheat

Results from supervised trials on wheat and barley conducted in Northern and Southern EU were provided to the meeting.

A total of 23 independent supervised trials were conducted in EU on wheat (15) and barley (8). The wheat trials were conducted according to the Slovenia GAP which allows two applications at a maximum rate of 0.07 kg ai/ha with a 28-day PHI.

As there is no GAP for barley, these trials were not considered further.

Residues of flonicamid in wheat forage matching the Slovenia Gap were: 0.64, 0.69, 0.83, 0.88 and 0.99 (2).

The Meeting estimated a maximum residue level of 3.0 mg/kg and a median of 0.86 mg/kg for wheat forage.

Residues of flonicamid in wheat straw matching the Slovenia GAP were: < 0.02 (5), 0.02, 0.04 (2), 0.05 (3), 0.08, 0.09, 0.11 and 0.23 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg and a median of 0.04 mg/kg for wheat straw and fodder, dry.

Alfalfa

Results from six independent supervised field trials on alfalfa (4) and clover (2) conducted in the US were provided to the Meeting.

The US GAP for alfalfa grown west of the Rockies allows two applications at a maximum rate of 0.10 kg ai/ha with PHIs of 14 days for seed and forage and 60 days for hay.

Two supervised trials were conducted on clover in the US, however, in the absence of a US GAP, these trials were not considered.

Four trials were conducted on alfalfa in the US, of which only two were conducted according to the US GAP. In the absence of a sufficient number of trials, the Meeting could not estimate a maximum residue level or a median residue for alfalfa seed, forage and hay.

Miscellaneous fodder and forage crops (fodder)

Almond hulls

Results from supervised field trials on almonds conducted in the US were provided to the Meeting.

Five independent trials were conducted on almonds in the US. The GAP in the US allows three applications at a maximum rate of 0.10 kg ai/ha with a PHI of 40 days.

Residues in almond hulls (dry weight) from five trials matching US GAP were: 0.92, 1.09, 1.81, 2.75 and 4.73 mg/kg. The meeting estimated a maximum residue level of 9 mg/kg and a median residue of 1.8 mg/kg.

Cotton gin trash

Results from supervised field trials on cotton conducted in the US and Australia were provided to the Meeting.

The GAP in the US is three applications at a maximum rate of 0.1 kg ai/ha with a 30-day PHI while the GAP in Australia is three applications at a maximum rate of 0.07 kg ai/ha with a 7-day PHI.

As the critical GAP is in Australia, only the Australian trials were considered.

The residues of flonicamid in cotton gin trash from eight independent supervised trials matching the Australian critical GAP were: 0.66, 1.20, 1.33, 1.60, 1.70, 2.30, 2.75, 3.00 and 3.72 mg/kg.

The Meeting estimated a median residue of 1.7 mg/kg.

Fate of residues during processing

High temperature hydrolysis

To simulate the degradation of flonicamid during pasteurization, baking, brewing, boiling and sterilisation, the hydrolysis of radio-labelled flonicamid was investigated in sterile buffered aqueous solutions.

After incubation at 90 °C (pH 4) for 20 minutes, 100 °C (pH 5) for 60 minutes or 120 °C (pH 6) for 20 minutes, no loss of radioactivity occurred. More specifically, flonicamid accounted

for at least 96% of the applied radioactivity. Therefore, very limited degradation of flonicamid was observed in aqueous buffer solutions under all the conditions tested with no significant degradation product being formed.

Processing

The Meeting received information on the fate of flonicamid residues and its metabolites TFNA-AM, TFNA and TFNG during the processing of raw agricultural commodities (RAC) like apples, peaches, plums, tomatoes, potatoes, rape seed, cotton and mint.

Processing factors calculated for the processed commodities of the above raw agricultural commodities are shown in the table below. STMR-Ps were calculated for processed commodities for which maximum residue levels were estimated.

RAC	Processed Commodity	Calculated processing factors	Best estimate	STMR-P
		Flonicamid		
Peaches	Canned peaches	0.3, 0.5, 0.3, 3.3	0.3 (median)	0.08
	Juice	1.0, 1.0, 0.3, 0.5	0.8 (median)	1.8
	Jam	0.3, 1.0, 1.0, 0.2	0.7 (median)	0.16
	Puree	0.7, 1.0, 1.0, 0.8	0.9 (median)	0.21
Plums	Dried prunes	1.0	1.0	0.04
Tomato	Paste	16.1	16.1	1.45
Potato	Chips	0.95	0.95	0.01
	Flakes	2.7	2.7	0.03
Canola	Refined oil	< 0.1	0.1	0.004
Cotton	Refined oil	< 0.24 (US), 0.6 and 0.04 (AUS)	0.32 (mean; AUS)	0.02
Mint	Oil	< 0.03	0.03	0.06

As the residue concentration in both apple juice and apple pomace were higher than in fresh apple which is not physically possible, the Meeting determined that the apple processing study was not reliable and did not calculate a processing factor for juice.

As the residue concentration is higher in tomato paste than in fresh tomato, the Meeting estimated a maximum residue level of 7.0 mg/kg by multiplying the maximum residue level for fruiting vegetables, other than cucurbits, (0.4 mg/kg) by 16.1.

Residues in animal commodities

Farm animal feeding studies

The Meeting received information on the residue levels arising in tissues and milk when three groups of dairy cows were fed with a diet containing 2.50, 6.89 and 23.7 ppm of a 1:1 mixture of flonicamid:TFNG for 28 consecutive days. As demonstrated in the metabolism studies, residues of TFNG present in feed items may be converted to TFNA-AM. Therefore, the Meeting concluded that the test material used in the feeding studies was appropriate.

In milk, no quantifiable (< LOQ) residues of flonicamid were detected in any test group. For TFNA-AM, the average residues increased from < LOQ in the low dose group to 0.02 mg/kg in the mid dose group and to 0.08 mg/kg in the high dose group.

In liver, no quantifiable residues of flonicamid were detected. For TFNA-AM, residues were detected in the mid and high dose groups above the LOQ using two different analytical methods (FMC-P-3580/RCC 844743) with different LOQ (0.025/0.01 mg/kg). TFNA-AM levels increased from less than LOQ in the low dose group to 0.039/0.02 mg/kg in the mid dose group and 0.113/0.05 mg/kg in the high dose group.

In kidney, TFNA-AM was detected in the medium and high dose groups above the LOQ using the same analytical methods as those used for kidney. TFNA-AM levels increased from

levels below LOQ in the low dose group to 0.031/0.02 mg/kg in the mid dose group and 0.105/0.09 mg/kg in the high dose group.

In muscle, only TFNA-AM was found. The level increased from below LOQ (0.025 mg/kg) in the low dose group to 0.027 mg/kg in the mid dose group and 0.088 mg/kg in the high dose group. Similarly, only TFNA-AM was measurable in fat and only at the high dose level (0.015 mg/kg).

The Meeting also received information on the residue levels arising in tissues and eggs when groups of laying hens were fed with a diet containing 0.26, 2.51, 7.47 and 25.83 ppm of a 1:1 mixture of flonicamid:TFNG for 28 consecutive days.

The average flonicamid residues in eggs increased from < LOQ in the very low and low dose groups to 0.02 mg/kg in the mid dose group and to 0.08 mg/kg in the high dose group. Average residues of TFNA-AM increased from < LOQ in the very low and low dose groups to 0.27 mg/kg in the mid dose group and 0.95 mg/kg in the high dose group.

No quantifiable residues (< LOQ) of flonicamid were found in muscle in any treatment group. No quantifiable residues (< LOQ) of TFNA-AM was measurable in muscle at the very low dose group, but there appeared to be a dose response relationship at all other dose levels; 0.049 mg/kg in the low dose group, 0.168 mg/kg in the mid dose group and 0.654 mg/kg in the high dose group.

In liver and fat, no quantifiable residues (< LOQ) of flonicamid were found at any dosing level. For liver, TFNA-AM residues increased from < 0.01 mg/kg (very low) to 0.05 mg/kg (low) to 0.17 mg/kg (mid) and 0.71 mg/kg (high) while for fat, TFNA-AM residues increased from 0.01 mg/kg (very low) to 0.02 mg/kg (low) to 0.06 mg/kg (mid) and 0.29 mg/kg (high).

Estimated dietary burdens of farm animals

Maximum and mean dietary burden calculations for flonicamid are based on the feed items evaluated for cattle and poultry as presented in Annex 6. The calculations were made according to the livestock diets from Australia, the EU, Japan and US-Canada in the OECD feeding table.

The foliar application of flonicamid to apples, cabbage, potato, almonds, rape seed, cotton and wheat resulted in residues of flonicamid in the following feed items: wet apple pomace, head cabbage with wrapper leaves, potato culls, almond hulls, rape seed meal, undelinted cottonseed, cotton seed hulls, cottonseed meal, gin trash, wheat forage, grain and straw. Based on the named feed items, the calculated maximum animal dietary burden for dairy or beef cattle was in Australia (3.96 ppm), followed by EU (1.39 ppm) and US-Canada (0.29 ppm).

	Livestock dietary burden, flonicamid, ppm of dry matter							
	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0.27	0.13	1.39	1.02	3.96 a	3.44 c	0.003	0.003
Dairy cattle	0.81	0.70	0.82	0.71	2.38 b	2.07 d	0.002	0.002
Poultry—broiler	0.03	0.03	0.01	0.01	0.02	0.02	0	0
Poultry—layer	0	0	0.40 e	0.34 f	0	0	0	0

[a] Suitable for MRL estimates for mammalian meat, fat and edible offal

[b]. Suitable for MRL estimates for milk

[c] Suitable for STMR estimates for mammalian meat, edible offal

[d] Suitable for STMR estimate for milk

[e] Suitable for MRL estimates for eggs, meat, fat and edible offal of poultry

[f] Suitable for STMR estimates for eggs, meat, fat and edible offal of poultry

Animal commodities maximum residue level estimation

As all dietary burdens were lower than the lowest feeding levels from the dairy cow and laying hen feeding studies and since all residues of flonicamid and TFNA-AM were below the limit of quantitation at the lowest feeding levels, there is no expectation of any measurable transfer of residues from the feed items into the livestock commodities (see tables below).

	Feed level (ppm) for milk residues	Total flonicamid and TFNA-AM residues in milk (mg/kg)	Feed level for tissue residues (ppm)	Flonicamid and TFNA-AM Residues			
				Muscle	Liver	Kidney	Fat
Maximum residue level—beef or dairy cattle

Dietary burden and residue estimate	0.40	0.03	0.40	0.02	0.02	0.02
STMR—poultry broiler or layer						
Feeding study	0.26 2.51	0.02 0.09	0.26 2.51	< 0.02 0.06	< 0.02 0.06	< 0.02 0.03
Dietary burden and residue estimate	0.34	0.02	0.34	0.02	0.02	0.02

The Meeting estimated maximum residue levels of 0.02* mg/kg for mammalian fats, 0.04 mg/kg for milks and 0.05 mg/kg for meat from mammals other than marine mammals and 0.06 mg/kg for edible offal (mammalian). The STMRs for mammalian fats, milks, meat from mammals other than marine mammals and edible offal (mammalian) are 0.02 mg/kg, 0.04 mg/kg. 0.047 mg/kg and 0.051 mg/kg, respectively.

In addition, the Meeting estimated maximum residue levels of 0.02* mg/kg for poultry meat (including Pigeon meat), poultry fats and edible offal of poultry and 0.03 mg/kg for eggs. The STMRs were 0.02 mg/kg, 0.02 mg/kg, 0.02 mg/kg and 0.02 mg/kg for meat, edible offal, fat and eggs, respectively.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with the MRL and for estimation of dietary intake for plant commodities: *Flonicamid*

Definition of the residue for compliance with the MRL and for estimation of dietary intake for animal commodities: Sum of flonicamid, N-cyanomethyl-4-(trifluoromethyl)nicotinamide and the metabolite TFNA-AM, 4-(trifluoromethyl)nicotinamide.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Dietary Intakes (IEDIs) of flonicamid were calculated for the 17 GEMS/Food cluster diets using STMRs and STMR-Ps estimated by the current Meeting (Annex 3 to the 2015 Report) estimated by the current Meeting (Annex 3). The ADI is 0–0.07 mg/kg bw and the calculated IEDIs were 1–10% of the maximum ADI. The Meeting concluded that the long-term intake of residues of flonicamid resulting from the uses considered by the current JMPR is unlikely to present a public health concern.

Short-term intake

The Meeting decided that an ARfD is unnecessary and concluded that the short-term intake of residues resulting from the use of flonicamid, considered by the present Meeting, is unlikely to present a public health concern.

FLUMIOXAZIN (284)

The first draft was prepared by Mr David Lunn, Plants, Food & Environment Directorate, Ministry for Primary Industries, Wellington, New Zealand

EXPLANATION

Flumioxazin (S-53482) is variously described as a dicarboxamide, diphenyl-ether or a phenyl-phthalimide herbicide, used for pre-emergent and post-emergent control of a range of broad-leaf weeds and suppression of some grass weed species in a range of fruit, vegetable and field crops. It is non-systemic but is readily absorbed by the foliage of susceptible plants. In the presence of oxygen and light flumioxazin inhibits protoporphyrinogen oxidase resulting in accumulation of porphyrins. The photosensitising action of the accumulated porphyrins enhances peroxidation of membrane lipids and this leads to irreversible damage to the membrane function and structure.

Authorisations exist for the use of flumioxazin as pre-emergence or early post-emergence broadcast treatments, as directed inter-row band soil treatments and as a pre-harvest desiccant (harvest aid) treatment in North America, Europe, Latin America, Australia and some Asian countries.

Flumioxazin was scheduled by the 46th Session of the CCPR as a new compound for consideration by the 2015 JMPR. Residue and analytical aspects of flumioxazin were considered for the first time by the present meeting. The manufacturer submitted studies on metabolism, analytical methods, supervised field trials, processing, freezer storage stability and environmental fate in soil.

In this evaluation, the values presented in the tables are as reported in the various studies, but in the accompanying text, they have generally been rounded to two significant digits.

IDENTITY

ISO common name:	Flumioxazin
Code number	S-53482, V-53482
IUPAC name:	*N*-(7-fluoro-3,4-dihydro-3-oxo-4-prop-2-ynyl-2*H*-1,4-benzoxazin-6-yl)cyclohex-1-ene-1,2-dicarboximide
Chemical Abstracts name:	2-[7-fluoro-3,4-dihydro-3-oxo-4-(2-propynyl)-2*H*-1,4-benzoxazin-6-yl]-4,5,6,7-tetrahydro-1*H*-isoindole-1,3(2*H*)-dione
CAS number	103361-09-7
CIPAC number	578
Molecular mass:	354.3
Molecular formula	$C_{19}H_{15}FN_2O_4$
Structural formula:	
PHYSICAL AND CHEMICAL PROPERTIES

Pure active ingredient

A detailed chemical and physical characterisation of the active ingredient is given in the following table.

Test or Study & Annex point	Test material purity and specification	Findings and comments	Reference
Melting point	Pure ai (99.6%)	203.51–209.74 °C	SBP-0056
Boiling point	Pure ai (99.6%)	No boiling point measured decomposition at *ca.* 273 °C	SBP-0056
Relative density	Pure ai (99.6%)	1.4157 (20.1 °C)	SBP-0056
Vapour pressure	Pure ai (99.5%)	3.2×10^{-4} Pa at 22 °C	SBP-0010
pH	Technical (97.6%)	7.29 (25 °C) in saturated solution	SBP-0009
Henry's law constant	calculated	K_H = 0.145 Pa m³ mol^{-1} (20–22 °C)	SBH-059
Appearance	Pure ai (99.5%) Technical (97.6%)	White odourless powdery solid Yellowish brown odourless powder	SBP-0011
Solubility in water	Pure ai (99.6%)	0.786 ± 0.1081 mg/L (20 °C) in distilled water pH effect not investigated because of the neutral properties of flumioxazin	SBP-0057
Solubility in organic solvents (g/L, 25 °C)	Technical (97.6%)	Dichloromethane: 191 Tetrahydrofuran: 53.8 Acetonitrile: 32.3 Ethyl acetate: 17.8 Acetone: 17 Methanol: 1.56 n-Octanol 0.163 Hexane: 0.0247	SBP-0011
Octanol/water partition coefficient	Pure ai (99.9%)	Log P_{OW} 2.55 (20 °C, pH 5.92–5.98)	SBP-0001
Hydrolysis (sterile buffer in the dark, 25 °C)	^{14}C labelled pure ai (> 99%)	THP-label / Phenyl-label DT_{50} (pH 5): 3.4 days / 5 days DT_{50} (pH 7): 19–24 hours / 23–26 hours DT_{50} (pH 9): 14–15 minutes / 21–23 minutes	SBM-0006 SBM-0005
Photolysis characteristics	^{14}C labelled pure ai (> 99%)	DT_{50} (pH 5, 25 °C):20.94 hrs (phenyl-label) DT_{50} (pH 5, 25 °C):26.31 hrs (THP-label) under artificial sunlight conditions Degradates: THPA, APF and 482-PHO	JMPS 578

Formulations

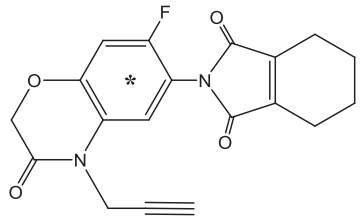
Formulations of flumioxazin are available for use as pre-emergent or post-emergent broadcast or banded soil applications, directed inter-row band sprays in established crops and pre-harvest desiccants, both as solo products or co-formulated or tank-mixed with other herbicides.

Specifications for flumioxazin technical material have been established by the JMPS (2015) and published as FAO Specification 578, available on the FAO Website.

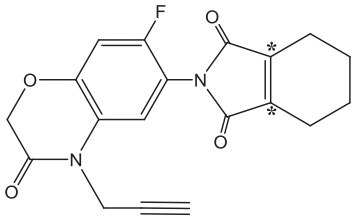
FORMULATION TYPE	FLUMIOXAZIN CONTENT	OTHER ACTIVE INGREDIENTS
WG (Water dispersible granule)	510 g/kg 500 g/kg 400 g/kg	chlorimuron ethyl
GR (Granule)	2.5 g/kg	

METABOLISM AND ENVIRONMENTAL FATE

The Meeting received flumioxazin metabolism studies on plants (soya beans, grapes, sugar cane, apples and peanuts), animals (rats, lactating goats and laying hens) and rotational crops (lettuce, carrots and wheat). Flumioxazin radio-labelled on the phenyl ring or the tetrahydrophthaloyl (THP) ring were used in these studies. The label positions (*) are shown below:



[phenyl-^{14}C]-flumioxazin



[THP-^{14}C]-flumioxazin

Major metabolites identified in these studies and discussed in this evaluation are listed below.

Compound Name/Code	Structure		Matrices
Flumioxazin (S-53482) (V-53482)		*N*-(7-fluoro-3,4-dihydro-3-oxo-4-prop-2-ynyl-2*H*-1,4-benzoxazin-6-yl)cyclohex-1-ene-1,2-dicarboxamide	Plants Goat Hen Rat Soil Photolysis
3-OH-Flumioxazin		7-fluoro-6-(3-hydroxy-3,4,5,6-tetrahydrophthalimido)-4-(2-propynyl)-2H-1,4-benzoxazin -3(4H)-one	Goat Hen Rat
4-OH-Flumioxazin		7-fluoro-6-(4-hydroxy-3,4,5,6-tetrahydrophthalimido)-4-(2-propynyl)-2H-1,4-benzoxazin-3(4H)-one	Goat Hen Rat

Compound Name/Code	Structure		Matrices
Metabolite B or metabolite F 3-OH-SAT-482		7-fluoro-6-(3-hydroxy-1,2-cyclohexanedicarboximido)-4-(2-propynyl)-2*H*-1,4-benzoxazin-3(4*H*)-one	Goat Rat
4-OH-SAT-482 Exponent asked for revised structures		7-fluoro-6-(4-hydroxy-1,2-cyclohexanedicarboximido)-4-(2-propynyl)-2*H*-1,4-benzoxazin-3(4*H*)-one	
Metabolite C	 OR 	not available	Goat
3-OH-Flumioxazin-SA		7-fluoro-6-(1-sulfo-3-hydoxy-1,2-cyclohexanedicarboximido)-4-(2-propynyl)-2H-1,4-benzoxazin-3(4H)-one	Goat Hen Rat
3-OH-Flumioxazin-ASA		5-fluoro-2-(2-propynylamino-4-(1-sulfo-3-hydroxy-1,2-cyclohexanedicarboximide)phenoxyacetic acid	Rat
4-OH-Flumioxazin-SA		7-fluoro-6-(1-sulfo-4-hydroxy-1,2-cyclohexanedicarboximido)-4-(2-propynyl)-2H-1,4 benzoxazin-3(4H)-one	Goat Hen Rat

Compound Name/Code	Structure		Matrices
482-HA		N-(7-fluoro-3,4-dihdyro-3-oxo-4-prop-2-ynyl-2H- 1,4-benzoxazin-6-yl)cyclohex-1-ene-1-carboxamide-2-carboxylic acid	Plants (rotational) Goat Rat Soil Photolysis
482-CA		2-[7-fluoro-3-oxo-6-(3,4,5,6-tetrahydrophthalimido)-2H-1,4-benzoxazin-4-yl] propionic acid	Plants (rotational) Soil
SAT-482		6-(cis-1,2-cyclohexanedicarboximido)-7-fluoro-4-(2-propynyl)2H-1,4-benzoxazin-3(4H)-one	Goat Rat
1-OH-SAT-482		not available	Plants (rotational)
IMOXA		2-[7-fluoro-3,4-dihydro-3-oxo-2H-1,4-benzoxazin-6-yl]-4,5,6,7-tetrahydro-1H-isoindole-1,3(2H)-dione	Plants (rotational) Soil Photolysis
APF		6-amino-7-fluoro-4-(2-propenyl)-2H-1,4-benzoxazin-3(4H)-one	Plants Goat Hen Rat Soil Photolysis
Ac-APFA		4-acetylamino-5-fluoro-2-(2-propynylamino)phenoxyacetic acid	Rat

Compound Name/Code	Structure		Matrices
1-OH-HPA		1-hydroxy-*trans*-1,2-cyclohexanedicarboxylic acid	Plants Rat Photolysis
THPA		3,4,5,6-tetrahydrophthalic acid	Plants Goat Hen Rat Soil Photolysis

3-OH-THPA		3-hydroxy-1-cyclohexene-1,2-dicarboxylic acid	Hen
4-OH-THPA		4-hydroxy-1-cyclohexene-1,2-dicarboxylic acid	Goat Hen
PNF		7-fluoro-6-nitro-4-(2-propynyl)-2*H*-1,4-benzoxazin-3(4*H*)-one	Plants

Environmental fate

The Meeting received information the environmental fate and behaviour of flumioxazin, including hydrolytic stability, photochemical degradation in soils and aerobic metabolism studies.

Hydrolysis

The hydrolytic degradation of flumioxazin was investigated at pH 5, 7 and 9 using either [phenyl-^{14}C]-flumioxazin or [THP-^{14}C]-flumioxazin and reported by Katagi, 1990 [Ref: SBM-0005 and Ref: SBM-0006].

Radio-labelled flumioxazin (0.1 mg/L) was incubated in the dark in sterile aqueous buffered solutions at pH 5, 7, and 9 for up to 30 days at 25 °C. Samples were taken at regular intervals throughout the study and were analysed for total radioactivity by LSC. HPLC was used

to determine the hydrolysis rate and identify the degradation products. Further characterization of degradation products was carried out by two-dimensional TLC with reference standards. The hydrolytic half-lives at each pH were calculated from the analytical data.

In both studies, 94–105% of the applied radioactivity was recovered in all samples analysed. Flumioxazin was rapidly hydrolysed in all three buffered solutions and the half-lives were calculated to be about 3.4–5 days at pH 5, 19–26 hours at pH 7 and 14–23 minutes at pH 9.

The major degradation products after 30 days of incubation in the phenyl-label study were APF (87%) at pH 5; APF (80%) and 482-HA (8–10%) at pH 7; and 482-HA (99%) at pH 9. In the THP-label study, the major degradation products were THPA (96%) and Δ^1-TPA (2.5%) at pH 5; THPA (84%), Δ^1-TPA (6%) and 482-HA (8%) at pH 7; and 482-HA (96%) at pH 9.

The proposed degradation pathway involves hydrolysis to the amide 482-HA, with further cleavage of the amide link occurring at pH 7 or below, forming THPA (and its anhydride Δ^1-TPA) and APF.

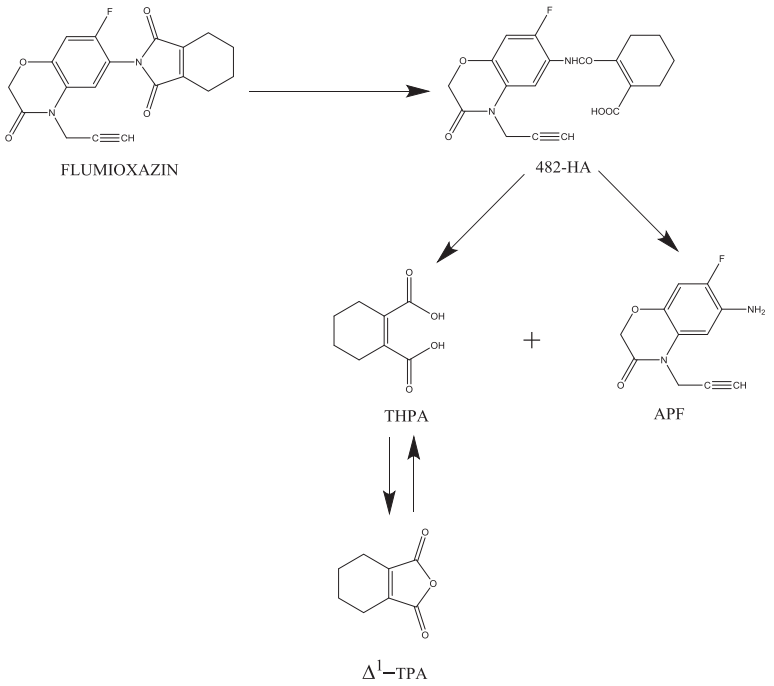

Fig 1 Proposed degradation pathway of flumioxazin in aqueous solutions

Photochemical degradation in soil

Artificial sunlight photo-degradation of [phenyl-^{14}C]-flumioxazin and [THP-^{14}C]-flumioxazin in sandy loam soils was investigated in two studies reported by Fathulla, 1993 [Ref: SBM-0029 and Ref: SBM-0035], respectively.

In these studies, the radio-labelled flumioxazin was applied in acetonitrile to thin layers (1–2 mm thick) of similar Californian sandy loam soils (61–63% sand, 29–30% silt, 8–9% clay, 0.9–1.4% O.M., pH 7.6–7.9) and the soil moisture was adjusted to 75% FC. Samples were irradiated (xenon lamp) for about 12 hours/day at 25–28 °C and duplicate samples were analysed immediately after fortification (Day 0) and intervals for the next 6–14 days.

Soil samples were extracted with acetone:water (5:1, v/v) and then with acidified (pH 1) acetone:water, and analysed using thin-layer chromatography. In the phenyl-label study, the post-

extracted samples containing more than 10% AR were more exhaustively extracted by acid then base refluxing in methanol or by refluxing in dimethylformamide/oxalic acid then basic methanol.

The mean recovery of the applied radioactivity in both studies ranged from 89% to 108%. Volatiles did not exceed 0.5% of the applied radiocarbon for the irradiated samples or 0.2% for the dark controls.

In the phenyl-label study, the acetone extracts from the Day-0 samples contained 102% AR and this decreased in the Day-6 irradiated samples to 48% AR (86% AR in the dark control samples). The more aggressive reflux treatments were able to extract most of the remaining residue, leaving less than 10% AR unextracted.

In the THP-label study, the radioactivity in the combined acetone:water extracts decreased from an initial 99% AR to 83% AR (irradiated) and 87% AR (dark controls) by the end of the 14-day study period, with an increase in the amount of ^{14}C bound to soil, up to 9.3% AR in the irradiated samples and 5% AR in the dark controls.

Flumioxazin accounted for 97–99% AR in the Day-0 samples, decreasing in the irradiated samples to 29% (Day 6—phenyl-label) and 82% AR (Day 7—THP-label) and to 37% AR in the THP-label samples on Day 14. No other TLC areas of radioactivity were more than 10% AR except for Δ^1-TPA and THPA.

Levels of Δ^1-TPA peaked at 22% AR on Day 9 in the irradiated samples, but were < 10% AR in all other sampling times (and in all dark control samples). THPA reached a maximum of about 13% AR (10% AR in the dark control samples). Other minor components were identified as IMOXA and 1-OH-HPA, both measured at < 4% AR in the irradiated samples.

[a] Samples taken on Day 6 in the phenyl-label study and Day 7 in the THP-label study

Radio-labelled flumioxazin degraded more rapidly on irradiated soil than on dark soil, with the amount of ^{14}C bound to soil increasing over time. The calculated soil degradation half-lives were 3.2 days (phenyl-label study) and 8.4 days (THP-label study) and were 12–16 days in non-irradiated samples.

The proposed degradation pathways include hydrolysis of the parent to the amide 482-HA, with further cleavage of the amide link, forming THPA (and its anhydride Δ^1-TPA) and then 1-OH-HPA and also the dealkylation of flumioxazin to form IMOXA.

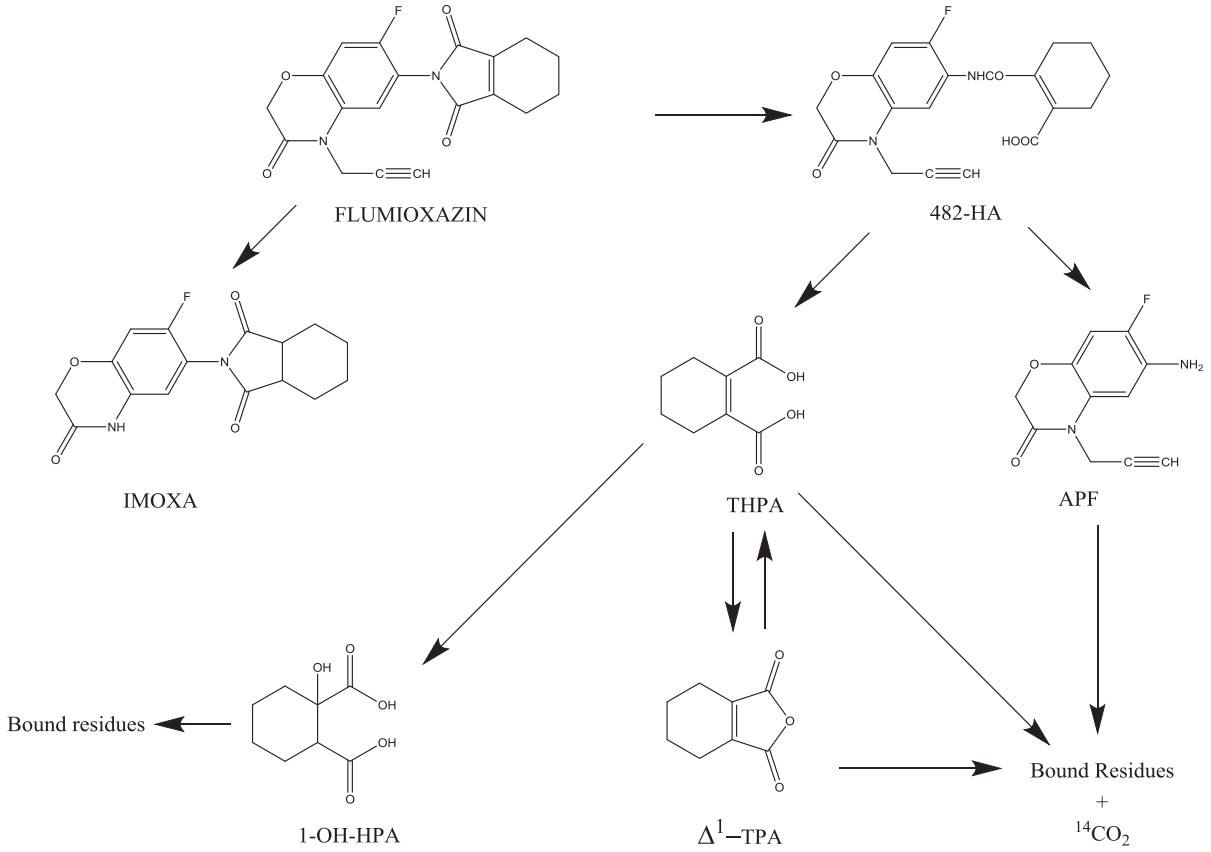

Fig 2 Metabolic pathway proposed for photochemical degradation of flumioxazin on soil

Aerobic soil metabolism

The degradation of flumioxazin in soil was investigated under aerobic conditions using phenyl-labelled flumioxazin (Fathulla, 1991 [Ref: SBM-0012]) and using THP-labelled flumioxazin ((Fathulla, 1993 [Ref: SBM-0030]). In these studies, radio-labelled flumioxazin was applied to sieved, sandy loam soils at a rate of 0.25–0.26 mg/kg, equivalent to about 0.3 kg ai/ha (7.6 cm depth). The characteristics of the soils are summarized below.

Table 3 Characteristics of the soils used in the flumioxazin aerobic soil metabolism studies

SOIL CHARACTERISTICS	PHENYL-LABEL STUDY	THP-LABEL STUDY
Soil type	Sandy Loam	Sandy Loam
Sand	67%	61.2%
Silt	29%	30%
Clay	4%	8.8%
Organic matter	1.2%	1.4%
Cation exchange capacity	18 meq/100 g	6.4 meq/100 g
pH (H_2O)	7.8	7.9
Field moisture capacity	8.9% (at 0.33 bar)	13.4

The soil samples were incubated at 25 °C in glass chambers maintained in a dark, temperature-controlled room for up to 181 days in the phenyl-label study and up to 91 days in the

THP-label study. The glass chambers were connected to traps containing charcoal, ethylene glycol and 2-ethoxyethanol:ethanolamine (1:1, v/v) for collection of volatile organic components and carbon dioxide. Samples were collected for analysis of radioactivity on Day 0 and at various intervals throughout the study periods and extracted with acetone:water (5:1, v/v) and acetone: 0.1 N HCl (9:1, v/v). The combined extracts were analysed by LSC and the distribution of radioactivity in the samples was determined by two-dimensional TLC, HPLC, and comparison with reference standards. The radioactivity remaining in the soil was determined by combustion and LSC. Residues were further extracted with acetonitrile: 0.25 N HCl (4:1, v/v) then 0.5 N sodium hydroxide in the phenyl-label study and acetonitrile: methanol:0.1 N HCl (25:15:10) followed by 0.5 N sodium hydroxide in the THP-label study, with analysis by TLC or LSC. Extraction efficiencies ranged from 94–102% in the two studies.

Radioactivity was distributed primarily among unchanged flumioxazin, CO_2 and soil-bound residues with minor identified components being 482-HA, 482-CA, APF, Δ^1-TPA, THPA and IMOXA. None of these individually exceeded 8% AR. Radioactivity recovered as CO_2 accounted for 12% of the applied radioactivity by Day 181 in the phenyl-label study and accounted for 55% AR at the end of the 91-day TPH-label study period.

Flumioxazin accounted for about 3.5% of the applied radioactivity in phenyl-label soils incubated for 89–181 days, and about 12% AR in the THP-label soils incubated for 90 days and the calculated half-lives in the respective studies were 12 days and 17.5 days. Calculated DT_{90} values (FOMC) were about 51 days (phenyl-label) and 95 days (THP-label).

[a] Mean of duplicate samples

[b] Identified as IMOXA plus an unknown component

[c] Identified as 482-HA and 482-CA

Flumioxazin degrades in aerobic soil with calculated half-lives of 12–18 days, with degradation products being CO_2 and a number of minor soil-bound degradates. The proposed metabolic pathways include hydrolysis of the parent compound to 482-HA, oxidation to 482-CA, and by dealkylation to IMOXA. Both IMOXA and 482-HA hydrolyse to THPA, which would be in equilibrium with Δ^1-TPA. THPA appears to be an end product that is incorporated into soil organic components or oxidized to CO_2.

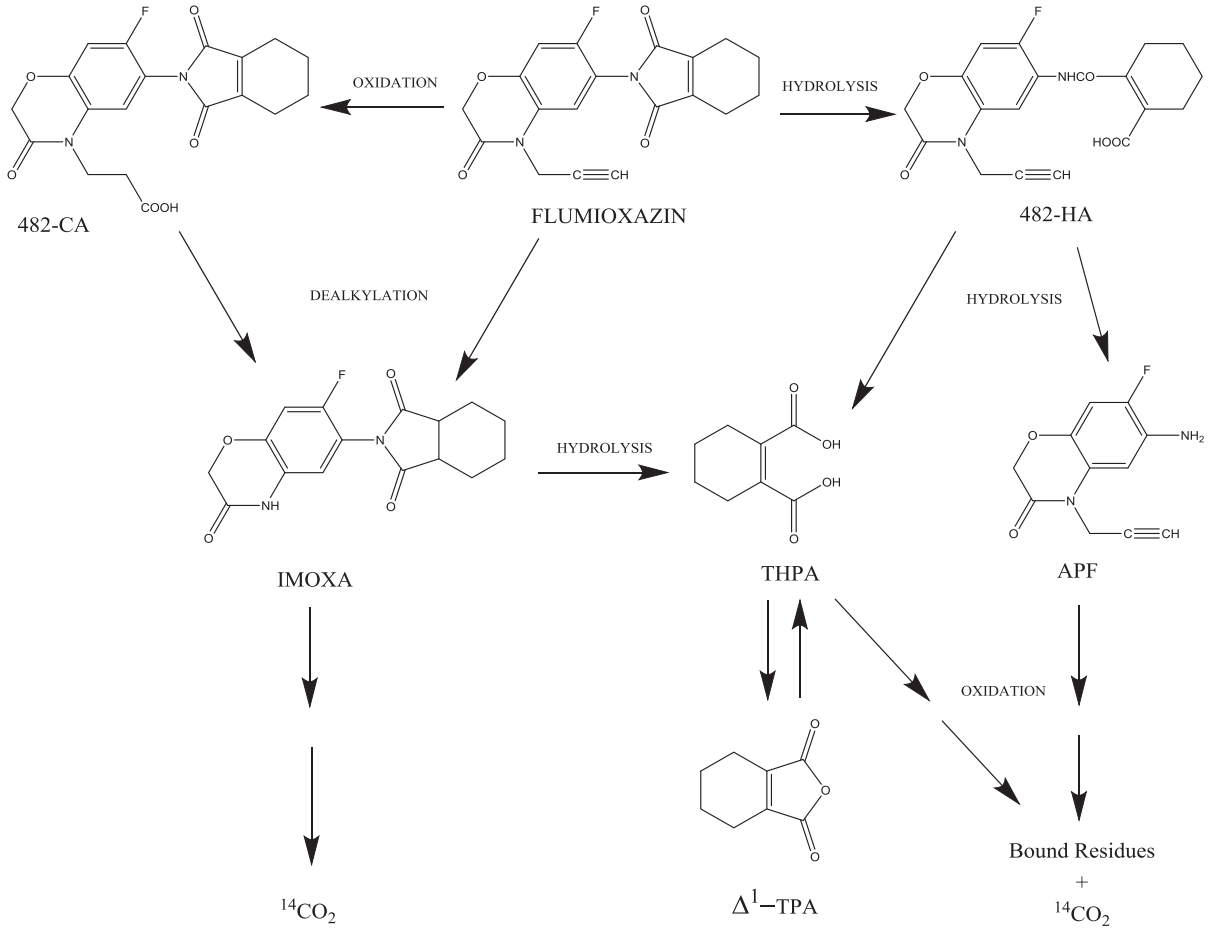

Fig 3 Metabolic Pathway for Aerobic Degradation of Flumioxazin in Soil

Flumioxazin is rapidly hydrolysed in aqueous solutions with average half-lives of 4–5 days (pH 5) decreasing to about 20 minutes at pH 9. Degradation products include 482-HA, THPA (and its anhydride Δ^1-TPA) and APF. The compound 482-HA was the predominant degradate (> 97%) in the pH 9 solution and the cleavage compounds APF and THPA were the major components in the pH 5 and 7 solutions.

Radio-labelled flumioxazin degraded more rapidly on irradiated soil than on dark soil, with the amount of ^{14}C bound to soil increasing over time. THPA and its anhydride Δ^1-TPA together accounted for up to 29% AR in irradiated samples (up to 17% in dark samples). The calculated soil degradation half-lives were 3.2 days (phenyl-label study) and 8.4 days (THP-label study) and were 12–16 days in non-irradiated samples.

In aerobic soil, calculated half-lives for flumioxazin are 12–18 days, with degradates 482-HA, 482-CA and IMOXA, each accounting for less than 7% of the applied radioactivity and generally present at < 0.01 mg/kg. The parent compound accounted for the majority of extractable radioactivity in almost all samples examined.

Plant metabolism

The Meeting received plant metabolism studies on soya beans, grapes, sugar cane, apples, peanuts and rotational crops following treatments with flumioxazin radio-labelled in the phenyl ring or the tetrahydrophthaloyl (THP) ring.

Grape

In a confined metabolism study on grape vines reported by Goodyear, 1998 [Ref: SBM-0064], flumioxazin, radio-labelled in the phenyl ring or the THP ring, was applied to soil surrounding grape vines at a rate equivalent to 0.6 kg ai/ha, the vines were grown to maturity in a glass house and at maturity (91 DAT), samples of grapes and shoots were extracted with acetone:water (1:1, v/v) and radioactivity in the extracts was measured by liquid scintillation counting (LSC) and by combustion analysis in the post-extraction solids.

Total radioactivity in the mature grapes and shoots were extremely low. The mean levels of radioactivity in grapes were 0.0021 mg/kg (-phenyl label) and 0.0054 mg/kg (THP-label) and in the shoots, radioactivity measured 0.014 mg/kg (-phenyl label) and 0.04 mg/kg (THP-label).

The majority of the residue (78–92%) was extracted into acetone or acetone:water with 9–21% of the residue remaining "bound" to the plant material. HPLC analysis of the aqueous extracts indicated the presence of a number of metabolites, the majority of which were polar in nature and were not retained on the column under the chromatographic conditions used. The polar fraction contained about 58% TRR, one other metabolite was present at about 11–14% TRR and eight other components were each present at < 6% TRR. Co-chromatography of the radioactivity with the known standards was not possible due to the high levels of UV-absorbing co-extracted samples.

Apple

In a metabolism study on apples reported by Jalal, 2003 [Ref: SBM-0073], flumioxazin, radio-labelled in the phenyl ring or the THP ring, was applied twice as broadcast sprays to bare soil (1.2 m × 1.2 m loamy sand plots) surrounding 4 year-old trees, with about 30 cm of tree trunk receiving direct spray. Treatments equivalent to 0.47 kg ai/ha were applied 47 days before fruit thinning and 60 days later (about 60 days before fruit maturity).

Apples were sampled and analysed at tree thinning (immature apples) and at harvest (mature apples. Combustion analysis was validated using spiked control apples, with a recovery rate of about 95%.

Total radioactive residues (TRR) were 0.002 mg/kg in immature apples from either the [phenyl-^{14}C]flumioxazin treated plot or from the [THP-^{14}C]flumioxazin treated plot. TRRs were 0.001 mg/kg in the mature apples from the [phenyl-^{14}C]flumioxazin treated plot and 0.003 mg/kg in apples from the [THP-^{14}C]flumioxazin treated plot. Since these residue levels were extremely low, further characterization or identification of the residues could not be conducted.

Table 5 Radioactive residues in apples following 1–2 soil/trunk applications of [^{14}C]flumioxazin at rates equivalent to 0.47 kg ai/ha

TREATMENT	TOTAL RADIOACTIVITY (MG/KG)	
	Immature apple (47 days after 1st application)	Mature apple (60 days after 2nd application)
Control	< 0.001	< 0.001
Phenyl-label	0.002	0.001
THP-label	0.002	0.003

Peanut

In a metabolism study on peanuts reported by Comezoglu, 1994 [Ref: SBM-0044], flumioxazin radio-labelled in the phenyl ring or the THP ring was applied once as a pre-emergent broadcast soil treatment at rates equivalent to 0.11 kg ai/ha (3 days after sowing) or 0.33 kg ai/ha as a pre-plant treatment, 32 day before sowing (treated plots were re-sown following poor initial crop emergence). Treatments were made by mixing the labelled flumioxazin into soil (sandy loam) taken from each plot and adding the treated soil back to the tops of the respective plots.

Samples of mature foliage and whole peanuts were harvested from the 0.11 kg ai/ha plots 194 days after treatment (DAT) and from the 0.33 kg ai/ha plots 245 days after resowing (277 DAT). Samples of foliage (vines) were frozen immediately after sampling. Whole peanuts were washed to remove adhering soil and separated into hulls, seed coats and nutmeats. Samples were frozen and shipped on dry ice by overnight courier to the analytical laboratory where samples were stored at < –10 °C prior to analysis.

Samples were homogenized with dry ice and total radioactive residues (TRR) were measured by combustion and LSC analysis.

Total radioactive residues (TRR) in all matrices from the 0.11 kg ai/ha pre-plant treatment were < 0.04 mg/kg, with ^{14}C-residues being lower in the phenyl-label samples. TRRs in samples from the 0.33 kg ai/ha pre-plant treatment were ca.3× higher than those from the 0.11 kg ai/ha treatment except for the phenyl-label hulls and the THP-label vines. Radioactive residues were generally lowest in vines (0.009–0.027 mg/kg) and highest in hulls (0.019–0.166 mg/kg).

Table 6 Radioactive residues in peanut matrices following single pre-plant or pre-emergence soil treatments of [^{14}C]flumioxazin

MATRIX	TOTAL RADIOACTIVITY (MG/KG FLUMIOXAZIN EQUIVALENTS)			
	PRE-EMERGENT TREATMENT (0.11 KG AI/HA) 3 DAYS AFTER SOWING, SAMPLED 194 DAT		PRE-PLANT TREATMENT (0.33 KG AI/HA) 32 DAYS BEFORE SOWING, SAMPLED 277 DAT	
	PHENYL-LABEL	THP-LABEL	PHENYL-LABEL	THP-LABEL
Nutmeats	0.012	0.031	0.044	0.085
Hulls	0.019	0.02	0.166	0.097
Vines	0.009	0.021	0.027	0.023
Seed coats	0.013	0.036	0.045	0.093

Samples were also extracted with acetone:water (4:1) and partitioned with hexane, with total radioactivity in the extracts and the post-extraction solids being measured by combustion and LSC analysis. Radioactivity in the hexane fraction from vines and hulls was too low (≤ 0.002 mg/kg) to permit further characterisation or identification.

The hexane fractions from the nutmeat samples were further partitioned between hexane:acetonitrile (1:1), with essentially all the radioactivity remaining in the hexane phase. Attempts to separate this radioactivity from the oil fraction by freezing to precipitate fats or by chromatography using a silica gel, C_{18}, or gel permeation columns were not successful. However, data from extraction of control nutmeat samples fortified with flumioxazin indicated that parent is unlikely to be present in this fraction.

The aqueous fractions from all samples (except the vines from the pre-plant treatment) were acidified to pH 2–3 and partitioned with ethyl acetate (EtOAc), and selected fractions from various samples were then analysed by reverse-phase HPLC.

Following solvent extraction, the majority of ^{14}C-residues in nutmeats (67–83% TRR), hulls (62–69% TRR) and vines (51–59% TRR) remained in the post extraction solids. To further characterize these residues, the post-extraction solids (PES) fractions from the pre-emergence treatment samples were subjected to sequential enzymatic (cellulase), acid (2 N HCl) and base

(2 N NaOH) hydrolyses. Radioactive residues remaining in the final PES fractions accounted for 23–35% TRR (0.003–0.01 mg/kg) in nutmeats and hulls and 6.4–8.6% TRR (0.001–0.002 mg/kg) in vines.

Radioactive residues in selected aqueous, organic and hydrolysate fractions containing ≥ 10% of the TRR were analysed by reverse phase HPLC using a C_{18} column. Radioactive residues were detected and quantified by LSC and reference standards were detected using a UV absorbance detector (220 nm). Peak retention times for ^{14}C-residues were compared to retention times of reference standards. HPLC peaks containing significant amounts of radioactivity were also analysed by TLC using silica gel plates with a variety of solvent systems.

Flumioxazin residues were measured at levels of < 1% TRR (< 0.001 mg/kg) in the ethyl acetate fractions from hulls and vines. The majority of ^{14}C-residues in solvent and hydrolysate fractions was generally comprised of four regions (A, B, C, and D). Regions A and B were polar in nature and did not correspond to any of the reference standards used in the study. Region C was typically a broad peak, suggesting multiple components, such as 1-OH-HPA, THPA, APF, and 482-HA. Region D was a minor peak with peaks similar to the standards IMOXA, PNF, and 482-CA.

In the nutmeats and vine extracts, each of these general regions accounted for ≤ 0.01 mg/kg in each fraction analysed by HPLC. These regions also each accounted for ≤ 0.005 mg/kg in fractions from hulls, with the exception of Region C which accounted for 0.025–0.038 mg/kg in solvent extracts from the pre-plant (0.33 kg ai/ha) hulls. Subsequent TLC analyses suggested that this region contained minor levels of 1-OH-HPA (≤ 4% TRR, ≤ 0.006 mg/kg) and THPA (≤ 2% TRR, ≤ 0.004 mg/kg) in hulls and vines from the pre-plant samples, however, the majority of ^{14}C-residues in Region C were multiple unknown polar components.

Soya bean—Study 1

In a confined metabolism study on soya beans reported by Hubert, 1992 [Ref: SBM-0021], flumioxazin, radio-labelled in the phenyl ring or the THP ring, was applied to soil (sandy loam) three days after sowing at rates equivalent to 0.1 kg ai/ha or 0.2 kg ai/ha. Forage and root samples were taken 70 days after treatment and samples of plants (without pods), pods, seeds and roots were harvested at maturity, 100 days after treatment.

Soya bean forage and seed samples were extracted with acetone:water (4:1) followed by acetone:0.1 M HCl (4:1). The concentrated extracts were partitioned with ethyl acetate and the radioactivity quantified by LSC. The radioactivity in the post-extraction solids was determined by oxidation and LSC. In order to liberate further amounts of radioactivity, successive hydrolysis with 2 N HCl and 2 N sodium hydroxide under reflux (2 hours) was carried out. Following hydrolysis, the aqueous phases were acidified (pH 2–3), extracted with ethyl acetate and

radioactivity in the extracts and post-extraction solids was measured by liquid scintillation counting (LSC). Residues in the post-extraction solids were also analysed by HPLC.

Analysis of the radioactivity in the immature forage and mature plants, pods and seeds indicated preferential uptake from the ^{14}C-THP-radio-labelled material. Total radioactive residues in immature forage were 0.03 mg/kg and 0.06 mg/kg flumioxazin equivalents for the low and high rates of ^{14}C-phenyl-labelled material, respectively. The corresponding values for ^{14}C-THP-labelled treatments were 0.12 mg/kg and 0.14 mg/kg flumioxazin equivalents. Hay from immature forage (dried for 3–7 days to achieve a moisture content of 8.5–12%) contained 0.19 and 0.29 mg/kg flumioxazin equivalents for the high rate ^{14}C-phenyl and ^{14}C-THP treatments, respectively. In pods and seeds, radioactivity levels were 0.02–0.03 mg/kg (phenyl-label) and 0.23–0.36 mg/kg and 0.12–0.18 mg/kg respectively in the THP-label treatments.

Table 10 Radioactive residues in soya bean forage, pods and seeds following a pre-emergent soil application of [^{14}C]flumioxazin

MATRIX	DOSE (KG AI/HA)	RADIOACTIVE RESIDUES (MG/KG FLUMIOXAZIN EQUIVALENTS)			
		70 DAT		100 DAT

Sequential acetone:water and acetone:HCl extractions were able to extract close to 60% TRR in hay and when followed by acid and base hydrolysis in the case of the forage and seed, was able to extract more than 90% TRR in immature forage and more than 95% TRR in seed.

Unextracted residue	6.6	0.01	3.3	0.003		

None of the radioactivity measured in forage, mature seeds or hay from immature forage could be identified as either the parent flumioxazin or any of the available reference standards. Analysis of some of the solubilized forage fractions indicated the presence of 10–16 unknown components that together accounted for 59–89% (0.017–0.086 mg/kg) TRR.

Soya bean—Study 2

In a further confined metabolism study on soya beans reported by Miyashita & Nambu, 1993 [Ref: SBM-0031], flumioxazin, radio-labelled in the phenyl ring or tetrahydrophthaloyl (THP) ring, was applied to sandy loam soil three days after sowing, at rates of about 0.1 kg ai/ha and 0.2 kg ai/ha. Samples of immature whole plants (forage) were taken 53 days after soil treatment and dried to prepare forage hay. Samples of seeds, pods and straw were harvested at maturity, 138 days after treatment.

Forage, hay and seed samples were extracted three times with acetone/water (4:1). The combined acetone/water extracts were concentrated and the aqueous remainder was partitioned three times with hexane. The aqueous remainder was adjusted to pH 2 with hydrochloric acid and partitioned three times into ethyl acetate. Finally the aqueous remainder was neutralised with sodium hydrogen carbonate. In each fraction, radioactivity was quantified by LSC and characterized by HPLC and TLC. The post-extraction solids were further extracted using cellulase digestion, acid and base hydrolysis with the liberated radioactivity being partitioned into ethyl acetate and quantified by LSC.

Total radioactive residues in immature forage (53 DAT) did not exceed 0.7% of the applied radioactivity, indicating that the radioactivity applied to the soil surface did not tend to translocate into the soya bean plants until a later stage. In the phenyl-label study, TRRs in forage from the 0.1 kg ai/ha and 0.2 kg ai/ha plots were about 0.06 mg eq/kg and 0.11 mg eq/kg respectively. Higher levels were present in the forage in the THP-label study (about 0.07 mg eq/kg and 0.2 mg eq/kg in the low and high rate plots). The TRR levels in hay were approximately three to four times higher compared to forage reflecting a concentration of residues due to the loss of water.

In mature soya bean seeds (138 DAT) in the phenyl-label study, TRRs were about 0.03 mg eq/kg (low rate) and about 0.06 mg eq/kg (high rate), and significantly higher in seeds from the equivalent plots in the THP-label study (about 0.25 mg eq/kg and 0.18 mg eq/kg respectively), indicating a preferential uptake of the THP-label.

Table 12 Total radioactive residues in soya bean forage, hay, seeds, pods and straw following a pre-emergent soil application of [^{14}C]flumioxazin

Matrix	Dose (kg ai/ha)	Radioactive residues (mg eq/kg flumioxazin)							
		53 DAT				138 DAT

		mg eq/kg	%AR	mg eq/kg	%AR	mg eq/kg	%AR	mg eq/kg	%AR
Forage (immature)	0.1	0.055	0.6	0.069	0.7				
	0.2	0.108	0.7	0.196	0.5				
Hay (immature)	0.1	0.155		0.257					
	0.2	0.348		0.617					

Matrix	Dose (kg ai/ha)	Radioactive residues (mg eq/kg flumioxazin)							
		53 DAT				138 DAT			
Seeds	0.1					0.033	0.1	0.245	0.7
	0.2					0.055	0.1	0.177	0.9
Pods	0.1					0.06	0.1	0.326	1.7
	0.2					0.118	0.1	0.551	0.3
Straw	0.1					0.152	0.6	0.207	0.8
	0.2					0.176	0.3	0.254	0.6

Acetone:water extraction was able to retrieve 61–71% TRR from immature forage and hay and 36–66% TRR from seeds. Further partitioning and more aggressive cellulase digestion, acid and base hydrolysis was able to extract most of the remaining radioactivity, with about 1–4% TRR remaining in the post extraction solids.

Flumioxazin made up < 1.8–6.1% TRR in forage and hay, at levels of < 0.01 mg/kg in forage and up to 0.03 mg/kg in hay with trace levels (< 2.3% TRR, < 0.004 mg/kg) reported only in seed from the 0.2 kg ai/ha treatment in the THPA-label study.

The major component of the residue was metabolite 1-OH-HPA (free or partly cellulose conjugated), making up about 15–31% of the TRR in immature forage and hay and about 38–42% TRR (0.06–0.09 mg/kg) in seed. Minor metabolites included THPA (up to 8.6% TRR in forage and hay and < 3.2% TRR, < 0.007 mg/kg) in seeds) and 482-HA and APF found at trace amounts (< 1.8% TRR) in the immature commodities forage and hay.

Sugar cane

In a metabolism study on sugar cane reported by Jalal, 2003 [Ref: SBM-0074], flumioxazin, radio-labelled in the phenyl ring or the THP ring, was applied at a rate equivalent to 0.48 kg ai/ha as a directed spray to 1.5–2 m high sugar cane prior to stem elongation, at the 6–10 leaf stage, with up to 1 m of the cane receiving direct spray. Immature sugarcane forage (leaves and cane) were sampled about a month after the application and mature canes and leaves (3–3.6 m high) were also sampled at maturity, 90 days after treatment, when the canes were 5 cm in diameter.

Samples were homogenized with dry ice and combusted to determine the total radioactive residue (TRR) and were also sequentially extracted with acetonitrile and water with total radioactivity in the extracts and the post-extraction solids being measured by combustion and LSC analysis.

The total radioactive residues determined by combustion analysis were 0.001–0.004 mg/kg in mature cane, 0.23–0.89 mg/kg in immature forage and 0.5–0.52 mg/kg in mature leaves. Acetonitrile and water extraction was able to retrieve more than 90% TRR in immature forage and mature canes. Higher levels (0.53–1.0 mg/kg) were reported in the extracted mature leaf samples (with larger aliquots of a more homogenous mixture of vascular and non-vascular tissues).

Table 17 Total radioactive residues in sugarcane immature forage, mature leaves and canes after a directed foliar application equivalent to 0.48 kg ai [^{14}C]flumioxazin/ha

DETERMINATION METHOD		TOTAL RADIOACTIVITY (MG/KG FLUMIOXAZIN EQUIVALENTS)		
		IMMATURE FORAGE (30 DAT)	MATURE LEAVES (90 DAT)	MATURE CANE (90 DAT)
Combustion:	Phenyl-label	0.227	0.517	0.001
Extraction:	Phenyl-label	0.209	1.046	0.002
Combustion:	THP-label	0.889	0.496	0.004
Extraction:	THP-label	0.888	0.526	0.004

The acetonitrile extracts of the forage, mature leaves and cane were analysed by HPLC and TLC. The post-extraction solids from the mature leaf samples were hydrolysed by refluxing in 2 M HCl for 2 hours, and after ethyl acetate partitioning, the remaining solid fractions were then refluxed in 2 M NaOH for approximately 2 hours and the base hydrolysate was adjusted to pH 1 to precipitate and centrifuge out the insoluble lignin fraction.

More than 90% TRR was able to be solvent-extracted, with the more aggressive extraction methods able to retrieve all but 2% of the remaining TRR.

Flumioxazin was the predominant residue in immature forage (leaves and canes) accounting for 90–93% TRR (0.19 mg/kg—phenyl-label, 0.83 mg/kg—THP-label). Among the minor components, one polar constituent made up 2.8–3.8% of TRR (0.008–0.025 mg/kg). The unextracted residue in the post-extraction solids accounted for 2.3–4.7% of the TRR (0.01–0.02 mg/kg).

Flumioxazin was also the predominant residue in mature leaves, making up 81–88% of TRR (0.92 mg/kg—phenyl-label, 0.427 mg/kg—THP-label). Among the minor components, a polar constituent was found in various extract fractions, making up a total of 5.1–8.7% of TRR (0.046–0.053 mg/kg). In the post-extraction solids, radioactivity was distributed into all plant constituents including the starch, cellulose, lignin, lipids and proteins, but did not exceed 0.03 mg/kg in any individual PES sub-fraction, with none of the individual TLC bands containing significant residue and none corresponded to any of the reference standards.

Flumioxazin also accounted for most of the mature cane residue (68–75% of TRR, 0.001–0.003 mg/kg), with the aqueous extract and PES contained only a trace level (≤ 0.001 mg/kg) of the radioactivity

When applied to soil prior to crop emergence or as directed treatments to soil surrounding established plants, flumioxazin does not translocate or accumulate in significant concentrations in plant matrices. In general, no parent or identifiable metabolites were found in the plant matrices analysed although very low levels of metabolites (most also identified as rat metabolites) were identified in peanut plant samples.

Following directed foliar applications, flumioxazin is not translocated, with the majority of the residue remaining as the parent, with some incorporation into natural plant constituents.

Rotational crop metabolism

The Meeting received information on the metabolism of flumioxazin in lettuce, carrot and wheat grown as rotational crops in flumioxazin-treated soil.

Two confined rotational crop studies using lettuce, carrots and wheat were conducted with flumioxazin labelled in the phenyl ring (Patrick, 1993 [Ref: SBM-0034]) or in the THP ring (Patrick, 1993 [Ref: SBM-0048]). In both studies, the radio-label was applied to bare sandy loam soil plots at rates equivalent to 0.11 kg ai/ha or 0.21 kg ai/ha and the rotational crops were planted 30 days after treatment in all plots and 120, 180 and 365 days after treatment in the higher treatment plots. Fallowed plots were maintained outdoors, and except during periods of heavy rainfall when they were covered to prevent flooding, they were exposed to the environment. Planted crops were maintained in screen houses. Phytotoxicity was observed in most of the rotational crops, particularly in lettuce and carrots, with some plots being replanted because of crop failure (See footnotes to the following Tables).

Radioactive residues in soil and plant materials were determined by combustion followed by Liquid Scintillation Counting and extracted residues were characterized and identified by HPLC or TLC using known reference standards. The stability of stored analytical samples was established by analysis of samples at the beginning and at the end of the study, with no significant degradation being observed.

Soils core samples were taken at each planting and sampling date and segmented into 0–10 cm and 10–20 cm samples prior to combustion analysis and in the phenyl-label study, extracted with acetone:water and acetone:aqueous 0.1 N HCl (5:1) prior to HPLC analysis.

In both studies, results showed that crops assimilated only very small amounts of radioactivity when grown in soil treated with radiolabelled flumioxazin. In the phenyl-label study (0.21 kg ai/ha treatment), TRRs above 0.01 mg/kg were found in wheat straw and chaff at all PBIs, in carrot tops (120 day PBI) and in wheat grain from the 30 day PBI plot. Highest residues were 0.02–0.03 mg/kg eq. in wheat straw.

In the THP-label study, TRRs above 0.01 mg/kg eq were found in carrot tops, wheat straw, chaff and grain from the 0.11 kg ai/ha 30 day PBI plots. TRRs increased in some commodities at the 120-day and 180-day plant-back intervals, suggesting that THP-derived cleavage products in soil are either more readily assimilated by the plants or less tightly bound to soil than those from the phenyl label. In the 0.21 kg ai/ha treated plots, highest residues were 0.015 mg/kg eq in wheat forage (180 day PBI), 0.012 mg/kg eq. in lettuce (180 day PBI), 0.045 mg/kg eq. in carrot tops (30 day PBI), 0.022 mg/kg eq. in carrot roots (30 day PBI), 0.13 mg/kg eq. in wheat straw (120 day PBI), 0.043 mg/kg eq. in wheat chaff (120 day PBI) and 0.023 mg/kg eq. in wheat grain (120 day PBI).

[a] 149 day Plant-back interval (crop failure)

In soil, the extractable radiocarbon showed a slow decrease over time, decreasing to about 50% during the second half of the study period and remained mostly in the top 0–10 cm layer. The major component was flumioxazin, with minor components (each < 0.01 mg/kg) being tentatively identified as 482-HA, 482-CA, IMOXA and APF based on their retention times.

Sequential solvent extractions of samples containing more than 0.01 mg/kg using acetone:water (4:1), acetone:0.1 N HCl (4:1) and refluxing with acetonitrile:0.25 N HCl was able to extract 62–85.5% TRR in wheat straw and chaff from the 30 day PBI plots and 36–61% TRR in the 120 day and 180 day PBI plots in the phenyl-label study and in the THP-label study, extraction efficiencies were 61–84% in wheat straw, chaff and carrot roots, 75–69% in carrot tops at PBIs of 30 days and 120 days, decreasing to 59% (180 day PBI) and 47% in the 365 day PBI samples. Some plant samples containing < 0.01 mg/kg were also analysed and the similar metabolic profile was confirmed.

In wheat grain, 5–13% TRR was able to be extracted in the 30 day and 120 day PBI plots with a further 22–26% TRR being extracted after cellulase incubation for 24 hours at 37 °C in the phenyl-label study and in the THP-label study, more aggressive digestion and fractionation was able to show that 12–21% TRR was present in cellulose, hemicellulose and starch fractions and 3–9% TRR was found in the protein, lignin and pectin fractions.

HPLC analysis of the acetone:water extracts containing more than 0.01 mg/kg TRR from the phenyl-label study identified the presence of flumioxazin and the metabolites 482-HA, IMOXA, and 482-CA, with wheat straw also containing low levels of 1-OH-SAT-482, 1-OH-HPA, THPA, and TPA, all at < 0.01 mg/kg eq. Flumioxazin residues above 0.01 mg/kg were only found in wheat straw (0.03 mg/kg) from the 120-day plant-back treatment.

[a] 1-OH-SAT (0.008 mg/kg eq, 9.7% TRR)

[b] 1-OH-HPA (0.004 mg/kg eq, 13.4% TRR)

THPA (0.004 mg/kg eq, 15.3% TRR)

TPA (0.004 mg/kg eq, 15.2% TRR)

Radioactive residues in rotational crops planted 30–365 days after bare soil treatments with [^{14}C]flumioxazin were low, generally less than 0.01 mg/kg and less than 0.05 mg/kg in all matrices except wheat straw, where up to 0.13 mg/kg were found in the THP-label study. The only significant residue identified in rotated crop matrices above 0.01 mg/kg was the parent, flumioxazin, in wheat straw (0.013 mg/kg). Low levels of 482-HA, IMOXA and 482-CA were found in most crop matrices, up to 6.6% TRR (< 0.002 mg/kg) with wheat straw also containing low levels of 1-OH-SAT-482, 1-OH-HPA, THPA, and TPA, all < 0.01 mg/kg.

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens where animals were dosed with flumioxazin radio-labelled in the phenyl ring or the tetrahydrophthaloyl (THP) ring.

Rats

The metabolism of flumioxazin in rats was evaluated by the WHO Core Assessment Group of the 2015 JMPR. Studies were carried out to investigate the metabolism of phenyl-label and THP-label flumioxazin in rats. Excretion of radioactivity was rapid, with 69–87% being eliminated in urine and faeces within 24 hours with the reminder found mainly in excretory organs. Flumioxazin was extensively metabolized (29–35 metabolites detected and quantified), with 7–10 of these being identified. Flumioxazin accounted for 47–66% of the administered dose in the 100 mg/kg bw and 0.3–2% in the 1 mg/kg bw dose group. Metabolites found at more than 5% of the administered dose were

3-OH-flumioxazin, 3-OH-flumioxazin-SA, 4-OH-flumioxazin and 4-OH-flumioxazin-SA. The proposed metabolic pathways included hydroxylation of the cyclohexene ring, cleavage of the imide linkage, cleavage of the amide linkage in the benzoxadine ring, reduction of the double bond in the THP ring, acetylation of the amino group of the aniline derivative and the addition of a sulphonic acid group to the THP ring.

Lactating goats

Two studies were carried out to investigate the absorption and deposition of phenyl-label and THP-label flumioxazin in lactating goats. In the first study, reported by Sharp, 1993 [Ref: SBM-0026], two lactating goats (average body-weight of 48 kg) were dosed orally for 5 days with capsules containing [^{14}C-phenyl] flumioxazin at the rate equivalent to 11.8 ppm in the diet (based on an average feed consumption of 2.1 kg/goat/day and a total dose of 2.63 mg/kg bw). Milk, urine and faeces were collected twice daily and liver, fat, muscle, blood, gastrointestinal tract and contents were collected at sacrifice, about 6 hours after the last dose.

The second study, reported by Panthani, 1994 [Ref: SBM-0040] used a similar protocol involving two goats (average body-weight of 45 kg) but with [^{14}C-THP] flumioxazin at a dose equivalent to 7.2 ppm in the diet (based on an average feed consumption of 2 kg/goat/day and a total dose of 1.44 mg/kg bw).

Radioactivity was quantified by LSC. Samples of liver, kidney, muscle, and fat were initially homogenized in dry ice, and then subjected to combustion/LSC.

The average total recoveries of radioactivity were 81% and 94% of the administered radioactivity (AR) in the phenyl-label and the THP-label studies respectively, mostly found in faeces, urine and the GI tract contents (80–93% AR). Tissues and milk contained relatively small amounts of radioactivity (< 1% and 0.22% AR respectively).

Average concentrations of radioactivity were low in muscle and fat, up to 0.014 mg/kg (phenyl-label) and 0.028 mg/kg (THP-label), but were higher in liver, up to 0.21 mg/kg (phenyl-label) and 0.33 mg/kg (THP-label). In kidney the radioactive residues were up to 0.18 mg/kg (phenyl-label) and 0.24 mg/kg (THP-label). The average total radioactivity concentration in milk plateaued around Day 3 at about 0.03 mg/kg (phenyl-label) and about 0.06 mg/kg in the THP-label study.

In the first study, milk and tissue samples (except fat) from goats dosed with the phenyl-label were solvent-extracted and subjected to protease digestion (liver and kidney) to characterize and identify residues. Milk samples were extracted with hexane and the extracted residues were triple-extracted into methanol, filtered, evaporated and redissolved in methanol for LSC and HPLC analysis. Muscle samples were extracted with acetonitrile and after evaporation and reconstitution in methylene chloride (to solubilise the lipids), the supernatants were partitioned between acetonitrile and hexane for analysis. The remaining solid phases from the acetonitrile extractions were also subjected to an additional sodium bicarbonate extraction step and aliquots were subjected to overnight enzyme digestion (protease) prior to sequential extraction with water, methanol and acetonitrile and analysis.

In the second study, milk and tissue samples (except fat) from goats dosed with the THP-label were solvent-extracted to characterize and identify residues. Milk samples were mixed with ethanol, filtered, concentrated and partitioned with hexane. The aqueous phases were concentrated, additional ethanol was added, and after centrifuging, the supernatants were concentrated for TLC and HPLC analysis. Tissue samples were extracted with acetonitrile and acetonitrile:water with 1%HOAc (1:1), filtered and the supernatants were concentrated for TLC and HPLC analysis. The solids fractions were dried and combusted to quantitate the unextracted radioactivity.

About 80–94% TRR in milk was able to be extracted with methanol or ethanol, and acetonitrile was able to extract 58–74% TRR from muscle (45–53% in the THP-label samples, with a further 30% extracted in acetonitrile:water). In the phenyl-label liver and kidney samples, sequential extractions with acetonitrile and bicarbonate were able to extract more than 90% TRR and further enzyme extraction released an additional 10% TRR. In the THP-label liver and kidney samples, sequential acetonitrile and acetonitrile:water extractions were able to extract 80–87% TRR.

Metabolites were characterized and identified following sample extraction and co-chromatography with known reference materials using thin-layer chromatography and HPLC with uv detection high-performance liquid chromatography within 4–6 months of sampling. Concurrent analysis of stored analytical samples indicated that residues were stable over the storage intervals in the studies.

Flumioxazin was extensively metabolized, with residues above 0.001 mg/kg found only in liver (up to 0.01 mg/kg and < 5% TRR).

The only identified metabolite present at more than 10% TRR was the 4-OH-flumioxazin, accounting for up to 14% TRR in kidney (up to 0.025 mg/kg) and muscle (up to 0.003 mg/kg). In liver, 4-OH-flumioxazin residues did not exceed 0.025 mg/kg (9.4% TRR) and were up to 0.002 mg/kg (8.6% TRR) in milk.

Other identified metabolites found at more than 5% TRR were 482-HA, found in liver and kidney (close to 10% TRR, 0.02 mg/kg), 3-OH-flumioxazin in liver (up to 8.6% TRR, 0.023 mg/kg) and kidney (up to 6% TRR, 0.011 mg/kg), APF in kidney (5.8% TRR, 0.011 mg/kg) and SAT-482 in liver and kidney (5–6% TRR, up to 0.013 mg/kg).

In kidney, metabolite B, tentatively identified as 3- or 4-OH-SAT-482, made up about 14% TRR (0.024 mg/kg) and residues of metabolite C was measured at 0.015 mg/kg (8.5% TRR).

In liver, metabolite F, tentatively identified as an isomer of 3- or 4-OH-SAT-482, made up about 11% TRR (0.03 mg/kg) and residues of metabolite D were measured at 0.013 mg/kg (4.9% TRR).

In muscle, metabolite C accounted for 20-23% TRR and in milk, metabolites B and C were found at 12–18% TRR. However, absolute levels were all 0.005 mg/kg or less.

The major metabolic pathways proposed for flumioxazin in goats include: the hydroxylation of the parent to 3-OH-flumioxazin and the subsequent incorporation of a sulfonic group to form 3-OH-flumioxazin-SA; the reduction of the parent molecule and subsequent hydroxylation to SAT-482; and the cleavage of the imide and amide linkages of the parent molecule to THPA and APF.

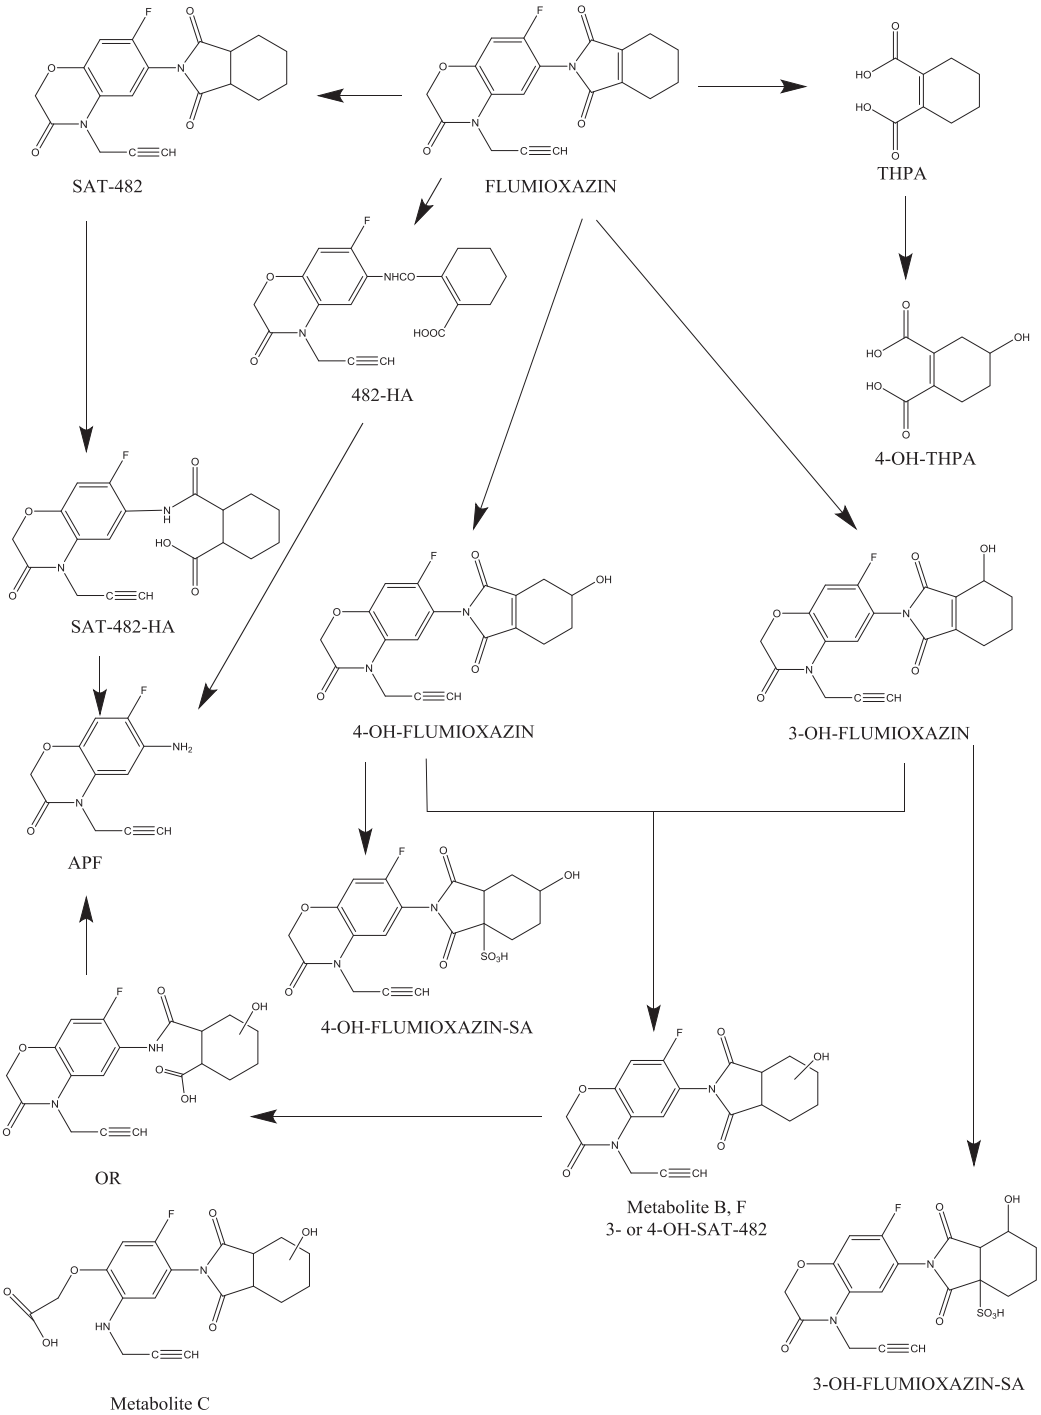

Fig 4 Metabolic Pathway of Flumioxazin in Lactating Goats

Laying Hens

Two studies were carried out to investigate the absorption and deposition of phenyl-label and THP-label flumioxazin in laying hens. In the first study, reported by Sharp, 1993 [Ref: SBM-0027], ten laying hens (average body-weight of 1.65 kg) were dosed orally for 14 days with capsules containing [^{14}C-phenyl] flumioxazin at the rate equivalent to 10 ppm in the diet (based on an average feed consumption of 0.122 kg/hen/day and an average daily dose of 0.683 mg/kg bw/day).

The second study, reported by Panthani, 1994 [Ref: SBM-0039] used a similar protocol involving 10 hens (1.3–1.9 kg bodyweight) and [^{14}C-THP] flumioxazin at a dose equivalent to 10 ppm in the diet (based on an average feed consumption of 0.127 kg/hen/day).

Eggs were collected twice daily. Eggs collected on the same day were pooled and then separated into yolks and whites. Samples of excreta were collected daily. The hens were sacrificed 4 hours after the last dose and the following samples were collected: kidney, heart, liver, muscle (breast and thigh), abdominal fat, skin with fat, gizzard, reproductive organs, and GI tract and contents.

Samples of kidney, liver, muscle, fat, and skin with fat were homogenized in dry ice, and then subjected to combustion/LSC. Egg yolk and white samples were blended and then subjected to combustion/LSC. Samples of excreta and cage washings were also collected and were analysed for TRR.

The average total recoveries of radioactivity in the samples collected for analysis from the treated animals were 95% of the administered dose (phenyl-label study) and 87% in the THP-label study. Most of the radioactivity was found in the excreta, GI tract contents and cage wash, which, together accounted for 94% and 83% of the doses in the respective studies. Liver, kidney, muscle, fat, skin and eggs contained relatively small amounts of radioactivity (totalling < 0.6% and < 0.9% of the administered dose, respectively).

Radioactivity in egg yolks accounted for 0.35–0.36% AR, with < 0.01% AR in the corresponding egg whites and liver contained 0.08% AR in the phenyl-label study and 0.27% AR in the THP-label study (0.24 mg/kg eq and 1.14 mg/kg eq respectively. In egg yolks, residues reached a plateau of 0.4–0.6 mg/kg eq by Day 10 or 11 in the two studies.

Egg yolk, egg white, and tissues samples were extracted with various solvents and the solvent-extracted radio-labelled residues were analysed by HPLC and TLC to characterize and identify the major metabolites. Identification was made by co-chromatography of extracts with known standards. The unextracted radioactive residues were characterized by acid or base hydrolysis, or by enzyme digestion. Additional metabolites were isolated from excreta extracts for mass spectral analysis to confirm the identity of the structures of the metabolites.

In the first study, egg (Day 7 and 13) and tissue samples from hens dosed with the phenyl-label were solvent-extracted and subjected to enzyme digestion to characterize and identify residues. Egg yolk samples were extracted with acetonitrile, the supernatant partitioned with hexane and the remaining residue subjected to enzyme (lipase) digestion and sodium bicarbonate extraction of the insoluble fraction with sequential extractions/elutions in hexane, methanol and acetonitrile. Egg white samples were extracted in acetonitrile. Liver samples were extracted with acetonitrile, the supernatant partitioned between acetonitrile and hexane and the remaining residue further extracted with sodium bicarbonate and subjected to enzyme (protease) digestion with the various fractions being sequentially extracted or eluted with water, methanol and acetonitrile. Kidney and muscle samples were extracted with acetonitrile, the supernatants partitioned between acetonitrile and hexane and the remaining residue further extracted with water (except breast muscle) and subjected to enzyme (protease) digestion and acid hydrolysis (6 N HCl), with the various fractions being sequentially extracted or eluted with water, hexane, methanol, dichloromethane and acetonitrile. Skin + fat and fat samples were extracted with chloroform:methanol (2:1) with the chloroform phase being partitioned between acetonitrile and hexane. The remaining residue from the skin + fat samples were subjected to enzyme (protease) digestion with the various fractions being sequentially extracted or eluted with water, methanol and acetonitrile.

In the second study, egg (Day 13) and tissue samples from hens dosed with the THP-label were extracted with acetonitrile and acetonitrile:water with 1% HOAc (1:1), filtered and the supernatants were concentrated for TLC and HPLC analysis. The post-extraction solids were also subjected to pronase hydrolysis. The remaining solids fractions were dried and combusted to quantitate the unextracted radioactivity.

In the THP-label and the phenyl-label studies respectively, highest concentrations of radioactivity were in liver (1.1 mg/kg and 0.24 mg/kg) and kidney (0.89 mg/kg and 0.27 mg/kg) with lower levels in egg yolks (0.63 mg/kg and 0.41 mg/kg). Radioactivity in fat and skin + fat were 0.23–0.67 mg/kg (THP-label) and 0.07–0.14 mg/kg (phenyl-label) respectively. In muscle, radioactive residues were 0.14–0.18 mg/kg (THP-label) and 0.04–0.05 mg/kg (phenyl-label) and egg white contained about 0.02 mg/kg in both studies.

More than 87% TRR in eggs was able to be extracted, and acetonitrile was able to extract 37–67% TRR from muscle. In the phenyl-label liver and kidney samples, sequential extractions with acetonitrile and bicarbonate were able to extract more than 60% TRR and further enzyme extraction released an additional 30% TRR. In the THP-label liver and kidney samples, sequential acetonitrile and acetonitrile:water extractions were able to extract 75–78% TRR. In fat and fat + skin, extraction efficiencies were 76–91% TRR and 54–95% respectively.

Values reported for eggs are from Day 13 Samples

Metabolites were characterized and identified following solvent extraction and co-chromatography with known reference materials using thin-layer chromatography and HPLC with uv detection high-performance liquid chromatography within 4.5 months of sampling. Concurrent analysis of stored analytical samples indicated that residues were stable (more than 93% recovery from spiked samples) over the storage intervals in the studies.

In the phenyl-label study, flumioxazin was the predominant residue in fat (49% TRR), skin + fat (25% TRR), muscle (10–14% TRR), liver (9.1% TRR) and kidney (6.9% TRR), made up about 3.8% TRR in egg yolk and was not detected in egg white. Absolute levels of

flumioxazin were < 0.05 mg/kg in skin + fat and fat, < 0.02 mg/kg in liver, kidney and egg yolk and about 0.005 mg/kg in muscle.

The major identified metabolites, present at more than 10% TRR were APF and 482-HA. The APF metabolite accounted for 20% TRR in egg white and 10% TRR in muscle (but both at absolute levels of < 0.005 mg/kg) and 482-HA made up about 20% of the TRR in egg white. All other identified metabolites were found at < 8% TRR and the highest level of any single unidentified metabolite was measured in liver, at 12% TRR.

Values reported for eggs are from Day 13 Samples

In the THP-label study, flumioxazin was the predominant residue in fat (49% TRR), skin + fat (12% TRR) and muscle (11% TRR) and was found at 7% TRR in liver, kidney and 9% TRR in egg yolk. Absolute levels of flumioxazin were 0.07–0.13 mg/kg in skin + fat and fat, < 0.08 mg/kg in liver and kidney, < 0.04 mg/kg in egg yolk and < 0.02 mg/kg in muscle.

The major identified metabolites, present at more than 10% TRR in tissues were 4-OH-flumioxazin, 3-OH-flumioxazin and 4-OH-THPA. The 4-OH-flumioxazin accounted for 9–12% TRR in all tissues (< 0.03 mg/kg in muscle and fat, < 0.08 mg/kg in kidney and skin + fat, 0.12 mg/kg in liver) while the 3-OH-flumioxazin accounted for 8–12% TRR (0.015 mg/kg) in muscle. The 4-OH-THPA metabolite made up 10% TRR (0.09 mg/kg) in kidney.

In eggs, metabolites present at more than 10% TRR were 4-OH-flumioxazin-SA in egg yolk (32% TRR, 0.14 mg/kg) and in egg white, THPA and 4-OH-THPA each accounted for 23–26% TRR and (but < 0.01 mg/kg), with TPA and 3-OH-THPA each present at 16–17% TRR. Absolute levels of these metabolites in egg white were all < 0.01 mg/kg.

Values reported for eggs are from Day 7 Samples

[a] Exact position of hydroxylation not determined

[b] Mixture of two metabolites

The major metabolic pathways proposed for flumioxazin in hens include the hydroxylation of the parent and the subsequent incorporation of sulfonic groups to form 3-OH-flumioxazin-SA and 4-OH-flumioxazin-SA and the cleavage of the imide and amide linkages of the parent molecule to THPA and APF.

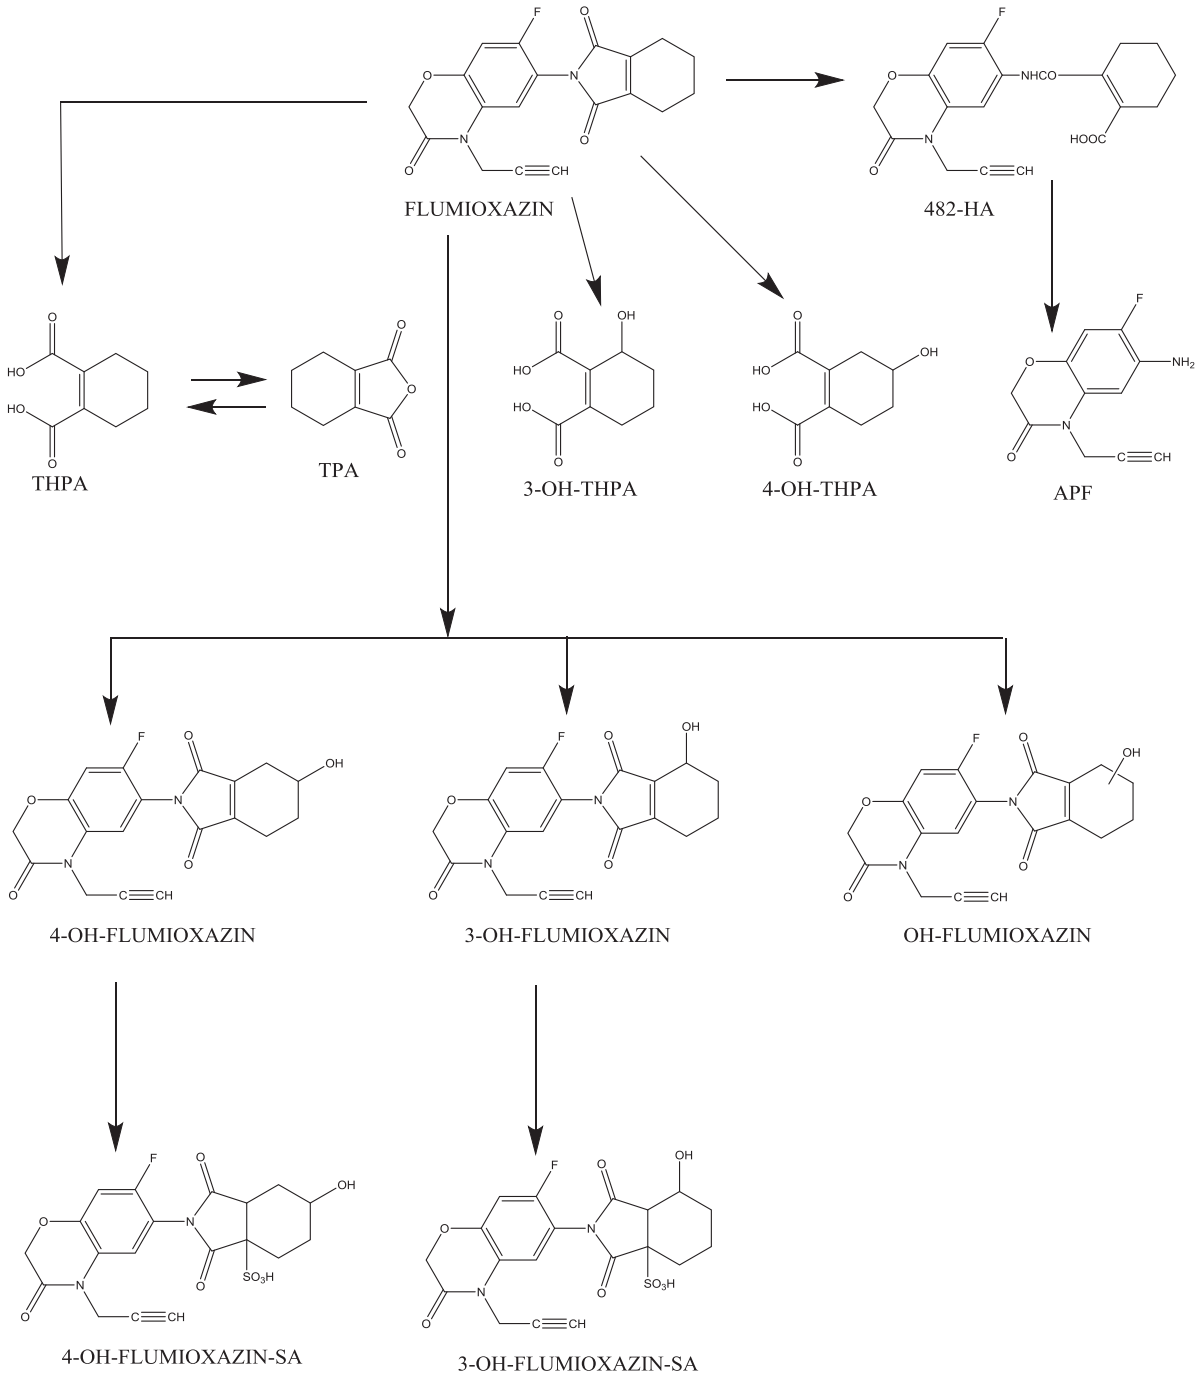

Fig 5 Metabolic Pathway of Flumioxazin in Poultry

Flumioxazin is extensively metabolized with limited absorption into tissues, eggs or milk (less than 0.5% of the administered dose). Flumioxazin was not found at levels above 0.01 mg/kg in goat milk or tissues and in poultry, highest residues found were in fat (0.13 mg/kg, 49% TRR), with lower levels (up to 0.08 mg/kg) in other tissues and egg yolks. The major identified metabolites found above 10% TRR and above 0.01 mg/kg in various matrices were 4-OH-flumioxazin, 4-OH-flumioxazin-SA, 3-OH-flumioxazin and 4-OH-THPA.

METHODS OF RESIDUE ANALYSIS

Analytical methods

The Meeting received analytical method descriptions and validation data for flumioxazin in plant and animal matrices and these are summarized below.

Table 31 Summary of analytical methods for flumioxazin and its 1-OH-HPA metabolite, developed for plant and animal matrices

Matrix	Analyte	Method	Principle	LOQ (mg/kg)	Reference

Data collection methods

Method RM 30A (Flumioxazin—fresh and processed plant matrices)

Method 30A, used with minor equipment modifications and sample preparation steps to measure residues of flumioxazin in fresh plant commodities and their processed fractions was first reported by Pensyl, 1992 [Ref: SBR-0003].

In this method, homogenised samples are double-extracted with acetone:water (4:1), partitioned into dichloromethane and after evaporation to dryness, dissolved in hexane:acetonitrile (30:1) then shaken with acetonitrile:hexane (5:1), After separation, the combined acetonitrile extracts are evaporated to dryness, redissolved in ethyl acetate and diluted with hexane and purified using Florisil columns eluted with hexane:ethyl acetate (2:1 v:v). Residues in the eluate are concentrated, reconstituted in acetone, and then analysed by GC/NPD or in some cases, GC/MSD, using an external standard. Validation studies were conducted in parallel with some of the supervised field trials. The LOQ for this method is 0.02 mg/kg for all matrices except grapes, almonds and cotton seed, where acceptable recovery rates were achieved at a lower fortification level of 0.01 mg/kg.

For some commodities, method validation was conducted prior to analysing the samples from the supervised field trials. Recovery validation data from these trials are summarized in the table below.

Table 32 Flumioxazin analytical method (GC-MS) validation recovery rates in plant matrices

Soya bean	0.1	3	81–84	80	2.5	RM 30A-3	SBR-0003

Method RM 30B (Flumioxazin—processed plant oils)

This method, similar to method RM 30A but without the initial acetone extraction and dichloromethane partitioning steps, used for the determination of flumioxazin in processed oils (maize oil, cottonseed oil and peanut oil) was first reported by Pensyl, 1994 [Ref: SBR-0019]. Samples are dissolved in hexane:acetonitrile (30:1), shaken with acetonitrile:hexane (5:1) and after separation, the acetonitrile extracts are evaporated and samples are cleaned-up using Florisil columns eluted with hexane:ethyl acetate (2:1 v:v). Residues in the eluate are concentrated, reconstituted in acetone, and then analysed by GC/NPD using an external standard. The LOQ of flumioxazin in oil matrices by this method is 0.02 mg/kg.

Method RM 30M (Metabolite 1-OH-HPA—animal feeds)

This method, developed for the determination of residues of the plant metabolite, 1-OH-HPA in animal feed commodities (almond hulls, peanut and soya bean forage/hay, cotton gin trash and sugar matrices) was first reported by Pensyl, 1994 [Ref: SBR-0019]. The metabolite, 1-OH-HPA is extracted from homogenized samples using acid hydrolysis (refluxing for 3 hours in 2.5 N HCl) prior to washing with hexane and partitioning into ethyl acetate. The concentrated extract is refluxed for 30 minutes with acetone, triisopropanolamine and dimethyl sulfate to convert the 1-OH-HPA to its dimethyl ester. The samples are then shaken with water and hexane, and after separation, the hexane extracts are cleaned-up using Florisil columns eluted with hexane:ether (1:2 v:v). Residues in the eluate are concentrated, reconstituted in acetone, and analysed by GC/MSD (m/z 157.2—

quantification and m/z 125.1—qualifier). The LOQs for the method are 0.02 mg/kg (peanut and soya bean forage/hay and sugar matrices) and 0.1 mg/kg (almond hulls and gin trash).

Method RM 30P (Metabolite 1-OH-HPA—processed plant oils)

This method, a modification of Method RM 30M (with an additional hexane partitioning step) to determine 1-OH-HPA in peanut and soya bean oils was reported by Pensyl, 1994 [Ref: SBR-0019]. Samples are hydrolysed in 2.5 N HCl and then partitioned with hexane to remove oils. The 1-OH-HPA is then extracted from the aqueous phase using ethyl acetate via solid phase extraction. The concentrated extract is re-dissolved in acetone and refluxed for 30 minutes with acetone, triisopropanolamine and dimethyl sulphate to convert the 1-OH-HPA to its dimethyl ester. The samples are then shaken with water and hexane, and after separation, are cleaned-up using Florisil columns eluted with hexane:ether (1:2 v:v). Residues in the eluate are concentrated, reconstituted in acetone, and analysed by GC/MSD. The LOQ for the method is 0.02 mg/kg.

Method ER-MT-9403 (Flumioxazin—animal matrices)

A method for determining residues of flumioxazin in milk, eggs and animal tissues was developed by Oishni, 1994 [Ref: SBA-0037]. Homogenised samples are double-extracted with acetone, partitioned into dichloromethane, evaporated to dryness, redissolved in ethyl acetate, diluted with hexane and purified using Florisil columns eluted with hexane:ethyl acetate (2:1 v:v for all tissues except chicken liver, where a 3:1 ratio is used). Meat and fat extracts also undergo an additional partitioning step before the Florisil clean-up, with samples being dissolved in hexane:acetonitrile (30:1), shaken with acetonitrile:hexane (5:1) and after separation, the combined acetonitrile extracts being evaporated to dryness. Residues in the eluate are concentrated, reconstituted in acetone, and then analysed by GC/NPD with a validated LOQ of 0.02 mg/kg for each analyte. Recovery data are summarized in the following table.

Table 33 Flumioxazin analytical method ER-MT-9403 (GC-MS) recovery rates in animal matrices [Ref SBA-0037]

Methods RM- 30T, RM-30MK (Flumioxazin, 3-OH-flumioxazin, 4-OH-flumioxazin—animal matrices)

A method (RM-30T) for determining residues of flumioxazin and the 3-OH and 4-OH metabolites in animal tissues and a modified version (RM-30MK) were reported by Kowalsky, 2006 [Ref: SBR-0138] in an dairy cattle feeding study. Tissue samples are homogenised in acetonitrile, extracted in acetonitrile:water (50:50) acidified with 1% acetic acid. Milk samples are extracted with acetone. Sample extracts are partitioned into dichloromethane, evaporated to dryness, then dissolved in hexane:acetonitrile (30:1), shaken with acetonitrile:hexane (5:1) and after separation, the combined acetonitrile extracts being evaporated to dryness. Residues in the eluate are concentrated, reconstituted

in methanol:water and analysed by LC-MS/MS ((flumioxazin: m/z 355MS/MS 3-OH-flumioxazin: m/z 371OH-flumi and 4-OH-flumioxazin: m/z 371 →and 4-OH with an LOQ of 0.02 mg/kg for each analyte. Recovery data are summarized in the following table.

Table 34 Flumioxazin analytical methods RM-30T, RM-30MK recovery rates in animal matrices [Ref SBR-0138]

Analytical (concurrent) recoveries in supervised crop trials

Analytical recovery rates were measured in all the supervised crop field trials, with control samples being fortified with flumioxazin at 0.01 mg/kg or 0.02 mg/kg and at higher levels that generally reflected the range of expected residues. For each study, average recoveries per fortification level generally fell within the 70–120% range, with a relative standard deviation of 20% or less. A summary of recovery data from the methods used for plant commodities evaluated by the Meeting where one or more individual recovery values were outside the above criteria are presented in the table below.

Table 35 Flumioxazin analytical concurrent recovery rates in studies where one or more individual recovery values were outside the 70–120% range

Commodity	Fortification (mg/kg)	n	%Recovery range	%Recovery mean	%RSD	Method	Determina-tion	Study reference

Enforcement methods

FDA Multi-residue method

Nandihalli, 1996 [Ref: SBA-0040] evaluated the suitability of the FDA PAM Multi-residue methods for measuring residues of flumioxazin. Testing according to Protocols A, C and F showed that retention times and sensitivity criteria were not met, and that none of the FDA multi-residue method test procedures are suitable for the regulatory analysis of flumioxazin.

Multi-residue method DFG S19 (plant matrices)

The multi-residue method DFG S19 (revised) was investigated and validated for the determination of flumioxazin in cereals and other dry crops (Rzepka, 2004; SBA-0048), potato (Rzepka and Klimmek, 2006; SBA-0051), and oily crops such as sunflower seeds (Class and Merdian, 2010; SBA-0064). Samples are extracted with acetone:water (2:1 v/v) and the extracts partitioned with 1:1 v/v ethyl acetate:cyclohexane (Module E 2). The organic phase is cleaned up by gel permeation chromatography using ethyl acetate:cyclohexane (1:1, v/v) as the eluent and after concentration, flumioxazin residues are determined by GC-MS (Module D4). The fragment ion m/z 354 was used for quantitation and m/z 287 and m/z 259 were used for confirmation. The LOQ was 0.02 mg/kg for all matrices tested.

The method showed good linearity (correlation coefficients > 0.997 and no significant interferences were detected at the retention time corresponding to flumioxazin in any control samples, although confirmatory analysis of wheat straw samples yielded chromatographic interferences. These were removed by an additional clean-up step using silica gel mini-columns. The mean recoveries for all matrices tested and at all fortification levels ranged from 70 and 110%, within the acceptable range, with relative standard deviations of 20% or less.

Stability of residues in stored analytical samples

The Meeting received information on the stability of residues of flumioxazin in a wide range of fresh and processed commodities with high water, starch, protein, oil and acid contents, stored at freezer temperatures of –20 °C (or below) for various intervals. Several studies were also provided on the stability of the 1-OH-HPA metabolite. Most of these studies were conducted concurrently with the supervised field trials, and the longest storage intervals reflected those used in the field trials.

USE PATTERNS

Information on GAP in the USA was provided to the Meeting on the use of flumioxazin, available as WG, SC or WP formulations, often co-formulated with other herbicides. The Meeting also noted that flumioxazin registrations existed in Australia, Europe, Canada, Latin America and some countries in Asia.

The following table summarizes the representative critical GAPs in the USA for crops relevant to the available residue field trials.

Table 44 Representative registered uses of flumioxazin (510 g ai/kg WG formulations)

Crop	Country	Application (max)		Max/season		PHI (days)	Comments
		kg ai/ha	water L/ha	no	kg ai/ha		
Pome fruit	USA	0.42	140–280		0.84	60	Directed inter-row band sprays, up to pink bud or bud-burst, min 30 day RTI
Stone fruit	USA	0.42	140–280		0.84	60	Directed inter-row band sprays, up to bud break, min 30 day RTI
Bush berries	USA	0.42	140–280		0.42	7	Directed inter-row band sprays. Min 30 day RTI
Grapes	USA	0.42	140–280		0.84	60	Directed inter-row band sprays. Min 30 day RTI. Not after bud-break on table grapes
Strawberries	USA	0.105	140–280		0.105		Pre-plant (at least 30 days before transplanting)
	USA	0.105	140–280		0.105		Broadcast to dormant plants
	USA	0.105	140–280		0.105		Directed inter-row band application up to fruit-set
Olives	USA	0.42	140–280		0.84	60	Directed inter-row band sprays. Min 30 day RTI
Pomegranates	USA	0.42	140–280		0.84	60	Directed inter-row band sprays. Min 30 day RTI
Garlic	USA	0.21	140–280		0.21		Pre-emergent application up to 3 days after planting
Onion, bulb	USA	0.07	140–180		0.105	45	Apply from 2-leaf and 6-leaf stage (BBCH12–16). Min 14 day RTI
Cabbage, head	USA	0.14	140–280		0.28		Pre-plant directed inter-row application (between raised plastic mulched beds)
Cucurbit vegetables	USA	0.14	140–280		0.28		Pre-plant directed inter-row applications (between raised plastic mulched beds), up to 14 days before planting
	USA	0.14	140–280		0.28		Directed inter-row band application up to 21 days after transplanting/emergence, not after start of flowering
Fruiting	USA	0.14	140–280		0.28		Pre-plant directed inter-row applications (between raised plastic mulched beds), up to 14 days before

Crop	Country	Application (max)		Max/season		PHI (days)	Comments
		kg ai/ha	water L/ha	no	kg ai/ha		
vegetables							planting
	USA	0.14	140–280		0.28		Directed inter-row band application up to 21 days after transplanting/emergence. Not after start of flowering
Beans, dry (incl lentils)	USA	0.07	140–280		0.07		Pre-plant or pre-emergent (up to 2 days after sowing)
	USA	0.105	140–560		0.105	5	Apply when crop is mature and at least 80% of pods are yellowing (BBCH 87–89)
Field peas	USA	0.07	140–280		0.07		Pre-plant or pre-emergent (up to 2 days after sowing)
	USA	0.105	140–560		0.105	5	Apply when crop is mature and at least 80% of pods are yellowing (BBCH 87–89)
Soya bean	USA	0.105	140–280		0.105		Pre-plant or pre-emergent (up to 3 days after sowing). No grazing or use for stock feed
Potato	USA	0.053	140–280		0.053		Pre-emergent after hilling or to soil-covered potatoes
Sweet potato	USA	0.105	140–280		0.105		Pre-plant
Artichoke, Globe	USA	0.21	94–280		0.21		Pre-plant (annual varieties) or pre-emergence (perennial varieties)
Asparagus	USA	0.21	140–280		0.21		Broadcast application min 14 days prior to spear emergence (perennial varieties) or fern emergence (annual varieties)
Celery	USA	0.105	140–280		0.105		Pre-transplant
	USA	0.105	140–280		0.105		Broadcast application, 3–7 days after transplanting
Maize	USA	0.105	140–280		0.105		Broadcast application 14–30 days prior to sowing
Wheat	USA	0.07	140–280		0.07		Pre-plant or pre-emergent (up to 2 days after sowing) in minimum tillage fields. No grazing until wheat is 13 cm high
	USA	0.07	min 93 air 47		0.07	10	Apply when crop reaches BBCH 87 (hard dough stage, grain 70% DM)
Sugar cane	USA	0.28	140–280		0.42		Broadcast up to 14 days before planting or broadcast pre-emergent
	USA	0.14	140–280		0.42	90	Directed inter-row band applications after canes are 60 cm height or at layby (canes > 76 cm height). Min 14 day application interval

Crop	Country	Application (max)		Max/season		PHI (days)	Comments
		kg ai/ha	water L/ha	no	kg ai/ha		
Tree nuts	USA	0.42	140–280		0.84	60	Directed inter-row band sprays. Min 60 day RTI
Cotton	USA	0.07	140–280		0.14		Autumn or spring burndown, up to 21 days before planting
	USA	0.07	140–280		0.14	60	Directed inter-row band applications after cotton is 15 cm height or at layby (cotton > 40 cm height). Min 30 day application interval. Use with non-ionic adjuvant
Linseed (flax)	USA	0.105	140–560		0.105	5	Apply when crop is mature and at least 75% of the seed heads are brown in colour (BBCH 87–89). Mix with MSO adjuvant
Sunflower seed Safflower seed	USA	0.105	140–560		0.105	5	Apply when crop is mature (BBCH 86–87—seedheads yellowing and the bracts turning brown). Mix with MSO adjuvant
Peanut	USA	0.105	140		0.105		Pre-plant or pre-emergent (up to 2 days after sowing). With adjuvant. No grazing or use for stock feed
Mints (spearmint, peppermint)	USA	0.14	140–180		0.28	80	Autumn-spring applications to established dormant plants. At least 60 days between applications
Alfalfa	USA	0.14	94–280		0.28	25	After last cut (Autumn) and/or after 1st cut, before crop reaches 15 cm height. PHI is for cutting and grazing

Pome fruit = apple, crabapple, loquat, mayhaw, pear, pear (oriental) and quince

Stone Fruit = apricot, cherries (sweet and tart), nectarine, peach, plum (chickasaw, damson, japanese), plumcot and prune

Bushberries = aronia berry, black currant, blueberry (highbush, rabbit-eye and lowbush), buffalo currant, chilean guava, cranberry (highbush), elderberry, european barberry, gooseberry, honeysuckle (edible), huckleberry, jostaberry, juneberry, lingonberry, native currant, red currant, salal and sea buckthorn

Cucurbits = chayote (fruit); chinese waxgourd (chinese preserving melon); citron melon; cucumber; gherkin; gourd, edible (includes hyotan, cucuzza, hechima, chinese okra); Momordica spp. (includes balsam apple, balsam pear, bittermelon, chinese cucumber); muskmelon (includes cantaloupe); pumpkin; squash, summer; squash, winter (includes butternut squash, calabaza, hubbard squash, acorn squash, spaghetti squash) and watermelon

Fruiting vegetables = eggplant, groundcherry (Physalis spp), okra, pepino, peppers (Capsicum spp incl bell, chili, cooking, pimento & sweet), tomatillo and tomato

Tree nuts = almond, beechnut, betelnut, black walnut, brazil nut, butternut, cashew, chestnut, chinquapin, coconut, english walnut, filbert (hazelnut), ginkgo, heartnut, hickory nut, macadamia nut, oak, pecan, pili nut, pine nut, pistachio and tropical almond

Dry beans = Dried cultivars of bean (Lupinus), bean (Phaseolus) (incl field bean, kidney bean, lima bean (dry), navy bean, pinto bean, tepary bean); bean (Vigna) (incl adzuki bean, blackeyed pea, catjang, cowpea, crowder pea, moth bean, mung bean, rice bean, southern pea, urd bean); broad bean (dry); chickpea; guar; lablab bean, lentil

RESIDUES RESULTING FROM SUPERVISED TRIALS

The Meeting received information on supervised field trials involving soil or foliar treatments of flumioxazin to the following crops.

Group	Crop	Countries	Table no
Pome fruits	Apple, Pear	USA	45
Stone fruits	Cherry, Peach Plum	USA	46
Berries and other small fruit	Blueberry	USA	47
	Grape	USA	48
	Strawberries	USA	49
Assorted tropical and sub-tropical fruits	Olives	USA	50
	Pomegranate	USA	51
Bulb vegetables	Onion, dry bulb	USA	52
Brassica vegetables	Cabbage	USA	53
Fruiting vegetables, Cucurbits	Cucumber	USA	54
	Melons	USA	55
	Summer squash	USA	56
Fruiting vegetables, other than Cucurbits	Peppers	USA	57
	Tomato	USA	58
Pulses	Beans (dry)	USA	59
	Peas (dry)	USA	60
	Soya bean (dry)	USA	61
Root and tuber vegetables	Potato	USA	62
Stalk and stem vegetables	Artichoke, Globe	USA	63
	Asparagus	USA	64
	Celery	USA	65
Cereal grains	Maize	North America	66
	Wheat	USA	67
Grasses for sugar or syrup production	Sugar cane	USA	68
Tree nuts	Almond	USA	69
	Pecan	USA	70
Oilseed	Cottonseed	USA	71
	Rape seed	USA	72
	Peanut	USA	73
	Sunflower seed	USA	74
Herbs	Mint leaves and oil	USA	75
Legume animal feeds	Alfalfa forage and fodder	USA	76, 77
	Peanut vines and fodder	USA	78
	Soya bean forage and fodder	USA	79
Straw, forage, fodder of cereal grains	Maize forage and fodder	USA	80
	Wheat forage, hay and straw	USA	81, 82

The supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation including procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ. In such cases, the residues found are noted as "c=nn mg/kg" in the Reference and Comments columns. Residue data are recorded unadjusted for recovery.

Results from replicated field plots are presented as individual values. Residues and application rates have been reported as provided in the study reports, although the results from trials used for the estimation of maximum residue levels (underlined) have been rounded to two significant digits (or if close to the LOQ, rounded to one significant digit) in the Appraisal.

When multiple applications were made to a crop, the application rate, spray concentration and spray volume were not always identical from one application to the next. In most trials, the actual treatment rates were within 10% of the listed 'target' application rates, but if not, the actual treatment rates are listed.

Pome fruits

In supervised trials on pome fruit (12 on apples and six on pears) conducted in the USA during 2002–2003, two inter-row/berm soil treatments of 0.42–0.45 kg ai flumioxazin/ha (WG or SC formulations) were applied using tractor-mounted boom sprayers or back-pack sprayers with hand-held booms. Treatments were applied about 60 days apart, with the last application about 60 days before harvest.

Duplicate samples of mature fruit (min 2 kg or 24 fruit) were frozen within 2 hours and analysed for flumioxazin within 1 year of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 80–115% and the validated LOQ was 0.02 mg/kg.

Table 45 Residues in pome fruit from supervised trials in the USA involving two directed inter-row soil applications of flumioxazin (SC or WG formulations)

Stone fruits

Cherry, peach, and plum

In supervised trials on stone fruit (six on cherries, nine on peaches, and six on plums) conducted in the USA during 2002–2003, two inter-row/berm soil treatments of 0.42–0.45 kg ai flumioxazin/ha (WG or SC formulations) were applied using tractor-mounted boom sprayers or back-pack sprayers with hand-held booms. Treatments were applied 50–60 days apart (except in two trials with shorter intervals of 34 and 15 days) with the last application about 60 days before harvest.

Duplicate samples of mature fruit (min 1 kg cherries, 2 kg peaches, plums) were frozen within 2 hours and after removing the stones, were analysed for flumioxazin within 10 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 75–120% and the validated LOQ was 0.02 mg/kg.

Berries and other small fruits

Blueberries

In supervised trials on blueberries (six) conducted in the USA during 2003, two inter-row/berm soil treatments of 0.41–0.45 kg ai flumioxazin/ha (WG formulations) were applied using back-pack sprayers with 1–4 nozzle hand-held booms. Treatments were applied 50–113 days apart with the last application 6–8 days before harvest (except in one lowbush trial where a single application was made to dormant bushes).

Duplicate samples of mature fruit (min 1 kg except at two sites) were frozen within 4 hours and analysed for flumioxazin within 6 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 74–113% and the validated LOQ was 0.02 mg/kg.

Grapes

In supervised trials on grapes (12) conducted in the USA during 1999, two directed inter-row/berm soil treatments of 0.4–0.43 kg ai flumioxazin/ha (WG formulations) with added crop oil were applied using tractor-mounted boom sprayers or back-pack sprayers with hand-held booms. Treatments were applied about 60 days apart with the last application about 60 days before harvest.

Duplicate samples of grapes (min 12 bunches or 1 kg) were frozen within 4 hours and analysed for flumioxazin within 6 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.01 and 0.05 mg/kg ranged from 82–123% and the LOQ was 0.01 mg/kg.

Strawberry

In supervised trials on strawberries (five) conducted in the USA during 2002, one inter-row soil treatment of 0.1–0.11 kg ai flumioxazin/ha (WG formulations) was applied 1–2 days before harvest using shielded back-pack sprayers with 1–4 nozzle mini-booms. In three additional trials, two applications of 0.1 kg ai/ha flumioxazin were made, the first being a broadcast application to dormant strawberries and the second as an inter-row shielded application 1–2 days before harvest.

Duplicate samples of at least 1 kg mature fruit (with sepals removed) were frozen within 4 hours and analysed for flumioxazin within 7 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 100–120% and the validated LOQ was 0.02 mg/kg.

Bulb vegetables

Onion, dry bulb

In supervised trials on bulb onions (nine) conducted in the USA during 2001, two foliar broadcast sprays of 0.1–0.11 kg ai flumioxazin/ha (WG formulations) with added adjuvant were applied using tractor-mounted, wheeled or back-pack sprayers with 3–6 nozzle minibooms. The first applications were made when the onions were at or about the 2-leaf stage, re-treatment intervals were 29–78 days and the last applications were 42–49 days before harvest. Phytotoxicity was observed in most trials.

Duplicate samples of topped and trimmed dry onion bulbs (min 12 bulbs, 1.3 kg) were frozen within 1 hour and analysed for flumioxazin within 2 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 70–120% and the validated LOQ was 0.02 mg/kg.

Table 52 Residues in onion bulbs from supervised trials in the USA involving two broadcast foliar applications of flumioxazin (WG formulations)

Brassica vegetables

Cabbage

In supervised trials on cabbage (eight) conducted in the USA during 2006, one pre-plant broadcast soil treatment of 0.05 kg ai/ha or 0.1–0.11 kg ai flumioxazin/ha (WG formulations) were applied using tractor-mounted or back-pack sprayers with 3–8 nozzle booms. Phytotoxicity was observed in most trials, particularly in the plots treated at the higher rate.

Duplicate samples of mature cabbage heads with wrapper leaves (min 12 heads) from most plots were quartered or halved in the field (to give sample sizes of at least 1.8 kg). In three trials, smaller sample sizes were taken because of reduced plant numbers. Samples were frozen within 2 hours and analysed for flumioxazin within 8 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 85–90% and the validated LOQ was 0.02 mg/kg.

[a] Reduced sample size—only two whole plants able to be collected

Fruiting vegetables, cucurbits

Supervised trials on fruiting vegetables, cucurbits were conducted in the USA between 2003 and 2005.

Cucumber

In eight trials on cucumbers, two treatments of 0.14–0.17 kg ai flumioxazin/ha (WG formulations) were applied as inter-row shielded applications, the first application about 14 days before crop emergence or before transplanting and the second application about 21 days after transplanting or 28 days after the crop emergence (at or before flowering). Treatments were made using tractor-mounted or backpack sprayers with 1–4 shielded nozzle minibooms.

Duplicate samples of mature fruit (min 12 units, 1.8 kg). In two trials, samples were quartered or halved in the field. Samples were frozen within 2.5 hours and analysed for flumioxazin within 5 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 70–120% and the validated LOQ was 0.02 mg/kg.

[a] 2nd application after the start of flowering

Melon (cantaloupe)

In eight trials on cantaloupes, two treatments of 0.14–0.15 kg ai flumioxazin/ha (WG formulations) were applied as inter-row shielded applications, the first application about 10–14 days before transplanting or 4–7 days before sowing and the second application about 21 days after transplanting or 28 days after the crop emergence (at or before flowering). Treatments were made using tractor-mounted or backpack sprayers with 1–2 shielded nozzle minibooms.

Duplicate samples of mature fruit (min 12 units) were subsampled in the field (2–5 cm longitudinal sections) to give sample sizes of at least 1.8 kg. Samples were frozen within 3 hours and analysed for flumioxazin within 4 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 72–108% and the validated LOQ was 0.02 mg/kg.

Fruiting vegetables other than cucurbits

Supervised trials on fruiting vegetables other than cucurbits were conducted in the USA in 2003.

Peppers (sweet, chili)

In nine trials on peppers (bell and non-bell/chilli), two treatments of 0.14–0.15 kg ai flumioxazin/ha (WG formulations) with added adjuvant were applied as inter-row shielded applications, the first application at transplanting or shortly after emergence and the second application from 15–21 days before harvest. Treatments were made using tractor-mounted or backpack sprayers with 1–2 shielded nozzle minibooms.

Duplicate samples of mature fruit (min 12 units, 1.8 kg) were frozen within 6 hours and analysed for flumioxazin within 27 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 86–121% (0.02 mg/kg spike level) and 59–111% (0.2 mg/kg spike level). The validated LOQ was 0.02 mg/kg.

Pulses

Supervised trials on pulses (beans, peas and soya beans) were conducted in North America between 1989 and 2009.

Beans (dry)

In twelve trials on beans, one foliar broadcast spray of 0.1–0.11 kg ai flumioxazin/ha (WG formulations) with added adjuvant was applied as a pre-harvest desiccant and harvest aid using tractor-mounted or back-pack sprayers with 4–11 nozzle booms.

Duplicate samples were harvested, allowed to dry in the field for up to 13 days before being shelled (manually or mechanically) to obtain minimum samples of 1 kg dry seeds. These samples were frozen within 5 hours and analysed for flumioxazin within 10 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 79–119% and the validated LOQ was 0.02 mg/kg.

Table 59 Residues in beans, dry from supervised trials in the USA involving one pre-harvest foliar application of flumioxazin (WG formulation)

Peas (dry)

In thirteen trials on field peas, one foliar broadcast spray of 0.11 kg ai flumioxazin/ha (WG formulations) with added adjuvant was applied as a pre-harvest desiccant and harvest aid using tractor-mounted or back-pack sprayers with 4–8 nozzle booms.

Duplicate plant samples were collected using small plot combines or cut and harvested using a stationary combine to obtain minimum samples of 1 kg dry seeds. These samples were frozen within 6 hours and analysed for flumioxazin within 4.5 months of harvest using method

RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 96–112% and the validated LOQ was 0.02 mg/kg.

Soya beans

In supervised trials on <u>soya beans</u> conducted in the USA between 1989 and 1993, single broadcast soil applications of 0.1–0.11 kg ai flumioxazin/ha (WG, FL or WP formulations) were applied using back-pack or tractor-mounted boom sprayers, either as pre-plant treatments (with or without soil incorporation) or just after sowing, before crop emergence.

Duplicate samples of seed (min 1 kg) were frozen within 24 hours and stored for up to 9 months before analysis for flumioxazin using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 mg/kg ranged from 71–112% in seeds, with a validated LOQ of 0.02 mg/kg.

In the trials conducted in 1992–93, seeds were also analysed for the 1-OH-HPA metabolite, using method RM 30M (GC-MS), with an LOQ of 0.02 mg/kg and recovery rates of 71–100% in samples spiked with 0.02 mg/kg.

The 1992–1993 supervised trials also analysed for residues of the metabolite, 1-OH HPA in seeds. Residues in all samples were below the LOQ of 0.02 mg/kg (18 trials).

PE = pre-emergence application (within 5 days after sowing)

PP = pre-plant application

Root and tuber vegetables

Potato

In supervised trials on potatoes (14) conducted in the USA during 2001, single broadcast soil applications of 0.13–0.15 kg ai flumioxazin/ha (WG formulations) were applied using back-pack, wheeled or tractor-mounted sprayers with 2–12 nozzle booms after the last hilling operation, before potato emergence. In several trials, transitory phytotoxicity and stunting was observed.

Duplicate samples of at least 1.8 kg potatoes were wiped, brushed or rinsed to remove adhering soil, frozen within 2.5 hours and analysed for flumioxazin within 9 months of harvest using method RM 30A-2 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 77–118% and the validated LOQ was 0.02 mg/kg.

Stem and stalk vegetables

Supervised trials on stem and stalk vegetables (asparagus, Globe artichoke and celery) were conducted in North America between 2003 and 2007.

Artichoke, Globe

In three supervised trials on Globe artichokes, single broadcast soil applications of 0.21 kg ai flumioxazin/ha (WG formulations) were applied 1–4 days before transplanting using back-pack sprayers with hand-held 5-nozzle minibooms.

Duplicate samples of flower heads (12 units, min 2.7 kg) were frozen within 1 hour and analysed for flumioxazin within 7.5 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 70–115% and the validated LOQ was 0.02 mg/kg.

Table 63 Residues in Globe artichokes from supervised trials in the USA involving one broadcast pre-plant soil application of flumioxazin (WG formulations)

Asparagus

In eight supervised trials on asparagus, single broadcast soil applications of 0.21–0.22 or 0.43–0.45 kg flumioxazin/ha (WG formulations) were applied using back-pack, ATV or tractor-mounted 3–6 nozzle booms about 2 weeks before spear emergence. Phytotoxicity was observed in several trials.

Duplicate samples of at least 1.3 kg spears were brushed (if necessary) to remove adhering soil, frozen within 4.5 hours and analysed for flumioxazin within 3.5 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 90–114% and the validated LOQ was 0.02 mg/kg.

Celery

In eight supervised trials on celery, single broadcast soil applications of 0.1–0.11 or 0.2–0.22 kg ai flumioxazin/ha (WG formulations) were applied 0–2 days before transplanting using back-pack plot sprayers with 3–4 nozzle minibooms or tractor-mounted 9-nozzle boom sprayers. Phytotoxicity was reported in several of the high-rate plots.

Duplicate samples of 12 untrimmed bunches (12 units, min 1.8 kg) were brushed or rinsed if necessary to remove adhering soil, frozen within 5 hours and analysed for flumioxazin within 9 months of harvest using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 90–120% (except for one recovery at 150%) and the validated LOQ was 0.02 mg/kg.

Cereal grains

Supervised trials on cereal grains (maize and wheat) were conducted in North America between 2005 and 2010.

Maize

In twenty-one supervised trials on maize, single broadcast soil applications of 0.1–0.11 or 0.2–0.22 kg ai flumioxazin/ha (WG formulations) with added surfactant were applied 6–14 days before sowing, using back-pack plot sprayers, wheeled or tractor-mounted boom sprayers (3–9 nozzles).

Duplicate samples of kernels (min 1 kg) were taken at maturity, frozen within 2 hours and analysed for flumioxazin within 14 months using method RM 30A-3 (GC-MS) in the 2005 trials and method NCL 293 (HPLC-MS/MS) in the 2006 trials. Recoveries from control kernel samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 85–122% in the two methods and the validated LOQ was 0.02 mg/kg.

Wheat

In twenty supervised trials on wheat, single foliar broadcast sprays of 0.07–0.075 kg ai flumioxazin/ha (WG formulations) with added adjuvants were applied as pre-harvest desiccants and harvest aids using tractor-mounted or back-pack sprayers with 4–8 nozzle booms.

Duplicate samples were collected using small plot combines or cut and harvested using a stationary combine to obtain minimum samples of 1 kg dry seeds. Samples were frozen within 5 hours and analysed for flumioxazin within 17 months of harvest using method RM 30A-3 (GC-MS). Concurrent recoveries from control grain samples fortified with flumioxazin at levels of 0.02–0.5 mg/kg ranged from 70–122% and the validated LOQ was 0.02 mg/kg.

Grasses for sugar production

Sugar cane

In supervised trials on sugar cane (nine) conducted in the USA during 1998, single broadcast applications of 0.4–0.42 kg ai flumioxazin/ha (WG formulations) with added crop oil were applied over the top of 2–2.5 m high canes using back-pack sprayers with elevated 6-nozzle booms or extended single-nozzle hand lances.

Duplicate samples of at least 12 canes with leaves attached (min 5 kg) were frozen within 10 hours and analysed for flumioxazin within 5 months of harvest using method RM 30A-1 (GC-MS). Samples were also analysed within 7 months of harvest for the 1-OH-HPA metabolite using method RM-30C (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.01–0.5 mg/kg ranged from 67–113% and in samples fortified with 0.02–0.2 mg/kg 1-OH-HPA, recoveries were 70–114%. The validated LOQs for both compounds were both 0.02 mg/kg.

Residues of 1-OH-HPA < 0.02 mg/kg in all samples

Tree nuts

Supervised trials on tree nuts (almonds and pecans) were conducted in the US during 1999 and 2003, respectively.

Almonds

In supervised trials on almonds (five), two inter-row/berm broadcast soil treatments of 0.42 kg ai flumioxazin/ha (WG formulations) with added crop oil were applied using tractor-mounted 4–8 nozzle boom sprayers. Treatments were applied about 60 days apart, with the last application about 60 days before harvest.

Duplicate samples of mature nuts (min 1 kg) shaken from the trees, shelled in the field, frozen within 3 hours and analysed for flumioxazin within 6 months of harvest using method RM 30A-1 (GC-MS). Samples of almond hulls were also analysed within 8.5 months of harvest for the 1-OH-HPA metabolite using method RM-30M (GC-MS).

Recoveries from control samples fortified with flumioxazin at levels of 0.01 and 0.05 mg/kg ranged from 89–114% in nutmeat and 71–96% in hulls. In hull samples fortified with 0.1 or 0.5 mg/kg 1-OH-HPA, recoveries were 81–98%.The validated LOQs were 0.01 mg/kg (flumioxazin) and 0.1 mg/kg for the 1-OH-HPA metabolite.

Pecans

In supervised trials on pecans (five), two inter-row/berm broadcast soil treatments of 0.42–0.43 kg ai flumioxazin/ha (WG formulations) were applied using knapsack or wheeled sprayers with 3–4 nozzle booms. Treatments were applied about 60 days apart, with the last application about 60 days before harvest.

Duplicate samples of mature nuts (min 1.2 kg) were shaken from the trees, shelled within 2 days of harvest, with nutmeat samples frozen within 6.25 hours of shelling and analysed for flumioxazin within 3.3 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 77–99% and the validated LOQ was 0.02 mg/kg.

Oilseeds

Supervised trials on oilseeds (oilseed rape, cotton seed, sunflower seed and peanuts) were conducted in the USA between 1992 and 2009.

Cotton seed

In supervised trials on cotton seed (13), two foliar broadcast sprays of 0.1–0.11 kg ai flumioxazin/ha (WG formulations) with added crop oil were applied using tractor-mounted boom sprayers. The first applications were made about 90 days before harvest using shielded nozzles to minimise spray contact with the plants and the second applications were made about 60 days before harvest as directed inter-row sprays at layby, with spray contacting only the lower 5–10 cm cotton stems.

Duplicate samples of cotton seed, either ginned in the field (min 1 kg) or unginned (min 20 kg), were frozen within 4 hours (undelinted seed) or within 24 hours (unginned cotton). The cotton seed samples were stored frozen for up to 30 days before being ginned to separate the undelinted seed and gin trash and refrozen. All samples were analysed for flumioxazin within 3 months using method RM 30A-1 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.01 and 0.05 mg/kg ranged from 76–106% (cottonseed) and 70–102% in gin trash. The validated LOQs were 0.01 mg/kg for cotton seed and gin trash.

Samples of gin trash were also analysed within 8 months of harvest for the 1-OH-HPA metabolite using method RM-30M (GC-MS) with recoveries from control samples fortified with 1-OH-HPA at levels of 0.1 and 0.5 mg/kg ranging from 81–121% and the validated LOQ was 0.1 mg/kg.

Table 71 Residues in cotton seed and gin trash from supervised trials in the USA involving two inter-row soil applications of flumioxazin (WG formulation)

DAT = Interval from last application to cutting + field drying interval (in days)

In trials V-32833-D, V-32833-G and V-32833-H, vines were cut and allowed to dry for up to 16 days before seeds were collected.

Peanuts

In fifteen supervised trials on peanuts, single broadcast soil applications of 0.1–0.11 kg ai flumioxazin/ha (WG formulations) were applied either as pre-plant broadcast sprays (with shallow soil incorporation) within 7 days before sowing or as pre-emergent broadcast sprays within 5 days after sowing, using tractor-mounted boom sprayers (8–13 nozzles).

Duplicate samples of whole peanuts were collected after 3–19 days of field drying, shelled in the field and samples of nutmeat (min 2.2 kg) and hulls (min 0.22 kg) were taken for analysis. All samples were kept in frozen storage up to 210 days before analysis for flumioxazin using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02–0.1 mg/kg ranged from 80–105% (nutmeat) and 70–101% (hulls), and the validated LOQs were 0.02 mg/kg.

Sunflower seed

In supervised trials on sunflowers (eight), single foliar broadcast sprays of 0.11 kg ai flumioxazin/ha (WG formulations) were applied with added adjuvant as pre-harvest desiccants and harvest aids using tractor-mounted or back-pack sprayers with 4–8 nozzle booms.

Duplicate samples of seed (min 1 kg from 12 flower heads) were frozen within 3.5 hours and analysed for flumioxazin within 11 months of harvest using method RM 30A-3 (GC-MS).

Concurrent recoveries from control samples fortified with flumioxazin at levels of 0.02–3.0 mg/kg ranged from 82–102% and the validated LOQ was 0.02 mg/kg.

Table 74 Residues in sunflower seed from supervised trials in the USA involving one pre-harvest foliar application of flumioxazin (WG formulation)

Herbs

Mints

In supervised trials on <u>mint</u> (six) conducted in the USA during 2001, two foliar broadcast sprays of 0.28 or 0.42 kg ai flumioxazin/ha (WG formulations) were applied to dormant mint plants (February-April). The intervals between treatments were not reported in the study report. Duplicate samples of mint tops (leaves and stems) were stored frozen for up to 9 months before analysis for flumioxazin using method RM 30A-2 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 72–113% and the validated LOQ was 0.02 mg/kg.

In two of the trials, mint oil was extracted on the same day of harvest and stored frozen for up to 8 months before dilution with acetone and analysis for flumioxazin using method RM 30A-2 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 91–111% and the validated LOQ was 0.02 mg/kg.

Legume animal feeds

Alfalfa forage and fodder

In supervised trials on alfalfa (six) conducted in the USA during 2003, two foliar broadcast sprays of 0.14–0.15 kg ai flumioxazin/ha (WG formulations) were applied 24–26 days before the first cutting (with added surfactant) and to the alfalfa regrowth 6–8 days after the first cutting using back pack or tractor-mounted boom sprayers (6–9 nozzles). Retreatment intervals ranged from 30–33 days. In further trials conducted in 2005, single foliar broadcast sprays of 0.14 kg ai flumioxazin/ha (with added surfactants) were applied to alfalfa regrowth 7–9 days after the first cutting using back pack or tractor-mounted boom sprayers (4–8 nozzles).

Duplicate samples of forage (min 1 kg) were taken 6–26 days after the second application and fodder (hay) samples (min 0.5 kg) were taken after a further 2–8 days drying in the field. Samples were frozen within 6 hours and analysed for flumioxazin within 15 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02–2.0 mg/kg (forage) and 0.02–7.0 mg/kg (fodder) ranged from 71–120% and the validated LOQ was 0.02 mg/kg.

Peanut forage and fodder

In fifteen supervised trials on peanuts, single broadcast soil applications of 0.1–0.11 kg ai flumioxazin/ha (WG formulations) were applied either as pre-plant broadcast sprays (with shallow soil incorporation) within 7 days before sowing or as pre-emergent broadcast sprays within 5 days after sowing, using tractor-mounted boom sprayers (8–13 nozzles).

Duplicate samples of peanut vines were collected immediately after digging, and samples of hay (min 0.45 kg) were collected after 3–19 days of field drying and kept in frozen storage up to 210 days before analysis for flumioxazin using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02–0.1 mg/kg ranged from 76–113% (vines) and 63–86% (hay) and the validated LOQs were 0.02 mg/kg.

Table 78 Residues in peanut vines and hay from supervised trials in the USA involving one broadcast pre-plant or pre-emergent soil application of flumioxazin (WG formulations)

Soya bean forage and fodder

In supervised trials on soya beans conducted between 1989 and 1993, single broadcast soil application of 0.1–0.11 kg ai flumioxazin/ha (WG, FL or WP formulations) were applied using back-pack or

tractor-mounted boom sprayers, either as pre-plant treatments (with or without soil incorporation) or just after sowing, before crop emergence.

Duplicate samples of forage (min 0.9 kg) and hay (min 0.45 kg) were frozen within 24 hours and stored for up to 13 months (forage) and 11 months (hay) before analysis for flumioxazin using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 mg/kg ranged from 67–120% in forage and 73–130% in hay, with a validated LOQ of 0.02 mg/kg.

The 1992–1993 supervised trials also analysed for residues of the metabolite, 1-OH HPA in seeds and the results also showed levels below the LOQ of 0.02 mg/kg.

Straw, forage, fodder of cereal grains

Maize forage and fodder

In twenty-one supervised trials on maize, single broadcast soil applications of 0.1–0.11 or 0.2–0.22 kg ai flumioxazin/ha (WG formulations) with added surfactant were applied up to 7 days before sowing, using back-pack plot sprayers, wheeled or tractor-mounted boom sprayers (3–9 nozzles).

Duplicate samples of forage (min 12 units) were taken at the late dough/early dent growth stage (about BBCH 86) and stover samples (min 12 units) were taken at grain harvest. Samples were all frozen within 2 hours and analysed for flumioxazin within 14 months using method RM 30A-3 (GC-MS) in the 2005 trials and method NCL 293 (HPLC-MS/MS) in the 2006 trials. Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 87–117% (forage) and 79–118% (stover) in the two methods and the validated LOQs were 0.02 mg/kg.

Wheat forage, hay and straw

In three supervised trials on wheat, single pre-plant broadcast soil applications of 0.07 or 0.14 kg ai flumioxazin/ha (WG formulations) with added surfactant were applied 7 or 14 days before sowing respectively, using tractor-mounted boom sprayers (4–8 nozzles).

Duplicate samples of wheat forage (from plants about 13 cm tall) and hay (sampled at BBCH 61–85 and allowed to dry to 10–20% moisture content) were frozen within 2 hours and analysed for flumioxazin within 38 days of harvest using method RM 30A-3 (GC-MS). Concurrent recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 93–109% in forage, 89–120% in hay and the validated LOQ was 0.02 mg/kg.

In twenty supervised trials on wheat, single foliar broadcast sprays of 0.07–0.075 kg ai flumioxazin/ha (WG formulations) with added adjuvants were applied as pre-harvest desiccants (harvest aids) using tractor-mounted or back-pack sprayers with 4–8 nozzle booms.

Duplicate samples of straw were collected using small plot combines or cut and harvested using a stationary combine, frozen within 5 hours and analysed for flumioxazin within 17 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control straw samples fortified with flumioxazin at levels of 0.02–5.0 mg/kg ranged from 70–115% and the validated LOQ was 0.02 mg/kg.

NIS = Non-ionic surfactant

MSO = Methylated seed oil surfactant

Fate of residues in storage and processing

The meeting received processing studies on apples, plums, grapes, olives, soya beans, potatoes, sugar cane, maize, wheat, sugar cane, oilseed rape, sunflower seed, peanuts and mint. In all cases, fresh commodity samples collected from supervised trials at exaggerated rates were processed simulating commercial practices.

Apple

In a supervised trial on apples conducted in the USA and reported by Stearns, 2004 [Ref: SBR-0031], two inter-row/berm soil treatments of 0.86 kg ai flumioxazin/ha (SC formulation) were applied using an ATV-mounted boom sprayer (six nozzles). Treatments were applied 60 days apart, with the last application 60 days before harvest.

Duplicate samples of 30 kg mature fruit were frozen within 1 hours and stored for 5 days before processing into apple wet pomace and juice, simulating commercial practices. Unwashed apples were ground using a hammer mill, then pressed in a hydraulic press to provide apple juice and wet pomace. The processed samples were stored frozen for up to 9 months before analysis for flumioxazin using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02–0.1 mg/kg ranged from 79–110% (apples) and 90–98% (wet pomace). Recoveries in juice spiked with 0.005–0.5 mg/kg were 95–103%. In juice the validated LOQ was 0.02 mg/kg.

Table 83 Residues in apples, pomace and juice from a supervised trial in the USA involving two directed inter-row soil applications of flumioxazin (SC formulation)

Plum

In a supervised trial on plums conducted in the USA and reported by Kowalsky, 2004 [Ref: SBR-0030], two inter-row/berm soil treatments of 0.86 kg ai flumioxazin/ha (SC formulation) were applied using a tractor-mounted boom sprayer (six nozzles). Treatments were applied 64 days apart, with the last application 60 days before harvest.

Duplicate samples of mature plums (33 kg) were processing into prunes on the day of harvest by removing stems and leaves, washing the fruits with a hose, and air dying in drying tunnels for about 19 at 86 °C and allowed to cool for 24 hours. Duplicate samples were analysed for flumioxazin within 9 months of processing using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 83–98% (plums) and 105–109% (prunes) and the validated LOQ was 0.02 mg/kg.

Table 84 Residues in plums and prunes from a supervised trial in the USA involving two directed inter-row soil applications of flumioxazin (SC formulation)

Grape

In a supervised trial on grapes conducted in the USA and reported by Schreier, 2000 [Ref: SBR-0025], two directed inter-row/berm soil treatments of 2.1 kg ai flumioxazin/ha (WG formulation) with added crop oil were applied using a back-pack sprayer with hand-held 4-nozzle boom. Treatments were applied 60 days apart with the last application 60 days before harvest. Duplicate samples of grapes (9 kg for juice processing and 56 kg for raisin processing) were processed into juice and raisins within 24 hours of sampling.

Juice was prepared by washing the grape bunches with water then hand feeding them into a crusher/stemmer machine. The grape pulp was separated from the stems and seeds and transferred to a hydraulic fruit press. The fresh juice collected from the press was filtered to remove coarse solids prior to freezing and storage for up to 1.6 months before analysis for flumioxazin using method RM 30A-1.

Grapes were processed into raisins by sun-drying on trays in the field for about a month before being screened to remove loose dirt, stems and debris and hand sorted to remove the cap stems and any additional unacceptable product. The raisins were batch washed for 10–15 seconds, re-hydrated to approximately 18% moisture, frozen and stored for up to 5 months before analysis for flumioxazin using method RM 30A-1.

Recoveries from control samples fortified with flumioxazin at levels of 0.01 and 0.05 mg/kg ranged from 82–123% (grapes), 95–115% (juice) and 96–106% (raisins). The validated LOQs were 0.01 mg/kg.

Table 85 Residues in fresh and processed grapes from a supervised trial in the USA involving two inter-row soil applications of flumioxazin (WG formulation)

Olive

In a supervised trial on olives conducted in the USA and reported by Arsenovic and Leonard, 2011 [Ref: SBR-0130], two directed inter-row/berm soil treatments of 2.1 kg ai flumioxazin/ha (WG formulation) with added crop oil were applied using a back-pack sprayer with a hand-held 3-nozzle miniboom. Treatments were applied 62 days apart with the last application 56 days before harvest.

Duplicate samples (22 kg) of olives were refrigerated overnight and sent to the processing facility where the samples were cleaned of extraneous materials and then warmed in an oven for about 20 minutes at 24–29 °C. Warmed olives were ground in a food chopper to produce a paste, which was then placed in a mixer and transferred into a filter press. Pressure was applied to remove oil from the paste. The oil was filtered, collected and stored frozen for up to 17 months before analysis for flumioxazin using method RM 30A-03 (GC-MDS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 76–122% (olives) and 82–116% (oil) and the validated LOQ was 0.02 mg/kg.

Soya bean

In a supervised trial on soya beans conducted in the USA and reported by Pensyl, 1996 [Ref: SBR-0021], one broadcast soil applications of 0.536 kg ai flumioxazin/ha (WG formulation) was applied using a tractor-mounted boom sprayer (six nozzles), immediately after sowing.

Duplicate samples of seed (min 22 kg) were frozen within 24 hours and shipped overnight to the processing facility where the samples were dried, aspirated and screening before being mechanically cracked. Aspiration was used to separate the hull and kernel fractions and the kernels were heat-conditioned, flaked, expanded into collets, and solvent extracted to obtain the crude oil. The crude oil was degummed, refined, bleached, and deodorized.

Samples were stored for up to 13 months before analysis for flumioxazin using method RM 30A-3 (GC-MS) and also for the 1-OH-HPA metabolite, using method RM 30M (GC-MS). Recovery rates in samples spiked with 0.02 mg/kg flumioxazin ranged from 75–113% in seed and the processed commodities and were 71–100% in samples spiked with the 1-OH-HPA metabolite.

Table 87 Residues in soya bean seeds and processed commodities from a supervised trial in the USA involving one broadcast pre-emergence soil application of flumioxazin (WG formulation)

The 1992–1993 studies also analysed for residues of the metabolite, 1-OH HPA. Residues in all samples were below the LOQ of 0.02 mg/kg.

Potato

In a supervised trial on potatoes conducted in the USA and reported by Arsenovic, 2003 [Ref: SBR-0091], one broadcast soil applications of 0.14 kg ai flumioxazin/ha (WG formulation) was applied using an ATV-mounted boom sprayer (five nozzles) after the last hilling operation, before potato emergence.

Duplicate samples of 22 kg potatoes were cool-stored for 2 days before processing into wet peel, chips, and flakes. Potato tubers were cleaned, washed, peeled with an abrasive peeler and sliced into chips using a food cutter. The slices of potato were rinsed in warm water to remove free starch, and then fried. The oil was drained and the chips salted, packed and stored. Potato flakes were prepared from cleaned potato tubers, which were washed, peeled using a steam peeler, inspected and trimmed. The potato peel was collected and pressed hydraulically in a fruit press. The pressed peel was then blended with trim waste and placed in a freezer. The peeled potatoes were cut into slabs and spray-washed with cold water to remove free starch. The slabs were then pre-cooked at 70–77 °C in a steam-jacketed kettle. The pre-cooked slabs were cooled to less than 32 °C. A small amount of the cooled slabs was removed and steam-cooked at atmospheric pressure at 94–100 °C for 40 minutes. The cooked potato slabs were then mashed and fed into a dryer to produce a thin sheet, which was initially broken into large flakes by hand. The flakes were then fed into a hammermill for uniform milling of the flakes.

Samples were stored frozen for up to 8 months before analysis for flumioxazin using method RM 30A-2 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 77–118% (tubers) and 98–111% in the processed commodities. The validated LOQ was 0.02 mg/kg.

Maize

In a supervised trial on maize conducted in the USA and reported by Kowalsky, 2007 [Ref: SBR-0078] one broadcast soil application of 0.536 kg ai flumioxazin/ha (WG formulation) with added surfactant was applied 7 days before sowing, using a tractor-mounted boom sprayer (six nozzles).

Duplicate samples of kernels (min 230 kg) were taken at maturity, frozen within 2 hours and stored for up to 4 months before processing (11 months for processing into refined oil) by dry milling (to obtain grits, meal, flour and refined oil) and by wet milling (to obtain starch and refined oil).

For the dry mill processing, samples were conditioned to 21% moisture content and tempered for 2.5 hours. The kernels were cracked in a mill and corn stock from the mill was dried in an oven at 54–71 °C. Dried corn stock was screened to separate germ, bran, grits, meal and flour. The germ material was heated to 71–79 °C, flaked and triple-extracted with hexane (at 50–60 °C). The spent flakes were exposed to ambient air to remove residual hexane. The resulting fractions were miscella (crude oil and hexane) and solvent extracted germ meal. The miscella was passed through a vacuum evaporator and heated to 73–90 °C to remove hexane from the crude oil which was then mixed with sodium hydroxide in a water bath and centrifuged, decanted, filtered to produce refined oil.

For the wet mill processing, samples of kernels were steeped in 49–54 °C water containing 0.1–0.2% sulphur dioxide for 22–48 hours and passed through a disc mill and centrifuged to remove most of the germ and hulls. After drying to 5–10% moisture content, the remaining germ and hull were separated by aspiration and screening. Corn stock (without germ and hull) was ground in a disc mill, passed over a 325 mesh screen. Material on top of the screen was discarded. Process water passing through the screen was separated into starch and gluten by centrifugation. Germ samples were conditioned to 12% moisture content, heated to 88–104 °C, flaked and pressed in an expeller to liberate part of the crude oil. The presscake was double-extracted with hexane (at 50–60 °C). The spent presscake were exposed to ambient air to remove residual hexane. The resulting fractions were miscella and solvent extracted presscake (germ cake). The miscella was passed through a vacuum evaporator and heated to 73–90 °C to remove hexane from the crude oil. The expelled and extracted crude oil samples were filtered, combined and mixed with sodium hydroxide in a water bath and centrifuged, decanted, filtered to produce refined oil.

The processed samples were analysed for flumioxazin within one month using the GC-MS methods RM 30A-3 and RM-30B for the dry milled samples. Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 85–100% (kernels) and 71–117% in the processed commodities. The validated LOQs were 0.02 mg/kg.

Wheat

In one supervised trial on wheat conducted in the USA and reported by Kowalsky, 2011 [Ref: SBR-0092], a single foliar broadcast spray of 0.344 kg ai flumioxazin/ha (WG formulation) with added adjuvant was applied as a pre-harvest desiccant/harvest aid using an ATV-mounted boom sprayer (eight nozzles).

Duplicate samples of wheat grain (400 kg) were collected using small plot combines, frozen within 2 days after harvest and stored for up to 3.5 months before processing into bran, flour, middlings, shorts, germ, and aspirated grain fractions.

Grain samples were aspirated to remove grain dust with the materials passing through a 2360 µm sieve being collected as the aspirated grain fraction. The cleaned grain samples were adjusted to 16% moisture content, milled and passed through a 34 mesh sieve to separate the bran from the germ fraction. This bran sample was further sieved through a number of 128 µm screens, with the material passing through the screen being collected as “shorts” and the retained material was collected as “bran”. The germ fraction (with endosperm) was passed through a reduction mill and again sifted to separate the germ from the endosperm. Cleaned grain samples (conditioned by 16.5% moisture content) were also milled to crack the grains and passed through sifter screens, with material passing through a 140 µm screen being collected as “break flour”. Material passing through an 800 µm screen was collected as “middlings” and the retained material was collected as “bran”. The “middlings” sample was subjected to further milling and sieving with material passing through a 160 µm screen being collected as “reduction flour” and the retained material collected as “shorts”. The “break flour” and “reduction flour” were mixed together to produce the flour samples.

Samples were analysed for flumioxazin within 14.5 months of harvest using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02–0.5 mg/kg ranged from 96–114% (grain) and 79–120% in the processed fractions. The validated LOQs were 0.02 mg/kg.

Middlings = The larger particles coming from the floury part (endosperm) of the grain during milling, possibly including small bits of bran

Shorts = A low-grade mill product containing principally germ and fine bran particles, used for animal feed

Sugar cane

In one supervised trial on sugar canes conducted in the USA and reported by Schreier, 1999 [Ref: SBR-0022], a single broadcast application of 1.25 kg ai flumioxazin/ha (WG formulation) with added crop oil was applied over the top of 2–2.5 m high canes using back-pack sprayers with an extended single-nozzle hand lance.

Duplicate samples of canes were frozen within 2 days of harvest and stored for up to 2 months before being processed into refined sugar and blackstrap molasses in a way that simulated commercial practices as closely as possible. Refined sugar was obtained by chopping the cane stalks, pressing out the juice, clarifying, and concentrating the juice to syrup. Syrup, water and seed sugar were vacuum-concentrated to massecuite, which was then centrifuged to produce raw sugar and 'final' or 'blackstrap' molasses. The raw sugar was dissolved in distilled water, adjusted to a pH to 7.2 with calcium hydroxide and heated. The resulting solution was filtered, decolorized with bone char, and filtered again before boiling under vacuum to crystallize out the sugar which was centrifuged and washed with a water spray to produce refined sugar.

Samples were stored frozen for up to 2 months before analysis for flumioxazin using method RM 30C (GC-MS) and for up to 2.7 months before analysis for the 1-OH-HPA metabolite using method RM-30M (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 67–113% in the canes and 97–110% in the processed commodities. In samples fortified with 0.02–0.2 mg/kg 1-OH-HPA, recoveries were 70–114% in canes and 78–114% in the processed commodities. The validated LOQs for both compounds were both 0.02 mg/kg.

Oilseed rape

In a supervised trial on oilseed rape conducted in the USA and reported by Stearns, 2011 [Ref: SBR 0123], one foliar broadcast spray of 0.54 kg ai flumioxazin/ha (WG formulation) was applied with added adjuvant as a pre-harvest desiccant/harvest aid using a tractor-mounted boom sprayer (seven nozzles).

Duplicate samples of seed (min 22 kg) were collected 9 days after cutting using a small plot combine, frozen within 1 hour and stored for 3 months until processed into oil and meal using simulated commercial practice. After conditioning to a moisture content of 7–10%, samples of seed were cleaned by aspiration and screening, flaked and heated to 82–90 °C, then pressed in an expeller to remove a portion of the crude oil. The residual oil in the presscake was extracted twice with hexane (50–60 °C) to produce miscella and after evaporating the remaining solvent, the resulting presscake fraction was collected as rape seed meal.

Miscella was passed through a vacuum extractor (90–96 °C) to separate the crude oil and hexane. Crude oil recovered from the expeller and solvent extraction was combined, filtered and refined by adding 85% phosphoric acid and mixing with sodium hydroxide for 20 minutes at 40–44 °C then 10 minutes at 65–70 °C. Neutralized oil was centrifuged to extract the refined oil which was then decanted, filtered, bleached (at 249 °C with bleaching earth) and deodorised with citric acid.

Samples were stored for up to 5.5 months before analysis for flumioxazin using method RM 30A-3 (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.02–1.0 mg/kg ranged from 92–101% (seed) and from 89–108% in the processed commodities. The validated LOQs were 0.02 mg/kg.

[a] Vines were cut and allowed to dry for 9 days before seeds were collected.

Cotton seed

In one supervised trial on cotton seed in the USA, reported by Schreier, 2001 [Ref: SBR-0026], two foliar broadcast sprays of 0.1–0.11 kg ai flumioxazin/ha (WG formulation) with added crop oil were applied using tractor-mounted boom sprayers. The first application was made 89 days before harvest using shielded nozzles to minimise spray contact with the plants and the second application were made 59 days before harvest as a directed inter-row spray at layby, with spray contacting only the lower 5–10 cm cotton stems.

Duplicate samples of 22 kg unginned cotton seed were frozen for up to 3 weeks before processing into cotton seed hull, meal and oil. The seed cotton samples were tower-dried, extracted (to remove burrs, sticks, and other plant parts), ginned and delinted. A huller was used to obtain the fractions kernels and hulls. The kernels were flaked and the flakes washed with hexane, dissolved and oil recovered with a precision laboratory evaporator. The oil was then refined by adding sodium hydroxide while stirring at 20–24 °C and then allowing the oil to settle at a temperature 60–65 °C. The oil was then refrigerated and filtered to obtain the refined oil and soapstock fractions.

Samples stored frozen for up to 3 months before analysis for flumioxazin using method RM 30A-1 (GC-MS) or in the case of the oil, method RM 30B (GC-MS). Recoveries from control samples fortified with flumioxazin at levels of 0.01 and 0.05 mg/kg ranged from 76–106% (cottonseed) and 97–135% in the processed commodities. The validated LOQs were 0.01 mg/kg.

Sunflower seed

In a supervised trial on sunflower conducted in the USA and reported by Stearns, 2011 [Ref: SBR-0126], one foliar broadcast spray of 0.54 kg ai flumioxazin/ha (WG formulation) was applied with added adjuvant as a pre-harvest desiccant/harvest aid using a back-pack sprayer with a 5-nozzle boom.

Duplicate samples of seed (20 kg) were frozen within 1 hour and stored for up to 3 months before being processed into sunflower oil and meal using a procedure similar to that described above for rape seed. (Stearns, 2011; SBR-0126). Processing was done simulating commercial practices as closely as possible. The procedure was very similar to that used in the processing of oilseed rape, involving conditioning, aspiration, flaking and crude oil extraction by pressing followed by hexane double-extraction of the remaining oil from the presscake, with the combined crude oil extracts being filtered, refined by heating with phosphoric acid and sodium hydroxide and the resulting neutral oil being centrifuged, decanted bleached and deodorized with citric acid.

Samples were stored frozen for up to 10 months before analysis for flumioxazin using method RM 30A-3 (GC-MS). Concurrent recoveries from control samples fortified with flumioxazin at levels of 0.02–3.0 mg/kg ranged from 90–101% (seed) and 70–110% in the processed commodities. The validated LOQs were 0.02 mg/kg.

MSO = Methylated seed oil

Peanut

In two supervised trials on peanuts conducted in the USA and reported by Pensyl, 1994 [Ref: SBR-0018] and Pensyl, 1996 [Ref: SBR-0019], single broadcast soil applications of about 0.53 kg ai flumioxazin/ha (WG formulations) were applied as pre-emergent broadcast sprays within 5 days after sowing, using tractor-mounted boom sprayers (6–13 nozzles).

Duplicate samples of 22–27 kg whole peanuts were collected and processed within 7 days to produce presscake, crude oil, refined oil, soapstock, bleached oil, and deodorized oil.

Peanut samples were dried and then cleaned by aspiration and screening. A sheller was used to mechanically crack the hull surrounding the kernel (nutmeat). Aspiration was used to separate the hull and kernel fractions. The raw peanut kernels were heat-conditioned and pressed in an expeller to extract most of the crude oil. After pressing, the presscake was flaked and the remaining oil was extracted from the flake with hexane. The hexane in the solvent-extracted presscake was evaporated. The crude oil recovered from the expeller and solvent extraction was combined, refined, bleached and deodorized.

Samples were kept in frozen storage up to 2.6 months before analysis for flumioxazin using method RM 30A-3 (GC-MS) and method RM 30B (GC-MS) for peanut oil. Residues of 1-OH-HPA were determined in one of these studies using method RM 30M (GC-MS) for nutmeats, hulls and presscake and method RM 30P (GC-MS) for all oil samples. Recoveries from control samples fortified with flumioxazin at levels of 0.02 and 0.1 mg/kg ranged from 80–99% (nutmeat) and 72–125% (other processed commodities), and in samples spiked with the 1-OH-HPA (0.02 mg/kg) recoveries were 84% in nutmeat and 63-119% in the processed commodities. The validated LOQs were 0.02 mg/kg.

Mints

In a supervised trial on mint conducted in the USA and reported by Schreier, 2003 [Ref: SBR-0136], two foliar broadcast sprays of 0.28 or 0.42 kg ai flumioxazin/ha (WG formulations) were applied to dormant mint plants (February-April).

Duplicate samples of mint tops (leaves and stems) were processed into oil on the day of harvest and samples were stored frozen for up to 8 months before dilution with acetone and analysis for flumioxazin using method RM 30A-2 (GC-MS). Recoveries from control samples of oil fortified with flumioxazin at levels of 0.02 and 0.2 mg/kg ranged from 91–111% and the validated LOQ was 0.02 mg/kg.

Summary of Processing Studies

Processing studies on apples, plums, grapes, olives, soya beans, potatoes, sugar cane, maize, wheat, sugar cane, oilseed rape, sunflower seed, peanuts and mint were conducted, simulating commercial practices. In all cases, except for wheat, there was no concentration of flumioxazin residues in processed commodities. Except for wheat, sugar cane, oilseed rape and sunflower seed, processing factors could not be estimated because residues in the fresh commodities were below the respective method LOQs. For wheat, residues do not concentrate in wheat bran, flour, middlings, shorts, and germ. However, residues of flumioxazin concentrate by 308× in aspirated grain fractions. For rape seed, sunflower, and sugar cane, there is no concentration of flumioxazin residues in the corresponding processed fractions.

Table 97 Summary of processing factors for flumioxazin

RAC	Matrix	Flumioxazin [a]	
		Calculated processing factors	PF median
Wheat grain (0.36 mg/kg)	bran	0.94	0.94
	flour	0.14	0.14
	middling	0.22	0.22
	shorts	0.31	0.31
	germ	1.03	1.03
	aspirated grain fraction	308	308
Sugar cane 0.11 mg/kg)	molasses	0.5	0.5
	sugar	< 0.18	< 0.18
Oilseed rape seed (0.63 mg/kg)	oil	< 0.04	< 0.04
	meal	0.12	0.12
Sunflower seed 2.31 mg/kg)	oil	< 0.009	< 0.009
	meal	0.065	0.065

[a] Each value represents a separate study where residues were above the LOQ in the RAC. The factor is the ratio of flumioxazin residues in the processed item divided by the residue of flumioxazin in the RAC.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

In a lactating cow feeding study reported by Kowalsky, 2006 [Ref: SBR-0138], three groups of dairy cattle (three cows per group, 3–7 years old and weighing 560–675 kg) were dosed orally with capsules containing flumioxazin at levels equivalent to 2, 6.2 and 19.5 ppm in the diet for 28 consecutive days (0.7 mg/kg bw/day, 0.22 mg/kg bw/day and 0.73 mg/kg bw/day respectively).

Composite milk samples from the post-dose afternoon and next morning (pre-dose) milk collections were taken at intervals during the dosing period and stored frozen for less than 30 days before analysis. On day 29, less than 24 hours after the final dosing, the animals were sacrificed and liver, muscle, kidney and fat were sampled and stored frozen for less than 30 days before analysis.

Tissue and milk samples were analysed for flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin by HPLC-MS/MS. Residues were extracted with acetone (milk) or acetonitrile and acidic acetonitrile:water (tissues), partitioned with dichloromethane:water and the organic phases containing the residues further partitioned with acetonitrile:hexane, concentrated and diluted in methanol:water for analysis. Mean recovery rates in samples spiked with 0.02 mg/kg and 0.1 mg/kg ranged from 77–98% (flumioxazin), 84–102% (3-OH-flumioxazin and 4-OH-flumioxazin) and the LOQ was 0.02 mg/kg.

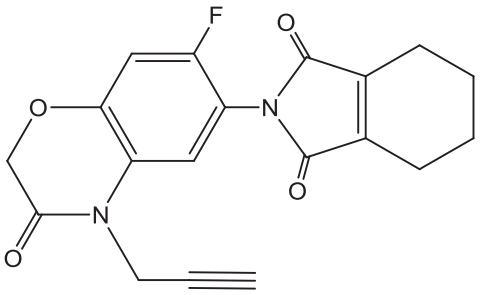
At the 19.5 ppm dose level in the feeding study, residues of flumioxazin were non-detectable (LOD of 0.01 mg/kg) in all samples of milk, skim milk, cream, liver, kidneys, muscle, and fat from all three cows. Samples from the lower dose group animals were not analysed.

APPRAISAL

Flumioxazin is a phenylthalimide protoporphyrogen oxidase inhibiting herbicide used for pre-emergent and post-emergent control of a range of broad-leaf weeds and suppression of some grass weed species in a range of fruit, vegetable and field crops.

It was scheduled by the Forty-sixth Session of the CCPR as a new compound for consideration by the 2015 JMPR. The manufacturer submitted studies on metabolism, analytical methods, supervised field trials, processing, freezer storage stability and environmental fate in soil.

Authorisations exist for the use of flumioxazin as pre-emergence or early post-emergence broadcast treatments, as directed inter-row band soil treatments and as a pre-harvest desiccant (harvest aid) treatment in North America, Europe, Latin America, Australia and some Asian countries.



Flumioxazin

(MW 354.3)

Flumioxazin has a low vapour pressure and water solubility (approximately 0.8 mg/L) that is not pH dependent. It is soluble in medium polarity organic solvents (e.g. dichloromethane, acetone or ethyl acetate), but only slightly soluble in hexane. The octanol/water partition co-efficient (Log P_{OW} 2.55) is not pH dependent and indicates limited potential to bioaccumulation. Hydrolysis in aqueous media is pH-dependant, with half-lives ranging from 3–5 days at pH 5 to less than 25 minutes at pH 9 and the photolytic half-life is about 1 day.

The following abbreviations are used for the major metabolites discussed below:

Major flumioxazin metabolites identified in plant, animal and soil matrices.

Compound Name/Code	Structure		Matrices
Flumioxazin (S-53482) (V-53482)		*N*-(7-fluoro-3,4-dihydro-3-oxo-4-prop-2-ynyl-2*H*-1,4-benzoxazin-6-yl)cyclohex-1-ene-1,2-dicarboxamide	Plants Goat Hen Rat Soil Photolysis
3-OH-Flumioxazin		7-fluoro-6-(3-hydroxy-3,4,5,6-tetrahydrophthalimido)-4-(2-propynyl)-2H-1,4-benzoxazin -3(4H)-one	Goat Hen Rat

Compound Name/Code	Structure		Matrices
4-OH-Flumioxazin		7-fluoro-6-(4-hydroxy-3,4,5,6-tetrahydrophthalimido)-4-(2-propynyl)-2H-1,4-benzoxazin-3(4H)-one	Goat Hen Rat
482-HA		N-(7-fluoro-3,4-dihdyro-3-oxo-4-prop-2-ynyl-2H- 1,4-benzoxazin-6-yl)cyclohex-1-ene-1-carboxamide-2-carboxylic acid	Plants (rotational) Rat Soil Photolysis
482-CA		2-[7-fluoro-3-oxo-6-(3,4,5,6-tetrahydrophthalimido)-2H-1,4-benzoxazin-4-yl] propionic acid	Plants (rotational) Soil
SAT-482		6-(cis-1,2-cyclohexanedicarboximido)-7-fluoro-4-(2-propynyl)2H-1,4-benzoxazin-3(4H)-one	Goat Rat
APF		6-amino-7-fluoro-4-(2-propenyl)-2H-1,4-benzoxazin-3(4H)-one	Plants Rat Soil Photolysis
1-OH-HPA		1-hydroxy-*trans*-1,2-cyclohexanedicarboxylic acid	Plants Rat Photolysis
THPA		3,4,5,6-tetrahydrophthalic acid	Plants Goat Hen Rat Soil Photolysis
Δ^1-TPA		3,4,5,6-tetrahydrophthalic anhydride	Plants (rotational) Hen Soil Photolysis

Environmental fate

The Meeting received information on the environmental fate and behaviour of flumioxazin, including hydrolytic stability, photochemical degradation in soils and aerobic metabolism studies.

Hydrolysis

Radiolabelled flumioxazin (0.1 mg/L) incubated in the dark in sterile aqueous buffered solutions at pH 5, 7, and 9 for up to 30 days at 25 °C was rapidly hydrolysed, with calculated half-lives of about 3.4–5 days at pH 5, 19–26 hours at pH 7 and 14–23 minutes at pH 9. At pH 7, hydrolysis was biphasic, with longer half-lives of 11–14 days after the first 2–3 days.

The major degradation products after 30 days of incubation at pH 7 and pH 5 were APF (80–87% AR) and THPA (84–96% AR). At pH 9, the major degradate was 482-HA (96–99% AR).

Photochemical degradation in soil

In a photochemical degradation study in a sandy loam soil, unextracted residues in the phenyl-label study increased from an initial 3% AR to 43% AR by Day 6 and were significantly lower in the THP-label study, up to 9.3% AR on day 14. Volatiles did not exceed 0.5% of the applied radiocarbon for the irradiated samples or 0.2% for the dark controls.

Flumioxazin accounted for 97–99% AR in the day-0 samples, decreasing in the irradiated samples to 29% (Day 6—phenyl-label) and 82% AR (Day 7—THP-label) and to 37% AR in the THP-label samples on day 14. The only significant degradates identified at more than 10% AR were Δ^1-TPA and THPA.

Levels of Δ^1-TPA peaked at 22% AR on Day 9 in the irradiated samples, but were < 10% AR at all other sampling times. THPA reached a maximum of about 13% AR (9% AR in the dark control samples) at the end of the 14-day study period.

The calculated photolytic soil degradation half-lives were 3.2 days (phenyl-label study) and 8.4 days (THP-label study) and were 12–16 days in non-irradiated samples.

Aerobic soil metabolism

Under aerobic conditions, unextracted or mineralised residues increased from about 6% AR to 84% AR after 91 days in the THP-label study (55% AR released as carbon dioxide) and in the phenyl-label study, increased to a plateaux level of about 77–85% AR from day 60 (6–12% AR released as carbon dioxide). Extraction efficiencies ranged from 94–102% in the two studies.

Flumioxazin residues decreased from 93–98% AR to 60–64% AR after 7 days and 7.6–12% AR by about day 60 with calculated half-lives of 12–17.5 days. Calculated DT_{90} values (FOMC) were about 51 days (phenyl-label) and 95 days (THP-label). No identified or characterized degradates accounted for more than 8% AR.

The proposed degradation pathways include hydrolysis of the parent compound to 482-HA or oxidation to 482-CA, leading to THPA (in equilibrium with Δ^1-TPA). THPA appears to be an end product that is incorporated into soil organic components or oxidized to CO_2.

In summary, flumioxazin is rapidly hydrolysed in aqueous solutions, with the cleavage products APF and THPA being the predominant degradates at pH 7. In soil it is susceptible to photochemical degradation (average DT_{50} of about 5 days) and is not persistent in soil, with an average DT_{50} of about 15 days. Aqueous hydrolysis, photochemical degradation and aerobic soil metabolism are all likely to be a significant degradation pathways.

Plant metabolism

The Meeting received information on the metabolism of [^{14}C]flumioxazin, separately labelled in the phenyl and the tetrahydrophthaloyl (THP) rings, in soya bean and peanut (pre-emergent treatments),

grape and apple (inter-row soil treatments), sugar cane (directed soil/foliar treatments) and rotational crops.

Peanut

In a metabolism study on peanuts, [^{14}C]flumioxazin was applied either as a pre-emergent broadcast soil treatment 3 days after sowing at a rate equivalent to 0.11 kg ai/ha, or as a pre-plant treatment 32 days before sowing at 0.33 kg ai/ha. Samples of mature foliage and whole peanuts were harvested from the Pre-em plots 194 days after treatment (DAT) and from the Pre-plant plots 245 days after resowing (277 DAT).

Total radioactive residues (TRR) in all matrices from the pre-emergent treatment were below 0.02 mg eq/kg (phenyl-label) and less than 0.04 mg eq/kg (THP-label). In the pre-plant treatment, TRRs were *ca.* 3× higher except for the phenyl-label hulls and the THP-label vines. Radioactive residues were generally lowest in vines (up to 0.03 mg eq/kg) and highest in hulls (up to 0.17 mg eq/kg). Nutmeat from the pre-emergent treatment contained up to 0.03 mg eq/kg and from the pre-plant treatment were up to 0.09 mg eq/kg.

Solvent extraction and more aggressive acid, base and enzyme hydrolysis were able to extract 65–77% TRR in nutmeats and hulls and more than 90% TRR in vines.

Flumioxazin residues were < 1% TRR (< 0.001 mg/kg) in hulls and vines and not detected in nutmeat. The majority of the ^{14}C-residues were found in four chromatographic regions, each of which accounted for up to 0.005 mg eq/kg in hulls and up to 0.01 mg eq/kg in nutmeat and vines except in hulls from the pre-plant treatment, where one region contained up to 0.04 mg eq/kg, mostly multiple unknown components.

Soya bean

In metabolism studies on soya beans, [^{14}C]flumioxazin was applied to soil (sandy loam) three days after sowing at rates equivalent to 0.1 kg ai/ha or 0.2 kg ai/ha. Forage and root samples were taken 53 or 70 days after treatment and samples of plants (without pods), pods, seeds and roots were harvested at maturity, 100 or 138 days after treatment.

In the 0.1 kg ai/ha treatment plots, total radioactive residues in mature seeds were less than 0.25 mg eq/kg and were found at up to 0.06 mg eq/kg (phenyl-label) and 0.33 mg eq/kg (THP-label) in pods. In immature foliage, TRRs were up to 0.05 mg eq/kg (phenyl-label) and 0.07 mg eq/kg (THP-label). Hay from immature forage contained up to 0.19 mg eq/kg (phenyl-label) and up to 0.29 mg eq/kg (THP-label). TRRs in the samples from the 0.2 kg ai/ha treatment plots were generally about twice those in the equivalent samples from the 0.1 kg ai/ha treatment plots. The higher levels of radioactivity found in the THP-label samples suggested a preferential uptake of the THP-derived cleavage products from soil.

Sequential acetone:water and acetone:HCl extractions were able to extract 60–76% TRR in hay and forage and 25–66% TRR in seeds and more aggressive extraction techniques were able to extract most of the remaining radioactivity, with about 1–4% remaining in the post-extraction solids.

Flumioxazin made up < 1.8–6.1% TRR in 53 DAT forage (< 0.01 mg/kg) and hay (< 0.03 mg/kg) and were found at trace levels (< 2.3% TRR, < 0.004 mg/kg) only in seed from the 0.2 kg ai/ha treatment in the THP-label study. Metabolite 1-OH-HPA (free or partly cellulose conjugated) was the predominant residue, making up 15–25% of the TRR in immature forage, 26–32% TRR in hay and about 38–42% TRR (0.06–0.09 mg/kg) in seed.

Apples and grapes

In metabolism studies on apples and grapes, [^{14}C]flumioxazin was applied as sprays to bare soil (1.2 m × 1.2 m loamy sand plots) surrounding the trees or vines. The apple study involved two treatments equivalent to 0.47 kg ai/ha, applied 47 days before fruit thinning and 60 days later (about

60 days before fruit maturity) with about 30 cm of tree trunks receiving direct spray. In the grape study, one treatment equivalent to 0.6 kg ai/ha was applied about 90 days before harvest.

Total radioactive residues (TRR) were extremely low in all samples analysed, up to 0.003 mg eq/kg in apples, up to 0.005 mg eq/kg in grapes and up to 0.04 mg eq/kg in grape shoots.

In the grape study, 78–92% TRR could be solvent-extracted and HPLC analysis indicated the presence of a number of metabolites, the majority of which (58% TRR) were polar in nature. In both studies, further characterization or identification of the residues was not conducted.

Sugar cane

In a metabolism study on sugar cane, [^{14}C]flumioxazin was applied at a rate equivalent to 0.48 kg ai/ha as a directed soil/foliar spray to 1.5–2 m high sugar canes prior to stem elongation (at the 6–10 leaf stage) with up to 1 m of the plants receiving direct spray. Immature sugarcane forage (leaves and canes) were sampled about a month after the application and mature canes and leaves (3–3.6 m high) were also sampled at maturity, 90 days after treatment, when the canes were 5 cm in diameter.

Total radioactive residues were 0.001–0.004 mg eq/kg in mature cane, 0.23–0.89 mg/kg in immature forage and 0.5–1.0 mg/kg in mature leaves. More than 90% TRR was able to be extracted in acetonitrile and water.

Flumioxazin was the predominant residue in immature forage and mature leaves, accounting for 81–93% TRR (up to 0.83 mg/kg and 0.92 mg/kg repectively) and 68–75% TRR in canes, but at levels below 0.003 mg/kg.

Other minor components were all < 5% TRR in imature foliage and below 10% TRR or < 0.001 mg eq/kg in mature leaves. In the post-extraction solids (PES), radioactivity was distributed into all leaf constituents including the starch, cellulose, lignin, lipids and proteins, but did not exceed 0.03 mg eq/kg in any individual PES sub-fraction, with none of the individual TLC bands containing significant residue and none corresponded to any of the reference standards.

In summary, when applied to soil prior to crop emergence or as directed treatments to soil surrounding established perennial plants, flumioxazin does not translocate or accumulate in significant concentrations in plant matrices. In general, no parent residues were found in any of the plant matrices except in soya beans and peanut hulls. Low levels of flumioxazin were found in soya bean forage and soya bean hay and trace levels were present in soya bean seed and peanut hulls. The only significant metabolite was 1-OH-HPA (free or partly cellulose conjugated), which was present at 15–25% TRR in immature soya bean forage, and about 38–42% TRR (0.06–0.09 mg/kg) in soya bean seed.

Following directed foliar applications to sugar canes, flumioxazin is not translocated, with only traces of radioactivity found in canes. Flumioxazin accounted for more than 90% of the TRR in immature leaves (30 days after treatment), more than 81% TRR in mature leaves (90 days after treatment) and up to 75% TRR (up to 0.003 mg/kg) in canes.

Rotational crops

Two confined rotational crop studies using lettuce, carrots and wheat as rotational crops planted in bare sandy loam soil, were treated at rates equivalent to 0.105 kg ai/ha or 0.21 kg ai/ha. The rotational crops were planted 30 days after treatment in all plots and 120, 180 and 365 days after treatment in the higher treatment plots.

Radioactive residues were only detected in small amounts in all rotational crops at all plant-back intervals, with the highest radioactivity being 0.13 mg eq/kg in the straw from wheat planted 120 days after treatment with the THP-label. In the phenyl-label study, TRRs decreased in the longer plant-back intervals but in the THP-label study, TRRs increased in some

commodities at the 120-day and 180-day plant-back intervals, suggesting that THP-derived cleavage products in soil are either more readily assimilated by the plants or less tightly bound to soil than those from the phenyl label.

In the soil the majority of the radioactivity stayed at the upper 0–10 cm layer, with flumioxazin accounting for the majority of the extracted residue in most samples.

From 47–84% TRR was able to be solvent-extracted (including refluxing with acetonitrile:0.25N HCl) from wheat forage, straw and chaff, lettuce, carrot tops and roots, with 5–12% TRR being extracted from wheat grain.

Flumioxazin residues were present at less than 0.01 mg/kg in all matrices except wheat straw where levels of 0.03 mg/kg were found in the 120-day plant-back treatment. The only identified metabolites found above 10% TRR were 1-OH-HPA, THPA, and Δ^1-TPA each found at up to 15% TRR (but below 0.004 mg/kg eq) in wheat straw from the 120-day and 180-day PBI plots.

In summary, radioactive residues in rotational crops planted 30–365 days after bare soil treatments with [^{14}C]flumioxazin were low, less than 0.05 mg eq/kg in all matrices except wheat straw, where THP-labelled radioactivity was present at up to 0.13 mg eq/kg, 40% of which was flumioxazin.

The Meeting concluded that since the application rates in the rotational crop studies generally covered the range of GAP treatment rates for annual crops, residues are not expected in rotational crops following treatments according to the GAPs under consideration.

Animal metabolism

The Meeting received information on the metabolism of [^{14}C]flumioxazin, separately labelled in the phenyl and the tetrahydrophthaloyl (THP) rings, in rats, lactating goats and laying hens.

The metabolism of flumioxazin in rats was evaluated by the WHO Core Assessment Group of the 2015 JMPR. Excretion of radioactivity was rapid, with 69–87% being eliminated in urine and faeces within 24 hours with the remainder found mainly in excretory organs. Flumioxazin was extensively metabolized (29–35 metabolites detected and quantified), with 7–10 of these being identified. Flumioxazin accounted for 47–66% of the administered dose in the 100 mg/kg bw dose group and up to 2% in the 1 mg/kg bw dose group. Metabolites found at more than 5% of the applied dose were 3-OH-flumioxazin, 3-OH-flumioxazin-SA, 4-OH-flumioxazin and 4-OH-flumioxazin-SA.

Lactating goats were orally dosed with [^{14}C]flumioxazin at doses equivalent to 11.8 ppm (phenyl-label) and 7.2 ppm (THP-label) in the feed for 5 consecutive days and sacrificed 6 hours after the last dose.

The majority of the radioactivity (80–93% AR) was found in urine, faeces or the GI tract, with < 1% AR remaining in tissues and 0.22% AR in milk. Radioactivity was extremely low in fat (up to 0.008 mg/kg), low in muscle, up to 0.014 mg/kg (phenyl-label) and 0.028 mg/kg (THP-label), but higher in liver, up to 0.21 mg/kg (phenyl-label) and 0.33 mg/kg (THP-label). In kidney the radioactive residues were up to 0.18 mg/kg (phenyl-label) and 0.24 mg/kg (THP-label). The average total radioactivity concentration in milk plateaued around Day 3 at about 0.04 mg/kg (phenyl-label) and about 0.06 mg/kg in the THP-label study.

More than 80% TRR from milk, liver and kidney and 58–74% TRR from muscle was able to be solvent-extracted. TRR in fat were not investigated further.

The parent compound was extensively metabolized, with residues above 0.001 mg/kg found only in liver (up to 0.01 mg/kg and < 5% TRR).

The 4-OH-flumioxazin metabolite accounted for up to 14% TRR in kidney (up to 0.025 mg/kg) and muscle (up to 0.003 mg/kg). In liver, both the 4-OH-flumioxazin and 3-OH-flumioxazin residues did not exceed 0.025 mg/kg (about 9% TRR).

Metabolite 482-HA was the predominant component in milk (14% TRR) but absolute levels were below 0.005 mg/kg eq and it was also found in liver and kidney at close to 10% TRR, 0.02 mg/kg).

Metabolite B, tentatively identified as 3- or 4-OH-SAT-482, made up about 14% TRR (0.024 mg/kg) in kidney and 18% TRR in milk (0.005 mg/kg). In liver, metabolite F, tentatively identified as an isomer of 3- or 4-OH-SAT-482, made up about 11% TRR (0.03 mg/kg).

In muscle, metabolite C accounted for 20–23% TRR and 12% TRR in milk but absolute levels were all below 0.005 mg/kg.

Laying hens were orally dosed with [^{14}C]flumioxazin (phenyl-label or THP-label) at doses equivalent to 10 ppm in the feed for 14 consecutive days and sacrificed 4 hours after the last dose (in order to ensure sufficient radiolabel remained to allow further investigation).

Radioactivity in the excreta, GI tract contents and cage wash accounted for 83–94% AR, with liver, kidney, muscle, fat, skin and eggs contained relatively small amounts of radioactivity (totalling < 0.6–0.9% of the administered dose). Radioactivity in egg yolks accounted for 0.35–0.36% AR, with < 0.01% AR in the corresponding egg whites. Liver contained 0.08–0.27% AR (0.24 mg/kg eq and 1.14 mg/kg eq) in the phenyl-label study and the THP-label study respectively. In egg yolks, residues reached a plateau of 0.4–0.6 mg/kg eq by Day 10 or 11 in the two studies.

More than 87% TRR in eggs was extracted with methanol or ethanol, and acetonitrile was able to extract 37–67% TRR from muscle. In the phenyl-label liver and kidney samples, sequential extractions with acetonitrile and bicarbonate were able to extract more than 90% TRR and further enzyme extraction released an additional 10% TRR. In the THP-label liver and kidney samples, sequential acetonitrile and acetonitrile:water extractions were able to extract 80–87% TRR.

In solvent-extracted samples, the parent compound was the predominant residue in fat (49% TRR), skin + fat (12–25% TRR), muscle (10–14% TRR), a significant component in liver and kidney (7–9% TRR), made up about 4–9% TRR in egg yolk and was not detected in egg white. Absolute levels of flumioxazin were up to 0.13 mg/kg in skin + fat and fat, < 0.08 mg/kg in liver and kidney, < 0.04 mg/kg in egg yolk and about 0.02 mg/kg in muscle.

Metabolites present at more than 10% TRR or more than 0.01 mg/kg were 4-OH-flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin-SA.

The 4-OH-flumioxazin accounted for 9–12% TRR in all tissues (< 0.03 mg/kg in muscle and fat, < 0.1 mg/kg in kidney and skin + fat and 0.12 mg/kg in liver) while the 3-OH-flumioxazin accounted for 8–12% TRR (0.015 mg/kg) in muscle. Metabolite 4-OH-flumioxazin-SA accounted for 32% TRR in egg yolk (0.14 mg/kg).

All other identified metabolites were found at < 8% TRR and the highest level of any single unidentified metabolite was measured in liver, at 12% TRR.

In summary, in the ruminant and poultry metabolism studies, flumioxazin is extensively metabolized with limited transfer into tissues, eggs or milk (less than 0.5% of the administered dose). Flumioxazin was not found at levels above 0.01 mg/kg in goat milk or tissues but was present in most poultry commodities, highest residues being found in fat (0.13 mg/kg, 49% TRR), with lower levels (up to 0.08 mg/kg) in other tissues and egg yolks.

Other metabolites present at more than 10% TRR in various commodities were 4-OH-flumioxazin, 4-OH-flumioxazin-SA, 3-OH-flumioxazin, metabolite B, tentatively identified as 3- or 4-OH-SAT-482 and metabolite F, tentatively identified as an isomer of metabolite B.

Analytical methods

Several analytical methods have been reported and validated for the analysis of flumioxazin in plant and animal commodities. The basic approach employs extraction with acetone/water or

hexane/acetonitrile, partitioning into dichloromethane and/or acetonitrile, Florisil or silica gel clean-up and analysis by GC-MS. For processed plant oils, the initial acetone extraction and dichloromethane partitioning steps are omitted and for animal commodities the dichloromethane partitioning step is also omitted. The LOQs for these methods is 0.02 mg/kg.

Two methods have also been validated for measuring residues of the 1-OH-HPA metabolite (free and conjugated) in some food and feed commodities. Residues are extracted using acid hydrolysis, partitioned into ethyl acetate and refluxed for 30 minutes with acetone, triisopropanolamine and dimethyl sulphate to convert the 1-OH-HPA to its dimethyl ester. After partitioning into hexane and Florisil column clean-up, residues are analysed by GC/MS. The LOQs for the method range from 0.02–0.1 mg/kg.

A more recent HPLC-MS/MS method was reported in the lactating cow feeding study for measuring residues of flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin. Tissue samples are extracted in acetonitrile and acidic acetonitrile:water and milk samples are extracted with acetone. The extracts are then partitioned with dichloromethane/water and the organic phase further partitioned with acetonitrile/hexane. Analysis for flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin was by HPLC-MS/MS (flumioxazin: m/z 355→299, 3-OH-flumioxazin: m/z 371→299/107 and 4-OH-flumioxazin: m/z 371 →299/107) with an LOQ of 0.02 mg/kg.

For plant and processed plant commodities, the DFG S19 (GC-MS) method was validated for the analysis of flumioxazin in cereals, potatoes and oily substrates (sunflower seeds). After extraction with aqueous acetone and partitioned into ethyl acetate/cyclohexane, extracts are cleaned-up by gel permeation chromatography and residues are determined by GC-MS. The LOQ is 0.02 mg/kg. Recovery rates ranged from 84–102% for all analytes in all matrices.

The Meeting concluded that suitable methods are available to measure flumioxazin in plant and animal commodities.

Stability of pesticide residues in stored analytical samples

Flumioxazin residues were stable in analytical samples stored frozen (–18 to –20 °C) for at least the storage intervals used in the supervised residue trials, with residues in the stored samples usually more than 80% of the spiked sample levels. In general, residue stability was shown for up to:

26–30 months	non-bell peppers, alfalfa (forage, hay)
12–18 months	maize (forage, grain, stover), olives, summer squash, olive oil, soya bean (forage, hay)
9–12 months	celery, cherries, cotton seed, soya bean seed, peanut (forage, hay, hulls, nutmeat), mint, potatoes (fresh and processed)
6–9 months	apple (juice, wet pomace), globe artichoke, asparagus, cabbage, cucumber, tomato, almond (nutmeat, hulls), mint oil, strawberry, grape (fresh, dried)
2–6 months	onions, cottonseed (meal, hulls gin trash), blueberries, melons, pecans, grape juice, sugarcane, molasses and refined sugar.

Definition of the residue

When flumioxazin is applied to soil prior to crop emergence or as directed treatments to soil surrounding established plants, flumioxazin does not translocate or accumulate in significant concentrations in plant matrices. In general, no parent or identifiable metabolites are found in the plant matrices except in soya beans, where low levels of flumioxazin (below 0.01 mg/kg) were found in forage and seeds, and up to 0.03 mg/kg in hay from immature forage.

The only significant metabolite in plant commodities following pre-emergence treatment is 1-OH-HPA (free or partly cellulose conjugated), present at 15–25% TRR in immature soya bean forage, and about 38–42% TRR (0.06–0.09 mg/kg) in soya bean seed. However, in supervised field trials on soya beans, residues of this metabolite were all below the LOQ (0.02 mg/kg) and the Meeting concluded that 1-OH-HPA need not be included in the residue definition for dietary intake estimation.

Following directed foliar applications, flumioxazin is not translocated, with the majority of the residue in sugar cane leaves about 1 month after treatment being the parent. The Meeting concluded that this would also be the case where flumioxazin was used as a pre-harvest treatment to scenescing plants.

In confined crop rotation studies, radioactive residues in rotational crops planted 30–365 days after bare soil treatments were low, generally less than 0.01 mg/kg eq in all matrices except wheat straw, where flumioxazin was found at up to 0.03 mg/kg in straw from wheat planted 120 days after treatment with 0.21 kg ai/ha (2× GAP).

Based on the above, the Meeting considered that a suitable residue definition for plant commodities would be flumioxazin (parent only), both for MRL-compliance and dietary intake estimation.

In animal commodities, metabolism studies in goats and poultry indicate that flumioxazin is almost completely excreted, with < 1% of the applied radioactivity remaining in milk, eggs and tissues after 6 hours. In animals dosed with about 7–10 ppm flumioxazin in the diet, residues of parent compound were below 0.01 mg/kg in goat milk and tissues, but were higher in poultry, being the predominant identified residue, found at up to 0.13 mg/kg (49% TRR) in poultry fat and up to 0.08 mg/kg in other tissues and egg yolks.

Identified metabolites found above 10% TRR and above 0.01 mg/kg in various matrices were 4-OH-flumioxazin and 3-OH-flumioxazin and 4-OH-flumioxazin-SA (only in egg yolk).

In the animal metabolism studies, metabolites 3-OH-flumioxazin and 4-OH-flumioxazin were present at up to 15% TRR in most tissues from animals sacrificed 6 hours after the last dose. However in the dairy cow feeding study, these metabolites were not found in milk or tissues from animals sacrificed 24 hours after dosing at about 2–3× the dose used in the goat metabolism study. The Meeting concluded that because of the short interval to sacrifice, the animal metabolism studies over-estimated the expected residues in cattle and noted that no detectable residues of parent or metabolites are expected in poultry. Since safety concerns with 3-OH-flumioxazin or 4-OH-flumioxazin are not anticipated, the Meeting agreed they need not be included in the residue definitions.

The Meeting noted that 4-OH-flumioxazin-SA was not a significant residue in any matrix except egg yolk and that the calculated dietary burden (0.57 ppm) was about 0.04% of the dose rate used in the metabolism study. The Meeting therefore considered that 4-OH-flumioxazin-SA need not be included in the residue definition for dietary intake estimation.

The Meeting noted that a multi-residue method exists to measure parent residues in plant commodities and that the analytical method used in the goat feeding study was able to measure both the parent compound and the 3-OH-flumioxazin and 4-OH-flumioxazin metabolites.

The Meeting agreed that for MRL-compliance and dietary intake estimation for plant and animal commodities the residue definitions should be flumioxazin.

The Meeting noted that the octanol/water partition coefficient (Log P_{ow}) for flumioxazin was 2.55, and while the information on the relative distribution of flumioxazin in fat/muscle and egg yolk/egg white was limited, the Meeting concluded that the residue was not fat soluble.

Proposed definition of the residue (for compliance with the MRL and estimation of dietary intake for plant and animal commodities): *flumioxazin.*

The residue is not fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised trial data for flumioxazin applied as pre-emergence or early post-emergence broadcast treatments on a range of vegetable and field crops, as directed inter-row band soil treatments on a number of fruit crops and as a pre-harvest desiccant (harvest aid) treatment on several pulse and cereal crops. These trials were conducted in North America.

Where residues have been reported in the studies as being not quantifiable, the values have been considered as < LOQ for the purposes of MRL setting

Perennial crops

The critical GAP for pome fruit, stone fruit, bush berries, grapes, olives, pomegranates and tree nuts in the USA is for soil treatments of up to 0.42 kg ai/ha as directed band sprays under the crop canopy, avoiding contact with trunks or vines, with a maximum seasonal rate of 0.82 kg ai/ha, a retreatment interval of at least 30 days and a PHI of 60 days (7 days for bush berries).

In more than 60 independent trials on these crops conducted in the USA and matching the USA GAP, flumioxazin residues in the fruit and nutmeat were all < 0.02 mg/kg.

The Meeting noted that when applied to soil, flumioxazin remained predominantly in the upper 10 cm layer and was not persistent or root-absorbed. In the grape and apple metabolism studies where the treatments reflected the above GAP, total radioactivity levels in the fruit were extremely low (< 0.005 mg eq/kg).

The Meeting therefore agreed to estimate maximum residue limits of 0.02(*) mg/kg for flumioxazin on pome fruit, stone fruit, bush berries, grapes, olives, pomegranate and tree nuts.

The Meeting also agreed that as no flumioxazin residues are to be expected in mature fruit at harvest, STMRs and HRs could be established at 0 mg/kg for these fruit and nut commodities.

Strawberry

The critical GAP for strawberries in the USA is for soil treatments of up to 0.105 kg ai/ha as a shielded inter-row band spray (avoiding contact with fruit or foliage) applied up to fruit set, with a maximum seasonal rate of 0.105 kg ai/ha.

Trials on strawberries conducted in the USA involved one directed inter-row soil application, 1–2 days before harvest, with a previous broadcast soil application to dormant strawberries in some of these trials.

The Meeting agreed that these trials did not match the USA GAP. No maximum residue level for strawberries was estimated.

Bulb vegetables

Results from supervised trials on bulb onions conducted in the USA were provided to the Meeting.

Onion, dry bulb

The critical GAP for bulb onions in the USA is for broadcast soil/foliar treatments of up to 0.07 kg ai/ha to onions between the 2-leaf and 6-leaf stage, with a maximum seasonal rate of 0.105 kg ai/ha.

In nine independent trials on bulb onions conducted in the USA where two broadcast applications of 0.1–0.115 kg ai/ha were applied at or about the 2-leaf stage and 29–78 days later (42–49 days before harvest), residues in the dry bulbs were all < 0.02 mg/kg.

The Meeting noted that since residues were all < LOQ in these supervised trials with application rates higher than specified in the USA GAP, the data could be used to estimate a maximum residue level.

The Meeting estimated an STMR of 0 mg/kg, and HR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on onion, bulb.

Garlic

The critical GAP for garlic in the USA is for one pre-emergent broadcast soil application of up to 0.21 kg ai/ha, no later than 3 days after planting. No trials matching this GAP were provided and no maximum residue level for garlic was estimated by the Meeting.

Cabbage, head

Results from supervised trials on head cabbages conducted in the USA were provided to the Meeting.

The critical GAP for head cabbages in the USA is for inter-row soil treatments of up to 0.14 kg ai/ha between raised plastic-mulched beds up to just before transplanting, with a maximum seasonal rate of 0.28 kg ai/ha.

In seven independent trials on head cabbages conducted in the USA where one broadcast soil application of 0.1–0.11 kg ai/ha was applied just before transplanting, residues in cabbage heads (with wrapper leaves) were all < 0.02 mg/kg.

Although the broadcast treatment method used in the supervised trials did not match the USA GAP for inter-row applications just before transplanting, the Meeting agreed that since the use directions specified treatment only to the row middles between raised plastic mulched beds that are at least 60 cm wide and since the broadcast treatment method represented the worst-case situation, the data set (all < LOQ) could be used to estimate a maximum residue level and that the STMR and HR could be established at 0 mg/kg as no flumioxin residues would be expected in mature cabbages at harvest.

The Meeting estimated an STMR of 0 mg/kg, an HR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on cabbages, head.

Fruiting vegetables, Cucurbits

Results from supervised trials on outdoor cucumbers, summer squash and melons (cantaloupes) conducted in the USA were provided to the Meeting.

The critical GAP for cucurbit vegetables in the USA is for inter-row soil treatments of up to 0.14 kg ai/ha between raised plastic-mulched beds up to 14 days before planting with an option to apply an additional inter-row soil treatment up to 21 days after transplanting/emergence but before the start of flowering, with a maximum seasonal rate of 0.28 kg ai/ha.

In six independent trials matching the GAP in the USA, residues of flumioxazin in cucumbers were all < 0.02 mg/kg.

In seven independent trials matching the GAP in the USA, residues of flumioxazin in summer squash were all < 0.02 mg/kg.

In eight independent trials matching the GAP in the USA, residues of flumioxazin in melons were all < 0.02 mg/kg.

Based on the combined results of the cucumber, summer squash and melon trials, with residues of < 0.02 (n=21), the Meeting agreed to consider establishing a group maximum residue level for fruiting vegetables, cucurbits.

The Meeting estimated an STMR of 0.02 mg/kg, an HR of 0.02 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on fruiting vegetables, cucurbits.

Fruiting vegetables, other than Cucurbits

Results from supervised trials on outdoor tomatoes, sweet peppers and chilli peppers conducted in the USA were provided to the Meeting.

The critical GAP for fruiting vegetables in the USA is for inter-row soil treatments of up to 0.14 kg ai/ha between raised plastic-mulched beds up to 14 days before planting with an

option to apply an additional inter-row soil treatment up to 21 days after transplanting/emergence but before the start of flowering, with a maximum seasonal rate of 0.28 kg ai/ha.

In seven independent trials matching the GAP in the USA but with the last application 15–21 days before harvest, when immature fruit were present, residues of flumioxazin in tomatoes were all < 0.02 mg/kg.

In nine independent trials on sweet peppers (6) and chilli peppers (3) matching the GAP in the USA but with the last application 15–21 days before harvest, when immature fruit were present, residues of flumioxazin in peppers were all < 0.02 mg/kg.

Although the timing of the last application in the supervised trials did not match the USA GAP for use up to the start of flowering, the Meeting agreed that the later applications (when fruitlets were present) represented a worst-case situation and that since residues were all < LOQ, the data set could be used to estimate a maximum residue level.

Based on the combined results of tomato, sweet pepper and chilli pepper trials, with residues of < 0.02 (16), the Meeting agreed to consider establishing a group maximum residue level for fruiting vegetables, other than cucurbits.

The Meeting estimated an STMR of 0.02 mg/kg, an HR of 0.02 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on fruiting vegetables, other than cucurbits (except sweetcorn and mushrooms).

Pulses

Results from supervised trials on dry beans, dry peas and soya beans conducted in North America were provided to the Meeting.

Beans (dry)

In the USA, the critical GAP for beans, dry is for a broadcast foliar application of up to 0.105 kg ai/ha as a harvest aid (desiccant) up to 5 days before harvest.

In 10 independent trials matching the GAP in the USA, residues of flumioxazin in dry bean seeds were < 0.02 (5), 0.02, (4), and 0.05 mg/kg.

The Meeting noted that the GAP in the USA for dry beans includes lupins, chickpeas and lentils, and agreed to extrapolate the data for dry beans to these commodities.

The Meeting estimated a maximum residue level of 0.07 mg/kg and an STMR of 0.02 mg/kg for flumioxazin on beans (dry), lupins (dry), chickpeas (dry) and lentils (dry).

Peas (dry)

The critical GAP for field peas in the USA is for a broadcast foliar application of up to 0.105 kg ai/ha as a harvest aid (desiccant) up to 5 days before harvest.

In 13 independent trials matching the GAP in the USA, residues of flumioxazin in dry pea seeds were < 0.02 (8), 0.02, 0.02, 0.03, 0.03 and 0.06 mg/kg. (Highest residue of duplicate samples = 0.07 mg/kg)

The Meeting estimated an STMR of 0.02 mg/kg and a maximum residue level of 0.07 mg/kg for flumioxazin on peas (dry).

Soya bean (dry)

The critical GAP for soya beans in the USA is for pre-plant or pre-emergent broadcast soil applications of 0.105 kg ai/ha (up to 3 days after sowing), with a maximum seasonal rate of 0.105 kg ai/ha.

In 39 independent trials matching the GAP in the USA, residues of flumioxazin in soya bean seeds were all < 0.02 mg/kg. In one processing study involving an exaggerated rate of 0.54 kg ai/ha, residues in soya bean were also < 0.02 mg/kg.

The Meeting estimated an STMR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on soya bean (dry).

Root and tuber vegetables

Results from supervised trials on potatoes conducted in the USA were provided to the Meeting.

Potato

The critical GAP for potatoes in the USA is for broadcast soil applications of up to 0.053 kg ai/ha, after planting (hilling) but before crop emergence, with a maximum seasonal rate of 0.053 kg ai/ha.

In 11 independent trials conducted in the USA, flumioxazin residues in tubers were all < 0.02 mg/kg following one pre-emergence application of 0.13–0.15 kg ai/ha.

The Meeting noted that since residues were all < LOQ in these supervised trials with application rates higher than specified in the USA GAP, the data could be used to estimate a maximum residue level and would support an STMR and HR of 0 mg/kg.

The Meeting estimated an STMR of 0 mg/kg, an HR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on potato.

Sweet potato

The Meeting noted that GAP also existed in the USA for the use of flumioxazin on sweet potato as a broadcast soil application of up to 0.105 kg ai/ha prior to transplanting and agreed that the results of the USA potato trials, matching this GAP could be used to estimate a maximum residue level for sweet potatoes.

The Meeting estimated an STMR of 0 mg/kg, an HR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on sweet potato.

Stem and stalk vegetables

Results from supervised trials on asparagus, globe artichoke and celery conducted in North America were provided to the Meeting.

Artichoke, Globe

The critical GAP for globe artichokes in the USA is for broadcast pre-plant or pre-emergence soil applications of up to 0.21 kg ai/ha, with a maximum seasonal rate of 0.21 kg ai/ha.

In three independent trials matching the pre-plant GAP in the USA, flumioxazin residues in artichoke heads were all < 0.02 mg/kg.

The Meeting estimated an STMR of 0.02 mg/kg, an HR of 0.02 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on artichoke, Globe.

Asparagus

The critical GAP for asparagus in the USA is for broadcast soil applications of up to 0.21 kg ai/ha not later than 14 days before spear emergence, with a maximum seasonal rate of 0.21 kg ai/ha.

In eight independent trials matching the GAP in the USA, flumioxazin residues in spears were all < 0.02 mg/kg.

The Meeting noted that in these trials, residues were all < LOQ in the 2× plots, and agreed that the data would support an STMR and HR of 0 mg/kg.

The Meeting estimated an STMR of 0 mg/kg, an HR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on asparagus.

Celery

The critical GAP for celery in the USA is for broadcast soil applications of up to 0.105 kg ai/ha, 3–7 days after transplanting), with a maximum seasonal rate of 0.105 kg ai/ha.

No trials matched this broadcast post-transplanting GAP in the USA and no maximum residue level for celery was estimated by the Meeting.

Cereal grains

Results from supervised trials on maize and wheat conducted in North America were provided to the Meeting.

Maize

The critical GAP for maize in the USA is for broadcast soil applications of up to 0.105 kg ai/ha applied from 30 to 14 days before sowing, with a maximum seasonal rate of 0.105 kg ai/ha.

In 21 independent trials matching the GAP in the USA, with pre-planting intervals of 6–14 days, flumioxazin residues in maize grain were all < 0.02 mg/kg.

The Meeting noted that in three of these trials and in the processing study involving exaggerated application rates, residues were also < LOQ, and agreed that the data would support an STMR of 0 mg/kg.

The Meeting estimated an STMR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on maize.

Wheat

The critical GAP for wheat in the USA is for a broadcast foliar application of up to 0.07 kg ai/ha as a harvest aid (desiccant) up to 10 days before harvest.

In 20 independent trials matching the GAP in the USA, residues of flumioxazin in wheat grain were 0.05 (4), 0.06, 0.06, 0.07, 0.08, 0.09, 0.1 (3), 0.11, 0.11, 0.12, 0.13, 0.13, 0.18, 0.23 and 0.31 mg/kg.

The Meeting estimated an STMR of 0.1 mg/kg and a maximum residue level of 0.4 mg/kg for flumioxazin on wheat.

Sugar cane

Results from supervised trials on sugar cane conducted in the USA were provided to the Meeting.

The critical GAP for sugar cane in the USA is for directed inter-row soil/stem band applications of up to 0.14 kg ai/ha after the canes are 60 cm in height or at layby (when canes are more than 76 cm in height), with a minimum 14-day retreatment interval, a maximum seasonal use of 0.42 kg ai/ha and a PHI of 90 days. The label also states that the spray solution must not contact foliage above 15 cm from the base of cane.

The Meeting noted that the supervised trials did not match the GAP in the USA, as they involved single foliar treatments applied over the top of the canes. No maximum residue level for sugar cane was estimated by the Meeting.

Oilseeds

Results from supervised trials on oilseed rape, cottonseed, sunflower seed and peanuts conducted in the USA were provided to the Meeting.

Cotton seed

The critical GAP for cotton seed in the USA is for directed inter-row band soil treatments of up to 0.07 kg ai/ha after cotton has reached 15 cm in height or at layby (when plants are more than 40 cm in height), with a maximum seasonal rate of 0.14 kg ai/ha, a retreatment interval of at least 30 days and a PHI of 60 days.

In 12 independent trials on cotton, involving higher application rates of 0.1–0.12 kg ai/ha but otherwise matching the GAP in the USA, residues in cotton seed were < 0.01(11) and 0.01 mg/kg. The Meeting agreed to use the proportionality approach to estimate a maximum residue level by scaling these results to the 0.07 kg ai/ha rate (scaling factors of 0.63-0.67). Proportionaly adjusted residues were all < 0.01 mg/kg (n=12).

The Meeting estimated an STMR of 0.01 mg/kg and a maximum residue level of 0.01 mg/kg for flumioxazin on cotton seed.

Linseed

The critical GAP for linseed (flax seed) is in the USA, involving a broadcast foliar application of up to 0.105 kg ai/ha as a harvest aid (desiccant) up to 5 days before harvest.

No trials on linseed were available and while there were trials provided on rape seed matching the GAP for linseed in the USA, the Meeting agreed not to extrapolate these data to linseed because of the different seed-head morphologies. No maximum residue level was estimated for linseed.

Peanuts

The critical GAP for peanuts in the USA is for broadcast soil applications of up to 0.105 kg ai/ha prior to sowing or pre-emergent (up to 2 days after sowing), with a maximum seasonal rate of 0.105 kg ai/ha.

In 13 independent trials on peanuts matching the GAP in the USA, flumioxazin residues in peanut nutmeat were all < 0.02 mg/kg. In one processing study involving an exaggerated rate of 0.54 kg ai/ha, residues in nutmeat were also < 0.02 mg/kg.

The Meeting estimated an STMR of 0 mg/kg and a maximum residue level of 0.02* mg/kg for flumioxazin on peanut.

Sunflower seed

The critical GAP for sunflower seed in the USA is for a broadcast foliar application of up to 0.105 kg ai/ha as a harvest aid (desiccant) up to 5 days before harvest.

In eight independent trials on sunflower seed matching the GAP in the USA, residues of flumioxazin in sunflower seed were 0.04, 0.04, 0.05, 0.1, 0.12, 0.18, 0.18 and 0.29 mg/kg.

The Meeting estimated an STMR of 0.11 mg/kg and a maximum residue level of 0.5 mg/kg for flumioxazin on sunflower seed.

Mints

Results from supervised trials on fresh mints conducted in the USA were provided to the Meeting.

The critical GAP for mints (spearmint, peppermint) in the USA is for broadcast applications of up to 0.14 kg ai/ha to dormant plants in autumn and spring, with a maximum seasonal rate of 0.28 kg ai/ha, a retreatment interval of at least 60 days and a PHI of 80 days.

In three independent trials on spearmint and peppermint, involving higher application rates of 0.28 kg ai/ha but otherwise matching the GAP in the USA, residues in fresh mint leaves were all < 0.02 mg/kg. In these trials, separate plots were also treated with 0.42 kg ai/ha (3× GAP), and residues in mint leaves from these plots ranged from < 0.02–0.03 mg/kg.

The Meeting agreed that the results from the 0.42 kg ai/ha application rate, when scaled down to the GAP application rate (scaling factor of 0.5) would support an STMR and HR of 0.01 mg/kg.

The Meeting estimated an STMR of 0.01 mg/kg, an HR of 0.01 mg/kg and a maximum residue level of 0.02 mg/kg for flumioxazin on mints.

Animal feeds

Results from supervised trials on alfalfa and on animal feed commodities from almonds (hulls), cotton (gin trash), peanuts (hulls, vines and hay), soya beans (forage and hay), maize (forage and stover) and wheat (forage, hay and straw) were provided to the Meeting.

For peanuts and soya beans, the US GAP includes a condition that treated crops must not be grazed or fed to livestock, and the Meeting did not evaluate the trial results for feed commodities from these crops.

Alfalfa forage and fodder

The critical GAP for alfalfa in the USA is for broadcast foliar applications of up to 0.14 kg ai/ha in winter (after the final cut) and in spring, after the first cut, before the crop reaches 15 cm in height, with a minimum retreatment interval of 60 days, a maximum seasonal rate of 0.28 kg ai/ha and a PHI of 25 days for harvest or grazing.

In six independent trials on alfalfa involving one broadcast application 24–26 days before the first cut and a second application to regrowth 6–8 days after the first cut, flumioxazin residues in forage were 0.04, 0.1, 0.11, 0.12, 0.14 and 0.39 mg/kg (fresh weight).

In six independent trials on alfalfa involving one broadcast application to regrowth 7–9 days after the first cut, flumioxazin residues in forage were 0.03, 0.06, 0.1, 0.18, 0.23 and 0.8 mg/kg (fresh weight).

The Meeting noted that the residue populations from the single and double treatments were not statistically different, suggesting that the residue contribution from first application (prior to the foliage being cut and removed) was not significant and agreed to use the data from the single post-cutting treatment to estimate median and highest residues for estimating livestock dietary burdens.

The Meeting estimated a median residue of 0.14 mg/kg (fresh weight) and a highest residue of 0.8 mg/kg (fresh weight) for alfalfa forage.

In alfalfa hay sampled from the same trials and same PHIs but allowed to dry in the field for 2-7 days, residues were: 0.11, 0.24, 0.3, 0.46, 0.86 and 1.5 mg/kg.

The Meeting estimated, a median residue of 0.38 mg/kg (fresh weight), a highest residue of 1.5 mg/kg (fresh weight) and after correcting for an average 89% dry matter, estimated a maximum residue level of 3.0 mg/kg (dry weight)for flumioxazin on alfalfa fodder.

Almond hulls

In five independent trials on almonds matching the inter-row soil band treatment GAP in the USA, residues in almond hulls were < 0.01, 0.01, 0.04, 0.06 and 0.55 mg/kg.

The Meeting noted that residues in perennial fruit and nuts are not expected following the use of flumioxazin as an inter-row soil band treatment, and that while in these trials, no residues were present in almond nutmeat, the levels reported in hulls were likely to have arisen from contamination at harvest when the nuts were shaken from the tree and picked up off the ground.

The Meeting estimated a median residue of 0.04 mg/kg for flumioxazin on almond hulls.

Cotton gin trash

In seven independent trials on cotton, involving higher application rates of 0.1–0.12 kg ai/ha but otherwise matching the GAP in the USA, residues in cotton gin trash were < 0.01, 0.03, 0.04, 0.16, 0.24, 0.25 and 0.48 mg/kg. When proportionally adjusted to the 0.07 kg ai/ha GAP application rate (scaling factor of 0.65), the scaled residues are < 0.01, 0.02, 0.03, 0.1, 0.15, 0.16 and 0.31 mg/kg.

The Meeting estimated a median residue of 0.1 mg/kg and a highest residue of 0.31 mg/kg for flumioxazin on cotton gin trash.

Maize forage and fodder

In 21 independent trials matching the pre-plant broadcast soil application GAP in the USA, flumioxazin residues in maize forage sampled at the late dough/early dent growth stage (BBCH 86) were all < 0.02 mg/kg.

The Meeting estimated a median residue of 0 mg/kg and a highest residue of 0 mg/kg for flumioxazin on maize forage.

In maize fodder (stover) sampled from the same 21 trials at grain maturity, flumioxazin residues were all < 0.02 mg/kg.

The Meeting estimated a maximum residue level of 0.02* mg/kg (dry weight), a median residue of 0 mg/kg and a highest residue of 0 mg/kg for flumioxazin on maize fodder.

Wheat forage and hay

The critical GAP for wheat grown for forage or hay in the USA is for a pre-plant or pre-emergence broadcast soil application of up to 0.07 kg ai/ha, with no grazing until the wheat is at least 13 cm high.

In three independent trials matching the pre-plant GAP in the USA, residues of flumioxin in forage were all < 0.02 mg/kg and residues in hay sampled at BBCH 61–85 were also < 0.02 mg/kg.

The Meeting estimated a maximum residue level of 0.02* mg/kg (dry weight), a median residue of 0 mg/kg (fresh weight) and a highest residue of 0 mg/kg (fresh weight) for wheat hay and a median residue of 0 mg/kg for wheat forage.

Wheat straw

The critical GAP for wheat in the USA is for a broadcast foliar application of up to 0.07 kg ai/ha as a harvest aid (desiccant) up to 10 days before harvest.

In 21 independent trials matching the pre-harvest desiccant GAP in the USA, residues of flumioxazin in wheat straw sampled at grain maturity (10 day PHI) were 0.23, 0.76, 1.1, 1.4, 1.5, 1.6, 1.6, 1.6, 1.6, 1.7, 1.7, 1.8, 1.8, 2.1, 2.4, 2.4, 2.6, 3.2, 3.2, 3.4 and 3.7 mg/kg.

The Meeting estimated a a median residue of 1.7 mg/kg (fresh weight), a highest residue of 3.7 mg/kg (fresh weight) and after correction for an average 88% dry matter content, estimated a maximum residue level of 7.0 mg/kg (dry weight), for wheat straw.

Fate of residues during processing

Hydrolysis in aqueous media is pH-dependant, with half-lives at 25 °C ranging from 3–5 days at pH 5 to less than 25 minutes at pH 9 in acetate buffer. After incubation at pH 7 for 2 hours, 482-HA was the only degradate observed (at about 5% TRR) and in the pH 5 buffer solution incubated for 8 hours, levels of 482-HA, THPA and Δ^1-TPA had each increased to about 5% TRR.

The fate of flumioxazin residues has been examined in a number of studies simulating household and commercial processing of apples, plums, grapes, olives, soya beans, potatoes, sugar cane, maize, wheat, oilseed rape, sunflower seed, peanuts and mint. Except for wheat,

sugar cane, oilseed rape and sunflower seed, processing factors could not be estimated because residues in the fresh commodities were below the respective method LOQs.

Estimated processing factors for sugar cane were 0.5 for molasses and < 0.18 for sugar and for oilseed rape, the calculated processing factors were 0.12 for meal and < 0.04 for oil.

Estimated processing factors and STMR-Ps for wheat and sunflower seed, where residues in the raw agricultural commodities (RACs) were above the respective method LOQs are summarized below.

Summary of selected processing factors and STMR-P values for flumioxazin

RAC	Matrix	Flumioxazin [a] Calculated processing factors	STMR-P (mg/kg)
Wheat (0.1 mg/kg)	bran	0.94	0.094
	flour	0.14	0.014
	middling	0.22	0.022
	shorts	0.31	0.031
	germ	1.03	0.103
	aspirated grain fraction	308	30.8
Sunflower seed (0.11 mg/kg)	oil	< 0.009	0.001
	meal	0.065	0.007

[a] Each PF value represents a separate study where residues were above the LOQ in the RAC and is the ratio of the flumioxazin residues in the processed item divided by the residues in the RAC.

The Meeting noted that for wheat, residues do not concentrate in wheat bran, flour, middlings, shorts, and germ. However residues of flumioxazin concentrate by 308× in the aspirated grain fractions. For rape seed, sunflower, and sugar cane, there is no concentration of flumioxazin residues in the corresponding processed fractions.

Residues in animal commodities

Farm animal feeding studies

In a lactating cow feeding study three groups of dairy cattle (three cows per group) were dosed orally with flumioxazin at levels equivalent to 2, 6.2 and 19.5 ppm in the diet for 28 consecutive days (0.7 mg/kg bw/day, 0.22 mg/kg bw/day and 0.73 mg/kg bw/day respectively) and the animals were sacrificed 24 hours after the last dose. Analysis for flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin was by HPLC-MS/MS with an LOQ of 0.02 mg/kg.

At the 19.5 ppm dose level, residues of flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin were all non-detectable (LOD of 0.01 mg/kg) in all samples of milk, skim milk, cream, liver, kidneys, muscle, and fat. Samples from the lower dose group animals were not analysed.

No poultry feeding studies were provided. In the poultry metabolism study, where two groups of 10 hens were dosed with at levels equivalent to 10 ppm [^{14}C]flumioxazin (phenyl-label or THP-label) in the diet for 14 consecutive days (average of 0.68 mg/kg bw/day), THP-labelled flumioxazin residues were found at levels of up to 0.13 mg/kg in fat, 0.06–0.08 mg/kg in edible offal (liver and kidney), 0.04 mg/kg in egg yolk and up to 0.17 mg/kg in muscle.

Residues of the 4-OH-flumioxazin metabolite (THP-label) were up to 0.07 mg/kg in skin + fat, 0.03 mg/kg in fat, 0.12–0.08 mg/kg in edible offal (liver and kidney), 0.02 mg/kg in egg yolk and up to 0.18 mg/kg in muscle.

Residues of the 3-OH-flumioxazin metabolite (THP-label) were up to 0.04 mg/kg in skin + fat, 0.03 mg/kg in fat, 0.08–0.06 mg/kg in edible offal (liver and kidney), 0.016 mg/kg in egg yolk and up to 0.16 mg/kg in muscle.

Farm animal dietary burden

The Meeting estimated the dietary burden of flumioxazin in farm animals on the basis of the diets listed in Appendix IX of the 2009 edition of the JMPR Manual. Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex X and are summarized below:

Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden, flumioxazin, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	2.6	2.2 [c]	2.5	0.7	3.8 [a]	1.6	0.39	0.26
Dairy cattle	1.0	0.41	1.9	0.67	2.3 [b]	0.71 [d]	0.59	0.28
Poultry—broiler	0.23	0.23	0.15	0.15	0.15	0.15	0.14	0.049
Poultry—layer	0.23	0.23	0.57 [e, g]	0.34 [f, h]	0.14	0.14	0.11	0.11

[a] Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues

[b] Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

[c] Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

[d] Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

[e] Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues.

[f] Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues.

[g] Highest maximum poultry dietary burden suitable for MRL estimates for poultry eggs.

[h] Highest mean poultry dietary burden suitable for STMR estimates for poultry eggs.

For beef and dairy cattle, the calculated maximum dietary burden is 3.8 ppm dry weight of feed and for poultry, noting that in some countries, laying hens may also be consumed, suitable calculated maximum and mean dietary burdens are 0.57 ppm and 0.34 ppm dry weight of feed respectively.

Animal commodity maximum residue levels

The Meeting noted that in the cow feeding study, no detectable residues of flumioxazin or the 3-OH-flumioxazin or 4-OH-flumioxazin metabolites were found in milk or any tissues from the 19.5 ppm dose group animals.

As this dose rate is more than 5× the maximum dietary burdens of 3.82 ppm for beef and dairy cattle, the Meeting concluded that residues of flumioxazin, 3-OH-flumioxazin and 4-OH-flumioxazin are not expected in mammalian milk, meat, fat or edible offal.

The Meeting estimated maximum residue levels of 0.02* mg/kg for flumioxazin in meat (from mammals other than marine mammals), edible offal (mammalian), mammalian fat and for milks. Estimated STMRs and HRs for dietary intake estimation are 0 mg/kg for meat, 0 mg/kg for edible offal, 0 mg/kg for fat and 0 mg/kg for milk.

In the hen metabolism study, the highest residues of flumioxazin were up to 0.08 mg/kg in liver and kidney, 0.13 mg/kg in fat, 0.02 mg/kg in muscle and 0.04 mg/kg in egg yolk, equivalent to 0.014 mg/kg in eggs (35:65 yolk:white). As the 10 ppm dose rate in this study is 17.5× the maximum dietary burdens of 0.57 ppm for poultry broilers and layers, the Meeting concluded that the maximum residues of flumioxazin are not expected to exceed 0.005 mg/kg in poultry edible offal, 0.007 mg/kg in fat and would be lower in poultry meat and eggs (0.001 mg/kg or less).

The 10 ppm dose rate is also 29× the mean dietary burdens of 0.34 ppm for poultry broilers and layers, and the Meeting concluded that the mean residues of flumioxazin are not expected to exceed 0.003 mg/kg in poultry edible offal, 0.004 mg/kg in fat and less than 0.001 mg/kg in poultry meat and eggs.

The Meeting estimated maximum residue levels of 0.02* mg/kg for flumioxazin in poultry meat, poultry offal, poultry fat and eggs. Estimated HRs for dietary intake estimation are

0.007 mg/kg for poultry fat, 0.001 mg/kg for poultry meat, 0.005 mg/kg for poultry offal and 0.001 mg/kg for eggs and the STMRs are 0.003 mg/kg for poultry offal, 0.004 mg/kg in fat, 0.001 mg/kg for poultry meat and 0.001 mg/kg for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for MRL-compliance and estimation of dietary intake, plant and animal commodities): *flumioxazin.*

The residue is not fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intake (IEDI) for flumioxazin was calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available. The results are shown in Annex 3.

The International Estimated Daily Intakes of flumioxazin for the 17 GEMS/Food cluster diets, based on estimated STMRs were 0–1% of the maximum ADI of 0.02 mg/kg bw (Annex 3). The Meeting concluded that the long-term intake of residues of flumioxazin from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short Term Intake (IESTI) for flumioxazin was calculated for food commodities and their processed fractions for which maximum residue levels were estimated and for which consumption data were available. The results are shown in Annex 4.

For flumioxazin, the IESTI varied from 0–7% of the ARfD (0.03 mg/kg bw for women of child-bearing age) and the Meeting concluded that the short-term intake of residues of flumioxazin from uses considered by the Meeting is unlikely to present a public health concern.

FLUOPYRAM (243)

The first draft was prepared by Mr David Lunn, Plants, Food & Environment Directorate, Ministry for Primary Industries, Wellington, New Zealand

EXPLANATION

Fluopyram, a pyridylethylamide broad spectrum fungicide was first evaluated by the 2010 JMPR, where residue definitions were proposed, an ADI of 0–0.01 mg/kg bw and an ARfD of 0.5 mg/kg bw were established and maximum residue levels were recommended for a limited number of uses where GAP information was available. New GAP and supporting information were evaluated by the JMPR in 2012 and in 2014, with a number of additional maximum residue levels being recommended.

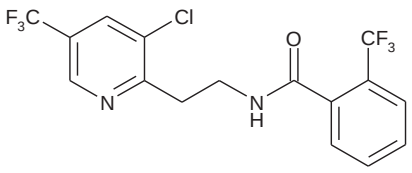
The 2010 JMPR also established residue definitions for fluopyram:

- For plant products (compliance with MRLs and dietary intake assessment)—*fluopyram*
- For animal products (compliance with MRLs)—*sum of fluopyram and 2-(trifluoromethyl) benzamide, expressed as fluopyram*
- For animal products (dietary intake assessment)—*sum of fluopyram, 2-(trifluoromethyl)benzamide and the combined residues N-{(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide and N-{(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide, all expressed as fluopyram.*

The 46th Session of the CCPR (2014) listed fluopyram for further evaluation by the 2015 JMPR for additional MRLs and the current Meeting received new GAP information and/or new supporting residue information from the manufacturer for tomatoes, eggplants, beans, peas, soya beans (dry), sunflower seeds and cotton seed.

The Meeting also considered relevant residue information provided to the JMPR in 2010 for tomatoes, beans and peas (fresh and dry) and sunflower seeds.

Fluopyram is N-{2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethyl}-2-(trifluoromethyl)benzamide. It is relatively insoluble in water (15 mg/L), stable to hydrolysis, of low volatility (1.2×10^{-6} Pa at 20 °C), has a log P_{OW} of 3.3 and is soluble (> 250 g/L) in methanol, dichloromethane, acetone, ethyl acetate and dimethyl sulfoxide.



Fluopyram (AE C656948)

The following abbreviations are used for the metabolites discussed below.

BZM	-benzamide	2-(trifluoromethyl)benzamide
E-olefine		N-{(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl}-2-trifluoromethyl) benzamide
Z-olefine		N-{(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide

Methods of residue analysis

Analytical methods

The 2010 JMPR reviewed and summarized analytical method descriptions and validation data for fluopyram and major metabolites (BZM, 7-OH, PCA, PAA and the methyl-sulfoxide) in crop and animal commodities, and in soil. These included Methods 00984 and GM-001-P07-01, which were used to measure residues of fluopyram in the new supervised residue trials on tomatoes, beans and peas, soya beans, sunflower and cotton.

In Method 00984 and its minor variants, fluopyram residues were extracted by maceration with acetonitrile/water and residues were quantified by reversed-phase chromatography with tandem mass spectrometry (MS/MS) with electrospray ionisation. Method GM-001-P07-01, a modification Method 00984, used an isotopically labelled internal standard and included an additional C_{-18} solid phase extraction (SPE) clean-up step.

USE PATTERNS

Information on GAP in the USA and Canada, South Africa and a number of countries in Europe was provided to the Meeting for foliar applications or seed treatments to crops for which new or previously submitted data were available. This GAP information is summarized in Table 1.

Table 1 Registered uses of fluopyram, SC or FS formulations (including co-formulations with tebuconazole, trifloxystrobin and triadimenol)

RTI = Re-treatment interval

[a] SC formulation containing 200 g ai/L fluopyram + 200 g ai/L tebuconazole

[b] SC formulation containing 250 g ai/L fluopyram + 250 g ai/L trifloxystrobin

[c] SE formulation containing 125 g ai/L fluopyram + 125 g ai/L prothioconazole

[d] SC formulation containing 250 g ai/L fluopyram + 250 g ai/L triadimenol

[e] FS seed treatment formulation containing 600 g ai/L fluopyram

Residues resulting from supervised trials

The Meeting reviewed supervised field trial information provided to the JMPR in 2010 and received new information on supervised field trials involving applications of fluopyram to the following crops.

Crop Group	Commodity	Region	Table No.
Fruiting vegetables, other than cucurbits	Tomato (protected)	Europe	2
	Tomato (outdoor)	Europe	3
Legume vegetables	Beans (protected)	Europe	4 [a]
	Beans (outdoor)	Europe	5 [a], 6
	Peas	Europe	7 [a], 8
Pulses	Soya bean (dry)	North America	9 [a], 10
Oilseeds	Sunflower seed	Europe	11
	Cottonseed	North America	12, 13
Legume animal feeds	Bean forage	Europe	14 [a], 15
	Pea vines and hay	Europe	16 [a], 17

[a] Data from trials evaluated by the 2010 JMPR

The supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation including procedural recoveries with spiking at residue levels

similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ.

When multiple applications were made to a crop, the application rates, spray concentrations and spray volumes were not always identical from one application to the next. If the variation was small, only the final values for application rate, concentration and spray volume were recorded. For larger variations all values were recorded.

Intervals of freezer storage between sampling and analysis were recorded for all trials and were covered by the conditions of the freezer storage stability studies reviewed by the 2010 JMPR.

Results from replicated field plots are presented as individual values and have not been corrected for concurrent method recoveries unless indicated. When residues were not detected they are shown as below the LOQ (e.g. < 0.01 mg/kg). Residues and application rates have been rounded to two significant digits (or if close to the LOQ, rounded to one significant digit). Average values have been calculated from the residue results prior to rounding, and the results from trials conducted according to the maximum GAP and used for the estimation of maximum residue levels have been underlined.

In addition to the description and details of the field trials and analytical methods, each report includes a summary of the method validation, procedural recoveries, and in most cases, concurrent recoveries in stored frozen samples.

In the trials, where multiple analyses are conducted on a single sample the average value is reported, and where duplicate samples have been analysed, both the individual results and the average values have been reported. Where results from separate plots with distinguishing characteristics such as different formulations, varieties or treatment schedules were reported, results are listed for each plot, and the highest value has been used in calculations of MRLs and STMRs.

Fruiting vegetables (except Cucurbits)

Tomatoes

Results from supervised trials from Europe on greenhouse and field tomatoes were provided to the Meeting to supplement the data provided to the 2010 JMPR.

In four greenhouse trials provided to the Meeting, three applications of fluopyram (SC formulations) were made at 13–14 day intervals to mature plants as foliar sprays using knapsack sprayers with hand lances (1–4 nozzles) to apply 0.15 kg ai/ha in 1000–1500 L water/ha. Plot sizes in these trials ranged from 15–46 m^2. In a further eight greenhouse trials, two applications of 0.15 kg ai/ha fluopyram in 1000 L water/ha were made at 7-day intervals using similar equipment and with plot sizes of 12–38 m^2.

In eight field trials provided to the Meeting, two applications of fluopyram (SC formulations) were made at 6–7 day intervals to mature plants as foliar sprays using knapsack or motorised sprayers with 1–2 nozzle hand lances or mini-booms (3–9 flat-fan nozzles) to apply 0.15 kg ai/ha in 500–1000 L water/ha. Plot sizes in these trials ranged from 23–80 m^2.

In all trials, unreplicated samples of at least 2 kg or 24–28 fruit (48–100 for cherry tomatoes) were taken from each plot, frozen within 24 hours of sampling and stored at or below –18 °C for up to 440 days before analysis for fluopyram and metabolites using LC/MS/MS Methods 00984 or 00984/M001 (LOQ 0.01 mg/kg). Mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 87–109%.

Legume vegetables

Common beans

Results from supervised trials from Europe on protected and outdoor common beans were provided to the Meeting to supplement the data provided to the 2010 JMPR.

In the 2007–2008 trials evaluated by the 2010 JMPR, two applications of fluopyram (SC 500 formulations) were made 7–8 days apart as foliar sprays using knapsack or wheel barrow sprayers with 1–4 flat-fan, solid or hollow-cone nozzles or hand-held-booms (3–12 flat-fan nozzles), applying 0.3 kg ai/ha in 600-1500 L water/ha to the protected crops and 0.25 kg ai/ha in 300–1000 L water/ha to the outdoor crops. Plot sizes in these trials ranged from 8–108 m^2.

In the more recent trials, two foliar applications of 0.2 kg ai/ha fluopyram (SC formulations) were made 7–9 days apart using knapsack sprayers with 1–3 flat-fan, solid or hollow-cone nozzles or plot boom sprayers (5–12 nozzles) to apply 300–500 L spray mix/ha to the protected crops and 0.25 kg ai/ha in 300–1000 L water/ha to the outdoor crops. Plot sizes in these trials ranged from 18–125 m^2.

Unreplicated samples of 1–3 kg of pods (including seeds) and in the outdoor trials at least 12–18 kidney bean plants (min 1 kg green material, including pods and seeds) were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 456 days before analysis for fluopyram using LC/MS/MS Methods 00984 or 00984/M001. The reported LOQs were 0.01 mg/kg for each analyte. Mean fluopyram recovery rates ranged from 87–98% in fresh pods spiked with 0.01–4.0 mg/kg, 85–100% in vines spiked with 0.01–10 mg/kg and 101% in seeds (fresh) spiked with 0.01–0.1 mg/kg.

Peas

Results from supervised trials from Europe conducted in 2012 on <u>field peas</u> were provided to the Meeting to supplement the data provided to the 2010 JMPR.

In the trials evaluated by the 2010 JMPR, two applications of fluopyram (SC formulation) were made to peas 7–8 days apart as foliar sprays using knapsack or wheel barrow

sprayers with hand-held spray booms (3–12 flat-fan or hollow cone nozzles), applying 0.25 kg ai/ha in 300–600 L water/ha. Plot sizes in these trials ranged from 24–101 m^2.

Unreplicated samples of at 0.5–4 kg succulent seeds, pods and/or whole plants (including pods and seeds but without roots) were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 329 days before analysis for fluopyram and its metabolites using LC/MS/MS Method 00984. The reported LOQs were 0.01 mg/kg for each analyte and average fluopyram recovery rates were 100–101% in plants and pods spiked with 0.01–10 mg/kg and 88–99% in succulent seeds spiked with 0.01–0.5 mg/kg.

In the 2012 trials, two applications of fluopyram (SC formulations) were made to peas 7–9 days apart as foliar sprays using knapsack or plot sprayers with hand-held single-nozzle lances or spray booms (3–12 flat-fan or hollow cone nozzles), applying 0.2–0.25 kg ai/ha in 300–500 L water/ha. Plot sizes in these trials ranged from 45–160 m^2.

Unreplicated samples of at least 1 kg of fresh pods and vines (without pods and roots) and at least 0.5 kg of dry seeds and straw were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 467 days before analysis for fluopyram using LC/MS/MS Method 00984 or 00984/M003. The reported LOQs were 0.01 mg/kg for each analyte and average fluopyram recovery rates ranged from 91–100% in fresh pods spiked with 0.01–2.0 mg/kg, 93–101% in vines spiked with 0.01–20 mg/kg, 87–100% in seeds (fresh and dry) spiked with 0.01–1.0 mg/kg and 89–98% in straw spiked with 0.01–20 mg/kg.

Pulses

Soya bean (dry)

Results from supervised trials from the USA on <u>soya beans</u> were provided to the Meeting. In these trials, fluopyram (SC formulation) was applied either as seed treatment to soya bean seeds, or as a seed treatment followed by two foliar applications to the plants. In the plots involving seed treatments, the seeds were slurry-treated with either 0.15 or 0.25 mg ai/seed and the targeted seeding rate was about 544,000 seeds/ha (equivalent to 0.082 kg ai/ha or 0.136 kg ai/ha respectively). Actual seeding rates ranged from 257,000–642,000 seeds/ha. Plot sizes in these trials ranged from 46–370 m^2.

In the plots that also included foliar fluopyram treatments, one application of 0.11–0.12 kg ai/ha was made about 21 days before harvest with a second treatment of 0.25–0.26 kg ai/ha applied 5–8 days later, using CO_2 plot or knapsack sprayers with hand-held spray booms or tractor-mounted boom sprayers to apply 90–190 L spray mix/ha.

Duplicate samples of at least 1 kg seeds were taken from each plot, frozen within 4 hours of sampling, held in frozen storage for up to 585 days before analysis for fluopyram using LC/MS/MS Method GM-001-P07-01, with a reported LOQ of 0.01 mg/kg and with an average fluopyram recovery rate of 93% in dry soya bean seeds spiked with 0.01–0.4 mg/kg.

Oilseeds

Sunflower seed

Results from supervised trials from Europe on sunflowers were provided to the Meeting. In these trials, two applications of 0.117–0.13 kg ai/ha (SC formulations) were made to sunflower plants, 13–15 days apart as foliar sprays using knapsack or CO_2 plot sprayers with hand-held or wheeled spray booms (1–12 nozzles) to apply 275–400 L spray mix/ha. Applications were made up to the seed development or early ripening stages (BBCH 67–85)Plot sizes in these trials ranged from 36–740 m^2.

Unreplicated samples (min 1 kg seed) were taken from each plot, frozen within 24 hours of sampling, held in frozen storage for up to 358 days before analysis of whole seeds. In a number of trials, seeds (min 9 kg samples) were also conditioned to < 8% moisture content, cleaned, crushed (between 1 mm rubber rollers), shelled and dry-fractioned to separate the kernels (the commodity in trade), prior to analysis. The analytical methods used in these trials for measuring fluopyram residues were LC/MS/MS Method 00948/M001 or 00948/M003, with a reported LOQ of 0.01 mg/kg and with average fluopyram recovery rates of 92–100% in seeds, kernels and seed fractions spiked with 0.01–0.1 mg/kg.

[a] Seeds stored for 6 days at 18–31 °C before sampling

Cotton seed

Results from supervised trials from the USA on cotton were provided to the Meeting. In these trials fluopyram was applied either as a pre-plant seed treatment, as a seed treatment in combination with an in-furrow soil treatment at planting or as a combination of a seed treatment, in-furrow soil treatment and a foliar spray applied about 30 days before harvest.

For the plots receiving treated seed, cotton seeds were slurry-treated with 0.5 mg ai/seed and the targeted seeding rate was about 148,000 seeds/ha (equivalent to 0.074 kg ai/ha). Actual seeding rates ranged from 144,495–148,650 seeds/ha. Residues in cotton seed and gin byproducts from the seed treatment plots and from plots involving the combination of seed treatment and in-furrow soil treatments are summarized in the following tables.

Plots were harvested by mechanical picker, mechanical stripper or manually, with duplicate samples of at least 30 kg (undelinted seed plus gin trash) taken from the mechanically harvested plots and at least 1 kg (seed cotton) from the manually harvested plots. Samples were frozen within 24 hours of sampling, ginned and held in frozen storage for up to 148 days before analysis for fluopyram using LC/MS/MS Method GM-001-P07-01, with a reported LOQ of 0.01 mg/kg and with average fluopyram recovery rates of 98% in undelinted seed spiked with 0.01–1.0 mg/kg and 97% in gin by-products spiked with 0.01–18 mg/kg.

Primary feed commodities

Legume animal feeds

Bean fodder and forage

In the European outdoor field trials on beans evaluated by the Meeting, two applications of fluopyram (SC 500 formulations) were made 7–8 days apart as foliar sprays using knapsack or wheel barrow sprayers with 1–4 flat-fan, solid or hollow-cone nozzles or hand-held-booms (3–12 flat-fan nozzles), applying 0.25 kg ai/ha in 300–1000 L water/ha to plots ranging from 8–108 m^2.

Unreplicated samples of 1–3 kg of pods (including seeds) and at least 12–18 bean plants (min 1 kg green material, including pods and seeds) were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 456 days before analysis for fluopyram using LC/MS/MS Methods 00984 or 00984/M001. The reported LOQs were 0.01 mg/kg for each analyte. Mean fluopyram recovery rates ranged from 87–98% in fresh pods spiked with 0.01–4.0 mg/kg, 85–100% in vines spiked with 0.01–10 mg/kg and 101% in seeds (fresh) spiked with 0.01–0.1 mg/kg.

Pea vines and hay

In the European trials on <u>peas</u> evaluated by the Meeting, two applications of fluopyram (SC formulation) were made to peas 7–9 days apart as foliar sprays using knapsack or wheel barrow sprayers with hand-held spray booms (1–12 flat-fan or hollow cone nozzles), applying 0.2–0.25 kg ai/ha in 300–600 L water/ha. Plot sizes in these trials ranged from 24–160 m^2.

Unreplicated samples of at 0.5–4 kg whole plants (including pods and seeds but without roots), at least 1 kg of fresh pods and vines (without pods and roots) and at least 0.5 kg of dry seeds and straw were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 467 days before analysis for fluopyram and metabolites using LC/MS/MS Method 00984 or 00984/M003. The reported LOQs were 0.01 mg/kg for each analyte and average fluopyram recovery rates ranged from 100–101% in plants spiked with 0.01–10 mg/kg, 93–101% in vines spiked with 0.01–20 mg/kg, 87–100% in seeds (fresh and dry) spiked with 0.01–1.0 mg/kg and 89–98% in straw spiked with 0.01–20 mg/kg.

APPRAISAL

Fluopyram, a pyridylethylamide broad spectrum fungicide was evaluated for the first time by the 2010 JMPR, where an ADI of 0–0.01 mg/kg bw and an ARfD of 0.5 mg/kg bw were established, residue definitions were proposed and maximum residue levels were recommended for a number of uses where GAP information was available. New GAP and supporting information were evaluated by JMPR in 2012 and 2014 JMPRs and a number of additional maximum residue levels were recommended.

Residue definitions established by the 2010 JMPR are:

- for plant products (compliance with MRLs and dietary intake assessment): *fluopyram*
- for animal products (compliance with MRLs): sum of fluopyram and 2-(trifluoromethyl) benzamide, expressed as fluopyram
- for animal products (dietary intake assessment): sum of fluopyram, 2-(trifluoromethyl)benzamide and the combined residues N-{(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide and N-{(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide, all expressed as fluopyram.

New GAP information and supporting residue data were provided by the manufacturer for evaluation by the Meeting.

Results of supervised residue trials on crops

The Meeting received new supervised trial data for foliar applications of fluopyram (SC formulations, generally in combinations with other fungicides) on tomatoes, beans, peas, and sunflower and for seed treatments or in-furrow soil treatments on soya bean and cotton. The Meeting also noted that data for some of these crops had been provided to the 2010 JMPR.

The results from these new trials and those previously reported by the 2010 JMPR and either matching critical GAP or where the results can be proportionally adjusted (scaled) to reflect GAP application rates were used to estimate maximum residue levels, STMRs and HRs for a number of commodities for which GAP information was available. Frozen sample storage times in the new trials were within the storage intervals considered acceptable by the 2010 JMPR and the analytical methods used in these trials were the same as those evaluated by JMPR in 2010.

Fruiting vegetables (except Cucurbits)

Tomato

The Meeting was advised that new GAP exists in Greece for fluopyram on protected tomatoes, involving up to three foliar applications of 0.15 kg ai/ha with a 3-day PHI.

In four independent protected tomato trials matching this GAP in Greece, residues were 0.04, 0.07, 0.08 and 0.13 mg/kg.

New GAP was also provided for tomatoes in Ukraine, up to two foliar applications of 0.15 kg ai/ha with a 7 day PHI.

In eight independent trials on field tomatoes conducted in Europe and matching this GAP in Ukraine, fluopyram residues were: < 0.01, 0.02, 0.06, 0.07, 0.1, 0.13, 0.13 and 0.17 mg/kg.

The Meeting noted that the 2010 JMPR had recommended a fluopyram maximum residue level of 0.4 mg/kg based on trials on protected tomatoes where residues had been proportionally adjusted to the GAP in Morocco.

The Meeting agreed that the 2010 JMPR recommendations accommodated the new GAPs for tomatoes in Greece and Ukraine.

Peppers and eggplant

The Meeting noted that the new GAP in Greece for fluopyram on protected tomatoes (3× 0.15 kg ai/ha, 3-day PHI) also applied to protected peppers and eggplants and that the 2012 JMPR had recommended a maximum residue level of 0.5 mg/kg for peppers based on the GAP in Turkey.

No trials matching the GAP in Greece on peppers and eggplants were available. The Meeting noted that the previous trials on protected peppers provided to the 2010 and 2012 JMPRs all involved only two applications and application rates of either 0.06 kg ai/ha or 0.3 kg ai/ha and agreed that the proportionality approach could not be used to support revised recommendations for peppers and/or extrapolation to eggplants.

Legume vegetables

Beans (except broad bean and soya bean)

The critical GAP for beans in Netherlands and Belgium is for up to two foliar applications of 0.25 kg ai/ha, with a 7-day PHI and results from supervised trials from Europe on protected and outdoor beans were provided to the Meeting to supplement the data provided to the 2010 JMPR.

In nine independent trials on protected beans matching this critical GAP, fluopyram residues were: 0.07, 0.15, 0.16, 0.16, 0.2, 0.22, 0.22, 0.43 and 0.69 mg/kg in beans with pods.

In 32 independent trials on outdoor beans conducted in Europe and matching this critical GAP, fluopyram residues were: **< 0.01, < 0.01, 0.01,** 0.03, **0.04,** 0.04, **0.05**, 0.05, 0.07, **0.08, 0.08**, **0.09, 0.1**, 0.1, 0.11, 0.11, 0.12, **0.14**, **0.15**, **0.17**, **0.17**, 0.17, 0.18, 0.19, 0.2, 0.21, 0.24, 0.24, 0.25, 0.26, **0.32** and 0.43 mg/kg in beans with pods. (Results in bold are from the new trials).

The Meeting noted that the data sets for protected and outdoor bean were statistically different and agreed to use the data from the trials on protected beans to estimate a maximum residue level of 1 mg/kg, an STMR of 0.2 mg/kg and an HR of 0.69 mg/kg for fluopyram on beans (except broad bean and soya bean).

Peas, shelled

The critical GAP for peas (without pods) in Netherlands and Belgium is for up to two foliar applications of 0.25 kg ai/ha, with a 7-day PHI and results from supervised trials from Europe on outdoor peas were provided to the Meeting to supplement the data provided to the 2010 JMPR.

In 30 independent trials conducted in Europe and matching this critical GAP, fluopyram residues were: **< 0.01, < 0.01, < 0.01**, < 0.01, **0.01, 0.01**, 0.01, **0.02, 0.02, 0.02**, 0.02, 0.02, 0.02, 0.02, **0.03, 0.03**, 0.03, 0.03, **0.04**, 0.05, 0.05, 0.05, **0.05**, **0.06, 0.06**, **0.06**, **0.09, 0.09**, 0.1 and **0.12** mg/kg in peas without pods. (Results in bold are from the new trials).

The Meeting estimated a maximum residue level of 0.2 mg/kg, an STMR of 0.03 mg/kg and an HR of 0.12 mg/kg for fluopyram on peas, shelled.

Beans, shelled

The Meeting noted that the GAP for beans in Netherlands and Belgium (up to two foliar applications of 0.25 kg ai/ha, with a 7-day PHI) was for beans with and without pods, and since this GAP for beans was the same as for peas, the Meeting agreed to extrapolate the data from peas, shelled to beans, shelled.

The Meeting estimated a maximum residue level of 0.2 mg/kg, an STMR of 0.03 mg/kg and an HR of 0.12 mg/kg for fluopyram on beans, shelled.

Soya bean (dry)

Results from supervised trials from the USA on soya beans were provided to the Meeting. In 21 independent trials matching the GAP in the USA for use as a seed treatment (0.25 mg ai/seed) fluopyram residues were < 0.01 (12), 0.01, 0.01, 0.01, 0.02, 0.02, 0.03, 0.03 and 0.03 mg/kg in dry soya beans.

The Meeting noted that the metabolism studies did not cover the use of fluopyram as a seed treatment. However the Meeting noted the 2010 JMPR conclusions that fluopyram is slowly degraded in soil and when present, is the major residue in 30-day PBI rotational crops and agreed that the established residue definitions would also cover the use of fluopyram as a seed treatment.

The Meeting estimated a maximum residue level of 0.05 mg/kg and an STMR of 0.01 mg/kg for fluopyram on soya bean (dry).

Oilseeds

Sunflower seed

Results from supervised trials from Europe on sunflowers were provided to the Meeting.

The critical GAP in Ukraine and Moldovia is for up to two foliar sprays of 0.125 kg ai/ha, applied before the start of flowering (BBCH 57) and with a minimum PHI of 50 days.

The Meeting received results from 12 independent trials conducted in Europe, where two foliar sprays of 0.125–0.13 kg fluopyram/ha were applied up to the seed development or early ripening stages (BBCH 67–85). As these trials did not match the critical GAP, the Meeting did not recommend a maximum residue level for fluopyram on sunflower seed.

Cotton seed

Results from supervised trials from the USA on cotton were provided to the Meeting. These trials included separate plots where fluopyram was applied as a pre-plant seed treatment, or as as a combination of a seed treatment and an in-furrow soil treatment at planting.

In the USA, GAP exists for the use of fluopyram as a pre-plant seed treatment (0.35 mg ai/seed) and also as an in-furrow soil treatment of 0.25 kg ai/ha.

In the plots from 11 independent trials where the seed was treated with 0.5 mg/kg/seed (1.4× GAP), fluopyram residues in cotton seed were all < 0.01 mg/kg (n=11) and in the plots treated with a seed treatment (0.5 mg ai/seed—1.4× GAP) followed by an in-furrow soil treatment matching the US GAP (0.25 kg ai/ha) residues in cotton seed were also < 0.01 mg/kg.

The Meeting noted that the US GAP did not exclude the use of both a seed treatment and an in-furrow treatment at planting, and since residues following the seed treatment + in-furrow soil treatment were all < 0.01 mg/kg (n=11), the Meeting estimated a maximum residue level of 0.01 mg/kg and an STMR of 0.01 mg/kg for fluopyram on cotton seed.

Animal feeds

Bean forage

In 22 of the European trials on outdoor beans evaluated by the Meeting, residues of fluopyram in fresh bean forage from trials matching the GAP in Belgium and Netherlands (two applications of 0.25 kg ai/ha, PHI 7 days) were: 0.24, 0.25, 0.26, 0.31, 0.34, **0.38**, 0.42, **0.55**, 0.57, **0.58**, 0.68, 0.71, 0.72, 0.8, **0.82**, **0.85**, 0.86, 0.88, 1.3, 1.6, 2.8 and 4.3 mg/kg (Results in bold are from the new trials).

The Meeting estimated a median residue of 0.7 mg/kg (fresh weight) and a highest residue of 4.3 mg/kg (fresh weight) for fluopyram on bean forage.

Cotton gin by-products

In the trials from the USA on cotton, residues of fluopyram were measured in gin by-products from six plots that were treated with a combination of a seed treatment (at 1.4× GAP) and an in-furrow soil treatment (at GAP). Residues in these trials were: < 0.01, 0.02, 0.02, 0.03, 0.03 and 0.06 mg/kg.

The Meeting noted that although the in-furrow soil treatment rates in these trials matched the USA GAP, the seed treatment rates were 1.4× higher than GAP and agreed it was not possible to apply the proportionality approach for this combined treatment regime to derive median and highest residues for calculating the livestock dietary burden.

Pea vines and hay

In 30 of the European trials on outdoor peas evaluated by the Meeting, residues of fluopyram in fresh pea vines from trials matching the GAP in Belgium and Netherlands (two applications of 0.25 kg ai/ha, PHI 7 days) were: **0.14**, 0.2, **0.28**, **0.4**, 0.45, **0.46**, 0.46, **0.5**, **0.54**, **0.63**, 0.81, **0.92**, 0.93, 1.1, **1.7**, 1.9, **2.1**, 2.3, **3.2**, 3.3, 3.5, **4.0**, 4.3, **4.9**, 6.6, **7.7**, **8.0**, **8.4**, **9.2** and **9.6** mg/kg (Results in bold are from the new trials).

The Meeting estimated a median residue of 1.8 mg/kg (fresh weight) and a highest residue of 9.6 mg/kg (fresh weight) for fluopyram on pea vines (green).

Residues of fluopyram in pea hay/straw from the new European trials matching the GAP in Belgium and Netherlands and sampled 20–43 days after the last application were: 0.15, 0.33, 0.44, 0.44, 0.64, 0.8, 0.82, 0.93, 3.4, 3.6, 3.6, 4.8, 4.9, 6.3, 7.2, 11, 18 and 19 mg/kg (n=18).

The Meeting estimated a median residue of 3.5 mg/kg (fresh weight), a highest residue of 19 mg/kg (fresh weight) and after correction for an average 88% dry matter content, estimated a maximum residue level of 40 mg/kg for fluopyram on pea hay.

Animal commodity maximum residue levels

Farm animal feeding studies

The 2010 JMPR reviewed feeding studies with fluopyram on lactating dairy cows and laying hens and the conclusions from these residue transfer studies were used to estimate residue levels of fluopyram and its metabolites in milk, eggs and livestock tissues, based on the above dietary burdens.

Farm animal dietary burden

The Meeting estimated the dietary burden of fluopyram in farm animals on the basis of the diets listed in Annex 6 of the 2009 JMPR Report (OECD Feedstuffs Derived from Field Crops) and using the estimated residues in livestock feed commodities evaluated by the Meeting and by previous JMPRs.

	Animal dietary burden, fluopyram, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0.14	0.13	16	2.4	32 a	7.6 c	0.04	0.04
Dairy cattle	4.5	1.3	21	2.7	25 b	7 d	0.07	0.07
Poultry—broiler	0.041	0.041	0.21	0.12	0.021	0.021	–	–
Poultry—layer	0.041	0.041	5.8 e, g	0.92 f, h	0.021	0.021	–	–

[a] Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues

[b] Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

[c] Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues

[d] Highest mean dairy cattle dietary burden suitable for STMR estimates for milk

[e] Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues

[f] Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues

[g] Highest maximum poultry dietary burden suitable for MRL estimates for poultry eggs

[h] Highest mean poultry dietary burden suitable for STMR estimates for poultry eggs

Animal commodity maximum residue levels

The calculations used to estimate total residues for use in estimating maximum residue levels, STMRs and HRs are shown below. For maximum residue level estimation, the total residues are the sum of fluopyram plus BZM (expressed as fluopyram equivalents) and for dietary intake estimation (STMRs and HRs) the total residues are the sum of fluopyram, BZM and total olefins (expressed as fluopyram equivalents).

Cattle

For beef and dairy cattle, the highest maximum dietary burdens were 32 ppm and 25 ppm (dairy) and the mean dietary burdens were 7.6 ppm and 7 ppm (dairy).

	Feed level for milk (ppm)	Total residues in milk (mg/kg)	Feed level for tissues (ppm)	Total residues (mg/kg)			
				Muscle	Liver	Kidney	Fat
MRL beef or dairy cattle (fluopyram + BZM)							
Feeding study [a]	14.4 44	0.25 0.64	14.4 44	0.045 0.83	2.88 6.	0.39 0.93	0.4 0.78
Dietary burden/residue estimate	25	0.38	32	0.52	4.7	0.71	0.63
High residue beef or dairy cattle (fluopyram + BZM + Total olefins)							
Feeding study [a]			14.4 44	0.47 0.86	2.9 6.1	0.41 0.97	0.52 1.2
Dietary burden/residue estimate			32	0.7	4.8	0.74	0.86
STMR beef or dairy cattle ((fluopyram + BZM + Total olefins)							
Feeding study [b]	1.5 14.4	0.02 0.27	1.5 14.4	0.02 0.32	0.35 2	0.03 0.31	0.04 0.31
Dietary burden/residue estimate	7	0.12	7.6	0.16	1.1	0.16	0.17

[a] For estimating highest residues for tissues and mean residues for milk

[b] For estimating mean residues for tissues and for milk

Total residues of fluopyram and BZM (expressed as fluopyram equivalents) calculated in cattle milk and tissues for use in estimating maximum residue levels are: 0.63 mg/kg (fat), 0.52 mg/kg (muscle), 4.7 mg/kg (liver) and 0.71 mg/kg (kidney) and the mean residue for milk is 0.38 mg/kg.

The Meeting estimated maximum residue levels of 0.7 mg/kg for fluopyram in meat (from mammals other than marine mammals), 0.7 mg/kg for mammalian fats (except milk fats), 0.8 mg/kg for edible offal (mammalian) except liver, 5 mg/kg for liver of cattle, goats, pigs and sheep and 0.5 mg/kg for milks and agreed to withdraw the previous recommendations.

Estimated HRs for dietary intake estimation for fluopyram (and including residues of BZM and total olefins) are 0.86 mg/kg for mammalian fat, 0.7 mg/kg for mammalian muscle, 4.8 mg/kg for liver and 0.74 mg/kg for kidney and other edible offal.

Estimated STMRs for dietary intake estimation for fluopyram (and including residues of BZM and total olefins) are 0.17 mg/kg for mammalian fat, 0.16 mg/kg for mammalian muscle, 1.1 mg/kg for liver of cattle, goats, pigs and sheep, 0.16 mg/kg for kidney and other edible offal of cattle, goats, pigs and sheep and 0.12 mg/kg for milks

Poultry

The dietary burdens for poultry broilers are 0.21 ppm (maximum) and 0.12 ppm (mean) but the Meeting decided to estimate residue levels in poultry tissues using the higher maximum and mean dietary burdens in poultry layers (5.8 ppm and 0.92 ppm respectively) as they may also be consumed. Since the dose-response curves in the poultry feeding study showed a linear relationship (R^2 values of 0.97–0.99) and as the maximum dietary burden estimates were not more than 120% of the highest dose, the Meeting agreed to estimate maximum total residues by extrapolation from the results of the poultry feeding study.

	Feed level for eggs (ppm)	Total residues in eggs (mg/kg)	Feed level for tissues (ppm)	Total residues (mg/kg)		
				Muscle	Liver	Skin with Fat
MRL broiler or laying hen (fluopyram + BZM)						
Feeding study [a]	4.8	0.72	4.8	0.33	1.6	0.64
Dietary burden/residue estimate	5.8	0.87	5.8	0.39	1.9	0.75
High residue broiler or laying hen (fluopyram + BZM + Total olefins)						
Feeding study [a]	4.8	0.74	4.8	0.39	1.64	0.72
Dietary burden/residue estimate	5.8	0.8	5.8	0.46	1.9	0.85
STMR broiler or laying hen (fluopyram + BZM + Total olefins)						
Feeding study [b]	0.49 1.6	0.08 0.22	0.49 1.6	0.03 0.09	0.16 0.43	0.06 0.12
Dietary burden/residue estimate	0.92	0.13	0.92	0.058	0.26	0.086

[a] For estimating highest residues for tissues and mean residues for eggs

[b] For estimating mean residues for tissues and for eggs

Combined residues of fluopyram and BZM (expressed as fluopyram equivalents) expected in poultry eggs and tissues for use in estimating maximum residue levels are: 0.75 mg/kg (fat), 0.39 mg/kg (muscle), 1.9 mg/kg (liver) and 0.87 mg/kg (eggs).

The Meeting estimated maximum residue levels of 0.5 mg/kg for fluopyram in poultry meat, 1 mg/kg for poultry fat, 2.0 mg/kg for poultry edible offal and 1.0 mg/kg for eggs.

Estimated HRs for dietary intake estimation for fluopyram (and including residues of BZM and total olefins) are 0.85 mg/kg for poultry fat, 0.46 mg/kg for poultry muscle, 1.9 mg/kg for poultry edible offal and 0.8 mg/kg for eggs.

Estimated STMRs for dietary intake estimation for fluopyram (and including residues of BZM and total olefins) are 0.086 mg/kg for poultry fat, 0.058 mg/kg for poultry muscle, 0.26 mg/kg for poultry edible offal and 0.13 mg/kg for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with the MRL and for the estimation of dietary intake for plant commodities: *fluopyram*

Definition of the residue for compliance with the MRL for animal commodities: *Sum of fluopyram and 2-(trifluoromethyl) benzamide, expressed as fluopyram*

Definition of the residue for the estimation of dietary intake for animal commodities: Sum of fluopyram, 2-(trifluoromethyl)benzamide and the combined residues N-{(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide and N-{(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl) benzamide, all expressed as fluopyram.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) for fluopyram were calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available. The results are shown in Annex 3 to the 2015 Report.

The International Estimated Daily Intakes of fluopyram for the 17 GEMS/Food regional diets, based on estimated STMRs were 4–30% of the maximum ADI of 0.01 mg/kg bw (Annex 3). The Meeting concluded that the long-term intake of residues of fluopyram from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short-term Intakes (IESTIs) for fluopyram were calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available (Annex 4 to the 2015 Report).

For fluopyram the IESTI varied from 0–10% of the ARfD (0.5 mg/kg bw) and the Meeting concluded that the short-term intake of residues of fluopyram from uses considered by the Meeting is unlikely to present a public health concern.

FLUTRIAFOL (248)

First draft prepared by Dr D.J. MacLachlan, Department of Agriculture and Water Resources, Canberra, Australia

EXPLANATION

Flutriafol is a triazole fungicide used in many crops for control of a broad spectrum of leaf and ear cereal diseases, particularly embryo borne diseases e.g., bunts and smuts. The Meeting received information on identity, animal and plant metabolism, environmental fate in soil, rotational crops, analytical methods, storage stability, use patterns, supervised trials, farm animal feeding studies and fates of residues in processing. It was first evaluated for residues and toxicology by the 2011 JMPR. The ADI of flutriafol was 0–0.01 mg/kg bw and the ARfD was 0.05 mg/kg bw. The compound was listed by the 46th Session of CCPR for the JMPR to consider additional MRLs. The residue definition for compliance with MRL and for estimation of dietary intake (for animal and plant commodities) is flutriafol.

For the current evaluation the Meeting received new metabolism studies in lactating goats, storage stability data for animal commodities, residue trials on apples, pears, peaches/nectarines, plums, cherries, strawberries, Brassica vegetables (cabbages and broccoli), cucurbits (cucumbers, summer squash and muskmelons), tomatoes, peppers, leafy vegetables (lettuce, spinach, celery and mustard greens), sugar beets, maize, rice, sorghum, almonds, pecans, cotton, and rape, as well as a lactating cow feeding study (residue transfer study).

The chemical structures of the major degradation compounds from the metabolism of flutriafol are provided below.

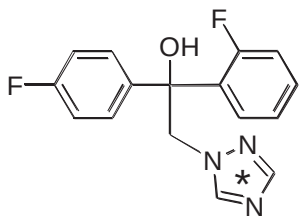
List of metabolites in this evaluation:

Code	Compound	Structure	
M1 T	1,2,4-triazole		
M3	hydroxyl flutriafol glucuronide		
M3e	dihydroxy flutriafol		

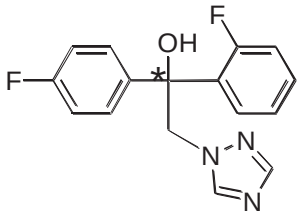
Code	Compound	Structure	
M3e-f1	trihydroxymethoxy flutriafol glucuronide		
M4	flutriafol glucuronide		
M5	hydroxymethoxy flutriafol		
M7	methoxy flutriafol glucuronide		
M10	flutriafol sulfate		
TA	1,2,4-triazole analine		
TAA	1,2,4-triazole acetic acid		

METABOLISM

La Mar (2012 2470) studied the metabolism of flutriafol in lactating goats.



Triazole-label



Carbinol-label

Two lactating goats (crossbreeds, 2–4 years old, 35 and 41 kg bw) were administered either [triazole-3(5)-^{14}C]-flutriafol or [carbinol-^{14}C]-flutriafol by capsule once daily in the morning for five consecutive days at a rate equivalent to 12.0 ppm in the feed (triazole) or 12.2 ppm (carbinol). Animals were fed 1.5 kg goat chow and 1 kg alfalfa hay daily. Milk production during the study averaged 0.54 L/day and 0.65 L/day respectively for the two goats. Excreta were collected once a day (in the morning, before dose administration). Milk was collected twice daily (morning and evening). The goats were sacrificed approximately 20–22 h after the last dose was administered and the following tissues were collected at necropsy—liver, kidney, muscle (loin and flank), fat (subcutaneous, omental and renal), bile, blood and gastrointestinal tract with contents. Analytical work was completed within 30 days after sacrifice.

The majority of the administered dose was recovered in the faeces (60–69%) with 31.5–40.6% excreted in urine and 0.05–0.07% in milk (Table 1). The amount of administered radioactivity found in tissues was 0.35–0.45% while the gastrointestinal tract and contents contained 2.5–7.1% giving a total recovery of administered radioactivity of 103–110%. TRR in edible tissues were generally low (0.002–0.01 mg equiv/kg) with the exception of liver (0.264–0.305 mg equiv/kg) and kidney (0.035–0.061 mg equiv/kg).

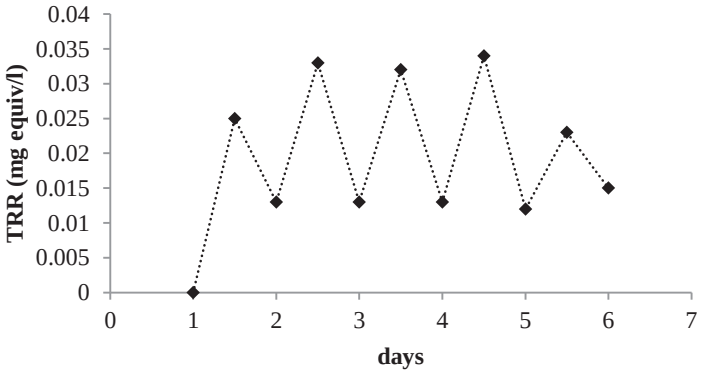
Residues in milk appeared to reach plateau levels by Day 3 of dosing, with significant differences in ^{14}C levels between milk collected in the morning (low levels) compared to evening

milk (higher levels), suggesting flutriafol residues are rapidly eliminated following dosing (Figure 1).

A



B

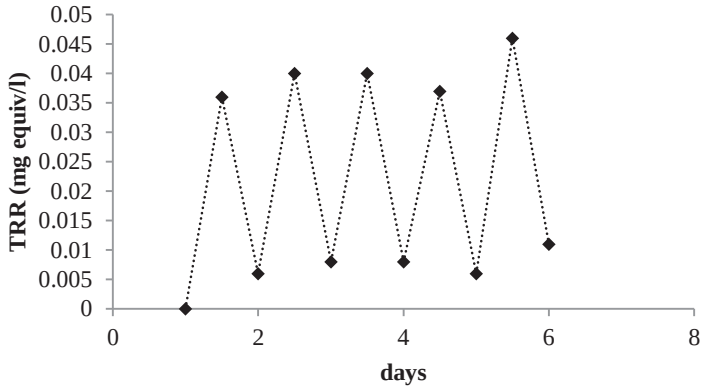


Figure 1 TRR in milk for goats dosed at the equivalent of 12 ppm in the feed with flutriafol (A) triazole label, (B) carbinol label

Acetonitrile and water extraction (2× CH_3CN/H_2O, 1× CH_3CN) of liver, kidney and in the case of the triazole-label also composite muscle, resulted in extraction efficiencies of 25.5–27.5% (liver), 67.7–79.7% (kidney) and 90% (muscle) (Table 2). The CH_3CN/H_2O extracts were concentrated, acidified (0.1% formic acid) and then partitioned with ethyl acetate to give aqueous/acetonitrile (aqueous) and ethyl acetate (organic) phases. Muscle from the carbinol-label and fat (both labels) were not subject to further analysis as the TRR levels were insignificant (< 0.01 mg eq/kg).

Radioactivity in PES of liver and kidney was characterized further. Samples of PES were treated with 1 M HCl in CH_3CN/H_2O (1:1) followed by 1 M KOH in H_2O. Sub-samples of liver PES were also treated with and without pepsin in 0.1 M HCl/glycine buffer pH 2.2 at 37 ºC overnight, followed by treatment with and without pancreatin and bile extract in 0.1 M sodium bicarbonate overnight at 37 ºC. Any remaining radioactivity was solubilised by treatment with 24% KOH.

Milk samples (whole milk) with the highest residue present (typically Day 4, pm) were separated into milk fat and skim milk for extraction. Protein was precipitated from skim milk by adding acetone and chilling in an ice bath. The protein pellet was then extracted with acetone/H_2O (1:1) followed by acetone. Skim milk and protein pellet extracts were combined, concentrated, acidified (0.1% formic acid) and then partitioned with ethyl acetate. Milk fat was extracted with acetone/hexane 1:4 (2×) and acetone (1×). Solids were separated by centrifugation and fat extracts were then concentrated to remove acetone, and partitioned with acetonitrile.

For the TZ label, extraction of liver with CH_3CN/H_2O released M1 (2.9% TRR), M2 (1.5% TRR), M3 (2.6% TRR), M3e (1.8% TRR), M5 (4.7% TRR) and flutriafol (1.5% TRR). The total identified residues in the liver accounted for 13.5% of TRR. A number of unidentified compounds (10% TRR) were observed that were individually present at $\leq$ 2.9% TRR ($\leq$ 0.008 mg equiv/kg). Hydrolysis of the liver PES under mild acid and alkaline conditions released all of the remaining ^{14}C residues which were able to be resolved into more than six peaks by chromatography. Subsequent treatment of the hydrolysis extracts with enzymes to release conjugates did not result in additional compounds being identified; largest individual component 9.8% TRR.

In kidneys the main ^{14}C residue components were 1,2,4-triazole (M1, 10% TRR), M2 (10% TRR), hydroxyl flutriafol glucuronide (M3, 30% TRR) and dihydroxy flutriafol (M3e, 3.4% TRR). No other single metabolite comprised more than 10% of TRR (0.006 mg equiv/kg).

Residues in skim milk were extracted with acetonitrile and water. Main components identified were 1,2,4-triazole (M1, 26.5% TRR), M2 (2.9% TRR), hydroxyl flutriafol

glucuronide (M3, 23.5% TRR) and dihydroxy flutriafol (M3e, 17.6% TRR). No other single metabolite comprised more than 8.8% of TRR (0.003 mg equiv/kg).

Residues in milk fat were extracted with acetone/hexane. Main components identified were 1,2,4-triazole (M1, 13.8% TRR), dihydroxyl flutriafol (M3e, 37.9% TRR) and flutriafol (3.4% TRR). No other single metabolite comprised more than 6.9% of TRR (0.002 mg equiv/kg).

[a] Solvent systems: CH_3CN/H_2O for liver, kidney, skim milk and muscle; acetone/hexane for fat and milk fat

[b] Represents free residues from partition of initial extracts with ethyl acetate. (Aqueous is CH_3CN phase and organic is hexane phase for milk fat)

[c] Extraction and analysis data represent composite of flank and loin muscle

[d] M3 is combination of M3 (major component), M4 and M7. Levels were too low to accurately quantify

M1 = 1,2,4-triazole, M3= hydroxyl flutriafol glucuronide, M4 = flutriafol glucuronide, M7 = methoxy flutriafol glucuronide, M3e = di-hydroxy flutriafol, M5= hydroxy methoxy flutriafol

For the carbinol-label, liver contained M2 (1.7% TRR), hydroxyl flutriafol glucuronide (M3, 4.3% TRR), dihydroxy flutriafol (M3e, 0.9% TRR), hydroxy methoxy flutriafol (M5 11.1% TRR) and flutriafol (0.9% TRR). The total identified residues in the liver accounted for 17.2% of TRR. A number of unidentified compounds (6.9% TRR) were observed that were individually present at $\leq$ 3% TRR ($\leq$ 0.007 mg equiv/kg). Hydrolysis of the liver PES under mild acid and alkaline conditions released all of the remaining ^{14}C residues which was able to be resolved into multiple peaks by chromatography. Subsequent treatment of the hydrolysis extracts with enzymes to release conjugates did not result in additional compounds being identified; largest individual component 9.0% TRR.

In kidneys the main ^{14}C residue components were M2 (9.7% TRR), hydroxyl flutriafol glucuronide (M3, 22.6% TRR) and dihydroxy flutriafol (M3e, 6.5% TRR). No other single metabolite comprised more than 6.5% of TRR (0.002 mg equiv/kg).

Residues in skim milk were extracted with acetonitrile and water. Main components identified were M2 (10.8% TRR, hydroxyl flutriafol glucuronide (M3, 27%TRR) and dihydroxy flutriafol (M3e, 29.7%TRR). No other single metabolite comprised more than 11% of TRR (0.004 mg equiv/kg).

Residues in milk fat were extracted with acetone/hexane. Main components identified were dihydroxy flutriafol (M3e, 42.3%TRR) and flutriafol (3.8% TRR). No other single metabolite comprised more than 11.5% of TRR (0.003 mg equiv/kg).

*Residues too low for further characterisation / identification

In an additional study on the metabolism of flutriafol in lactating goats La Mar (2012 2438) used a higher dose rate to allow for better identification of metabolites. Two lactating goats (crossbreeds, 2–4 yrs old, 38 and 58 kg bw) were administered either [triazole-3(5)-^{14}C]-flutriafol or [carbinol-^{14}C]-flutriafol once daily for five consecutive days at a rate equivalent to 30 ppm (triazole) or 30.7 ppm (carbinol) in the feed. Animals consumed 1.8 and 1.3 kg feed/d respectively for the 30 and 31 ppm dose goats. Milk production was 1.6 L/d and 1.5 L/d respectively for the two goats. Excreta were collected once a day (in the morning, before dose administration). Milk was collected twice daily (morning and evening). The goats were sacrificed approximately 20–22 h after the last dose was administered and the following tissues were collected at necropsy—liver, kidney, muscle (loin and flank), fat (subcutaneous, omental and renal), bile, blood and gastrointestinal tract with contents. Analytical work was completed within 30 days after sacrifice.

The majority of the administered dose was recovered in the faeces (35–55%) with 30–54% excreted in urine and 0.09–0.1% in milk. The amount of administered radioactivity found in tissues was 0.27–0.29% while the gastrointestinal tract and contents contained 2.1–6.8% giving a total recovery of administered radioactivity of 88–96%. TRR in edible tissues were generally low

(0.008–0.024 mg equiv/kg) with the exception of liver (0.68–0.70 mg equiv/kg) and kidney (0.11–0.31 mg equiv/kg).

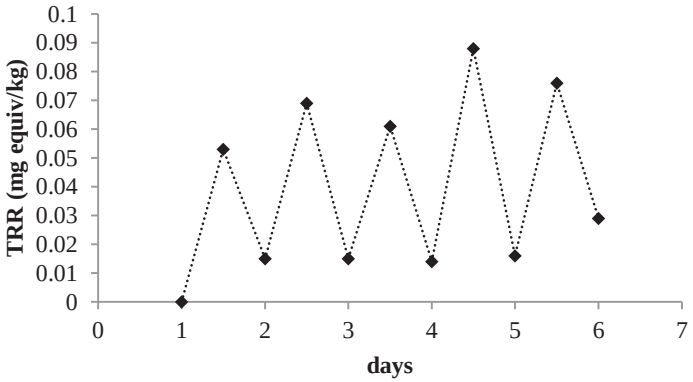
Residues in milk appeared to reach plateau levels by Day 3 of dosing with significant differences in ^{14}C levels between milk collected in the morning (low levels), compared to evening milk (higher levels), suggesting flutriafol residues are rapidly eliminated following dosing (Figure 2).

A



B

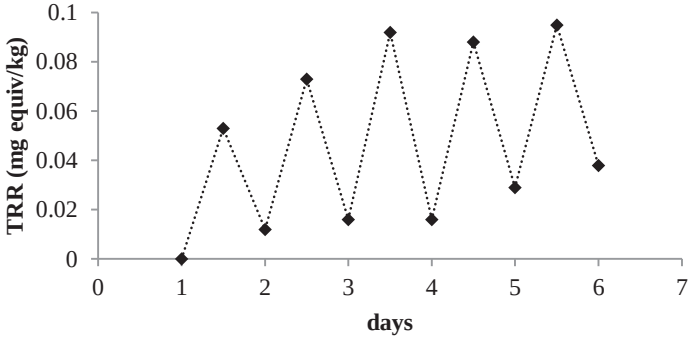


Figure 2 TRR in milk for goats dosed at the equivalent of 30 ppm in the feed with flutriafol (A) triazole label, (B) carbinol label

Acetonitrile and water extraction of liver, kidney, muscle, fat, skim milk and milk fat resulted in extraction efficiencies of 28.7–38.7% (liver), 66.7–86.5% (kidney), > 82% (muscle), > 72% fat, 98% (skim milk) and 82–87% (milk fat) (Tables 5 and 6).

For the TZ label, extraction of liver with CH_3CN/H_2O released 1,2,4-triazole (M1, 2.5% TRR), M2 (1.3% TRR), hydroxy flutriafol glucuronide (M3, 1.8% TRR), dihydroxy flutriafol (M3e, 0.7% TRR), flutriafol glucuronide (M4, 1.6% TRR), hydroxy methoxy flutriafol (M5, 6.9% TRR) and flutriafol (1.0% TRR). The total identified residues in the liver accounted for 16.9% of TRR. A number of unidentified compounds (7.9% TRR) were observed that were individually present at ≤ 2.5% TRR (≤ 0.015 mg equiv/kg). Hydrolysis of the liver PES under mild acid and alkaline conditions released all of the remaining ^{14}C residues which was able to be resolved into more than eight peaks by chromatography. Subsequent treatment of the hydrolysis extracts with enzymes to release conjugates did not result in additional compounds being identified.

In kidneys the main ^{14}C residue components were 1,2,4-triazole (M1, 8.9% TRR), M2 (1.3% TRR), hydroxy flutriafol glucuronide (M3, 9.8% TRR) and dihydroxy flutriafol (M3e, 3.3% TRR), hydroxy methoxy flutriafol (M5, 1.6% TRR), methoxy flutriafol glucuronide (M7, 5.7% TRR) and M8 (4.1% TRR). No other single metabolite comprised more than 4.9% of TRR (0.006 mg equiv/kg).

Muscle and fat contained low levels of ^{14}C. Major metabolites identified were 1,2,4-triazole (M1, 21–42% TRR), M2 (< 5–5.3% TRR), hydroxy flutriafol glucuronide (M3, 5.3–10% TRR). No other single metabolite comprised more than 0.003 mg equiv/kg.

Main components identified in skim milk were 1,2,4-triazole (M1, 14.9% TRR), M2 (3.2% TRR), hydroxy flutriafol glucuronide (M3, 23.4% TRR) and dihydroxy flutriafol (M3e, 35.1% TRR). No other single metabolite comprised more than 0.004 mg equiv/kg.

In milk fat components identified were 1,2,4-triazole (M1, 10.6% TRR), M2 (2.1% TRR), dihydroxy flutriafol (M3e, 43.6% TRR) and M8 (10.6% TRR). No other single metabolite comprised more than 0.005 mg equiv/kg.

[a] Solvent systems: CH_3CN/H_2O for liver, kidney, skim milk and muscle; acetone/hexane for fat and milk fat

[b] Represents free residues from partition of initial extracts with ethyl acetate. (Aqueous is CH_3CN phase and organic is hexane phase for fat matrices)

[c] up to five components each < 0.007 mg equiv/kg and < 14% TRR in tissue with the exception of renal fat = 0.03 mg equiv/kg and 38% TRR

M1 = 1,2,4-triazole, M2 = possible amino acid conjugate, M3 = hydroxyl flutriafol glucuronide, M3e = di-hydroxy flutriafol, M4 = flutriafol glucuronide, M5 = hydroxy methoxy flutriafol, M7 = methoxy flutriafol glucuronide, M10 = flutriafol sulfate

For the carbinol-label the metabolites identified were M2 (2.5% TRR), hydroxyl flutriafol glucuronide (M3, 2.2% TRR), dihydroxy flutriafol (M3e, 1.1% TRR), flutriafol glucuronide (M4, 4.3% TRR), hydroxy methoxy flutriafol (M5, 7.3% TRR), methoxy flutriafol glucuronide (M7, 3.3% TRR), M8 (2.2% TRR) and flutriafol (2.5% TRR). The total identified residues in the liver accounted for 22.9% of TRR. A number of unidentified compounds (7.9% TRR) were observed that were individually present at $\leq$ 3.6% TRR ($\leq$ 0.023 mg equiv/kg). As with the earlier study and the triazole-label, hydrolysis of the liver PES under mild acid and alkaline conditions released all of the remaining ^{14}C residues. In the case of the carbinol label the released

^{14}C was able to be resolved into more than seven peaks by chromatography. Subsequent treatment of the hydrolysis extracts with enzymes to release conjugates did not result in additional compounds being identified.

In kidneys, the main ^{14}C residue components were M2 (8.6% TRR), hydroxyl flutriafol glucuronide (M3, 12.8% TRR) and dihydroxy flutriafol (M3e, 1.6% TRR), flutriafol glucuronide (M4, 24% TRR), hydroxy methoxy flutriafol (M5, 1.0% TRR), methoxy flutriafol glucuronide (M7, 10.5% TRR), M8 (5.3% TRR) and flutriafol (0.7% TRR). No other single metabolite comprised more than 4.3% of TRR (0.013 mg equiv/kg).

Muscle and fat contained low levels of ^{14}C. Major components identified in muscle were hydroxyl flutriafol glucuronide (M3, 4.3–5.9% TRR) and flutriafol glucuronide (M4, 5.9–17.4% TRR). No other single metabolite comprised more than 0.004 mg equiv/kg. In fat, the major component identified was flutriafol (21–59% TRR).

Main components identified in skim milk were M2 (4.7% TRR), hydroxyl flutriafol glucuronide (M3, 17.6% TRR), dihydroxy flutriafol (M3e, 27.1% TRR), methoxy flutriafol glucuronide (M7, 3.5% TRR), M8 (5.9% TRR) and flutriafol sulfate (M10, 8.2% TRR). Flutriafol was present at 1.2% TRR. No other single metabolite comprised more than 0.005 mg equiv/kg.

In milk fat components identified were M2 (4.3% TRR), hydroxyl flutriafol glucuronide (M3, 30.5% TRR), hydroxy methoxy flutriafol (M5, 2.1% TRR), M8 (7.8% TRR), flutriafol sulfate (M10, 17% TRR) and flutriafol (4.3% TRR). No other single metabolite comprised more than 0.01 mg equiv/kg.

[a] Solvent systems: CH_3CN/H_2O for liver, kidney, skim milk and muscle; acetone/hexane for fat and milk fat

[b] Represents free residues from partition of initial extracts with ethyl acetate. (Aqueous is CH_3CN phase and organic is hexane phase for fat matrices)

M1 = 1,2,4-triazole, M2 = possible amino acid conjugate, M3 = hydroxyl flutriafol glucuronide, M3e = di-hydroxy flutriafol, M4 = flutriafol glucuronide, M5 = hydroxy methoxy flutriafol, M7 = methoxy flutriafol glucuronide, M10 = flutriafol sulfate

Residues in goat milk and edible tissues resulted from extensive metabolism of flutriafol. In the major metabolic pathway, one of the phenyl rings is oxidised and then conjugated with glucuronic acid to form flutriafol glucuronide (M4), or is further oxidised to form dihydroxy flutriafol (M3e), of which there are a number of possible isomers. M3e is then further transformed via methylation to hydroxyl methyl flutriafol (M5) which can in turn be conjugated with glucuronic acid to form methoxy flutriafol glucuronide (M7). M3e was also conjugated with glucuronic acid to form hydroxyl flutriafol glucuronide (M3). A minor pathway is the cleavage of flutriafol at the 1-nitrogen of the triazole ring to give free triazole. One unique carbinol metabolite designated as M10 was identified as flutriafol sulfate.

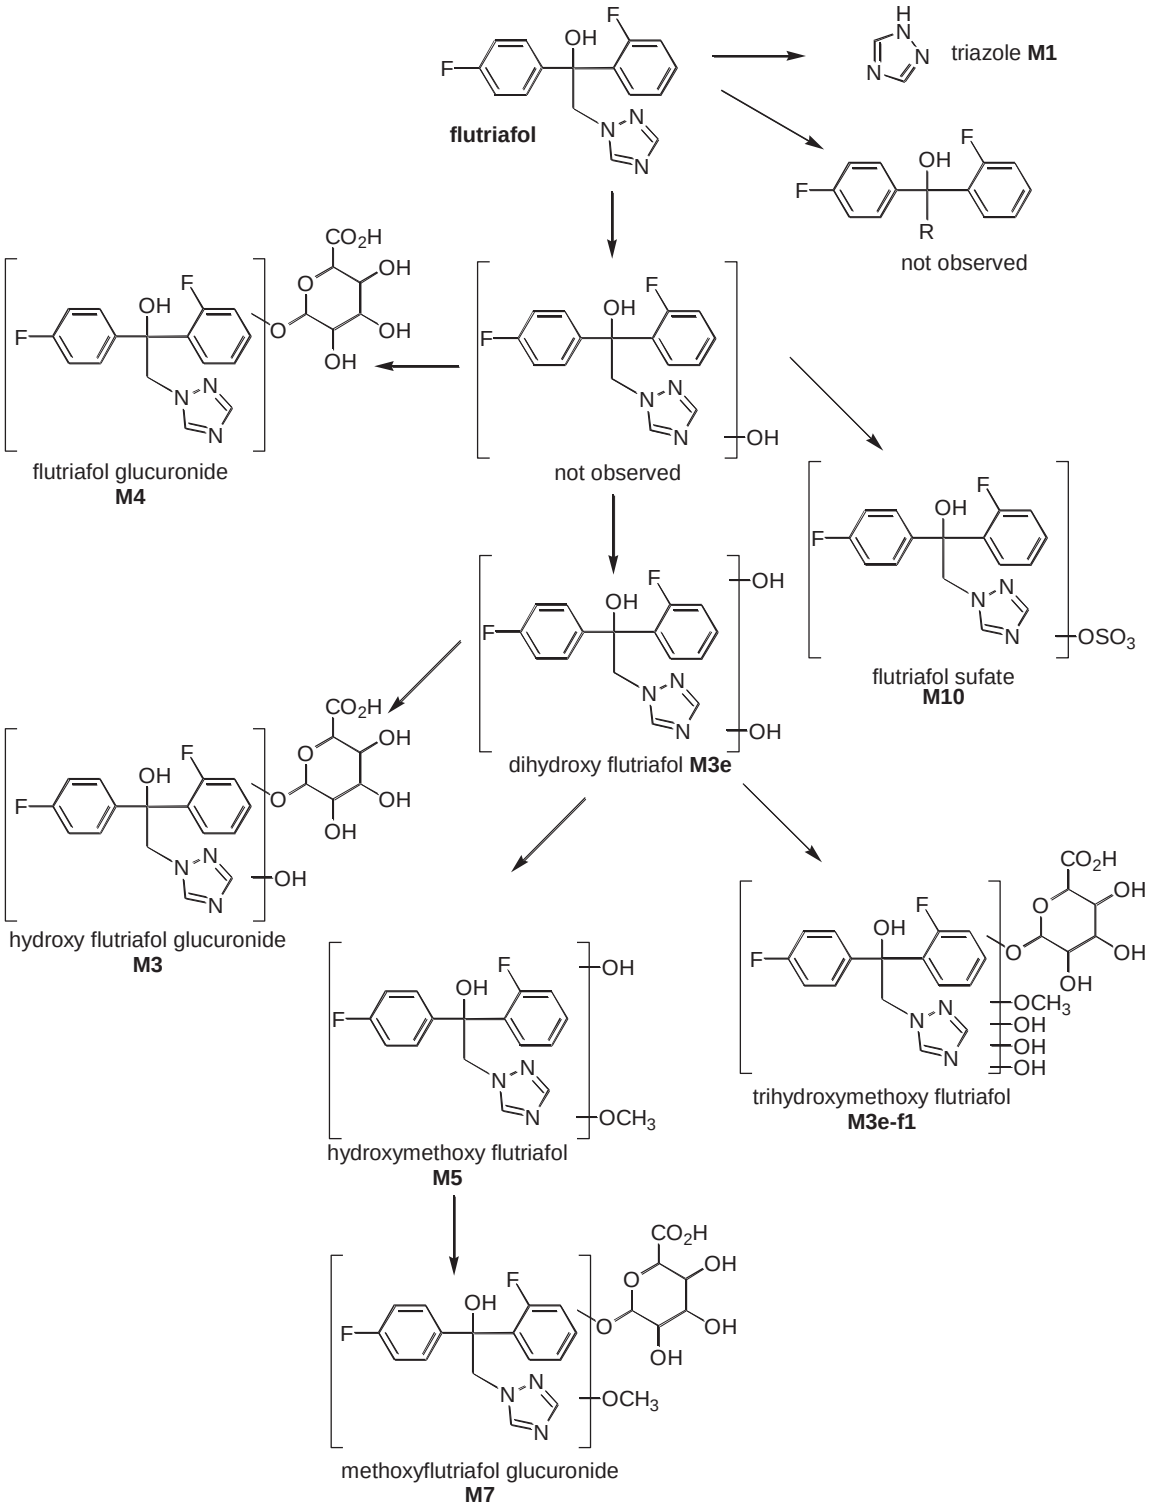

Figure 3 Possible metabolic pathway for flutriafol in goats

RESIDUE ANALYSIS

Analytical method

Stability of pesticide residues in stored analytical samples

The 2011 JMPR evaluated data on the storage stability of flutriafol residues in plant commodities that included apples, grapes, cabbages, sugar beet roots, pea seeds, soybeans, barley grains, wheat and oilseed rape, processed commodities (apple juice, soybean meal and refined oil) and animal commodities (milk, eggs, muscle and fat).

The 2011 JMPR also received information on the freezer storage stability of triazole metabolites in apple (fruit and juice), milk, eggs, muscle and fat.

Storage stability results indicate that flutriafol residues were stable for at least 4 months in animal commodities, for at least 5 months in soybean seeds, for at least 12 months in apples, barley grains and coffee beans, for at least 23 months in grapes, for at least 24 months in cabbages and oilseed rape, and for at least 25 months in wheat (grains and straw), pea seeds, and sugar beet roots. The results also indicate that triazole metabolite residues were stable for at least 4 months in apple fruits and juice, and for at least 5 months in animal commodities.

Mason (2012 2649) studies the freezer storage stability of residues in bovine matrices. The deep freeze storage stability of flutriafol and triazole metabolites 1,2,4-triazole (T), triazole alanine (TA) and triazole acetic acid (TAA) in muscle, fat, liver and kidney was conducted by fortifying separate control samples of homogeneous matrix with flutriafol, T, TA and TAA at levels of 0.1 mg/kg. These samples were placed in freezer storage and analysed after 0, 1, 3, 6, 9 and 12 months frozen storage. All samples were analysed in duplicate. Unfortified control samples were analysed at the same time alongside duplicate freshly fortified samples of control matrix at 0.1 mg/kg.

Residues of flutriafol, and T, TA and TAA in ruminant tissues (muscle, fat, liver and kidney) remain stable for at least 12 months for flutriafol, TA and TAA and at least 6 months for T when samples are stored under deep frozen conditions.

Table 7 Recovery of flutriafol and metabolite residues on frozen storage of animal commodity samples separately fortified with flutriafol, T, TA or TAA

Stone Fruit: Apricot, Nectarine, Peach, Plum, Cherries (Sweet and Tart), Chickshaw plum, Damson plum, Japanese plum, Plumcot, Prune

Muskmelons: True Cantaloupe, Cantaloupe, Casaba, Crenshaw Melon, Golden Pershaw Melon, Honeydew Melon, Honey Balls, Mango Melon, Persian Melon, Pineapple Melon, Santa Claus Melon, and Snake Melon

Cucurbits: Chayote (Fruit), Chinese Waxgourd, Citron Melon, Cucumber, Gherkin, Gourd Edible (Lagenaria spp.) (Includes Hyotan, Cucuzza, Hechima, Chinese Okra), Momordica spp. (Includes Balsam Apple, Balsam Pear, Bittermelon, Chinese Cucumber), Pumpkin, Squash (Summer), Squash (Winter—Includes Butternut Squash, Calabaza, Hubbard Squash, Acorn Squash, Spaghetti Squash), Watermelon

Brassica (Cole) Leafy Vegetables: Broccoli, Broccoli (Chinese and Raab), Brussels Sprouts, Cabbage, Cabbage (Chinese, Bok Choy, Chinese Mustard/Gai Choy), Cauliflower, Cavalo Broccolo, Collards, Kale, Kohlrabi, Mizuna, Mustard Greens, Mustard Spinach, Rape Greens. Including all cultivars and/or hybrids of these crops.

Leafy Vegetables (except Brassica): Amaranth, Arugula, Cardoon, Celery, Celery (Chinese), Celtuce, Chervil, Chrysanthemum (Edible and Garland), Corn Salad, Cress (Garden and Upland), Dandelion, Dock, Endive, Fennel (Florence), Lettuce (Head and Leaf), Orach, Parsley, Purslane (Garden and Winter), Radicchio, Rhubarb, Spinach, Spinach (New Zealand and Vine), Swiss Chard. Including cultivars and/or hybrids of these crops.

Pecans and other tree nuts: African Tree Nut, Brazil Nut, Burr Oak, Butternut, Cajou, Cashew, Castanha-Do-Maranhao, Coconut, Coquito Nut, Dika nut, Guiana Chestnut, Hazelnut, Heartnut, Hickory Nut, Japanese Horse-Chestnut, Macadamia Nut, Monogongo Nut, Monkey-Pot, Pachira Nut, Pecan, Sapucaia Nut

Fruiting Vegetables (group 8-10): African Eggplant, Bell Pepper, Eggplant, Martynia, Non-Bell Pepper, Okra, Pea Eggplant, Pepino, Roselle, Scarlet Eggplant. Including cultivars, varieties and/or hybrids of these crops.

Crop Rotation: Fields treated with an application rate of greater than 252 g ai/ha/season may be planted to crops that have tolerances established for residues of flutriafol including: field corn, popcorn, cucurbits, fruiting vegetables, grapes, peanuts, pome fruits, soybeans, stone fruits, strawberries, sugar beets, tree nuts, triticale, or wheat immediately after last application.

Fields treated with application rates less than or equal to 252 g ai/ha/season may be planted to the crops listed above, and may also be planted to cotton or sweet corn 180 days after the last application. Rotation to any other crop is prohibited.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised residue trials of foliar treatments of flutriafol for apples, pears, peaches/nectarines, plums, cherries, strawberries, Brassica vegetables (cabbage and broccoli), cucurbits (cucumbers, summer squash and muskmelons), tomatoes, peppers, leafy vegetables (lettuce, spinach, celery and mustard greens), sugar beets, maize, rice, sorghum, almonds, pecans, cotton, and rape.

Residues, application rates and spray concentrations have been rounded to two figures. Residue data are recorded unadjusted for percentage recoveries or for residue values in control samples. Where multiple analyses were conducted on a single sample, the average value is reported. Residues from the trials conducted according to critical GAP have been used for the estimation of maximum residue levels, STMR and HR values. Those results are underlined.

Table 9 Summary of sprayers, plot sizes and field sample sizes in the supervised trials

Location	Year	Crop	Sprayer	Plot size	Sample size	SAI (days)
Europe	2004	Sugar beet	Boom sprayer, knapsack sprayer	60–120 m^2	Plants ≥ 0.6 kg Leaves ≥ 0.5 kg Roots ≥ 1.0 kg Leaves with tops ≥ 1.0 kg	< 80
Europe	2005	Tomato	CO_2 sprayer	14–33 m^2	≥ 2.0 kg	< 52
Europe	2005	Rape	Boom sprayer	60–90 m^2	Shoots no roots ≥ 1.1 kg Pods ≥ 0.6 kg Shoots no pods ≥ 1.0 kg Seeds ≥ 0.5 kg	< 30
Europe	2005	Sugar beet	Boom sprayer	30–90 m^2	Leaves with tops ≥ 1.0 kg Roots ≥ 1.0 kg	< 80
Europe	2006	Rape	Boom sprayer	30–60 m^2	Seeds ≥ 0.5 kg	< 20
Spain	2006	Sugar beet	Boom sprayer	30 m^2	Leaves with tops ≥ 2.8 kg Roots ≥ 4.8 kg	< 20
France	2007	Rape	Boom sprayer	120 m^2	Seeds ≥ 0.5 kg	< 38
Spain	2005	Rice	Boom sprayer	25–50 m^2	Seeds ≥ 1.0 kg	< 130
USA	2009	Cherry sweet	Tractor-mounted Airblast Sprayer	6–16 trees	Fruit ≥ 1.1 kg	79 F 84 T
USA	2009	Cherry tart	Tractor-mounted Airblast Sprayer	6–16 trees	Fruit ≥ 1.1 kg	64–107 F 58–127 T
USA	2009	Peach	Tractor-mounted Airblast Sprayer	6–8 trees	Fruit ≥ 2.0 kg	45–135 F 40–114 T
USA	2009	Plum	Tractor-mounted Airblast Sprayer	6–8 trees	Fruit ≥ 2.0 kg	9–154 F 13–149 T
USA	2009	Pear	Tractor-mounted Airblast Sprayer	6–7 trees	Fruit ≥ 2.3 kg	24–188 F 23–192 T
USA	2009	Maize	CO_2 backpack sprayer, Tractor mounted side-mount sprayer	56–1110 m^2	Forage ≥ 1.6 kg Grain ≥ 1.0 kg Stover ≥ 0.4 kg	Forage 64–211 F 67–211 T Grain 84–186 F 72–201 T
USA	2009	Sugar beet		46–372 m^2	Leaves with tops ≥ 1.0 kg Roots 12 roots	183 F 194 T
USA	2010	Strawberry	CO_2 backpack sprayer, Hand-held boom sprayer	31–186 m^2	Fruit ≥ 0.6 kg	12–90 F 31–88 T

Location	Year	Crop	Sprayer	Plot size	Sample size	SAI (days)
USA	2010	Apple	Tractor-mounted Airblast Sprayer	6–8 trees	Fruit ≥ 3.0 kg	33–60 F 64–89 T
USA	2010	Tree nuts (Almond, Pecan)	Tractor-mounted Airblast Sprayer	6–8 trees	≥ 1.2 kg	Pecan 162 Almond 230 Hulls 92
Spain	2006	Peach	Boom + knapsack sprayer	3–4 trees	≥ 2.0 kg	< 139
USA	2011	Cucurbits	CO_2 backpack + tractor mounted sprayers	48–180 m^2	≥ 1.5 kg (melon: each fruit quartered opposing 2 quarters selected 24 quarters)	16–104 F 16–176 T
USA	2011	Tomato	CO_2 backpack + boom + tractor mounted sprayers	48–180 m^2	≥ 2.0 kg	18–134
USA	2011	Pepper	CO_2 backpack + boom + tractor mounted sprayers	45–140 m^2	≥ 2.0 kg	18–134
Spain	2004	Strawberry	Backpack + knapsack sprayer	16.5–44 m^2 macrotunnels	≥ 1.0 kg	212
USA	2012	Brassica vegetables	CO_2 backpack + tractor mounted sprayers	45–167 m^2	≥ 1.0 kg (cabbage: Heads were quartered and one quarter of 12 heads collected for each sample OR **Heads were halved and one half of 12 heads collected for each sample	7–195 F 24–178 T
USA	2011	Leafy vegetables	CO_2 backpack + tractor mounted sprayers	43–206 m^2	≥ 1.0 kg	18–184 F 11–212 T

USA	2012	Cotton	CO_2 backpack + tractor mounted sprayers	93–696 m^2	≥ 1.0 kg	15–110 F 21–141 T

Residues of the triazoles, TA and TAA were frequently observed in both untreated control and samples from treated plots, however, the source of the residues is unknown. That residues were detected in untreated controls suggests a natural origin. Triazole-related compounds are also common metabolites of a number of fungicides which contain the 1,2,4-triazole moiety.

Analytical method flutriafol: RAM 219/04

Analytical method T, TA, TAA: Meth-160, revision 2 LOQ 0.01 mg/kg for flutriafol T and TAA and 0.08 mg/kg for TA, however this was based on lowest fortification level and background found in the untreated sample used for spiking. Subsequent work with tart cherries shows an LOQ of 0.01 mg/kg id more appropriate.

Plots were established for the collection of the forage samples and the applications timed such that the forage samples were collected nominally at soft dough to hard dough stage (BBCH 85–87) 30 days (± 1) after the last application (30-day PHI).

Table 45 Residues of flutriafol in sorghum forage following application of an SC formulation in the USA (Carringer 2013 2699) (duplicate samples, applications include non-ionic surfactant, separate plots to those used for grain and stover)

FATE OF RESIDUES IN STORAGE AND POCESSING

In processing

The hydrolytic behaviour of [^{14}C]flutriafol was studied under conditions at high temperatures in sterile aqueous buffers at pH 4, 5 and 6 for periods of up to 60 minutes in order to simulate common processing practices (pasteurisation, baking/brewing/boiling, and sterilisation) (Hiler 2012 2441). The concentration of flutriafol was approximately 1 mg/L.

Table 49 Conditions for simulated processing trials (Hiler 2012 2441)

Simulated process	pH	Nominal temperature	Test period
Pasteurisation	4 ± 0.1	90 ± 5 °C	20 minutes
Baking/Brewing/Boiling	5 ± 0.1	100 ± 5 °C	60 minutes
Sterilisation	6 ± 0.1	120 ± 5 °C	20 minutes

Recoveries of ^{14}C ranged from 98.6 to 108.1% of that applied. Flutriafol was not degraded under any of the sets of conditions tested. Therefore it is concluded that flutriafol should remain stable in /on processed commodities during common processing practices.

Table 50 Stability of flutriafol during simulations of typical processing conditions (Hiler 2012 2441)

Time 20 min Rep A	100.7	101	108.1
Time 20 min Rep B	100.4	100.4	105.9

Peach

Two processing trials were conducted on peaches and nectarines in Spain (Martos 2011 2187.2 FLU amdt-1). Three foliar air blast applications were made using an SC formulation of flutriafol at a rate of 30 g ai/ha with a 7 day interval. Mature peaches and nectarines were sampled at a PHI of 7 days and were transported at ambient temperature to the processing facility where they were processed into juice and jam within 24 hours.

The fresh fruit was washed with water sprayed from a constant gas pressure sprayer (approx. 0.75 L water per kg fruit). Thereafter the fruit sample was divided into two portions and a minimum of 10 kg was used for processing into juice and 2 kg was used for processing into jam. Stones were removed and the separated pulp and stones weighed before discarding the stones.

Processing to Juice

Fruit pulp was then passed through a liquidiser to obtain the juice. Extracted fruit pulp (flesh) and raw juice were both weighed before discarding the extracted fruit pulp (waste). The pH of the juice was checked to be in the region of pH 3.5 before filtration and bottling.

Processing to jam

The fruit flesh was then cut into small pieces and heated until boiling. The heat was then reduced and the fruit allowed to simmer for approximately 15 minutes to provide raw fruit purée. Sugar was added at a ratio of 1:1 to the purée and the jam heated for 45 minutes until the Brix reached 65–68 °. The pH of the jam was checked to be in the region of pH 3.5 before being filled into glass bottles. The bottles were then tightly sealed and sterilized for 10 minutes (boiling water method).

Samples were stored frozen until analysed using a validated analytical method for residues of flutriafol. The LOQ of the method is 0.01 mg/kg for flutriafol.

Results show no significant difference of residues in processed products compared to the raw agricultural commodity with residues ranging from 0.03 to 0.05 mg/kg in fruit, 0.05 to 0.04 mg/kg in juice and 0.05 to 0.02 mg/kg in jam. The worst case PF was approximately 1.7 for juice and 1.0 for jam.

Plums

One processing trial has been conducted on plums in the USA in 2009 (Carringer 2010 1808). Four foliar air blast applications were made using flutriafol formulated as a 125 g/L SC. All applications

were made at a rate of 640 g ai/ha. Applications were made with a 7 day interval with the final application being made 7 days before harvest. Mature plums were transported overnight at ambient temperature to the processing facility where they were processed into prunes.

Fruit (18 kg) were inspected, sorted and culls removed. The fresh plums were washed for 5 minutes using a ratio of 2 kg of cold water to each 1 kg of fruit. The washed fruit were placed on drying trays and air-dried at 68–79 °C. The fruit was removed when average moisture contents of 19.3 to 20.0% were achieved which is lower than the target of approximately 21 to 32%. The prunes were allowed to cool for approximately 20 minutes. The cooled prunes were packaged, labelled, and placed in frozen storage for the required prune sample fraction. The LOQ of the method is 0.01 mg/kg for flutriafol, T, TA and TAA in plums but the LOQ was raised to 0.05 mg/kg for TA in prunes due to the presence of endogenous material.

Fresh plums and prunes were analysed for residues of flutriafol and the three triazole metabolites using a validated analytical method. Results show an increase in residues of flutriafol in prunes from 0.64 mg/kg to 1.4 mg/kg. No residues of T or TAA were observed in fresh plums or prunes. Residues of TA were 0.07 mg/kg in plums and 0.10 mg/kg in prunes. It is therefore concluded that flutriafol and TA do concentrate in processed commodities. The PF was approximately 2.2 for flutriafol.

Grapes

Two trials have been conducted in Germany and Southern France, one trial in white grapes and one in red grapes in each country (Block 2013 2650). Each trial consists of three plots—one untreated and two treated plots. Four applications of an SC formulation of flutriafol were made to grape vines at an exaggerated rate of 450 g ai/ha. The interval between applications and the interval between last application and harvest was 14 days.

At the processing facility a total of eight processing trials were conducted, one for each treated plot. Two of these trials were balance trials, one balance trial in red wine and one in white wine. In the balance trials red grapes were processed into stems, must, alcohol fermented wine (AF wine), wet and dry pomace, malolactic fermented wine (MF wine), lees, sediments and red wine. The white grapes were processed into must, wet and dry pomace, must deposit, AF wine, sediments and white wine. In trials for magnitude of residues, samples were only taken in fresh grapes, must, dry pomace and wine.

For red wine, fresh grapes were crushed and stemmed. Potassium metabisulphite and dry yeast was added to must to initiate the fermentation. During this process sugar was added to enhance the alcohol content. The fermented must was then separated in a liquid (free-run wine) and solid part. The solid part was pressed to produce pressed wine and wet pomace. Pomace was dried at 60 °C to produce dry pomace. Free-run and pressed wine was combined (AF wine) before further processing. Lactic bacteria (*Leuconostoc oenos*) was added to AF wine in air-free conditions. Potassium metabisulphite was added and the clarification process started. The intermediate wine was racked to produce MF wine and lees. Further potassium metabisulphite plus gelatine was added to the MF wine. Clarification proceeds while the wine was stored at

10 °C. Solid matter was removed before filtration of the red wine. Finally potassium metabisulphite was added to the wine before bottling.

For white wine, fresh grapes were pressed directly into must and wet pomace. Dry pomace was produced as for red wine production. Pectolic enzymes and potassium metabisulphite were added to the must before racking. Then dry yeast was added to initiate the fermentation. During this process sugar was added to enhance the alcohol content. Potassium metabisulphite was added and the clarification process started. Then the fermented must was racked to produce AF wine and lees. Further clarification, removal of solid matter, filtration and bottling was performed as for red wine.

Both samples of fresh grapes and processed samples were stored and shipped at frozen conditions before analysis. All samples were analysed for the content of flutriafol and the three metabolites 1,2,4-triazole, triazole alanine and triazole acetic acid using two separate validated analytical methods. The LOQ and LOD are 0.01 mg/kg and 0.003 mg/kg respectively for both flutriafol and the metabolites.

For flutriafol in the mass balance processing results for red wine gave an increase in flutriafol mass to 300% of that originally present in the starting grapes. The results were recalculated assuming the original mass present is the sum of the mass of must and stems. Following the adjustment the mass balance for red and white wine are in general agreement. Most flutriafol is retained in the must (48–97%) and wet pomace (25–95%). The AF wine contained 32–35% of the flutriafol mass. Lees taken after fermentation contained 5–8% of the initial flutriafol amount. Wine at bottling contained 31–37% of the initial mass of flutriafol.

Table 53 Red wine balance—mass balance

Sample	Weight	Corrected weight	Residue flutriafol (mg/kg)	Mass flutriafol (mg)	%mass (grapes 38.56)	%mass (stems + must 118.51)
Grapes prior to processing	56.7	56.7	0.68	38.6	100

MLF wine, after malolactic fermentation	29.5	37.6	0.92	34.6	90	29
Lees, after malolactic fermentation	1.7	2.2	2.8	6.0	16	5
Sediments, after clarification	0.53	1.3	1.0	1.3	3	1
Red wine, at bottling	14.9	35.9	1.0	37.0	96	31

Table 54 White wine balance—mass balance

Sample	Weight	Corrected weight	Residue flutriafol (mg/kg)	Mass flutriafol (mg)	%mass (grapes)
grape, prior processing	55.0	55.0	1.2	68.2	100
Must, after pressing	32.9	33.9	0.97	32.9	48
Wet pomace, after pressing	20.5	21.1	3.1	65.0	95
Dry pomace, after drying	1.2	4.98	6.7	33.6	49
Must deposit, after racking	3.0	3.2	1.2	3.9	6
AF wine, after alcoholic fermentation	24.4	26.8	0.90	24.1	35
Lees, after alcoholic fermentation	2.6	2.9	1.8	5.3	8
Sediment, after clarification	0.96	1.7	1.0	1.7	3
White wine, at bottling	14.2	24.6	1.0	25.5	37

No residues or very low levels of residues were seen for the metabolites in both fresh grapes and processed fractions. Therefore no PF is calculated for the metabolites. Flutriafol residues levels were higher and increased slightly in must and white wine. The PF is 1.8 for red

must, 1.6 for white must and 1.7 for white wine. No significant change in residue levels in red wine (PF of 1.1). A significant increase in flutriafol residues in dry pomace was observed with PFs of 10.7 and 6.5 for dry pomace from red and white wine production respectively.

Analytical method flutriafol: AGR/MOA/FLUTRI-1

Analytical method T, TA, TAA: AGR/MOA/TRZ-1

Strawberry

Four processing trials were conducted on protected strawberries in Spain in 2004 (Clark 2005 2583). Three applications of flutriafol were made, formulated as a 125 g/L SC using a hydraulic knapsack sprayer. All applications were made at a nominal rate of 18.75 g ai/hL using a nominal water volume

of 1000 L/ha. Applications were made with a 10 day interval with the final application being made 3 days before commercial harvest.

Mature fresh strawberries were harvested from the field and transported at cool temperature to the processing facility where they were processed into strawberry jam using processes considered typical of commercial practice.

Whole strawberries were washed with an automatic fruit washer (500–750 mL water per kg fruit) and strained. Strawberries (1.4–1.7 kg) were sorted and crushed and the Brix degree measured. White sugar was added to the crushed strawberries and then the sample was reduced in a double jacketed saucepan in order to reach 62 °Brix. The pH was adjusted with citric acid to approximately pH 3.5 and bottled. Packaged samples were then sterilised at 115 °C for 10 minutes.

Untreated and treated samples of fresh fruit prior to processing and processed jam were stored frozen and shipped under frozen conditions to the analytical laboratory for analysis. Samples were analysed using a validated analytical method. The LOQ of the method is 0.01 mg/kg.

Fresh strawberries and jam were both analysed for residues of flutriafol using a validated analytical method. Results show a decrease in residues in jam. The mean PF was 0.875 (range 0.75 to 0.96).

Cabbage

Three processing trials were conducted on cabbage in the USA in 2011 (Carringer 2013 2697). Four applications of an SC flutriafol formulation were made at a nominal rate of 128 g ai/ha. Applications were made with a 7 day interval with the final application being made 7 days before harvest.

The cabbage heads for the Sample Prepared for Consumption (SPFC) samples were visually examined and any damaged or wilted leaves, as well as the wrapper leaves, removed. Each cabbage head was then rinsed under cold running tap water for approximately 15–20 seconds. The heads were turned top side down and allowed to drain for at least two minutes.

The control, RAC and SPFC samples were placed in frozen storage within 2.5 hours after collection from the field and maintained frozen during transportation to the analytical laboratory. Samples were analysed using validated analytical methods. The LOQ of the methods is 0.01 mg/kg for all analytes.

RAC samples and SPFC samples were all analysed for residues of flutriafol and triazole metabolites using a validated analytical method. Results show a decrease in residues of flutriafol in the samples prepared for consumption with PFs ranging from 0.05 to 0.14.

Tomato

One processing study has been conducted on tomatoes in the USA in 2011 (Carringer 2012 2440). Four applications of flutriafol (SC formulation) were made at five times the nominal rate of 128 g ai/ha with a 7 day interval and the final application being made 0 days before commercial harvest. Mature tomato fruit were transported cool (approximately 4 °C) to the processing facility where they were processed into tomato purée and tomato paste.

For juice, tomatoes were soaked in aqueous NaOH (ca. 0.1 N) at 52–60 °C for 3 minutes and rinsed with warm (68–74 °C) water before being crushed, rapidly heated to 79–85 °C, held for 30 seconds and separated into pomace and juice. The wet pomace was pressed to recover additional juice which was combined.

For purée, an aliquot of 9 kg juice was evaporated under vacuum and when the required Brix was achieved, 1% salt and distilled water were added to adjust the Brix range to 12–13 °. The puree was then heated to 82–88 °C and sealed into cans before being placed into a boiling bath for 15 minutes at 96–100 °C. Cans were then cooled and stored frozen prior to analysis.

For paste, a 9 kg aliquot of juice was evaporated under vacuum until the desired Brix range was achieved, 0.5% salt and distilled water were added to adjust the Brix range to 24–33 °. The paste was then heated 82–88 °C and sealed into cans before being placed into a boiling bath for 15 minutes at 96–100 °C. Cans were then cooled and stored frozen prior to analysis.

The LOQ of the method is 0.01 mg/kg except for TA in purée (0.02 mg/kg) and paste (0.03 mg/kg).

Fresh tomatoes, purée and paste were analysed for residues of flutriafol and triazole metabolites T, TA and TAA using a validated analytical method. Results showed an increase in flutriafol residues in puree with a PF of 1.2 and an increase in residues in paste with a PF of 3.6. No residues of T, TA or TAA were present above LOQ in any control or treated samples analysed.

Head lettuce

Three processing trial have been conducted on head lettuce in the USA in 2011 (Carringer 2013 2698). Four applications of flutriafol were made, formulated as a 125 g/L SC using a backpack or tractor-mounted boom sprayer. All applications were made at a nominal rate of 128 g ai/ha. Applications were made with a 7 day interval with the final application being made 7 days before harvest. Mature head lettuce (RAC) and samples prepared for consumption (SPFC) were transported frozen to the analytical facility for analysis.

The head lettuce for the SPFC samples were visually examined and any damaged or wilted leaves, as well as wrapper leaves, removed. Each head was rinsed under cold running tap water for 15 to 20 seconds and allowed to drain top side down for at least two minutes.

The control, RAC and SPFC samples were placed in frozen storage within 3.17 hours after collection from the field and maintained frozen during transportation to the analytical laboratory. Samples were analysed using validated analytical methods. The LOQ of the methods is 0.01 mg/kg for all analytes.

RAC samples and SPFC samples were all analysed for residues of flutriafol and triazole metabolites using a validated analytical method. PFs for flutriafol range from 0.03 to 0.4 (mean of 0.21). Flutriafol does not concentrate in processed commodities.

PF = for flutriafol residues only

SPFC = samples prepared for consumption

Sugar beet

In a processing study conducted on sugar beet in the USA (Jones 2009 1812) three applications of flutriafol (SC formulation) were made at a nominal rate of 640 g ai/ha with a 14 day interval and the final application 14 days before harvest. Mature sugar beet roots were transported at ambient temperature to the processing facility where they were processed into refined sugar, molasses and dry pulp samples.

Sugar beets (45.4 kg batch) were cleaned prior to processing by washing with a brush and water thereby removing excess soil, loose leaves and other debris. Cleaned beets were then sliced in a Hobart food cutter and the slices (cossettes) were first exposed to 88.5–93 °C water for 30–45 seconds (only) and then diffused in five kettles in a 69–74.5 °C water bath for a minimum of 9 minutes. After diffusion the raw juice was screened with a US#100 standard sieve to remove small pieces of beet from the juice.

Diffused cossettes were then dewatered with a FMC pulper/finisher. Beet pulp was produced by drying the dewatered material in a Steelman Industries oven at 55–72 °C for final moisture of 15% or less. Juice from dewatering was screened with the 100 mesh sieve and combined with juice from diffusion. The resulting fraction from this step is dried beet pulp.

During the first phosphatisation step, raw juice was mixed and the temperature increased to 81–86 °C. 20% calcium oxide solution and if required 3 M phosphoric acid was added until a pH of around 10.5 was achieved resulting in a precipitate. The sample was centrifuged to separate the precipitate from the juice.

During the second phosphatisation step, the juice was mixed and the temperature increased to 81–86 °C and pH reduced using 3 M phosphoric acid to around 9.1–9.3. The juice was then centrifuged and vacuum filtered to separate precipitate from the clear juice (thin juice). The juice was light yellow to light brown in colour. The thin juice was mixed and heated to 81–86 °C and pH reduced to 8.8–9.0 with sodium bisulphite.

The juice was evaporated under vacuum until the juice was 50–60% solids (thick juice) during which time the temperature was maintained below 86 °C). After evaporation the thick juice was filtered through cotton.

Evaporation continued under vacuum until the juice was 70–80% solids (syrup). Commercially available white cane sugar was added to the juice (seeding) after which crystallisation began.

The solution was allowed to cool after which the sugar and molasses were separated by centrifuging in a Western States basket centrifuge with filter basket. Steam was added to remove residual molasses from crystallised sugar. After removing the molasses the refined white sugar could be dried if necessary in a Steelman Industry oven at 55–72 °C to achieve a final moisture content of 10%. Samples did not require drying. The resulting fraction from this step is refined sugar and molasses.

Untreated and treated samples of sugar beet, refined sugar, molasses and beet pulp were stored frozen and shipped under frozen conditions to the analytical laboratory for analysis. Samples were analysed using a validated analytical method. The LOQ of the method is 0.01 mg/kg.

Sugar beet roots, refined sugar, molasses and dry pulp samples were all analysed for residues of flutriafol and triazole metabolites using a validated analytical method. Residues were < 0.01 mg/kg in the RAC and the processed commodities with the exception of TA being observed in both untreated and treated molasses samples at 0.02 mg/kg. It is therefore concluded that flutriafol does not concentrate in refined sugar, molasses or dry pulp.

Celery

Three processing trial have been conducted on celery in the USA in 2011 (Carringer 2013 2698). Four applications of flutriafol SC formulation were made at a nominal rate of 128 g ai/ha.

The celery heads for the SPFC samples were prepared by removing the inedible portion of the stalk (i.e. the woody part at the base of the stalk) to separate the stems. The leaves were not removed unless discoloured or damaged. The stems were then rinsed under cold running tap water for approximately 15–20 seconds and allowed to drain for at least 2 minutes.

The control, RAC and SPFC samples were placed in frozen storage within 3.17 hours after collection from the field and maintained frozen during transportation to the analytical laboratory. Samples were analysed using validated analytical methods. The LOQ of the methods is 0.01 mg/kg for all analytes.

Mature celery (RAC) and samples prepared for consumption (SPFC) were transported frozen to the analytical facility for analysis.

RAC samples and SPFC samples were all analysed for residues of flutriafol and triazole metabolites using a validated analytical method. PFs for flutriafol ranging from 0.73 to 1.24 (mean of 0.9) indicates that flutriafol does not concentrate significantly in celery processed commodities.

SPFC = samples prepared for consumption

Maize

Processing trials were conducted on field corn in the USA (Carringer 2010 1810). Two applications of flutriafol, formulated as a SC, were made at 128 g ai/ha and samples of mature field corn grains were used for generation of aspirated grains fractions (AGF). Additionally at one trial, applications were made at an exaggerated rate of 640 g ai/ha/application and samples from this site were processed into grits, meal, flour, starch and refined oil (wet and dry milled). At all sites applications were made with a 7 day interval with the final application being made 7 days before harvest. Mature corn grain were transported frozen to the processing facility and stored frozen until processing. Field corn grains samples were dried at 43–57 °C until the moisture content was 9–15%.

Generation of aspirated grain fractions (AGF)

To generate AGF, dried field corn grain samples were placed in a dust generation room containing a holding bin, two bucket conveyors and a screw conveyor. As the samples were moved in the system, aspiration was used to remove light impurities (grain dust). The grain dust was sieved for classification before being recombined for analysis.

Refined oil, dry milling process.

In preparation for processing field corn grain into refined oil utilising the dry milling process, samples of dried field corn grains were cleaned by aspiration and screening. Light impurities were removed by aspiration after which samples were screened to separate large and small foreign particles (screenings) from the field corn. The dried and cleaned samples were then moisture conditioned to 21% and fed into a mill to crack the kernels. Cornstock from the mill was dried in an oven for 30 minutes at 54–71 °C and screened with a 3.2 mm screen to separate bran, germ and large grits from grits, meal and flour.

Material below 3.2 mm was separated into grits, meal and flour using a sieve fitted with two screens of different sizes. Material greater than 3.2 mm was by means of screening, aspiration and milling (if necessary) separated into grits, meal, flour and germ.

Germ material was heated to 72–80 °C and flaked in a flaking roll. The flakes were then placed in batch extractors and submerged in 49–60 °C hexane. The crude oil/hexane mixture was drained and the extraction process repeated twice more with fresh hexane. After extraction the

spent flakes were air dried to produce solvent extracted germ meal. The crude oil/hexane was passed through an evaporator to separate the crude oil from the hexane and then crude oil was heated to remove residual hexane before being filtered and refined. Crude oil and sodium hydroxide were mixed for 15 minutes at high RPM at approximately 20 °C and then for 12 minutes at low RPM at approximately 63–68 °C. The neutralised oil was centrifuged and the refined oil decanted and filtered.

Refined oil, wet milling process

A sample of dried and cleaned corn was steeped in 49–54 °C water containing 0.1–0.2% sulphur dioxide for 22–48 hours. The whole corn was then passed through a disc mill and the majority of the germ and hull was removed using a water centrifuge. Germ and hull were dried and separated using aspiration and screening.

Cornstock (without germ and hull) ground in the disc mill was passed over a 50µm screen where only bran was retained. The process water passing through the screen was separated into starch and gluten by centrifugation. Starch was dried in a dehydrator oven at 54–71 °C until moisture content was less than 15.0%.

The dried germ samples were moisture conditioned to 12%, heated to 88–104 °C in a mixer, flaked in a flaking roll and pressed in an expeller to liberate part of the crude oil (expelled crude oil). Residual crude oil was extracted from the presscake utilising the batch extractors submerged in hexane at 49–54 °C. The extraction procedure was repeated twice more with fresh hexane. The crude oil/hexane was passed through an evaporator to separate the crude oil from the hexane and then crude oil was heated to remove residual hexane before being filtered and refined. Crude oil and sodium hydroxide were mixed for 15 minutes at high RPM at approximately 20 °C and then for 12 minutes at low RPM at approximately 63–68 °C. The neutralised oil was centrifuged and the refined oil decanted and filtered.

Untreated and treated samples of from the processes were stored frozen and shipped under frozen conditions to the analytical laboratory for analysis. Samples were analysed using validated analytical methods. The LOQ of the methods is 0.01 mg/kg for flutriafol and its metabolites T and TAA. For TA the LOQ was 0.01 mg/kg in all matrices except grits (0.15 mg/kg), field corn grains (0.03 mg/kg), meal 0.034 mg/kg, flour (0.034 mg/kg) and AGF (0.1 mg/kg), where endogenous residues of TA resulted in LOQs higher than the target LOQ of 0.01 mg/kg.

Corn grains, AGF, grits, meal, flour, starch and refined oils were all analysed for residues of flutriafol and the triazole metabolites T, TA and TAA. Results show an increase in residues in meal, flour and oil (wet and dry milled), AGF. PFs range from > 4 for AGF, 3 for meal flour and oil and < 1 for grits and starch.

Rice

Four processing trial have been conducted on rice in Spain in 2006 (Gimeno 2007 1630). Two applications of flutriafol were made, formulated as a 125 g/L SC formulation using sprayer equipment typical of broadcast application. Applications were made at nominally 187.5 g ai/ha/application with a 14 day interval with the final application being made 14 days before harvest. Mature paddy rice were used for generation of husked (brown) rice and polished (white) rice.

At harvest plants were cut down and left to dry in a threshing floor, grains were then separated from straw and paddy rice samples obtained. The paddy rice was further dried and was then passed through a machine which removed the husks to obtain husked rice. The husked rice was fed into a mill where a set of huller reels removed the germ, outer bran and the waxy cuticle producing polished rice.

All samples were frozen immediately after processing and transported to the analytical facility. Samples were analysed for residues of flutriafol using a validated analytical method. See earlier table.

Sorghum

One processing trial has been conducted on grain sorghum in the USA in 2012 (Carringer 2013 2699). Two applications of flutriafol were made, formulated as a 125 g/L SC using sprayer equipment typical of broadcast application. Applications were made at the maximum use rate of nominally 128 g ai/ha/application with a 7 day interval with the final application being made 30 days before harvest. Mature grain sorghum grains were used for generation of aspirated grains fractions (AGF). Mature grain sorghum grain were transported frozen to the processing facility.

To generate AGF, dried field corn grain samples were placed in a dust generation room containing a holding bin, two bucket conveyors and a screw conveyor. As the samples were moved in the system, aspiration was used to remove light impurities (grain dust). The grain dust was sieved for classification before being recombined for analysis.

Untreated and treated samples from the processes were stored frozen and shipped under frozen conditions to the analytical laboratory for analysis. Samples were analysed using validated analytical methods. The LOQ of the methods is 0.01 mg/kg for flutriafol and its metabolites T, TA and TAA.

Residues are higher in AGF compared to grain with a processing factor of 8. The triazole metabolites T, TA and TAA are not concentrated in during processing into AGF.

PF = flutriafol only

Cotton

One processing trial has been conducted on cotton in the USA in 2012 (Carringer 2013 2700).

The plot received one T-band application of flutriafol 125 g/L SC formulation at 290 g ai/ha/application at planting applied using a commercial tractor mounted T-band sprayer.

The T-band application was followed by two foliar applications at 5× rate (640 g ai/ha/application) 37 and 30 days before harvest applied using a CO_2 backpack sprayer. Seed cotton was ginned on the same day as harvest resulting in undelinted seeds with approximately 11–15% remaining lint. Undelinted cotton seeds were transported frozen to the processing facility and processed into meal, hulls and refined oil.

Delinting (Mechanical)

The undelinted cottonseed samples (41 kg) were saw delinted in a delinter to remove most remaining lint producing delinted cottonseed with approximately 3% lint remaining on the seed.

Hulling and separation

Delinted cottonseed was mechanically cracked in a roller mill. Kernel and hull material was separated with a careen cleaner.

Kernel material moisture was determined and then adjusted to 13.5% by placing the kernel material in a rotating mixer and adding water.

Oil and meal production

Kernel material was heated in a steam heated mixer to 79.4–90.6 °C and held for 30 minutes. After heating, kernel material was flaked in a flaking roll. Flaked kernel material was then fed into an expander. As the material moved through the expander, steam was injected directly on the product. Maximum exiting temperature range of the material was 93.3–121.1 °C. Collets were ground, dried in an oven at 65.6–82.2 °C for 30–40 minutes.

Ground collets were placed in batch extractors and submerged in 49–60 °C hexane. After 30 minutes the hexane/crude oil mixture was drained and extraction repeated three more times with fresh hexane.

After extraction the solvent extracted meal was toasted in a steam jacketed paddle mixer with steam injected directly on the material until the temperature of the meal reached 101.7–104.4 °C. Steam injection was stopped and the meal heated to 104.4–115.6 °C and held for 45–60 minutes. After toasting, the meal was cooled to room temperature.

The crude oil/hexane was passed through an evaporator to separate the crude oil from the hexane and then crude oil was heated to remove residual hexane before being filtered and refined.

Alkali refining, bleaching and deodorisation

Crude oil and sodium hydroxide was mixed for 15 minutes at high RPM at approximately 20 °C and then for 13 minutes at low RPM at approximately 63–68 °C. The neutralised oil was centrifuged and the refined oil decanted and filtered.

The refined oil was bleached by heating it to 40–50 °C and adding an activated bleaching earth. The mixture was placed under vacuum, heated to 85–100 °C and held there for 10–15 minutes. Heating was stopped and the oil was allowed to cool. During the cooling phase vacuum was broken, filter aid added and vacuum resumed. When the mixture reached approximately 60 °C vacuum was broken and the bleached oil filtered.

The blanched oil was then deodorised by steam bathing for approximately 30 minutes under vacuum at 220–230 °C. During the following cooling period 0.5% citric acid solution was added.

Untreated and treated samples from the processes were stored frozen and shipped under frozen conditions to the analytical laboratory for analysis. Samples were analysed using validated analytical methods. The LOQ of the methods is 0.01 mg/kg for flutriafol and its metabolites T and TAA. For TA the LOQ was 0.01 mg/kg in all matrices except for TA in undelinted

cottonseed and cottonseed meal, where the LOQs were 0.03 and 0.04 mg/kg respectively due to endogenous residues in available control samples.

Undelinted cotton seeds, meal, hulls and refined oil were all analysed for residues of flutriafol using a validated analytical method. Residues of flutriafol in undelinted cotton seeds were present at 0.12 mg/kg. Residues were all lower in the processed commodities ranging from < 0.01 mg/kg in refined oil to 0.04 mg/kg in hulls. Results indicates, that flutriafol does not concentrate during processing into refined cottonseed oil.

Table 63 Residues of flutriafol in cotton processed products (meal, hulls, oil) on processing seed from a treated crop (Carringer 2013 2700) (duplicate samples)

Location	N	g ai/ha	DALA	Sample	Residue (mg/kg) Flutriafol	TA	PF

Livestock feeding

A livestock feeding study has been conducted in Holstein dairy cows to determine the magnitude of residues of flutriafol and three triazole metabolites 1,2,4-triazole (T), triazole alanine (TA) and triazole acetic acid (TAA) in milk, muscle, liver, kidney and fat (Rice 2012 2479). Three groups of three Holstein cows (3–7 years old, 450–690 kg bw) cows (three additional cows used for depuration phase) plus two concurrent control cows were dosed at 0, 5, 16 and 50 ppm (equivalent to 0, 0.15, 0.45 and 1.59 mg/kg bw of flutriafol) once daily for 28 consecutive days. Average feed consumption for the 5, 16 and 50 ppm groups were 18.5, 17.7 and 17.9 kg/day. Average milk production was 25.6, 22.0 and 21.3 L/d respectively for the 5, 16 and 50 ppm dose groups. Milk was collected twice daily and samples at 0, 3, 7, 10, 14, 17, 21, 24, 26 and 28 days were pooled and mixed before analysis. All cows were sacrificed within 24 hours after final dosing and samples of muscle (composite of round and loin), liver, kidneys, fat (renal, omental and subcutaneous fat deposits) were collected for analysis. Residues of flutriafol and triazole metabolites were analysed using validated analytical methods with an LOQ of 0.01 mg/kg for each analyte/matrix combination.

Highest average residues of flutriafol were found in liver and ranged from 0.33 mg/kg for the 5 ppm group, 0.59 mg/kg for the 16 ppm group and 1.83 mg/kg for the 50 ppm group. No residues were observed in liver samples taken from the depuration phase at 31, 35 and 42 days. For remaining matrices, highest average flutriafol residues ranged from < 0.01 mg/kg in milk, 0.01 mg/kg (50 ppm group) in cream at day 21, < 0.01 mg/kg in skimmed milk, 0.096 mg/kg (50 ppm group), 0.01 mg/kg (16 ppm group) in kidney, 0.04 mg/kg (50 ppm group) in muscle and 0.07–0.195 mg/kg (50 ppm group), 0.01 mg/kg (16 ppm group) in fat. All other residues of flutriafol from all dose groups were < 0.01 mg/kg. No residues were observed above LOQ in tissue or milk samples taken from the depuration phase at 31, 35 and 42 days.

Highest average residues of triazole metabolite residues were found in liver and ranged from < 0.01–0.02 mg/kg for 1,2,4-triazole, 0.03 to 0.157 mg/kg for triazole alanine and < 0.01 mg/kg for triazole acetic acid. Only triazole alanine residues were found during the depuration phase and ranged from 0.093 to 0.135 mg/kg. For remaining matrices, highest average residues ranged from 0.020 mg/kg 1,2,4-triazole in milk (50 ppm group), 0.015 mg/kg 1,2,4-triazole (50 ppm group) in cream at day 14/21, 0.021 mg/kg 1,2,4-triazole in skimmed milk (50 ppm group), 0.029 mg/kg 1,2,4-triazole and 0.058 mg/kg triazole alanine (50 ppm group) in kidney, 0.020 mg/kg 1,2,4-triazole and 0.086 mg/kg triazole alanine (50 ppm group) in muscle

and 0.02 mg/kg triazole alanine (50 ppm group) in fat. No average residues of triazole acetic acid were observed in tissue or milk samples. Only triazole alanine was observed above LOQ in tissues during the depuration phase

Note: residues of triazole analine were detected in muscle (loin and round) samples from control animals: The levels detected were < 0.01–0.01, mean < 0.01 mg/kg in round and 0.08–0.09 mg/kg, mean 0.09 mg/kg in loin muscle. The large difference between loin and round residues as well as the fact that no residues of TAA were detected in corresponding control liver, kidney or fat samples suggesting this detection is due to a mislabelling of the sample or cross-contamination during processing for analysis.

APPRAISAL

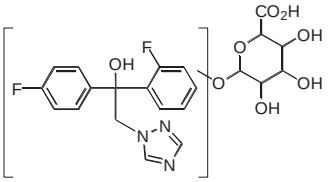
Flutriafol is a triazole fungicide used in many crops for control of a broad spectrum of leaf and ear cereal diseases, particularly embryo borne diseases e.g., bunts and smuts. It was first evaluated for residues and toxicology by the 2011 JMPR. The ADI of flutriafol was 0–0.01 mg/kg bw and the ARfD was 0.05 mg/kg bw. The compound was listed by the Forty-sixth Session of CCPR for the JMPR to consider additional MRLs. The residue definition for compliance with MRL and for estimation of dietary intake (for animal and plant commodities) is flutriafol.

For the current evaluation the Meeting received new metabolism studies in lactating goats, storage stability data for animal commodities, residue trials on apples, pears, peaches/nectarines, plums, cherries, strawberries, Brassica vegetables (cabbage and broccoli), cucurbits (cucumbers, summer squash and muskmelons), tomatoes, peppers, leafy vegetables (lettuce, spinach, celery and mustard greens), sugar beet, maize, rice, sorghum, almonds, pecans, cotton, and rape, as well as a lactating cow feeding study (residue transfer study).

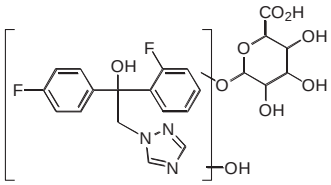
Metabolites referred to in the appraisal were addressed by their common names

1,2,4-triazole (M1, T)

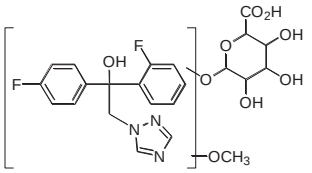
flutriafol glucuronide (M4)



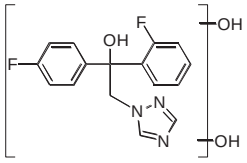
hydroxy flutriafol glucuronide (M3)



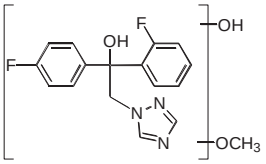
methoxy flutriafol glucuronide (M7)



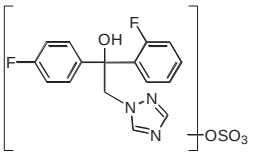
dihydroxy flutriafol (M3e)



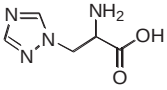
hydroxymethoxy flutriafol (M5)



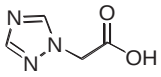
flutriafol sulfate (M10)



1,2,4-triazole analine (TA)



1,2,4-triazole acetic acid (TAA)



Animal metabolism

Metabolism of flutriafol in cattle involves hydroxylation of flutriafol to hydroxy flutriafol and a range of polar water soluble metabolites that are present at low levels, presumably additionally hydroxylated flutriafol compounds and their conjugates. The current Meeting received two additional studies on the metabolism of flutriafol in ruminants involving dosing lactating goats with triazole- or carbinol-labelled flutriafol at the equivalent of 12 or 30 ppm in the feed.

The majority of the ^{14}C residues were recovered in the excreta (urine 30–54% AD, faeces 35–55% AD). For tissues of goats dosed at 30 ppm, ^{14}C residues were highest in liver, (0.68–0.70 mg equiv/kg), followed by the kidney (0.11–0.31 mg equiv/kg) with only low levels detected in fat (0.011–0.018 mg equiv/kg) and muscle (0.02 mg equiv/kg). Residues in milk appeared to reach plateau levels by day three of dosing with significant differences in ^{14}C levels between milk collected in the morning (low levels) compared to evening milk (higher levels) suggesting flutriafol residues are rapidly eliminated following dosing. TRR in milk reached a maximum of 0.095 mg equiv/kg.

Acetonitrile and water extraction of liver, kidney, muscle, fat, skim milk and milk fat resulted in extraction efficiencies of 28.7–38.7% (liver), 66.7–86.5% (kidney) and > 82% (muscle), > 72% fat, 98% (skim milk) and 82–87% (milk fat).

Flutriafol was extensively metabolized and accounted for ≤ 2.5% TRR in liver, ≤ 0.7% TRR in kidney, ≤ 4.3% TRR in milk fat, not detected in muscle and ≤ 0.01 mg/kg in fat. Significant metabolites and the highest % TRR in tissues are 1,2,4-triazole (M1: 15% skim milk, 11% milk fat, 42% muscle, 27% fat), hydroxy flutriafol glucuronide (M3: 13% kidney, 23%

skim milk, 44% milk fat, 10% muscle), di-hydroxy flutriafol (M3e: 35% skim milk), flutriafol glucuronide (M4: 25% kidney, 17% muscle) and methoxy flutriafol glucuronide (M7: 10% kidney).

The Meeting noted that in the lactating cow evaluated by the 2011 JMPR, animals were dosed orally twice daily at the equivalent of 2 ppm in the diet for seven days and sacrificed at 4 hours after the last dose. In the current studies, goats were dosed once daily at 12 or 30 ppm with sacrifice occurring 20–22 hours after the last dose. The difference in sacrifice times and the higher dose rates have allowed for increased identification of residue components. The major residues in kidney, in both the lactating cow and goat studies, is flutriafol glucuronide (M4) (reported as M1B in the lactating cow study) at 22% TRR in cows and 13–15% TRR in goats at the highest dose. With the longer interval between the last dose and sacrifice, flutriafol is no longer found as the major component of the residue in liver (cow 27% TRR; goat 1.0–2.5% TRR) and no metabolite was individually present at > 10% TRR in liver in the goat studies. The levels of radioactivity in milk from the cow study were too low to allow for adequate characterisation and identification of components. In the goat study, considering the levels found in skim milk and in milk fat, three components are likely to be present at more than 10% TRR in whole milk: hydroxy flutriafol glucuronide (M3), di-hydroxy flutriafol (M3e) and flutriafol sulphate (M10).

The major metabolic pathway involves oxidation of one of the phenyl rings followed by conjugation with glucuronic acid to form flutriafol glucuronide (M4). Further oxidation results in formation of dihydroxy flutriafol (M3e), of which there are a number of possible isomers. M3e is then further transformed via methylation to hydroxyl methyl flutriafol (M5) which can, in turn, be conjugated with glucuronic acid to form methoxy flutriafol glucuronide (M7). M3e was also conjugated with glucuronic acid to form hydroxy flutriafol glucuronide (M3). The lactating goat study extends the knowledge of flutriafol metabolism and is consistent with earlier studies in lactating cow as well as laboratory animals.

The new goat metabolism studies have identified potential marker residues that could be included in the residue definitions for compliance and dietary intake risk assessment. However, the Meeting noted at the current livestock dietary burdens, residues in animal commodities of these components are expected to be at the limit of quantification or below. The Meeting agreed that the residue definitions for animal commodities did not need to be revised although this may change in the future if there are significant increases in the estimated livestock dietary burdens.

Stability of pesticide residues in stored analytical samples

The 2011 JMPR concluded that when stored, frozen flutriafol residues were stable for at least 5 months in soya bean seed, for at least 12 months in apple, barley grains and coffee beans, for at least 23 months in grapes, for at least 24 months in cabbage and oilseed rape, and for at least 25 months in wheat (grains and straw), pea seed, sugar beet root. Triazole metabolite residues were stable for at least 4 months in apple fruits and juice, and for at least 5 months in animal commodities.

The 2015 Meeting received information on the stability of flutriafol and triazole metabolites T, TA and TAA in samples of animal commodities stored frozen. Residues of flutriafol, TA and TAA in ruminant tissues (muscle, fat, liver and kidney) remain stable for at least 12 months, residues of T remains stable for at least 12 months in muscle and liver, and for a maximum 6.6 months in kidney and 10.7 months in fat when samples are stored under deep frozen conditions.

The periods of demonstrated stability cover the frozen storage intervals used in the residue studies.

Results of supervised residue trials on crops

Pome fruit

Field trials involving apples and pears conducted in the USA were made available to the Meeting. The cGAP for pome fruit in the USA is four applications at 119 g ai/ha (7–10 day interval between sprays, PHI 14 days). None of the trials on apples and pears submitted matched cGAP. However, the number of sprays in the trials was six and available decline data suggest the additional two sprays do not significantly contribute to the final residues and trials conducted at the maximum application rate but with six sprays were considered to approximate cGAP.

Apples

Residues in trials evaluated by the 2015 JMPR approximating *c*GAP were (n=4): 0.02, 0.02, 0.06 and 0.11 mg/kg.

The 2011 JMPR reported residues from sixteen trials on apples that also approximated *c*GAP (n=16): 0.03, 0.04, 0.05 (3), 0.06 (3), 0.08 (2), 0.09, 0.10 (2), 0.12 (2) and 0.16 mg/kg.

Pears

Residues in trials on pears approximating *c*GAP were: 0.04, 0.09, 0.13, 0.18, 0.21 and 0.24 mg/kg.

The GAP in the USA is for the group Pome fruit. The median residues in apples and pears differed by less than a factor of five and the Meeting decided to recommend a group maximum residue level. In deciding which data set to use for the recommendation, as a Mann Whitney U-test indicated that the residue populations were not different it was decided to combine the data sets.

The combined apple and pear dataset is: 0.02 (2), 0.03, 0.04 (2), 0.05 (3), 0.06 (4), 0.08 (2), 0.09 (2), 0.10 (2), 0.11, 0.12 (2), 0.13, 0.16, 0.18, 0.21 and 0.24 mg/kg

The Meeting estimated a maximum residue level of 0.4 mg/kg for pome fruit together with an STMR of 0.08 mg/kg and an HR 0.26 mg/kg (highest individual analytical result from duplicate samples) and agreed to replace the previous recommendation of 0.3 mg/kg.

Stone fruit

Field trials involving applications to cherries, peaches and plums were made available from the USA.

The cGAP for stone fruit in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7day interval between sprays, PHI 7 days).

Residues in cherries (sweet and tart) from trials matching GAP were: 0.16, 0.24, 0.25, 0.26, 0.30, 0.30, 0.32, 0.33, 0.34, 0.38, 0.39, 0.40, 0.42, 0.46, 0.47 and 0.59 mg/kg.

Residues in peaches from trials matching cGAP were: 0.05, 0.12, 0.13, 0.14, 0.15, 0.16, 0.18, 0.18, 0.19, 0.24, 0.24 and 0.41 mg/kg

Residues in plums from trials matching cGAP were: 0.02, 0.03, 0.04, 0.06, 0.09, 0.10, 0.12 and 0.22 mg/kg.

The Meeting noted the use in the USA is for the group stone fruit and that a group MRL recommendation might be possible. Although the median residues differed by less than a factor of five, the Meeting decided to recommend maximum residue levels for all the sub-groups of stone fruit as there were sufficient trials available for each sub-group.

The Meeting estimated a maximum residue level of 0.8 mg/kg for the sub-group cherries together with an STMR of 0.335 mg/kg and an HR 0.66 (highest individual analytical result from duplicate samples) mg/kg.

The Meeting estimated a maximum residue level of 0.6 mg/kg for sub-group peaches together with an STMR of 0.17 mg/kg and an HR 0.42 (highest individual analytical result from duplicate samples) mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg for sub-group plums together with an STMR of 0.075 mg/kg and an HR 0.25 (highest individual analytical result from duplicate samples) mg/kg.

Strawberries

Trials were available from Spain and the USA. The cGAP for strawberries in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 0 days).

Residues in strawberries from trials matching cGAP were (n=10): 0.14, 0.24, 0.30, 0.36, 0.42, 0.44, 0.45, 0.55, 0.63 and 0.72 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg for strawberries together with an STMR of 0.43 mg/kg and an HR 0.78 (highest individual analytical result from duplicate samples) mg/kg.

Brassica vegetables

Residue trials were available from the USA. The cGAP for Brassica (Cole) leafy vegetables in the USA is four applications 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 7 days). Residues in trials matching cGAP were cabbage (n=6) 0.08, 0.09, 0.10, 0.20, 0.44, 0.74 mg/kg and broccoli (n=5) 0.06, 0.08, 0.14, 0.18, 0.35 mg/kg.

The GAP in the USA is for the group Brassica vegetables. The median residues in cabbage and broccoli differed by less than a factor of five and the Meeting decided to recommend a group maximum residue level. In deciding which data set to use for the recommendation, as a Mann Whitney U-test indicated that the residue populations were not different it was decided to combine the data sets.

The combined data set is (n=11): 0.06, 0.08, 0.08, 0.09, 0.10, 0.14, 0.18, 0.20, 0.35, 0.44 and 0.74 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg for Brassica (Cole or cabbage) vegetables together with an STMR of 0.14 mg/kg and an HR 0.80 mg/kg (highest individual analytical result from duplicate samples).

Fruiting vegetables, cucurbits

Residue trials were available from the USA. The Meeting noted that there are GAPs in the USA that cover the whole group fruiting vegetables, cucurbits and that the cGAP is the same for all crops that are members of the group. It was agreed to consider the trials on melons and other cucurbits together. The cGAP for the muskmelons and cucurbit vegetables (except muskmelons) in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 0 days).

Residues matching cGAP were muskmelons, whole fruit (n=8), 0.02, 0.04, 0.07, 0.08, 0.10, 0.10, 0.12 and 0.12 mg/kg (whole fruit); muskmelons, flesh (n=4), < 0.01, < 0.01, 0.02 and 0.02 mg/kg; cucumbers, (n=8), 0.02, 0.02, 0.03, 0.04, 0.04, 0.04, 0.06 and 0.06 mg/kg; summer squash, (n=7), 0.04, 0.04, 0.04, 0.05, 0.05, 0.06 and 0.06 mg/kg.

The GAP in the USA covers the whole group cucurbit vegetables. The median residues in cucumbers, muskmelons and summer squash datasets differed by less than a factor of five and the Meeting decided to recommend a group maximum residue level. In deciding which data set to use for the recommendation, as a Kruskal-Wallis H-test indicated that the residue populations were different it was decided to use the muskmelon dataset which has the highest residues.

The Meeting estimated a maximum residue level of 0.3 mg/kg for fruiting vegetables, cucurbits, together with an HR 0.13 mg/kg (highest individual analytical result from duplicate samples from muskmelons) and an STMR of 0.09 mg/kg.

Tomatoes

Flutriafol is approved in the USA for use on tomatoes. The cGAP for tomatoes in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 0 days). Residues from trials matching cGAP were (n=18): 0.04, 0.05, 0.06, 0.06, 0.06, 0.06, 0.07, 0.08, 0.10, 0.12, 0.12, 0.12, 0.15, 0.18, 0.33, 0.40, 0.42 and 0.55 mg/kg.

The Meeting estimated a maximum residue level of 0.8 mg/kg for tomatoes together with an STMR of 0.11 mg/kg and an HR 0.63 (highest individual analytical result from duplicate samples) mg/kg.

Peppers

Residue trials were available from the USA. The cGAP for fruiting vegetables (USA group 8–10) which includes peppers in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 0 days).

Residues in trials matching USA GAP were peppers, sweet (n=9), 0.03, 0.06, 0.06, 0.08, 0.10, 0.11, 0.14, 0.15 and 0.16 mg/kg, and chilli, (n=4), 0.12, 0.20, 0.26 and 0.31 mg/kg.

Residues in peppers and chilli, from trials submitted to the 2015 JMPR are covered by maximum residue levels recommended by the 2011 JMPR of 1 mg/kg for peppers, sweet however, the Meeting noted the commodity description from the 2011 JMPR should have been VO 0051 Peppers (subgroup including Peppers, Chilli and Peppers, Sweet) and not VO 0445 Peppers, Sweet (including pimento or pimiento). To resolve this Meeting recommends a maximum residue level of 1 mg/kg, STMR of 0.28 mg/kg and an HR of 0.41 mg/kg for peppers (VO 0051) to replace the previous recommendation of 1 mg/kg for peppers, sweet (VO 0445).

Leafy vegetables

Residue trials were available from the USA. The *c*GAP for leafy vegetables (except Brassica leafy vegetables) in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 7 days). Brassica (Cole) leafy vegetables in the USA have the same *c*GAP as for other leafy vegetables and as mustard greens are considered leafy vegetables under Codex, the Meeting agreed to evaluate all leafy vegetables together.

Residues in trials matching *c*GAP were, head lettuce, (n=7), 0.04, 0.05, 0.14, 0.22, 0.46, 0.52 and 0.66 mg/kg; leaf lettuce, (n=5), 0.30, 0.32, 0.36, 1.45 and 2.64 mg/kg; Cos lettuce (Romaine), (n=2), 0.20 and 0.28 mg/kg; spinach, (n=8), 0.55, 0.94, 1.32, 1.55, 1.78, 2.1, 5.05 and 5.45 mg/kg; and mustard greens, (n=8), 1.20, 1.49, 2.02, 2.12, 2.12, 2.15, 2.78 and 3.42 mg/kg.

GAP in the USA is for leafy vegetables and a group maximum residue level recommendation may be possible. However, as the median residue levels in the datasets differed by more than 5×, residues in the individual commodities cannot be considered similar and the Meeting decided to recommend levels for the individual leafy vegetables for which data are available.

The Meeting estimated a maximum residue level of 1.5 mg/kg for head lettuce together with an STMR of 0.22 mg/kg and an HR 0.67 mg/kg (highest individual analytical result from duplicate samples).

The Meeting estimated a maximum residue level of 5 mg/kg for leaf lettuce together with an STMR of 0.36 mg/kg and an HR 2.95 mg/kg (highest individual analytical result from duplicate samples).

The Meeting agreed there were insufficient residue trials to estimate a maximum residue level for Cos lettuce.

The Meeting estimated a maximum residue level of 10 mg/kg for spinach together with an STMR of 1.665 mg/kg and an HR 5.5 mg/kg (highest individual analytical result from duplicate samples).

The Meeting estimated a maximum residue level of 7 mg/kg for mustard greens together with an STMR of 2.12 mg/kg and an HR 3.53 mg/kg (highest individual analytical result from duplicate samples).

The IESTI represented greater than 100% of the ARfD of 0.05 mg/kg bw in the case of leaf lettuce (110% children), mustard greens (350% children; 140% general population) and spinach (460% total or 160% raw spinach only, children; 130% general population). No alternative GAP was available.

Sugar beet

Residue trials were available from the countries of the EU and also the USA.

The *c*GAP for sugar beet in the USA is two applications at 128 g ai/ha (maximum application per year 256 g ai/ha, 14 day interval between sprays, PHI 21 days).

No trials matched cGAP as the number of sprays differed and there is insufficient data to conclude the additional spray does not significantly contribute to the terminal residue (three sprays in trials versus two sprays cGAP, PHI 14 day trials versus 21 days cGAP).

GAP in Russia is for two applications at 62.5 g ai/ha with a 30 day PHI. Residues in trials from northern Europe at approximately double the application rate were (n=8), < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, 0.01, 0.02 and 0.03 mg/kg. The Meeting decided to apply proportionality to the residue data.

Trial application rate (2nd spray) g ai/ha	Scaling factor = 62.5/trial application rate	Trial residue (mg/kg)	Scaled residue =scaling factor × trial residue (mg/kg)
135	0.463	< 0.01	< 0.01
111	0.563	< 0.01	< 0.01
120	0.521	< 0.01	< 0.01
131	0.477	< 0.01	< 0.01
138	0.453	< 0.01	< 0.01
126	0.496	0.01	0.0050
130	0.481	0.02	0.0096
138	0.453	0.03	0.0136

Based on the residues from Europe scaled to cGAP for Russia, the Meeting estimated an STMR of 0.01 mg/kg, an HR of 0.0136 mg/kg and a maximum residue level of 0.02 mg/kg for sugar beet.

Celery

Celery is classified as a leafy vegetable in the USA but as a stalk and stem vegetable in Codex. Residues in celery (whole plant) conducted according to cGAP in the USA (4× 128 g ai/ha, PHI 7 days) were (n=7), 0.44, 0.48, 0.73, 0.78, 0.92, 1.08 and 1.40 mg/kg.

The Meeting estimated a maximum residue level of 3 mg/kg for celery together with an STMR of 0.78 mg/kg and an HR 1.41 mg/kg (highest individual analytical result from duplicate samples).

Cereal grains

Maize

Residue trials were available from the USA. The cGAP for maize (field corn, popcorn and seed corn) in the USA is two applications at 128 g ai/ha (maximum application per year 256 g ai/ha, 7 day interval between sprays, PHI 7 days). Residues in trials matching cGAP were: < 0.01 (20) mg/kg. At

one site two applications were also made at an exaggerated rate of 640 g ai/ha with harvest of grain 7 days later. Residues in grain were < 0.01 mg/kg.

The Meeting estimated an STMR of 0 mg/kg and a maximum residue level of 0.01 (*) mg/kg for maize.

Rice

The Meeting received field trials performed in Italy on rice. The cGAP for Italy is for 2× 187.5 g ai/ha with a PHI of 28 days. In trials approximating critical GAP in the Italy total residues in rice grain (with husk) were (n=4), Paddy rice, 0.74, 1.06, 1.32 and 1.51 mg/kg.

The number of trials is insufficient to make a maximum residue level recommendation for rice.

Sorghum

Residue trials were available from the USA. The cGAP for sorghum in the USA is two applications at 128 g ai/ha (maximum application per year 256 g ai/ha, 7 day interval between sprays, PHI 30 days). Residues in trials matching *c*GAP were (n=12), 0.03, 0.16, 0.16, 0.20, 0.24, 0.26, 0.28, 0.34, 0.38, 0.40, 0.74 and 0.74 mg/kg.

The Meeting estimated an STMR of 0.27 mg/kg and a maximum residue level of 1.5 mg/kg for sorghum.

Tree nuts

Residue trials were available from the USA. The cGAP for almonds and walnuts as well as for pecans and other tree nuts in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 14 days). No trials matched *c*GAP as the number of sprays differed and there is insufficient data to conclude the additional spray does not significantly contribute to the terminal residue.

Cotton seed

Residue trials were available from the USA. The cGAP for cotton in the USA is a pre-plant soil application at up to 290 g ai/ha followed by foliar applications at 128 g ai/ha (maximum application per year 547 g ai/ha, 7 day interval between sprays, PHI 30 days). Residues in trials matching cGAP were (n=11), < 0.01, 0.02, 0.04, 0.06, 0.07, 0.08, 0.09, 0.14, 0.16, 0.26 and 0.26 mg/kg.

The Meeting estimated an STMR of 0.08 mg/kg and a maximum residue level of 0.5 mg/kg for cotton seed.

Rape seed

Residue trials were available from the USA and member states of the European Union. The cGAP for rape in Russia is application at 125 g ai/ha (maximum two applications/year, interval 10–14 days, PHI 30 days). In trials conducted in member countries of the European Union approximating critical GAP in Russia, residues in rape seed were (n=8), mg/kg, Northern Europe, 0.04, 0.07, 0.13, 0.15 and 0.31 mg/kg, and Southern Europe, 0.03, 0.05 and 0.15 mg/kg.

The Meeting estimated an STMR of 0.1 mg/kg and a maximum residue level of 0.5 mg/kg for rape seed.

Animal feeds

Straw, forage and fodder of cereal grains and grasses

Maize forage and fodder

Residue trials were available from the USA. The cGAP for maize (field corn, popcorn and seed corn) in the USA is two applications at 128 g ai/ha (maximum application per year 256 g ai/ha, 7 day interval between sprays, PHI 7 days, 0 days for forage). Residues in forage from trials matching cGAP were (n=20), 0.53, 0.74, 0.91, 1.08, 1.14, 1.36, 1.45, 1.47, 1.53, 1.63, 1.65, 1.66, 1.75, 1.77, 1.85, 1.89, 2.19, 2.44, 2.66 and 2.74 mg/kg (as received basis). When corrected for measured moisture contents (33–70%) residues were , 1.86, 1.92, 3.17, 3.17, 3.82, 4.18, 4.53, 4.80, 4.88, 5.10, 5.52, 5.61, 5.66, 5.73, 5.78, 6.39, 6.89, 7.29, 8.30 and 8.47 mg/kg.

The Meeting estimated median residue of 5.31 mg/kg and a highest residue of 8.47 mg/kg for maize forage (dry weight basis).

Residues in maize fodder (stover) from trials matching cGAP were (n=20), < 0.02, 0.72, 0.88, 1.00, 1.04, 1.32, 1.40, 1.44, 1.46, 1.94, 2.07, 2.27, 2.38, 2.48, 2.64, 2.99, 2.99, 3.04, 3.98 and 5.44 mg/kg (as received basis). When corrected for measured moisture contents (54–73%) residues were 0.03, 1.62, 1.90, 3.00, 3.42, 3.72, 3.79, 3.99, 4.35, 4.84, 5.03, 5.04, 6.72, 6.92, 6.99, 7.21, 7.81, 8.12, 8.17 and 10.45 mg/kg.

The Meeting estimated median residue of 4.93 mg/kg, a highest residue of 10.45 mg/kg and a maximum residue level of 20 mg/kg for maize fodder (dry weight basis).

Sorghum

Residue trials were available from the USA. The *c*GAP for sorghum in the USA is two applications at 128 g ai/ha (maximum application per year 256 g ai/ha, 7 day interval between sprays, PHI 30 days for grain, forage and stover).

Sorghum forage (n=12), 0.08, 0.19, 0.20, 0.24, 0.26, 0.28, 0.52, 0.54, 0.64, 0.72, 0.78 and 1.0 mg/kg (fresh weight). Median and highest residues in sorghum forage are 0.40 and 1.0 mg/kg (fresh weight basis) or 1.1 and 2.85 mg/kg (dry weight basis) as forage contains 35% dry matter.

Sorghum fodder (n=12), 0.30, 0.42, 0.45, 0.52, 0.68, 0.80, 0.88, 0.92, 1.14, 1.46, 1.52 and 4.40 mg/kg (fresh weight). The Meeting estimated median and highest residues of 0.84 mg/kg and 4.4 mg/kg (fresh weight basis) or 0.95 and 5 mg/kg when expressed on a dry weight basis and assuming fodder contains 88% dry matter. The Meeting estimated a maximum residue level of 7 mg/kg for sorghum fodder (dry weight basis).

Miscellaneous fodder and forage crops

Sugar beet tops

The Meeting received trials performed in countries of the EU and also the USA.

The *c*GAP for sugar beet in the USA is two applications at 128 g ai/ha (maximum application per year 256 g ai/ha, 14 day interval between sprays, PHI 21 days). No trials matched GAP as the number of sprays differed and there is insufficient data to conclude the additional spray does not significantly contribute to the terminal residue (three sprays in trials vs two sprays cGAP).

GAP in Russia is for two applications at 62.5 g ai/ha with a 30 day PHI. Residues in trials from northern Europe at approximately double the application rate were (n=8), 0.1, 0.14, 0.14, 0.18, 0.18, 0.22, 0.22 and 0.75 mg/kg (on an as received basis). The Meeting decided to apply proportionality to the residue data.

Trial application rate (2nd spray) g ai/ha	Scaling factor = 62.5/trial application rate	Trial residue (mg/kg)	Scaled residue =scaling factor × trial residue (mg/kg)

131	0.477	0.10	0.048
128	0.488	0.14	0.068
126	0.496	0.14	0.069
120	0.520	0.18	0.094
111	0.563	0.18	0.101
135	0.463	0.22	0.102
130	0.481	0.22	0.106
138	0.453	0.75	0.340

Based on the residues from Europe scaled to cGAP for Russia, the Meeting estimated a median residue of 0.098 mg/kg and a highest residue of 0.340 mg/kg (on an as received basis). Sugar beet tops contain approximately 23% DM. The Meeting estimated a median residue of 0.424 mg/kg, a highest residue of 1.477 mg/kg and a maximum residue level of 3 mg/kg for sugar beet tops (on a dry weight basis).

Rape seed forage

Residue trials were available from the USA and member states of the European Union. The GAP for rape in Russia is application at 125 g ai/ha (maximum two applications/year, interval 10–14 days, PHI 30 days). The late application precludes the use of plant material as forage.

Cotton gin by-products

Residue trials were available from the USA. The cGAP for cotton in the USA is a pre-plant soil application at up to 290 g ai/ha followed by foliar applications at 128 g ai/ha (maximum application per year 547 g ai/ha, 7 day interval between sprays, PHI 30 days). Three trial matched cGAP with residues 1.12, 1.77 and 2.26 mg/kg (fresh weight basis). Three residue trials is insufficient to estimate a maximum residue level for cotton gin by-products.

Almond hulls

Residue trials were available from the USA. The cGAP for almonds, walnuts, pecans and other tree nuts in the USA is four applications at 128 g ai/ha (maximum application per year 511 g ai/ha, 7 day interval between sprays, PHI 14 days). No trials matched cGAP as the number of sprays differed and there is insufficient data to conclude the additional spray does not significantly contribute to the terminal residue (six sprays in trials versus four sprays for cGAP).

Fate of residues during processing

The Meeting received information on the nature of residues under simulated processing conditions on the fate of incurred residues of flutriafol during the processing of peaches, plums, grapes, strawberries, cabbages, tomatoes, lettuce, celery, sorghum, rice, and cotton seed. Flutriafol residues are stable under simulated processing conditions (pasteurization, baking/brewing/boiling and sterilisation).

Summary of selected processing factors for flutriafol

Raw commodity	Processed commodity	Individual PF	Best estimate PF	$STMR_{RAC}$ (mg/kg)	$STMR_{RAC}$ × PF (mg/kg)	HR_{RAC} (mg/kg)	HR_{RAC} × PF (mg/kg)
Apple	Juice [a]	0.50 0.45	0.48	0.08	0.038

[a] Values from 2011 JMPR

Residues concentrated in prunes (dried plums). Based on the estimated maximum residue level for plums of 0.4 mg/kg, the Meeting recommended a maximum residue level for prunes of 0.9 mg/kg (MRL × PF = 0.4 × 2.2 = 0.88 mg/kg rounded to 0.9 mg/kg).

Residues in animal commodities

Farm animal feeding studies

The Meeting received information on the residue levels arising in tissues and milk when dairy cows were fed a diet containing flutriafol at dietary levels of 5, 16 and 50 ppm for 28 consecutive days. Residues in whole milk were < 0.01 mg/kg. In cream, residues were < 0.01 mg/kg except for Day 21 where a residue of 0.01 mg/kg was detected. The highest residues (mean in brackets) in liver, kidney, fat and muscle from the 50 ppm dose group were 1.95 (1.83), 0.15 (0.10), 0.34 (0.19) and 0.07 (0.04) mg/kg respectively.

Animal commodity maximum residue levels

Dietary burden calculations for beef cattle and dairy cattle and poultry are provided below. The dietary burdens were estimated using the OECD diets listed in Appendix IX of the 2009 edition of the FAO Manual.

Potential cattle and poultry feed items include maize, peanut, soya bean and wheat commodities.

Summary of livestock dietary burden (ppm of dry matter diet)

	US-Canada		EU		Australia		Japan	
	max	mean	Max	mean	max	Mean	max	Mean
Beef cattle	1.8	1.07	20.7 [a]	9.76 [c]	76	32	0.161	0.161
Dairy cattle	19.0	8.3	19.1 [b]	8.7 [d]	49.8	21.2	4.3	2.8
Poultry Broiler	0.26	0.26	0.24	0.24	0.24	0.24	0.23	0.23
Poultry Layer	0.26	0.26	7.9 [e]	3.45 [f]	0.24	0.24	0.20	0.20

[a] Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian meat

[b] Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

[c] Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat

[d] Highest mean dairy cattle dietary burden suitable for STMR estimates for milk

[e] Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs

[f] Highest mean poultry dietary burden suitable for STMR estimates for poultry meat and eggs.

The maximum dietary burden for cattle exceeds the maximum dosing level used in the feeding studies. It was noted that the dietary burdens are driven by the residues in wheat forage from trials that matched GAP in the USA (selected with a 0 day PHI) and that it may be possible to further refine the dietary burdens. In Australia, flutriafol is approved for use on wheat but the anticipated residues in forage are much lower as GAP requires a 49 day interval between last application and grazing and on other cereals with a 70 day interval for grazing. At these intervals

residues in forage and fodder are less than 3 mg/kg and the cattle dietary burdens for Australia listed in the table are overestimates. The Meeting decided to recalculate the cattle dietary burdens for Australia discounting cereal forages.

Additional refinement is also possible for the EU livestock burdens as in the EU uses on cereals are understood as "on cereal for grain production" and therefore, only residues in grains and straw are considered for the animal burden calculation and to utilise the cattle dietary burdens for the EU in estimating residues in cattle commodities (http://www.efsa.europa.eu/sites/default/files/event/140619-m.pdf). The maximum dietary burdens on refinement are 10.5 and 4.2 ppm for the maximum and mean burdens for beef and dairy cows in the Australian region. The refined poultry dietary burdens are 1.35 and 0.75 ppm for the maximum and mean burdens for laying hens in the EU region.

Animal commodity maximum residue levels

The calculations used to estimate highest total residues for use in estimating maximum residue levels, STMR and HR values are shown below.

Flutriafol feeding study	Feed level	Residues	Feed level	Residues (mg/kg) in			
	(ppm) for milk residues	(mg/kg) in milk	(ppm) for tissue residues	Muscle	Liver	Kidney	Fat
MRL and HR beef or dairy cattle							
Feeding study [a]	16	< 0.01	16	< 0.01	0.77	0.02	0.02
Dietary burden and high residue	10.5	< 0.0066	10.5	0.0066	0.505	0.013	0.013
STMR beef or dairy cattle							
Feeding study [b]	16	< 0.01	5	< 0.01	0.33	< 0.01	< 0.01
Dietary burden and median residue	4.2	< 0.0026	4.2	< 0.008	0.277	< 0.008	< 0.008

[a] Highest residues for tissues and mean residues for milk

[b] Mean residues for tissues and mean residues for milk

The Meeting estimated a maximum residue levels of 0.01 (*) mg/kg for milk, 0.02 mg/kg for mammalian meat [in the fat], 0.02 for mammalian fats (except milk fats) and 1 mg/kg for mammalian edible offal.

The refined maximum dietary burden for broiler and layer poultry is lower than that estimated by the 2011 JMPR at 1.35 ppm and is now lower than the highest dose level in the feeding study of 5.0 ppm. The Meeting utilised the refined estimates of poultry dietary burdens and estimated maximum residue levels of 0.01 (*) mg/kg for poultry meat, 0.02 mg/kg for poultry fats, 0.03 mg/kg for poultry edible offal and 0.01 (*) mg/kg for eggs.

Flutriafol feeding study	Feed level	Residues	Feed level	Residues (mg/kg) in			
	(ppm) for egg residues	(mg/kg) in eggs	(ppm) for tissue residues	Muscle	Liver		Fat
MRL and HR chickens							
Feeding study [a]	5	0.03	5	< 0.01	0.10		0.07
Dietary burden and high residue	1.35	0.0081	1.35	< 0.0027	0.027		0.0189
STMR chickens							
Feeding study [b]	5	0.03	5	< 0.01	0.07		0.06
Dietary burden and residue estimate	0.75	0.0045	0.75	0.0015	0.0105		0.009

[a] Highest residues for tissues and mean residues for eggs

[b] Mean residues for tissues and mean residues for eggs

RECOMMENDATIONS FURTHER WORK OR INFORMATION

On the basis of the data obtained from supervised residue trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with MRL and for estimation of dietary intake (for animal and plant commodities): *flutriafol.*

Definition of the residue for compliance with MRL and estimation of dietary intake (for animal and plant commodities): flutriafol.

The residue is fat soluble.

Table of recommendations

DIETARY RISK ASSESSMENT

Long-term intake

The 2011 JMPR established an Acceptable Daily Intake (ADI) of 0–0.01 mg/kg bw for flutriafol.

The evaluation of flutriafol resulted in recommendations for MRLs and STMR values for raw and processed commodities. Where data on consumption were available for the listed food commodities, dietary intakes were calculated for the 17 GEMS/Food Consumption Cluster Diets. The results are shown in Annex 3.

The IEDIs in the seventeen Cluster Diets, based on the estimated STMRs were 3–10% of the maximum ADI (0.01 mg/kg bw). The Meeting concluded that the long-term intake of residues of flutriafol from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The 2011 JMPR established an Acute Reference Dose (ARfD) of 0.05 mg/kg bw for flutriafol. The International Estimated Short-term Intake (IESTI) for flutriafol was calculated for raw and processed commodities for which maximum residue levels, HR and STMR values were estimated. The results are shown in Annex 4 to the 2015 Report.

The IESTI represented greater than 100% of the ARfD of 0.05 mg/kg bw in the case of leaf lettuce (360% children; 120% general population), mustard greens (350% children; 140% general population) and spinach (490% children; 150% general population). No alternative GAP was available. On the basis of information provided to the JMPR, the Meeting concluded that the short-term intake of residues of flutriafol from consumption of leaf lettuce, mustard greens and spinach may present a public health concern.

Estimates of intake for the other commodities considered by the 2015 JMPR were within 0–90% of the ARfD. The Meeting concluded that the short-term intake of flutriafol for these other commodities considered is unlikely to present a public health concern when flutriafol is used in ways that considered by the Meeting.

FLUXAPYROXAD (256)

First draft prepared by Dr S Margerison, Australian Pesticides and Veterinary Medicines Authority, Canberra, Australia

EXPLANATION

Fluxapyroxad is a fungicide belonging to the carboxamide group of chemicals. It acts through inhibition of the enzyme succinate dehydrogenase, which is also known as complex II, in the mitochondrial electron transport chain. It is used as a foliar and seed treatment fungicide for control of a range of fungal diseases in cereals, fruit and vegetables.

Fluxapyroxad was evaluated by JMPR for the first time in 2012, when an ADI of 0–0.02 mg/kg bw/day and an ARfD of 0.3 mg/kg bw were established. A residue definition of *fluxapyroxad* was recommended for plant and animal commodities, for compliance with MRLs. For estimation of dietary intake in plant commodities, a definition of *sum of fluxapyroxad, 3-(difluoromethyl)-N-(3',4',5'-trifluoro-1,1'-biphenyl-2-yl)-1H-pyrazole-4-carboxamide (M700F008), and 3-(difluoromethyl)-1-(β-D-glucopyranosyl)-N-(3',4',5'-trifluoro-1,1'-biphenyl-2-yl)-1H-pyrazole-4-carboxamide (M700F048), expressed as fluxapyroxad,* was recommended. For estimation of dietary intake in animal commodities, a definition of *sum of fluxapyroxad and 3-(difluoromethyl)-N-(3',4',5'-trifluoro-1,1'-biphenyl-2-yl)-1H-pyrazole-4-carboxamide (M700F008), expressed as fluxapyroxad,* was recommended. The residue is fat soluble.

At the 46th Session of the CCPR (2014), fluxapyroxad was scheduled for evaluation of additional use patterns by the 2015 JMPR.

The Meeting received residue data for citrus fruits, cherries, grapes, strawberries, caneberries, blueberries, mangoes, bananas, papaya, bulb vegetables, Brassica vegetables, cucurbits, leafy vegetables, root and tuber vegetables, celery, rice, sugar cane, almonds, pecans, and cotton (foliar application). Processing data for oranges, grapes, sugar cane and cotton were received. Product labels and information on MRLs established by national regulatory authorities were also provided.

Analytical methods

No new analytical methods were submitted to the Meeting. Residues of fluxapyroxad and its metabolites were determined using LC-MS/MS method number L0137/01 for all trials submitted to the Meeting. This method was reviewed by the 2012 Meeting. Appropriate concurrent recovery data was provided for all trials.

Stability of pesticide residues in stored analytical samples

Plant matrices

No new storage stability studies were submitted to the current Meeting. The 2012 Meeting evaluated the stability of residues of fluxapyroxad and the metabolites M700F002, M700F008, and M700F048 in a range of plant matrices. In the residue trials submitted to the Meeting, samples were analysed within 24 months of collection, within the period for which stability was verified by the studies submitted to the 2012 Meeting.

USE PATTERNS

Fluxapyroxad is a fungicide. It is registered for foliar and seed treatment use in a wide variety of fruits, vegetables, nuts, oilseeds, and cereals against a wide variety of diseases.

Table 1 Registered uses of fluxapyroxad on crops relevant to this submission

Crop	Country	Application						
		Formulation	Type	Rate, g ai/ha	Conc. (g ai/hL)	Spray volume (L/ha)	No. (RTI, days)	PHI, days

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received supervised trials for use of fluxapyroxad on citrus fruit (oranges, lemons and limes), cherries, berries and small fruits (grapes, blueberries, blackberries, raspberries and strawberries), tropical fruit, inedible peel (banana, papaya and mango), bulb vegetables (onion, bulb and green onion), Brassica vegetables (cabbage and broccoli), fruiting vegetables, cucurbits (cucumber, summer squash, melon (cantaloupe), and watermelon), leafy vegetables (head lettuce, leafy lettuce, spinach and mustard greens), root and tuber vegetables (carrots, radish and potato), celery, rice, sugar cane, tree nuts (almonds and pecans), and cotton.

Residue data for stone fruit, potatoes, sugar beet, and sorghum evaluated by the 2012 Meeting are also tabulated below. The data tables have been taken unaltered from the 2012 evaluation. These data were evaluated against registered uses for these crops submitted to the current Meeting.

In all trials, residues were determined using method L0137/01. The method LOQ was 0.01 mg/kg for each analyte as measured, or 0.01, 0.02, 0.01 and 0.01 mg/kg as parent equivalents for parent, M700F002, M700F008, and M700F048 respectively. For replicate samples from the same plot, the mean value was used for maximum residue level estimation, with the individual results being given in brackets. All residues below the LOQ are reported as < the appropriate LOQ value, as parent equivalents. For multiple trials from the same location in the same year, results from the trial yielding the highest residue were used for estimation of maximum residue levels and dietary intake assessment.

For dietary intake assessment, the residues are expressed as the sum of fluxapyroxad, M700F008, and M700F048, expressed as fluxapyroxad (total residues). Residues of the metabolites are reported as parent equivalents.

Citrus fruits

Residue trials in oranges, lemons and limes were conducted in Brazil and Argentina (Dantas *et al.*, 2012 and Guimaraes, 2014-a). Three foliar applications of an SC formulation containing 167 g/L fluxapyroxad and 333 g/L pyraclostrobin were made at each site using an airblast sprayer.

				14	Peel	0.11	< 0.02	< 0.01	< 0.01	0.11
				14	Pulp	< 0.01	< 0.02	< 0.01	< 0.01	< 0.01

No residues were detected in the untreated control samples

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad

[b] Residues in whole fruit were determined by analyses of separate sub-samples, not by summing the residues in peel and pulp after adjusting for the mass fraction of each portion. Hence, residues in whole fruit may not correspond with the values expected based on typical proportions of peel and pulp in oranges.

[a] All analytes are reported in terms of themselves, except for the 2011 trials where residues are expressed as parent equivalents. Total residues ((Fluxapyroxad + M700F008 + M700F048) are expressed as parent equivalents.

LOQ is 0.01 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

LOD is 0.002 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

Berries and other small fruits

Blueberries

Residue trials in blueberries (highbush type) were conducted in the USA (Korpalski, 2012-b). Three foliar applications of a 62.5 g/L EC formulation were made at each site using hand-held equipment. A spray adjuvant (non-ionic surfactant or crop oil concentrate) was included with all applications. Duplicate fruit samples were collected on the day of the last application, with additional samples being collected at intervals up to 7 days after the last application at one site in order to generate decline data.

Grapes

Residue trials in grapes were conducted in the USA (Belcher and Riley, 2012-a). Three applications of a 300 g/L SC formulation of fluxapyroxad were made at target rates of 200 g ai/ha using an airblast or backpack sprayer. An adjuvant (non-ionic surfactant, crop oil concentrate or organosiloxane) was included in all tank mixes. Duplicate treated fruit samples were collected at intervals from 0–21 days after the last application.

Table 11 Residues of fluxapyroxad and metabolites in grape berries

No residues were detected in the untreated control samples

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad

Strawberries

Residue trials in strawberries were conducted in the USA (Korpalski, 2012-a, and Lange and Korpalski, 2013).

Three foliar applications of a 62.5 g/L EC formulation were made at each site using hand-held equipment. A spray adjuvant (non-ionic surfactant or crop oil concentrate) was included with all applications. Duplicate treated fruit samples were collected on the day of the last application, with additional samples being collected at intervals up to 7 days after the last application at one site in order to generate decline data.

No residues were detected in the untreated control samples

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad

Tropical fruit—inedible peel

Banana

A total of 12 trials was conducted in bananas in Brazil (Guimaraes, 2013-a), Costa Rica, Ecuador and Colombia (Guimaraes, 2013-b). Four applications of a 300 g/L SC formulation were made at a target rate of 150 g ai/ha using a pressurised backpack sprayer. A mineral oil and an emulsifier were included in the spray tank for each application. Prior to application, half the fruits in each plot were covered with plastic bags. Bananas (both bagged and unbagged) were sampled at 0, 1, 5 and 10 days after the last application for the decline trials, and at day 0 only for the single point trials. In the single point trials, separate analyses of peel and pulp were conducted.

Mango

Four trials in mangoes were conducted in Brazil (Dantas and Cardoso, 2012). Four applications of an SC formulation containing 333 g/L pyraclostrobin + 167 g/L fluxapyroxad were made a target rate of 0.4 L/ha (0.133 kg ai/ha pyraclostrobin + 0.067 kg ai/ha fluxapyroxad) and a target interval of 7 days. Fruit was sampled 7 days after the last application, with additional samples being collected at intervals from 0–14 days at two sites to generate decline data.

Papaya

Four trials in papaya were conducted in Brazil (Jones, 2011). Four applications of an SC formulation containing 333 g/L pyraclostrobin and 167 g/L fluxapyroxad were made at a target rate of 50 g ai/ha fluxapyroxad (and 100 g ai/ha pyraclostrobin) at target intervals of 7 days using backpack sprayers. Spray adjuvants were not used in any of the applications. Fruit samples were collected at 7 days after the last application, with additional samples being collected at 0 and 14 days after the last application at the decline trial sites.

Bulb vegetables

Bulb onion

A series of trials in dry bulb onions was conducted in the USA (Csinos, 2012-a). Three foliar broadcast applications of a 62.5 g/L EC formulation were made at a target rate of 200 g ai/ha and a target interval of 7 days using pressurised backpack sprayers. Duplicate treated samples were collected at 7 days after the last application, with additional samples being collected at intervals from 0 to 14 days at one site to generate decline data.

Brassica vegetables

Broccoli

A series of trials in broccoli was conducted in the USA during 2011 and 2012 (Schreier, 2013-a). Three foliar broadcast applications of either a 62.5 g/L EC or a 300 g/L SC formulation of fluxapyroxad were made at target rates of 100 or 200 g ai/ha and an interval of 7 days. Duplicate broccoli head samples were collected at 0 and 3 days after the last application, with additional decline samples being collected from one site.

Fruiting vegetables, Cucurbits

Melons, except watermelon

A series of trials in melons (cantaloupe) was conducted in the USA (Csinos, 2012-b). Three foliar broadcast applications of a 62.5 g/L EC formulation of fluxapyroxad were made using pressurised backpack handheld sprayers at a target rate of 200 g ai/ha and a target interval of 7 days. Duplicated treated samples were collected on the day of the last application, with additional samples being collected at intervals up to 7 days at one site to generate decline data.

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad

A second series of trials was conducted in melons in Brazil (Guimaraes, 2010-a). Four foliar applications of an SC formulation (167 g/L fluxapyroxad and 333 g/L pyraclostrobin) were made at a target rate of 0.058 kg ai/ha fluxapyroxad + 0.117 kg ai/ha pyraclostrobin and a target interval of 7 days. Three trials were run as single point trials with sampling at 7 days after the last

application, and the other two were run to a reverse decline design, generating residues data for intervals of 0–28 days after the last application.

Watermelon

Trials in watermelon were conducted in Brazil (Guimaraes, 2010-b). Four applications of an SC formulation containing 167 g/L fluxapyroxad and 333 g/L pyraclostrobin were made at a target rate of 0.058 kg ai/ha fluxapyroxad + 0.117 kg ai/ha pyraclostrobin and an interval of days. Two single point residue trials, with scheduled sampling at 7 days after the last application were conducted along with two reverse decline design trials, giving decline data from 0 to 10 days after the last application.

Leafy vegetables

Lettuce, head

A series of trials in head lettuce was conducted in the USA (Schreier, 2013-b). Three foliar broadcast applications of a 62.5 g/L EC or a 300 g/L SC formulation were made at a target rate of 200 g ai/ha

and a target interval of 7 days using pressurised backpack sprayers. Duplicate treated samples were collected 0 and 1 day after the last application, with additional decline data samples being collected at one site.

Root and tuber vegetables

Carrot

A series of trials in carrots was conducted in the USA (Norris, 2012 and Schreier, 2015). Three applications of fluxapyroxad as a 62.5 g/L EC formulation were made a target rate of 100 g ai/ha and a target interval of 7 days. Carrot roots (duplicate samples) were sampled at 7 days after the last application, with additional samples being collected from 0-14 days at one decline trial site.

Potato

A number of residue trials in potatoes were conducted in Europe (Kramm, 2013-a, and Schaufele, 2013). Applications of a 300 g/L SC formulation were made using handheld equipment, at planting. The application was made in two passes, the first in the open furrow prior to sowing the seed potatoes, and the second over the top of the seed potatoes prior to filling in the furrow. The target total rate was 0.25 kg ai/ha. Samples of tubers were collected shortly prior to and at normal harvest maturity (BBCH growth stage 47–49).

In another study (Kramm, 2013-b), seed potatoes were treated with a 300 g/L fluxapyroxad SC formulation at a target rate of 0.006 kg ai/100 kg prior to planting. At the planting rate of 2500 kg/ha, this corresponds to a nominal application rate of 150 g ai/ha. Samples of tubers were collected shortly prior to and at normal harvest maturity (BBCH growth stage 47–49).

[a] All analytes are reported in terms of themselves. Total residues (**(**Fluxapyroxad + M700F008 + M700F048**)** are expressed as parent equivalents.

LOQ is 0.01 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

LOD is 0.002 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

Radish

A series of trials in radish was conducted in the USA (Norris, 2012). Three applications of fluxapyroxad as a 62.5 g/L EC formulation were made a target rate of 100 g ai/ha and a target interval of 7 days. Duplicate samples of radish roots and tops were collected at 7 days after the last application.

Table 36 Residues of fluxapyroxad and its metabolites in radish roots

Location, Year (variety)	Application				Residues, mg/kg, parent equivalents				
	No. (RTI, days)	Rate, g ai/ha	Spray volume (L/ha)	DALA	Fluxapyroxad	M700 F002	M700 F008	M700 F048	Total*

No residues were detected in the untreated control samples

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad equivalents

Sugar beet

Residue trials in sugar beet were considered by the 2012 Meeting and the data is reproduced below.

Table 37 Residues in sugar beet roots from the foliar application of fluxapyroxad to sugar beet in the USA and Canada (Johnston and Saha 2010, 2009/7003643)

[a] All analytes are reported in terms of themselves. Total residues ((Fluxapyroxad + M700F008 + M700F048) are expressed as parent equivalents.

LOQ is 0.01 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

LOD is 0.002 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

Celery

A series of trials in celery was conducted in the USA (Schreier, 2013-b). Three applications of a 62.5 g/L EC formulation of fluxapyroxad were made at a target rate of 200 g ai/ha, and an interval of 7 days. Duplicate treated samples were collected at 0 and 1 days after the last application, with additional decline samples being collected at a single site.

Table 38 Residues of fluxapyroxad and its metabolites in celery (untrimmed leaf stalks)

Residues were generally undetectable in the untreated control samples, apart from a single detection of parent compound at a level < LOQ

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad

Cereals

Rice

A series of trials in rice was conducted in the USA (Thiel, 2012). Two foliar broadcast applications of a 300 g/L SC formulation of fluxapyroxad were made using backpack boom sprayers at a target rate of 150 g ai/ha, and a target interval of 7 days. An adjuvant (non-ionic surfactant, fatty acid methyl ester, or crop oil concentrate) was included in the tank mix for all applications. Duplicate treated samples of rice grain with husk were collected 28 days after the last application, with additional decline samples being collected from some sites.

Residue data for rice straw is tabulated in Table 39 below.

Table 39 Residues of fluxapyroxad and metabolites in rice (with husk)

[a] All analytes are reported in terms of themselves. Total residues (**(**Fluxapyroxad + M700F008 + M700F048**)** are expressed as parent equivalents.

LOQ is 0.01 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

LOD is 0.002 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

Sugar cane

A series of trials in sugar cane (Schreier, 2012-b) was conducted in the USA. Two foliar broadcast applications of a 62.5 g/L EC formulation of fluxapyroxad were made at a target rate and interval of 0.125 kg ai/ha and 14 days using pressurised backpack sprayers. At one of the trial sites, a second treated plot was established, with 2× 0.625 kg ai/ha applications being made in order to generate raw sugar cane for processing (see below for further details of the processing phase of this study). Duplicate treated samples of sugar cane were collected by hand at a target interval of 14 days after the last application.

No residues of metabolites were detected in the untreated control samples, while residues of fluxapyroxad at levels < LOQ were found at four of the eight trial sites

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad equivalents

Tree nuts

Five trials each in almonds and pecans were conducted in the USA (Wyatt, 2012). Three foliar applications of a 62.5 g/L EC formulation were made at each site using an airblast sprayer. A spray adjuvant was included for all applications. Duplicate samples of treated kernels were collected a target interval of 14 days after the last application, with samples being collected at additional intervals from some sites to generate decline data.

Cotton

A series of residue trials in cotton were conducted in the USA (Schreier, 2014). Three foliar applications of a 62.5 g/L EC formulation of fluxapyroxad were made at a target rate of 0.1 kg ai/ha and a target interval of 7 days using hand held or tractor-mounted equipment. The plots were harvested at maturity by hand or by mechanical picker, then bolls were ginned to generate undelinted seed samples, with additional gin by-products samples from three sites (see below).

[a] All analytes are reported in terms of themselves. Total residues (**(**Fluxapyroxad + M700F008 + M700F048**)** are expressed as parent equivalents

LOQ is 0.01 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

LOD is 0.002 mg/kg for each of parent fluxapyroxad and metabolites M700F008, M700F002 and M700F048

Moisture content was determined for selected control samples using an infrared moisture determination balance

Fate of residues in processing

Citrus

A processing study in oranges was conducted in Brazil (Guimaraes, 2014-b). At four field trial sites, three applications of an SC formulation containing 333 g/L pyraclostrobin and 167 g/L fluxapyroxad were made by foliar airblast application at a target rate of 0.5 kg ai/ha pyraclostrobin + 0.25 kg ai/ha fluxapyroxad and a target interval of 28 days. Fruit was collected 14 days after the last application.

Oranges were processed into juice, dried pulp and oil using simulated commercial procedures. Untreated control samples were processed prior to the treated samples. Samples for processing (around 250 kg per sample) were first washed using an industrial water bath equipped with rotary brushes. The cleaned oranges were then juiced using a commercial machine (JBT model HP 391 citrus juice extractor). This juices the oranges by compressing the fruit between two cups with sharpened metal tubes at their bases. A water spray was maintained to separate the oil as an emulsion, with the oil separated from the wash water by centrifuging and decanting. The pulp/juice mixture was separated in a commercial finisher (JBT model UCF 35).

Residues of fluxapyroxad and its metabolites were determined using LC-MS/MS method number L0137/01. Processing was completed within a day of sample collection, and both raw orange and processed commodity samples were frozen within 24 hours of collection. Analyses were completed within 3 months of harvest of the raw oranges.

Grape

A processing study in grapes was conducted in the USA (Belcher and Riley, 2012-b).

At two sites, grapevines were treated with three foliar airblast applications of a 300 g/L SC formulation of fluxapyroxad at a target rate of 0.4 kg ai/ha and a target interval of 10 days. Two plots, one each of a red and a white grape variety, were treated at each site using the same application regime. Grape samples were collected 14 days after the last application.

Grapes were processed using methods simulating commercial processes as far as possible. The grapes (40–80 kg per sample for processing) were first crushed using a crusher/de-stemmer, and the stems were separated and for red grapes only, the stems and initial crush were sampled. The crush was then subdivided into portions for juice and wine making.

The crushed grapes (approx. 10–25 kg of crush were reserved for juicing) were transferred to a steam-jacketed kettle and heated to 52–57 °C for 8–12 minutes, and then to 60–66 °C for 8–12 minutes. The grape pulp was then pressed using a hydraulic fruit press, and wet pomace was separated. The fresh juice was filtered and pasteurised (79–85 °C for 15–30 seconds). Pasteurised juice was sampled.

For white/rosé winemaking, was approximately 20–35 kg of grape crush were transferred to a kettle, treated with pectic enzyme and potassium metabisulphite and allowed to stand for 1 hour, prior to pressing with a hydraulic press. Primary fermentation was conducted in a 5-gallon container. Yeast was added, and the container allowed to stand overnight at approximately 21 °C. The wine was racked to separate the lees, and transferred to glass carboys for secondary fermentation at approximately 13 °C until the specific gravity reached approximately 1.03. Once

carbon dioxide formation had ceased indicating completion of fermentation, the wine was racked again and gelatin added for fining. The wine was then racked a final time, and filtered through diatomaceous earth before sampling.

For red winemaking, the process was similar to white winemaking, with the addition of a step after the initial crushing and separation of the stems where the juice/pulp mixture was heated to approximately 60 °C to impart colour to the wine, then cooled to approximately 21 °C before addition of the enzyme and sodium metabisulphite. The processing then proceeded as for the white/rosé wine.

For generation of the raisin samples, grapes were harvested and sun dried in the field for 3–13 days before sampling (approx. 1.0–1.3 kg of sun dried grapes per sample). At the processing facility, the raisins were hand sorted to remove loose dirt and debris, stems, panicles and substandard raisins. The cleaned raisins were then spray washed in batches to remove any residual dirt and to raise the water content to $\leq$ 18%. The raisins were drained and dried if necessary to achieve the desired water content.

Residues of fluxapyroxad and its metabolites were determined using LC-MS/MS method number L0137/01. Processing of raw grapes into juice and wine commenced within 1–3 days of harvest, while processing of the sun dried raisins took place around 4–6 weeks after sampling. Raw grape samples for analysis were frozen within 4 hours of collection. Grapes for processing into juice and wine were shipped to the processor at ambient temperature and stored in a cooler pending processing. Raisins were shipped to the processor at ambient temperature, and stored frozen pending further processing. On completion of processing, processed commodity samples were frozen pending analysis. All analyses were completed within 5 months of harvest of the grapes.

Sugar cane

A sugar cane processing study was carried out in the USA (Schreier, 2012-b). At a site in Florida, a plot was treated at 2× 0.625 kg ai/ha, with a 14-day re-treatment interval, and sample collection 14 days after the last application.

Sugar cane samples (approximately 40 kg) were processed by expelling the juice by multiple passes through an AUM Enterprise cane crusher. The waste (bagasse) was discarded, while the juice was filtered (100 mesh sieve) and adjusted to pH 7.2–7.4 using calcium oxide solution. After stirring for approximately 15 minutes, the juice was brought to approximately 100 °C and held at that temperature for 3 minutes, then centrifuged to separate the 'mud' from 'thin juice'. The thin juice was concentrated to a solids content of 50–60% using a vacuum evaporator, at a temperature of ≤ 70 °C. Further concentration, to a solids content of 75–80%, was carried out at ≤ 55 °C. The resulting thick juice was seeded with a small amount of pulverised white sugar to commence the crystallisation process, and the batch cooled in a walk-in refrigerator. Molasses and raw sugar were separated by centrifuge, and the raw sugar was washed in the centrifuge to remove molasses by steaming prior to sampling. Refining was carried out by dissolving the raw sugar in an equal amount of water with stirring. The pH was adjusted to 5.5 with phosphoric acid, and the solution rested for 2 minutes prior to addition of calcium oxide under agitation to adjust the pH to 7.2. The batch was heated to 60 °C. Filter aid was added, and the solution was vacuum filtered. Activated charcoal was added to the filtrate, which was heated and then filtered again. The filtrate was seeded with pulverised sugar and evaporated under vacuum at ≤ 55 °C until the boiling slowed. The material was cooled, then dried at 43–55 °C to a moisture content of approximately 3%. Samples of unprocessed cane, molasses, raw sugar and refined sugar were collected and frozen for transport to the laboratory.

The process simulated commercial processing, albeit using a batch rather than a continuous process due to the small amount of material.

Samples of sugar cane and the processed commodities were analysed using LC-MS/MS method number L0137/01. Samples were analysed within 14 months of collection of the raw sugar cane, and within 9 months of finishing the processing phase. Raw sugar cane was stored frozen pending processing, which commenced 4 months after harvest, and was completed within a week (processed samples were frozen after collection).

Refined sugar	< 0.04	< 0.04

Cotton

A processing study in cotton was conducted in the USA (Woodard and Brungardt, 2014). Field trials were conducted at two sites. Three foliar broadcast applications of an SC formulation (333 g/L pyraclostrobin and 167 g/L fluxapyroxad) were made at a target rate of 3 L/ha and a target interval of 7 days. A spray adjuvant (non-ionic surfactant) was included in the tank mix for all applications. Cottonseed was harvested 30 days after the last application. Sample of treated and control raw cottonseed from each site were ginned within 1 day of harvest, frozen, and transported to the laboratory. Bulk treated and control seed samples were collected and transported to the processor, either frozen (Hinton site) or at ambient temperature (Sanger site). At the processing site, all samples were stored frozen pending processing, which took place around 4–6 weeks after harvest.

Cottonseed samples (approximately 70 kg per sample) were processed using batch methods simulating commercial processes as far as possible. Control samples were processed prior to treated samples to minimise contamination. Defrosted seed samples were tested for moisture, and dried if necessary to reduce the moisture content below 8%. The seed was passed through a stick/burr extractor to remove gin trash, then ginned to separate the cotton seed and lint. Undelinted cottonseed was sampled at this point. Further delinting was then carried out in a delinter to reduce the remaining lint from 11–15% to 3%. Using a roller mill, the delinted seed was cracked, and the kernel and hulls separated using a screen cleaner. Hulls were sampled at this point.

The moisture content of the kernel was checked, and water added to give a moisture level of ≥ 13.5% if necessary. After moisture equilibration, the kernels were heated to approximately 80–90 °C for approximately 30 minutes, then flaked and fed through an extruder with steam injection to produce collets. The collets were ground, dried in an oven at approximately 65–80 °C for 35–40 minutes, then extracted three times with hexane in stainless steel reactors at approximately 50–60 °C. The residual solvent allowed to evaporate from the meal, and the moisture content of the meal adjusted to ≥ 13.5% if necessary. The meal was then screened, and toasted at approximately 105–115 °C for 45–60 minutes, then cooled and sampled. A vacuum evaporator operating at approximately 90–95 °C was used to separate the crude oil from the extraction solvent.

The free fatty acid content of the crude oil was determined, and the required amount of sodium hydroxide solution was added for refining. Refining was carried out by heating with a water bath at approximately 20–25 °C with high rpm stirring for approximately 15 minutes, followed by approximately 12 minutes at low rpm and approximately 65 °C. The refined oil and soapstock were separated by centrifuge and the soapstock was discarded. The refined oil was filtered and bleached by heating at 40–50 °C with diatomaceous earth under vacuum. The temperature was increased to 85–100 °C for 10–15 minutes, then the oil was cooled and filtered. The bleached oil was deodorised by heating to 220–230 °C under vacuum for approximately 30 minutes, and adding 1 mL 0.5% citric acid solution per 100 mL oil. The deodorised oil was sampled.

All processed samples were frozen immediately after collection.

Residues of fluxapyroxad and its metabolites were determined using LC-MS/MS method number L0137/01. All analyses of cottonseed and processed commodities were completed within

3 months of collection of the seed samples and within approximately 1 month of completion of processing.

Table 55 Residues of fluxapyroxad and metabolites in cottonseed and processed fractions

Location, Year (variety)	Applications					Residues, mg/kg, parent equivalents			
	No. (RTI, days)	Rate, g ai/ha	Spray volume (L/ha)	DALA	Sample	Fluxapyroxad	M700 F008	M700 F048	Total*
Hinton, OK, USA, 2013 (FM9160 B2)	3 (6, 7)	510, 510, 510	190, 190, 200	30	Undelinted seed	0.14	<0.01	<0.01	0.14
					Undelinted seed pre-processing	0.64 (0.54, 0.74)	<0.01 (<0.01, <0.01)	<0.01 (<0.01, <0.01)	0.64 (0.54, 0.74)
					Meal	0.025	<0.01	<0.01	0.025
					Hulls	0.11	<0.01	<0.01	0.11
					Refined oil	0.015	<0.01	<0.01	0.015
Sanger, CA, USA, 2013 (FM835LLB2)	3 (7, 6)	500, 500, 500	190, 190, 190	29	Undelinted seed	0.16 (0.093, 0.21, 0.16, 0.16)[#]	<0.01 (<0.01, <0.01, <0.01)	<0.01 (<0.01, <0.01, <0.01)	0.16 (0.093, 0.21, 0.16, 0.16)

					Meal	<0.01	<0.01	<0.01	<0.01
					Hulls	0.028	<0.01	<0.01	0.028
					Refined oil	<0.01	<0.01	<0.01	<0.01

Apart from one of the oil samples, where residues of parent < LOQ were detected, residues were generally not detected in the untreated control samples

[a] Sum of fluxapyroxad, M700F008, and M700F048 (the dietary risk assessment residue definition), expressed as fluxapyroxad equivalents

[b] Control and treated samples of undelinted seed obtained directly from the Sanger trial site appear to have been inadvertently swapped, given that the sample labelled as treated did not contain detectable residues of fluxapyroxad, while the sample labelled as the control contained finite fluxapyroxad residues at a level similar to that observed in the unprocessed seed subsampled from the bulk treated sample for processing from the Sanger site. As a result, the finite residue sample will be regarded as the treated sample.

Table 56 Processing factors for fluxapyroxad in cottonseed

Commodity	Processing factor	
	Parent only	Total residues
Meal	0.04, < 0.07 (median = 0.055)	0.04, < 0.07 (median = 0.055)
Hulls	0.17, 0.2 (median = 0.185)	0.17, 0.2 (median = 0.185)
Refined oil	0.02, < 0.07 (median = 0.045)	0.02, < 0.07 (median = 0.045)

Residues in animal commodities

No new animal feeding studies were supplied to the Meeting.

APPRAISAL

Fluxapyroxad was first evaluated for residues and toxicological aspects by the 2012 JMPR. The 2012 Meeting established an ADI of 0–0.02 mg/kg bw and an ARfD of 0.3 mg/kg bw for fluxapyroxad. The 2012 Meeting recommended a number of maximum residue levels for fluxapyroxad.

The residue definition was established as *fluxapyroxad* for compliance with MRLs for both plant and animal commodities. For estimation of dietary intake, the residue definition was established as *sum of fluxapyroxad, 3-(difluoromethyl)-N-(3',4',5'-trifluoro-1,1'-biphenyl-2-yl)-1H-pyrazole-4-carboxamide (M700F008), and 3-(difluoromethyl)-1-(β-D-glucopyranosyl)-N-(3',4',5'-trifluoro-1,1'-biphenyl-2-yl)-1H-pyrazole-4-carboxamide (M700F048), expressed as fluxapyroxad* for plant commodities and *sum of fluxapyroxad and 3-(difluoromethyl)-N-(3',4',5'-trifluoro-1,1'-biphenyl-2-yl)-1H-pyrazole-4-carboxamide (M700F008),* expressed as *fluxapyroxad* for animal commodities.

Fluxapyroxad was scheduled by the Forty-sixth Session of the CCPR in 2014 for evaluation of residue data for additional crops by the 2015 JMPR.

Methods of analysis

No new methods of analysis were submitted to the Meeting.

Stability of residues in stored analytical samples

No new storage stability studies were submitted to the Meeting.

Results of supervised residue trials on crops

The Meeting received supervised trial data for foliar application of fluxapyroxad to citrus fruit, cherries, grapes, strawberries, blueberries, raspberries, bananas, papaya, mango, bulb vegetables, Brassica vegetables, cucurbits, leafy vegetables, carrots, radish, celery, rice, tree nuts, sugarcane and cotton, as well as data for seed treatment and in-furrow application to potatoes.

It is noted that a number of crops (bulb vegetables, Brassica vegetables, cucurbits, leafy vegetables, celery, rice, sorghum and cotton) for which the critical GAP considered is a foliar application use pattern in the USA also have seed treatment uses registered, and the same crops could be treated with both a seed treatment and foliar application of fluxapyroxad.

All residue data provided was for the foliar use pattern (no seed treatment data was available). The foliar use patterns involve application much closer to harvest, with multiple applications and much shorter pre-harvest intervals. The Meeting noted that residue data for seed treatment of cotton at rates up to 100 g ai/100 kg seed considered by the 2012 Meeting showed no detectable residues of fluxapyroxad in cottonseed or gin by-products at harvest. Seed treatment uses are therefore not expected to contribute significantly to the residues of fluxapyroxad in harvested commodities. The Meeting therefore considered that maximum residue levels recommended based on the foliar use patterns are sufficient to cover residues arising from seed treatment use alone, or combined seed treatment/foliar use.

For dietary intake assessment, the residues are expressed as the sum of fluxapyroxad, M700F008, and M700F048, expressed as fluxapyroxad (total residues). Residues of the metabolites are reported as parent equivalents.

The method LOQ was 0.01 mg/kg for each analyte as measured, or 0.01, 0.02, 0.01 and 0.01 mg/kg as parent equivalents for parent, M700F002, M700F008, and M700F048 respectively. The treatment of residues < LOQ for the purpose of summing residue components is illustrated in the table below.

Residues, mg/kg parent equivalents			Total (sum of fluxapyroxad, M700F008, and M700F048)
Fluxapyroxad	M700F008	M700F048	
0.10	< 0.01	< 0.01	0.10

< 0.01	< 0.01	< 0.01	< 0.01
< 0.01	0.03	< 0.01	0.03

Citrus fruits

The maximum GAP for the citrus fruit group is in Argentina, with 3× 0.0033 kg ai/hL applications, with a maximum spray volume of 5000 L/ha, giving a per hectare rate of 0.165 kg ai/ha, and a pre-harvest interval of 7 days. No trials matching that GAP were available.

The GAP in Brazil is 3× 0.0025 kg ai/hL applications at 7-day intervals, with a spray volume of 2000 L/ha (0.05 kg ai/ha), with a 14-day PHI.

Residue trials in oranges, lemons and limes in accordance with the Brazilian GAP were undertaken in Brazil and Argentina.

Residues of fluxapyroxad (parent only) in oranges (whole fruit) at a 14-day PHI were 0.03, 0.04, 0.05 (2), 0.06 (2), 0.07, 0.14 (2), 0.16, and 0.17 mg/kg.

Total residues in whole oranges were 0.03, 0.04, 0.05 (2), 0.06 (2), 0.07, 0.14 (2), 0.16, and 0.17 mg/kg.

Residue data in peel and pulp were available for some of the trials.

Total residues of fluxapyroxad in pulp (edible portion) in oranges (4 trials) and lemons (2 trials) were < 0.01 (6) mg/kg.

The Meeting concluded that there was sufficient edible portion data on which to estimate the STMR and HR for oranges.

The Meeting estimated a maximum residue level of 0.3 mg/kg for fluxapyroxad in oranges, sweet, sour, together with an STMR and an HR of 0.01 mg/kg (based on the edible portion data).

Residues of fluxapyroxad (parent only and total residues) in whole lemons at a 14-day PHI were 0.09 and 0.13 mg/kg.

Residues of fluxapyroxad (parent only and total residues) in limes at a 14-day PHI were 0.04 and 0.06 mg/kg.

The Meeting concluded that there were insufficient data available to estimate maximum residue levels for fruits other than oranges in the citrus fruit group.

Stone fruits

The critical GAP for the stone fruit group is in the USA, with 3× 0.123 kg ai/ha applications at 7-day intervals, and a 0-day pre-harvest interval.

Residue data in peaches, plums and cherries was considered by the 2012 Meeting in conjunction with the above GAP, and a group maximum residue level of 2 mg/kg was estimated for stone fruit.

A request was received by the present Meeting to reconsider the MRL for cherries, with a view to establishing a higher limit to facilitate trade, noting that the highest residue for stone fruit (in cherries) was 1.9 mg/kg. No new data for stone fruit were provided to the current Meeting: two cherry trials were submitted; however, these were considered by the 2012 Meeting. The 2012-submitted stone fruit data are reconsidered in accordance with the 2013 and 2014 JMPR general considerations relating to group MRLs.

Residues of fluxapyroxad (parent compound) in cherries from supervised trials in accordance with GAP were 0.26, 0.31, 0.55, 0.56, 0.59, 0.82, 1.1, and 1.9 mg/kg.

Total residues in cherries were 0.37, 0.50, 0.72, 0.73, 0.78, 1.1, 1.4, and 2.3 mg/kg.

Residues of fluxapyroxad (parent compound) in peaches from supervised trials in accordance with GAP were 0.28, 0.30, 0.32, 0.33, 0.34, 0.43, 0.45, 0.55, 0.57, 0.58, 0.59, and 0.63 mg/kg.

Total residues in peaches were 0.30, 0.31, 0.33, 0.34, 0.35, 0.45, 0.48, 0.58, 0.62, 0.63, and 0.66 (2) mg/kg.

Residues of fluxapyroxad (parent compound) in plums from supervised trials in accordance with GAP were 0.23, 0.24, 0.27, 0.37, 0.38, 0.49, 0.55, 0.56, 0.64, and 0.95 mg/kg.

Total residues in plums were 0.23, 0.24, 0.27, 0.38, 0.39, 0.49, 0.55, 0.56, 0.64, and 0.95 mg/kg.

The Meeting noted the use in the USA is for the stone fruit crop group. Although the median residues for each fruit differed by less than a factor of five, the Meeting decided to recommend maximum residue levels for the individual sub-groups of stone fruit as there are sufficient trials available for each sub-group. The Meeting estimated a maximum residue level for cherries of 3 mg/kg, together with an STMR and an HR of 0.755 and 2.3 mg/kg respectively. The Meeting estimated a maximum residue level of 1.5 mg/kg for the sub-group peaches, together with an STMR and HR of 0.465 and 0.66 mg/kg respectively. The Meeting estimated a maximum residue level of 1.5 mg/kg for the sub-group plums, together with an STMR and an HR of 0.44 and 0.95 mg/kg. The Meeting withdrew its previous recommendation of 2 mg/kg for stone fruit.

Berries and other small fruits (except grapes)

The critical GAP for bushberries, caneberries, low growing berries, and strawberries is in the USA, with 3× 0.2 kg ai/ha applications at 7-day intervals, and a 0-day pre-harvest interval.

A series of trials in blueberries (highbush type) was conducted in the USA. Residues of fluxapyroxad (parent only) immediately after the last of 3× 0.2 kg ai/ha applications were 1.3, 1.7, 2.4 (2), and 3.8 mg/kg.

Total residues were: 1.3, 1.7, 2.4 (2), and 3.8 mg/kg.

A trial in blackberries was conducted in the USA. Residues of fluxapyroxad (parent only and total residues) immediately after the last of 3× 0.2 kg ai/ha applications were 1.4 mg/kg.

A trial in raspberries was conducted in the USA. Residues of fluxapyroxad (parent only and total residues) immediately after the last of 3 × 0.2 kg ai/ha applications were: 2.0 mg/kg.

In a series of trials in strawberries conducted in the USA, residues of fluxapyroxad (parent only) immediately after the last of 3 × 0.2 kg ai/ha applications were: 0.21, 0.26, 0.76 (2), 0.87, 0.97, 1.0, and 2.3 mg/kg.

Total residues were: 0.22, 0.26, 0.76 (2), 0.87, 0.97, 1.0, and 2.4 mg/kg.

The Meeting noted that the GAPs for the subgroups bushberries, caneberries and low growing berries, and strawberries are the same, and noted that the medians for blueberries and strawberries differed by less than 5× (2.9×) and agreed to consider a group MRL. In determining which datasets to use for estimating the MRL, the Meeting noted that the datasets for blueberries and strawberries were not statistically similar (Mann-Whitney), and, based on the blueberries data set, estimated a maximum residue level of 7 mg/kg for berries and other small fruits (except grapes), together with an STMR and an HR of 2.4 and 3.9 mg/kg (based on the highest residue of duplicate samples) respectively.

Grapes

The critical GAP for grapes is in the USA, with 3× 0.2 kg ai/ha applications at 10-day intervals, and a 14-day pre-harvest interval.

A series of trials was conducted in the USA. Residues of fluxapyroxad (parent only) at a 14-day PHI after 3× 0.2 kg ai/ha applications were 0.11, 0.13, 0.23, 0.43, 0.51, 0.62, 0.71, and 1.4 mg/kg.

Total residues were: 0.11, 0.13, 0.23, 0.43, 0.51, 0.62, 0.71, and 1.4 mg/kg.

The Meeting estimated a maximum residue level of 3 mg/kg for fluxapyroxad in grapes, together with an STMR and an HR of 0.47 and 1.4 mg/kg respectively.

Tropical fruit—inedible peel

Banana

The critical GAP in bananas is 4× 0.15 kg ai/ha applications at 8-day intervals, with a 0-day pre-harvest interval, in Belize, Costa Rica, Dominican Republic, El Salvador, Guatemala, Honduras and Panama. Trials matching GAP and conducted in Brazil, Colombia, and Ecuador were available. Results were reported for both bagged and unbagged fruit for each trial plot; the results for unbagged bananas were considered for estimation of the maximum residue level and dietary risk assessment.

Residues of fluxapyroxad (parent compound) in unbagged bananas (whole fruit) after treatment in accordance with GAP were 0.06, 0.07, 0.08, 0.10, 0.14, 0.15, 0.16, 0.36, 0.66, 0.77, and 1.6 mg/kg.

Total residues of fluxapyroxad in banana pulp (edible portion) were 0.03 (2), 0.05, 0.06, 0.09, and 0.10 mg/kg.

The Meeting estimated a maximum residue level of 3 mg/kg for bananas, based on the whole fruit data, and an STMR and an HR of 0.055 and 0.10 mg/kg, based on the edible portion data.

Mango

The critical GAP for mango is in Brazil, with 4× 0.0067 kg ai/hL applications at 7-day intervals, a spray volume of up to 1000 L/ha (giving a maximum per-hectare rate of 0.067 kg ai/ha), and a pre-harvest interval of 7 days.

In trials conducted at GAP in Brazil, residues of fluxapyroxad (parent compound) at a 7-day PHI were 0.14, 0.16, 0.21, and 0.39 mg/kg. Total residues were 0.14, 0.16, 0.21, and 0.39 mg/kg.

The Meeting concluded that there was insufficient data to estimate a maximum residue level for mango.

Papaya

The critical GAP for papaya is in Mexico, with 2× 0.1 kg ai/ha applications at 14-day intervals, and a 7-day pre-harvest interval.

The Meeting concluded that the residue data did not match the GAP (maximum two sprays GAP versus four sprays in the trials).

Bulb vegetables

The critical GAP for the bulb vegetables group is in the USA (3× 0.2 kg ai/ha applications at 7-day intervals and a 7-day pre-harvest interval).

Residue trials were conducted in bulb onions (dry) and green onions.

Residues of fluxapyroxad (parent only) at a 7-day PHI in bulb onions were 0.03, 0.16, 0.23 (2), and 0.27 mg/kg.

Total fluxapyroxad residues were 0.03, 0.16, 0.23 (2), and 0.27 mg/kg.

The Meeting estimated a maximum residue level of 0.6 mg/kg for bulb onions, together with an STMR and an HR of 0.23 and 0.28 mg/kg respectively.

The Meeting agreed to extrapolate the maximum residue level, STMR and HR values estimated for bulb onions to garlic and shallot.

Residues of fluxapyroxad (parent only) at a 7-day PHI in green onions were 0.24 and 0.56 mg/kg.

Total fluxapyroxad residues were 0.24 and 0.56 mg/kg.

The Meeting concluded that there were insufficient data to estimate maximum residue levels for other crops in the bulb vegetables group.

Brassica vegetables

The critical GAP for Brassica vegetables is in the USA (3× 0.1 kg ai/ha applications, a re-treatment interval of 7 days, and a pre-harvest interval of 3 days).

Residue data in cabbage and broccoli from trials conducted in the USA in accordance with GAP were available to the Meeting.

Fluxapyroxad was accidentally applied at double the label application rate for one of the broccoli trials. The Meeting noted that the application rate was within the acceptable range of 0.3–4× GAP and that other parameters were in accordance with GAP. The Meeting agreed that this result could be scaled to GAP using proportionality.

Residues of fluxapyroxad (parent only) in broccoli (unscaled results) at a 3-day PHI were 0.17, 0.32, 0.35, 0.57, and 1.2 mg/kg. Total residues were 0.17, 0.34, 0.36, 0.61, and 1.5 mg/kg.

Residues of fluxapyroxad (parent only) in broccoli at a 3-day PHI were 0.17, 0.29 (s), 0.32, 0.35, and 1.2 mg/kg, where (s) indicates a result that was scaled to the proposed GAP.

Total residues in broccoli were 0.17, 0.31 (s), 0.34, 0.36, and 1.5 mg/kg.

Residues of fluxapyroxad (parent only) in cabbage (heads with wrapper leaves) at a 3-day PHI were 0.07, 0.11, 0.13, 0.14, 0.22, and 1.2 mg/kg.

Total residues in cabbage (head with wrapper leaves) were 0.07, 0.11, 0.14 (2), 0.22, and 1.3 mg/kg.

Total residues in cabbage heads (without wrapper leaves) were < 0.01, 0.01, 0.04 (2), 0.05, and 0.07 mg/kg.

The Meeting noted that the GAP was for the Brassica vegetables group and considered a group MRL. The Meeting further noted the similarity of the datasets (median for broccoli was 2.6× the median for cabbage, and agreed to consider a group MRL. In determining which datasets to use for estimating the MRL, the datasets were confirmed to be similar by the Mann-Whitney U test) and it was agreed to combine the datasets for the purpose of estimating a group maximum residue level.

Combined dataset for fluxapyroxad (parent only) in broccoli and cabbage (with wrapper leaves): 0.07, 0.11, 0.13, 0.14, 0.17, 0.22, 0.32, 0.35, 0.57, and 1.2 (2) mg/kg.

Combined dataset for total residues in broccoli and cabbage (with wrapper leaves): 0.07, 0.11, 0.14 (2), 0.17, 0.22, 0.31, 0.34, 0.36, 1.3, and 1.5 mg/kg.

The Meeting estimated a maximum residue level for Brassica vegetables of 2 mg/kg. Based on the data for total residues in cabbages with wrapper leaves removed, the Meeting estimated an STMR and an HR of 0.04 and 0.07 mg/kg respectively for cabbage. Based on the combined total residues data set, the Meeting estimated an STMR and an HR of 0.22 and 1.7 mg/kg respectively.

Fruiting vegetables, Cucurbits

The critical GAP for cucurbit fruiting vegetables is in the USA (3× 0.1 kg ai/ha, with a 7-day retreatment interval and a 0-day pre-harvest interval). Residue trials in excess of GAP (3× 0.2 kg ai/ha applications) were conducted in the USA in cucumber, melon (cantaloupe), and summer squash. Trials in melons, including watermelons were also conducted in Brazil, but these did not match the critical GAP (four applications rather than three, and the rate differed by more than ±30%).

Residue data for the crops at the appropriate PHI are summarized below.

Residues of fluxapyroxad (parent only and total residues) in cucumber: 0.03, 0.17 (2), and 0.24 mg/kg.

Residues of fluxapyroxad (parent only and total residues) in whole melons (other than watermelons): 0.05 (2), 0.08, 0.21, and 0.24 mg/kg.

Residues of fluxapyroxad (parent only and total residues) in summer squash: 0.05, 0.07, 0.10, 0.11, and 0.14 mg/kg.

Data for the three crops when scaled to the US GAP (divide by 2) are summarized below:

Residues of fluxapyroxad (parent only and total residues) in cucumber: 0.015, 0.085 (2), and 0.12 mg/kg.

Residues of fluxapyroxad (parent only and total residues) in melons (other than watermelons): 0.025 (2), 0.04, 0.105, and 0.12 mg/kg.

Residues of fluxapyroxad (parent only and total residues) in summer squash: 0.025, 0.035, 0.05, 0.055, and 0.07 mg/kg.

The Meeting noted that the GAP is for the cucurbit fruiting vegetables group and further noted that the datasets are similar (maximum difference in the median was 2.1×). In determining which datasets to use for estimating the MRL, the similarity of the datasets was confirmed by the Kruskal-Wallis test. The Meeting decided to combine the scaled datasets for the purpose of estimating a group maximum residue level.

The combined dataset for residues of fluxapyroxad (parent only) in cucumber, melon and summer squash is 0.015, 0.025 (3), 0.035, 0.04, 0.05, 0.055, 0.07, 0.085 (2), 0.105, and 0.12 (2) mg/kg.

The combined dataset for total residues in cucurbits (whole fruit) is 0.015, 0.025 (3), 0.035, 0.04, 0.05, 0.055, 0.07, 0.085 (2), 0.105, and 0.12 (2) mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg for fruiting vegetables, cucurbits, together with an STMR and an HR of 0.0525 and 0.13 mg/kg respectively.

Leafy vegetables

Brassica leafy vegetables

The critical GAP for Brassica leafy vegetables is in the USA (3× 0.1 kg ai/ha applications, a 7-day retreatment interval, and a 3-day pre-harvest interval).

Residue trials in mustard greens were conducted in the USA in accordance with GAP.

Residues of fluxapyroxad (parent only) at a 3-day PHI were 0.48, 0.57, 0.90, 1.7, and 1.9 mg/kg.

Total residues were 0.93, 1.3, 1.7, 2.7, and 3.1 mg/kg.

The Meeting agreed to extrapolate the residue data for mustard greens to the Brassica leafy vegetables subgroup. The Meeting estimated a maximum residue level of 4 mg/kg for brassica leafy vegetables, together with an STMR and an HR of 1.7 and 3.1 mg/kg respectively.

Leafy vegetables (except Brassica leafy vegetables)

The critical GAP for leafy vegetables other than Brassica leafy vegetables is in the USA (3× 0.2 kg ai/ha applications with a retreatment interval of 7 days, and a 1-day pre-harvest interval).

Residue trials in head lettuce, leaf lettuce, and spinach were conducted in the USA in accordance with the cGAP for leafy vegetables (except Brassica leafy vegetables).

Residues of fluxapyroxad (parent only and total residues) at a 1-day PHI in head lettuce were 0.14, 0.47, 0.51, 0.66, and 1.9 mg/kg.

Residues of fluxapyroxad (parent only) in leaf lettuce at a 1-day PHI were 2.7 and 4.4 mg/kg.

Total residues in leaf lettuce were 2.7 and 4.4 mg/kg.

Two of the residue trials reported as leafy lettuce were for cos lettuce varieties.

Residues of fluxapyroxad (parent only) in cos lettuce at a 1-day PHI were 3.3 and 6.2 mg/kg.

Total residues in cos lettuce were 3.4 and 6.2 mg/kg.

Residues of fluxapyroxad (parent only) in spinach at a 1-day PHI were 5.2, 6.0, 6.7, 8.3, and 11.5 mg/kg.

Total residues in spinach were 5.2, 6.3, 6.8, 8.8, and 12.2 mg/kg.

The Meeting estimated a maximum residue level of 4 mg/kg for head lettuce, together with an STMR and an HR of 0.51 and 2.0 mg/kg respectively.

The Meeting noted that there were insufficient leafy and cos lettuce data for estimation of maximum residue levels.

The Meeting estimated a maximum residue level of 30 mg/kg for spinach, together with an STMR and an HR of 6.8 and 13 mg/kg respectively.

Residue data for radish tops were also available from trials conducted on radish in the USA, in accordance with the GAP for root vegetables (3× 0.1 kg ai/ha, with a 7-day PHI).

Residues of fluxapyroxad (parent only) in radish tops at a 7-day PHI were 0.2 (2), 0.7, 1, and 4 mg/kg.

Total residues in radish tops were 0.4, 0.6, 1.2, 1.7, and 5 mg/kg.

The Meeting estimated a maximum residue level of 8 mg/kg for radish leaves, together with an STMR and HR of 1.2 and 6 mg/kg (based on the highest residue of duplicate samples) respectively.

Short term intake assessment showed that residues in spinach exceed the acute reference dose of 0.3 mg/kg bw, at 180% of the ARfD, for children.

Root and tuber vegetables

The 2012 Meeting considered residue data for potato and sugar beet, in accordance with GAP in the USA (3× 0.1 kg ai/ha foliar applications with 7-day retreatment interval and a 7-day PHI, and maximum residue levels of 0.03 and 0.15 mg/kg were estimated for potato and sugar beet respectively.

The current Meeting received residue data for potato (soil application at planting), carrots and radish (both for foliar applications).

Carrot

The critical GAP for carrots (for the group root and tuber vegetables except sugar beet) is in the USA, at 3× 0.1 kg ai/ha foliar applications, with a 7-day retreatment interval and a 7-day pre-harvest interval.

Trials were conducted in the USA in accordance with GAP.

Residues of fluxapyroxad (parent only and total residues) in carrots at a 7-day PHI were 0.04, 0.05, 0.06, 0.1, and 0.5 mg/kg.

Potato

A series of residue trials was conducted in northern and southern Europe involving a single, at planting, in-furrow application at 0.24 kg ai/ha. However, there are currently no registrations for that GAP. The Meeting therefore was unable to estimate a maximum residue level for potatoes based on at planting soil application.

The 2012 Meeting considered residue data for foliar application to potatoes from trials conducted in accordance with the US GAP for root and tuber vegetables (except sugar beet) group (3× 0.1 kg ai/ha foliar applications, with a 7-day pre-harvest interval).

Residues of fluxapyroxad (parent only and total residues) in potatoes at a 7-day PHI were < 0.01 (17), and 0.02 (2) mg/kg.

Radish

The critical GAP for radish (for the group root and tuber vegetables except sugar beet) is in the USA, at 3× 0.1 kg ai/ha foliar applications, with a 7-day retreatment interval and a 7-day pre-harvest interval.

Trials were conducted in the USA in accordance with GAP.

Residues of fluxapyroxad (parent only and total) in radish roots at a 7-day PHI were 0.03, 0.04, 0.05, and 0.1 (2) mg/kg.

Sugar beet

The critical GAP for sugar beet is in the USA, at 3× 0.1 kg ai/ha foliar applications, with a 7-day retreatment interval and a 7-day pre-harvest interval. Residue data for this GAP was considered by the 2012 Meeting.

Residues of fluxapyroxad (parent only and total residues) in sugar beet roots at a 7-day PHI were 0.01 (2), 0.03 (3), 0.04 (3), 0.05 (2), and 0.06 (2) mg/kg.

The Meeting noted that the critical GAPs for root and tuber vegetables (except sugar beet) and sugar beet were the same, and considered a group maximum residue level.

The Meeting noted that the median residue for potatoes differed from those carrot and radish by > 5-fold (> 6× and > 5× respectively) and concluded that a group maximum residue level was not appropriate. The Meeting confirmed the 2012 recommendation for a maximum residue level, STMR and HR of 0.03, 0.01 and 0.02 mg/kg respectively for fluxapyroxad in potatoes. The Meeting confirmed the 2012 recommendation for a maximum residue level, STMR and HR of 0.15, 0.04, and 0.06 mg/kg respectively for fluxapyroxad in sugar beet.

The Meeting estimated a maximum residue level of 1 mg/kg for fluxapyroxad in carrot, together with an STMR and an HR of 0.06 and 0.5 mg/kg respectively. The Meeting agreed to extrapolate these values to parsnips.

The Meeting estimated a maximum residue level of 0.2 mg/kg for fluxapyroxad in radish, together with an STMR and an HR of 0.05 and 0.1 mg/kg respectively.

Celery

The critical GAP for celery is in the USA, at 3× 0.2 kg ai/ha applications, with a 7-day retreatment interval, and a 1-day pre-harvest interval.

Residues of fluxapyroxad (parent only and total residues) in US trials matching GAP were 1.3, 1.4, 1.8, and 5.2 mg/kg.

The Meeting estimated a maximum residue level of 10 mg/kg for celery, together with an STMR and an HR of 1.6 and 5.5 mg/kg respectively.

Cereals

Rice

The critical GAP for rice is in the USA, with 2× 0.15 kg ai/ha applications, a 7-day retreatment interval, and a 28-day pre-harvest interval. Residue trials matching the GAP were conducted in the USA.

Residues of fluxapyroxad (parent only) in paddy rice (with husks) at a 28-day PHI were 0.26, 0.34, 0.37, 0.59, 0.60, 0.61, 0.80, 0.92 (2), 0.94, 1.1, 1.2 (2), 1.7, and 3.7 mg/kg.

Total residues were 0.35, 0.37, 0.49, 0.59, 0.61, 0.62, 0.83, 0.94, 0.95, 0.96, 1.1, 1.2 (2), 1.7, and 3.7 mg/kg.

The Meeting estimated a maximum residue level of 5 mg/kg for rice, together with an STMR of 0.94 mg/kg.

Sorghum

Residue data for sorghum were provided to the 2012 Meeting, however at the time no maximum residue level was estimated as the data did not match any label GAP. GAPs have now been provided to the Meeting for consideration against the previously submitted data.

The GAP for sorghum in Mexico is 2× 0.1 kg ai/ha applications 14 days apart, with a 10-day pre-harvest interval. No data matching that GAP is available to the Meeting.

The GAP for sorghum in the USA is 2× 0.1 kg ai/ha applications, with a 21-day pre-harvest interval. Data from trials conducted in the USA and submitted to the 2012 Meeting match the US GAP for sorghum.

Residues of fluxapyroxad (parent only) in sorghum at a 21-day PHI were 0.13, 0.15 (2), 0.17, 0.19, 0.21, 0.24, 0.31, and 0.40 mg/kg.

Total residues in sorghum were 0.13, 0.15, 0.17, 0.19, 0.20, 0.22, 0.30, 0.32, and 0.40 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg for sorghum, together with an STMR of 0.2 mg/kg.

Sugar cane

The critical GAP for sugarcane is in the USA, with 2× 0.125 kg ai/ha applications, a 14-day retreatment interval, and a 14-day pre-harvest interval. Residue trials matching GAP were conducted in the USA.

Residues of fluxapyroxad (parent only) in sugarcane at a 14-day PHI were 0.06, 0.26, 0.56, and 1.3 mg/kg.

Total residues were 0.06, 0.26, 0.58, and 1.4 mg/kg.

The Meeting concluded that there was insufficient data to estimate a maximum residue level for sugarcane.

Tree nuts

The critical GAP for fluxapyroxad in tree nuts is in the USA, with 3× 0.125 kg ai/ha applications, a 7-day retreatment interval, and a 14-day PHI.

Residue trials conducted in the USA in almonds and pecans and matching the US GAP were available to the Meeting.

Residues of fluxapyroxad (parent compound and total residues) in almond kernels at a 14-day PHI were < 0.01 (3), 0.01 and 0.02 mg/kg.

Residues of fluxapyroxad (parent compound and total residues) in pecan kernels at a 14-day PHI were < 0.01 (4), and 0.03 mg/kg.

The Meeting noted that the US GAP was for the tree nuts group and noted the similarity of the datasets for almonds and pecans (the medians were identical at 0.01 mg/kg). The Meeting decided to combine the datasets for almonds and pecans for the purpose of estimating a group maximum residue level.

Parent compound and total residues in almond and pecan kernels were: < 0.01 (7), 0.01, 0.02, and 0.03 mg/kg.

The Meeting estimated a maximum residue level of 0.04 mg/kg for tree nuts, together with an STMR and an HR of 0.01 and 0.03 mg/kg respectively.

Cotton

The 2012 Meeting considered a USA GAP and residue trials for seed treatment application to cotton, and estimated a maximum residue level of 0.01* mg/kg, together with an STMR of 0.

Residue data for foliar application to cotton was presented to the current Meeting.

The GAP for foliar application of fluxapyroxad to cotton in Brazil is 4× 0.058 kg ai/ha applications, with a 12-day retreatment interval and a 14-day pre-harvest interval. No data matching that GAP was available to the Meeting.

The USA GAP for cotton is 3× 0.1 kg ai/ha, with a 7-day retreatment interval and a 30-day pre-harvest interval. A series of trials conducted in the USA in accordance with the GAP was available to the Meeting.

Residues of parent compound in cottonseed after treatment in accordance with GAP were < 0.01, 0.01 (2), 0.03, 0.07, 0.09, 0.11 (2), and 0.13 mg/kg.

Total residues in cottonseed were < 0.01, 0.01 (2), 0.03, 0.07, 0.09, 0.11, 0.12, and 0.13 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for cottonseed, together with an STMR of 0.07 mg/kg. The Meeting withdrew the previous maximum residue level recommendation of 0.01* mg/kg for fluxapyroxad in cottonseed.

Animal feeds

Rice straw

The critical GAP for rice is in the USA, with 2× 0.15 kg ai/ha applications, and a 28-day pre-harvest interval.

Residues of fluxapyroxad parent compound in rice straw after treatment in accordance with GAP were 1.5, 1.8, 1.9, 2.5, 2.9, 3.1, 3.6, 4.0, 4.2, 5.2, 6.8, 6.9, 7.3, 10, and 42 mg/kg (dry weight basis).

Total residues were 1.5, 1.9 (2), 2.6, 2.9, 3.2, 3.8, 4.2 (2), 5.4, 7.0 (2), 7.4, 10, and 42 mg/kg (dry weight basis).

The Meeting estimated a maximum residue level of 50 mg/kg for rice straw and fodder, dry, together with a median residue and a highest residue of 4.2 and 48 mg/kg respectively.

Sorghum forage and stover

Residue data for sorghum were provided to the 2012 Meeting, but the Meeting was unable to estimate any maximum residue levels due to the data not corresponding with any label GAP. GAPs have now been provided to the Meeting for consideration against the previously submitted data.

The GAP for sorghum in the USA is 2× 0.1 kg ai/ha applications, with a 21-day pre-harvest interval. Data from trials conducted in the USA and submitted to the 2012 Meeting match the US GAP for sorghum.

Residues of fluxapyroxad (parent only) in sorghum forage at a 7-day PHI were 1.5, 1.8, 2.3, 2.7, 2.9, 3.1, 3.5, 6.4, and 7.0 mg/kg (dry weight basis).

Total residues in sorghum forage were 1.6, 2.0, 2.4, 2.8, 3.1, 3.2, 3.5, 6.8, and 7.1 mg/kg (dry weight basis).

The Meeting estimated a median residue and a highest residue of 3.1 and 7.1 mg/kg (dry weight basis) respectively.

Residues of fluxapyroxad (parent only) in sorghum stover at a 21-day PHI were 0.72, 1.3, 1.6 (2), 2.1, 2.5 (2), 2.8, and 3.2 mg/kg (dry weight basis).

Total residues in sorghum stover were 0.72, 1.4,1.8 (2), 2.2, 2.6 (2), 2.9, and 3.3 mg/kg (dry weight basis).

The Meeting estimated a maximum residue level of 7 mg/kg, together with a median residue and a highest residue of 2.2 and 3.3 mg/kg respectively, for sorghum straw and fodder, dry (dry weight basis).

Almond hulls

The critical GAP for fluxapyroxad in tree nuts is in the USA, with 3× 0.125 kg ai/ha applications (maximum two consecutive applications), and a 14-day PHI.

Residues of fluxapyroxad (parent compound and total residues) in almond hulls were 0.88, 0.92, 1.1, 1.4 and 1.7 mg/kg.

The Meeting estimated a median residue of 1.1 mg/kg.

Cotton gin trash

The USA GAP for cotton is 3× 0.1 kg ai/ha, with a 30-day pre-harvest interval.

Residues in cotton gin trash (parent compound) were 6.9 and 8.0 mg/kg, while total residues were 6.9 and 8.1 mg/kg.

The Meeting concluded that there were insufficient data for estimation of a median residue and highest residue for cotton gin trash.

Processing studies

The Meeting received processing studies for oranges, grapes, sugarcane, and cottonseed. The 2012 Meeting received processing studies for plums, rice and sorghum. Processing factors, HR-P, STMR-P and maximum residue levels are summarized in the table below.

Plums

Based on the processing factor of 2.81 for prunes (which was the same for both parent compound and total residues), the STMR and HR of 0.44 and 0.95 mg/kg for plums, the 2012 Meeting estimated an

STMR-P, HR-P and maximum residue level of 1.2, 2.7 and 5 mg/kg respectively for prunes. The current Meeting confirmed those recommendations.

Grapes

Based on the processing factor of 4.25 for raisins (for parent compound and total residues), the STMR of 0.47 mg/kg for grapes, and the HR of 1.4 mg/kg for grapes, the Meeting estimated an STMR-P, an HR-P and a maximum residue level of 2.0, 6.0, and 15 mg/kg respectively for dried grapes.

Using the parent compound and total residues processing factor of 5.25 for grape pomace (wet), the OECD guideline value of 15% for the dry matter content of wet grape pomace, and the above STMR value for grapes, the Meeting estimated a maximum residue level and STMR-P of 150 and 16.5 mg/kg respectively for grape pomace, dry.

Rice

Based on the processing factor of 0.07 for polished rice (which was the same for parent and total residues), the maximum residue level of 5 mg/kg for rice, and the STMR of 0.94 mg/kg, the Meeting estimated a maximum residue level and an STMR-P of 0.4 and 0.066 mg/kg respectively for rice, polished.

Based on the processing factor of 0.59 (for both parent and total residues) for rice, husked produced using the parboiling process, the maximum residue level and STMR of 5 and 0.94 mg/kg respectively, the Meeting estimated a maximum residue level and an STMR-P of 3 and 0.55 mg/kg respectively for rice, husked.

Sugarcane

Although a processing study was provided, there were insufficient data for sugarcane to estimate STMR and HR values, so values for processed commodities were not estimated.

RAC	Processed commodity	PF (parent)	RAC maximum residue level	Processed commodity maximum residue level	PF (total)	RAC STMR	Processed commodity STMR-P	RAC HR	Processed commodity HR-P

Residues in animal commodities

Farm animal dietary burden

Dietary burden calculations incorporating all commodities considered by the current and 2012 Meetings for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6. The calculations are made according to the livestock diets of the USA/Canada, the European Union, Australia and Japan as laid out in the OECD table.

	US/CAN		EU		AU		Japan	
	Max.	Mean	Max.	Mean	Max.	Mean	Max.	Mean
Beef cattle	4.73	2.64	22.8	6.81	45.2	12.7	27.3	3.25
Dairy cattle	19.7	4.63	23.3	7.95	40.9	11.9	14.1	2.43
Poultry—broiler	0.985	0.985	1.27	0.898	1.37	1.37	0.35	0.35
Poultry—layer	0.985	0.985	8.53	2.69	1.37	1.37	0.947	0.947

Animal commodity maximum residue levels

The animal commodity maximum residue levels were estimated by the 2012 Meeting based on the following maximum and mean dietary burdens:

Animal (commodities)	Dietary burden (ppm)	
	Maximum	Mean
Beef cattle (mammalian meat and offal)	40.7 (Australia)	11.4 (Australia)
Dairy cattle (milk)	39.2 (Australia)	9.37 (Australia)
Poultry–layers (poultry meat, offal and eggs)	7.14 (EU)	2.10 (EU)

The Meeting noted that the dietary burdens had not changed significantly from those determined by the 2012 Meeting and confirmed its previous recommendations for meat (from mammals other than marine mammals), edible offal (mammalian), milks, poultry meat, poultry, edible offal of, and eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for dietary intake assessment.

Definition of the residue (for compliance with the MRL for plant and animal commodities): *Fluxapyroxad.*

Definition of the residue (for estimation of dietary intake for plant commodities): *Sum of fluxapyroxad and 3-(difluoromethyl)- N-(3′,4′,5′-trifluoro[1,1′- biphenyl]-2-yl)-1H-pyrazole-4-carboxamide (M700F008) and 3-(difluoromethyl)- 1-(ß-D-glucopyranosyl)-N-(3′,4′,5′-triflurobipheny-2-yl)-1H-pyrzaole-4- carboxamide (M700F048) and expressed as parent equivalents.*

Definition of the residue (for estimation of dietary intake for animal commodities): *Sum of fluxapyroxad and 3-(difluoromethyl)- N-(3′,4′,5′-trifluoro[1,1′- biphenyl]-2-yl)-1H-pyrazole-4-carboxamide (M700F008) expressed as parent equivalents.*

The residue is fat soluble.

[a] edible portion

[b] On the basis of information provided to the JMPR, , the Meeting concluded that the short-term intake of residues of fluxapyroxad from consumption of spinach for children may present a public health concern.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Dietary Intakes (IEDIs) of fluxapyroxad were calculated for the 17 GEMS/food cluster diets using STMRs/STMR-Ps estimated by the current Meeting and by the 2012 JMPR. The results are shown in Annex 3 to the 2015 Report.

The calculated IEDIs of fluxapyroxad were 4–20% of the maximum ADI (0.02 mg/kg bw). The Meeting concluded that the long-term intakes of residues of fluxapyroxad, resulting from the uses considered by the current Meeting and by the 2012 JMPR, are unlikely to present a public health concern.

Short-term intake

The 2012 Meeting estimated an ARfD of 0.3 mg/kg bw for fluxapyroxad. The International Estimated Short Term Intakes were calculated for fluxapyroxad using the recommendations for STMRs and HRs

for raw and processed commodities in combination with consumption data for the corresponding food commodities. The results are shown in Annex 4 to the 2015 Report.

The IESTI for spinach represented 190% of the ARfD for children. On the basis of the information provided to the JMPR, the Meeting concluded that the short-term intake of fluxapyroxad from consumption of spinach may present a public health concern. The Meeting noted that no data for alternative GAPs in spinach were presented.

For the other commodities, the IESTI for fluxapyroxad calculated on the base of recommendations made by JMPR represented 0–60% of the ARfD for children, and 0–60% for the general population.

IMAZAPIC (266)

First draft prepared by Dr Yukiko Yamada, Ministry of Agriculture, Forestry and Fisheries, Tokyo, Japan

EXPLANATION

Imazapic is an imidazolinone herbicide developed for the control of grasses and broadleaf weeds in a variety of crops. It was first reviewed by the Meeting in 2013. The 2013 JMPR decided the following residue definition and toxicological endpoints:

Definition of the residue for plant and animal commodities (for compliance with MRLs and for estimation of dietary intakes): Imazapic

Residue is not fat-soluble.

The ADI is 0–0.7 mg/kg bw and an ARfD is unnecessary.

The 2013 JMPR received and considered the plant metabolism study and supervised residue trials on transgenic soya beans; and analytical methods, storage stability studies and processing studies on soya beans. However, at the time of the 2013 JMPR, no GAP had been approved for soya bean crops, regardless of whether they are transgenic or not. Due to the lack of approved GAP, it was not possible for the Meeting to estimate maximum residue level for soya beans.

Imazapic was included on the priority list by the CCPR at the 46th Session in 2014 for evaluation for additional MRLs by this Meeting. The current Meeting received information on use patterns now approved in Brazil. The supervised trial data provided to the 2013 Meeting are now reviewed on the basis of the new use pattern.

USE PATTERNS

Imazapic is used to control broad leaf and grassy weeds. It is formulated as a liquid or granular product either as a solo product or in combination with other active substances for use on pulses, cereal grains, grasses for sugar, oilseeds, and straw, forage and fodder of cereal grains. The use of imazapic, in combination with imazapyr, has been approved in Brazil only for soya bean cultivars resistant to imidazolinone herbicides as shown below.

Table 1 Registered use of imazapic relevant to the residue evaluation by the current Meeting.

Country	Formulation Type and g/kg [a] (Other active ingredient)	F/G /P	Application rate				PHI days	Notes Timing
			Method	No. per crop and season	Water L/ha[2/]	Rate kg ai/ha [b]		
Pulses: Soya bean

[a] In acid equivalents.

[b] Calculated from the dose of the formulation on the label and concentration of the active ingredient (acid equivalents) in the formulation.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The 2013 Meeting received residue data from supervised field trials conducted in Brazil on soya bean cultivars tolerant to imidazolinone herbicides, which were summarized in the Evaluation of the 2013 JMPR and reproduced here with some editorial modification, such as information on the analytical methods and storage, and additional information related to the application of imazapic.

Application rates and residue concentrations were reported as imazapic acid equivalents. Residue concentrations are recorded unadjusted for recoveries or for residue values in control samples.

Where multiple samples were taken from a single plot, individual results are reported, and the calculated average concentration is used for estimation of maximum residue level. Where trials were conducted in the same location, with the same or similar varieties, same or similar formulations, and same equipment, and at the same or similar timing, they are not regarded as independent and only the higher(est) result from these trials was chosen for the estimation of a maximum residue level. Residues from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels and they are underlined.

Soya beans

The formulation containing imazapic and imazapyr was approved in Brazil for use only on soya bean cultivars tolerant to imidazolinone herbicides. The following trials were conducted on GM soya bean cultivars to which the mutated AHAS gene (CSR1-2) of *Arabidopsis thaliana* was introduced for imidazolinone tolerance.

During the 2006/2007 growing season, eight field trials were carried out in Brazil to determine the residues levels of imazapic in soya bean after treatment with a mixed WG formulation of imazapic and imazapyr. In all trial sites, one trial plot was untreated to provide control samples and one trial plot received one post-emergence application at a rate of 0.0175 kg imazapic/ha (and 0.0525 kg imazapyr/ha) 60 days before harvest (BBCH 24-75). In three trials, the application was performed 40, 60, 80, 100 and 120 days before harvest, each on a separate plot. Samples were taken 60 days after the application (DALA) in all trials; but in three trials, additional samplings were performed 40, 80, 100 and 120 DALA. The soya bean samples were stored frozen until analysis. Soya bean samples were analysed for imazapic using Method SOP-PA.0249.

During the 2007/2008 growing season, a field trial was carried out in Brazil to determine the residues levels of imazapic in soya bean after treatment with a mixed formulation of imazapic and imazapyr. One trial plot was untreated to provide control samples, and one trial plot received one foliar post-emergence spray application at a rate of 0.0175 kg imazapic/ha (and 0.0525 kg imazapyr/ha), either 40, 60, 80, 100 or 120 days before harvest. Samples were taken 40, 60, 80, 100 or 120 days after the application. The soya bean samples were analysed for imazapic and the two metabolites using Method SOP-PA.0288.

During the 2010 growing season, two field trials were carried out in Brazil to determine the residues levels of imazapic in soya bean after treatment with a mixed formulation of imazapic and imazapyr. At both trial sites, one trial plot was untreated to provide control samples and four trial plots received one foliar post-emergence spray application at a rate of 0.0175 kg imazapic/ha (and 0.0525 kg imazapyr/ha), 20, 40, 60 or 80 days before harvest. Samples of soya bean grain were taken 20, 40, 60 and 80 days after the application. Soya bean samples were analysed for residues using Method SOP-PA.0288.

During the 2011 growing season, five field trials were carried out in Brazil to determine the residues levels of imazapic in transgenic soya bean after treatment with a mixed formulation of imazapic and imazapyr. At all trial sites, one trial plot was untreated to provide control samples, and one trial plot received one post-emergence application at a rate of 0.0175 kg imazapic/ha (and 0.0525 kg imazapyr/ha), 60 days before harvest (BBCH 66-73). At one trial with five plots, the application was performed 20, 40, 60, 80 and 100 days before harvest. Samples of soya bean grain were taken 60 days after the application (DALA) at all trials; at one trial, additional samplings were performed 20, 40, 80 and 100 DALA, and at one trial aspirated grain fractions were also sampled. Soya bean samples were analysed for residues using Method SOP-PA.0288.

[a] Amendment to Doc ID. 2007/1065863

[b] Unlikely value.

[c] From the stage at the time of application for 60 DALA and the stage at harvest, the growth stage at the application for the 60 DALT is speculated to be between BBCH 79 and 83.

BBCH 83: 30% of pods ripe (beans final colour, dry and hard)

BBCH 85: 50% of pods ripe (beans final colour, dry and hard)

BBCH 86: 60% of pods ripe (beans final colour, dry and hard)

BBCH 87: 70% of pods ripe (beans final colour, dry and hard)

BBCH 89: Full maturity: approx. all pods are ripe; beans final colour, dry and hard (= Harvest maturity)

BBCH 91: About 10% of leaves discoloured or fallen

BBCH 97: Above ground parts of plants dead

FATE OF RESIDUES IN STORAGE AND PROCESSING

In processing

The 2013 Meeting received information on effects of heating in water and processing on imazapic residues in soya bean. The estimated processing factors by the 2013 JMPR are reproduced below.

Table 3 Summary of processing factors for soya bean processing

Processed commodity	N	Processing factor	Mean or best estimate
Meal	3	1.00, 1.00, 1.13	1.04
Defatted meal	1	1.29	1.29
Toasted Meal	1	0.88	0.88
Toasted Defatted Meal	1	1.14	1.14
Oil	2	0.13, 0.14	0.14
Laminated Soya Bean	1	0.71	0.71
Flaked Soya Bean	1	0.50	0.50
Hulls	2	1.00, 1.00	1.00

APPRAISAL

Imazapic is an imidazolinone herbicide for the control of grasses and broadleaf weeds. It was reviewed for the first time by JMPR in 2013 when the residue definition was established for plant and animal commodities to be imazapic for compliance with the MRL and for estimation of dietary intake (The residue is not fat soluble). The Meeting established an ADI of 0–0.7 mg/kg bw and that no ARfD was necessary.

The 2013 JMPR received and considered the plant metabolism study and supervised residue trials on transgenic soya beans; analytical methods, storage stability studies and processing studies on soya beans.

Imazapic was included in the priority list by the CCPR at its Forty-sixth Session in 2014 for evaluation for additional MRLs by this Meeting. The current Meeting received information on the registration of imazapic for application on soya bean cultivars tolerant to imidazolinone herbicides in Brazil. The information on supervised residue trials on imidazolinone-tolerant soya beans provided to the 2013 JMPR is reviewed by the current Meeting against the new GAP in Brazil.

Results of supervised residue trials on crops

The 2013 Meeting received supervised trial data for imazapic on transgenic soya beans. The current Meeting evaluated the data against the new GAP for soya bean cultivars tolerant to imidazolinone herbicides.

Soya bean (dry)

A total of 16 supervised trials were conducted on imidazolinone-tolerant soya beans (transgenic) in different years in Brazil.

The new GAP in Brazil allows a single application of a WG formulation of imazapic (also containing imazapyr) to imidazolinone-tolerant cultivars at the rate of 0.014–0.0175 kg ai/ha (in acid equivalents; for both ground and aerial application) with a PHI of 60 days. For ground applications, the water volume should be 100–200 L/ha and for the aerial application, 40–50 L/ha. The trials employed an application rate of 0.0175 kg ai/ha and the application volume of 200 L/ha.

In one trial in the 2007/2008 growing season, the samples were stored for about 600 days; imazapic was demonstrated to be stable for up to 10 months, the longest storage period tested for imazapic in soya bean. The result of this trial was < 0.01 mg/kg.

Residues arising from the independent supervised residue trials following the critical GAP in Brazil were, in rank order (n=12): < 0.01, < 0.01, < 0.05, < 0.05, 0.05, 0.07, 0.07, 0.10, 0.12, 0.15, 0.23 and 0.25 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg and an STMR of 0.07 mg/kg.

Fate of residues during processing

Processing

The 2013 Meeting received information on processing of soya beans. The processing factor for imazapic in soya bean processed products is described below.

Processed commodity	N	Processing factor	Best estimate	STMR-P mg/kg
Soya bean				0.07 (STMR)
Oil	2	0.13, 0.14	0.14	0.01

The residues of imazapic concentrate marginally in defatted meal (processing factor of 1.29), and toasted defatted meal (1.14).

For the purpose of calculating the animal dietary burden, the Meeting calculated median residues for soya bean meal and hulls to be 0.09 mg/kg and 0.07 mg/kg, respectively, using the STMR of soya bean and the processing factors of 1.29 (highest of similar processed commodities) and 1.00, respectively.

Residues in animal products

Estimation of dietary burdens

The maximum and mean dietary burdens were calculated by the 2013 JMPR using the highest residues or median residues of imazapic estimated at that Meeting on a basis of the OECD Animal Feeding Table. As the highest maximum and mean dietary burden for estimating maximum residue levels and STMRs for foods of bovine origin were calculated on the basis of a ration of 100% grass forage, the inclusion of soya bean feed items, with significantly lower residue levels, would not have any measurable impact on the highest maximum and mean dietary burden.

The addition of soya bean feed items in the calculation of dietary burdens increases by approximately 0.2% the highest maximum and mean dietary burden for poultry. The highest maximum dietary burden calculated at this Meeting (9.65 ppm in feed as compared to 9.63 ppm calculated in 2013) was still lower than the dose of 10.9 ppm in the diet used in the metabolism study in which the TRR in all edible tissues were below the LOQ of 0.01 mg/kg

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant and animal commodities (for compliance with the MRL and for estimation of dietary intake): *Imazapic*.

Residue is not fat-soluble.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
VD 0541	Soya bean (dry)	0.5		0.07	
OR 0541	Soya bean oil, refined			0.01	

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
AB 1265	Soya bean meal			0.09	
AB 0641	Soya bean hulls			0.07	

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Dietary Intakes (IEDIs) of imazapic were calculated for the 17 GEMS/Food cluster diets using STMRs estimated by the 2013 JMPR and STMR/STMR-P for soya bean and soya bean oil estimated by the current Meeting (see Annex 3 to the 2015 Report). The ADI is 0–0.7 mg/kg bw and the calculated IEDIs were in the same range as those calculated by the 2013 JMPR using the 13 GEMS/Food Cluster Diet (0% of the maximum ADI). The Meeting confirmed its conclusion in 2013 that the long-term intake of residues of imazapic resulting from the uses considered by the current JMPR is unlikely to present a public health concern.

Short-term intake

The 2013 JMPR decided that an ARfD is unnecessary. The current Meeting therefore concluded that the short-term intake of residues of imazapic is unlikely to present a public health concern.

IMAZAPYR (267)

First draft prepared by Makoto Irie, Ministry of Agriculture, Forestry and Fisheries, Tokyo, Japan

EXPLANATION

Imazapyr is a broad-spectrum herbicide in the imidazolinone family. It was evaluated at the 2013 JMPR for the first time for toxicology and residues. The 2013 JMPR allocated an ADI of 0-3 mg/kg bw, and ARfD was considered unnecessary. It also determined that the definition of residue was imazapyr for plant and animal commodities (for compliance with MRLs and for estimation of dietary intake). It recommended maximum residue levels for various commodities.

The 2013 JMPR received and considered the plant metabolism study and supervised residue trials on imidazolinone-tolerant soya beans; and analytical methods, storage stability studies and processing studies on soya beans. However, at the time of the 2013 JMPR, no GAP had been approved for soya beans, regardless of transgenic or not. Due to the lack of approved GAP, the Meeting did not estimate a maximum residue level for soya beans.

Imazapry was included on the priority list by the CCPR at the 46th Session in 2014 for evaluation for additional MRLs by this Meeting. The current Meeting received information on analytical methods, use patterns and supervised residue trials to support estimation of maximum residue levels for soya bean and grasses.

RESIDUE ANALYSIS

Analytical methods

The Meeting received information on the analytical method (Method M3023) for the determination of imazapyr in grass, forage and hay (Flatcher, 1999: IZ-244-011).

Residues of imazapyr were extracted from forage and hay of grass with acidic acetone-water (50:148:2 acetone/water/conc. hydrochloric acid). After centrifugation, a 20 mL aliquot was partitioned with dichloromethane. The dichloromethane layer was subsequently cleaned up on a SCX cartridge followed by a RP102 cartridge. The eluted sample was evaporated to dryness and re-dissolved in water for capillary electrophoresis analysis or LC-MS confirmatory analysis.

The M3023 method was validated for the determination of residues of imazapyr in grass, forage and hay. The results were summarized in Table 1. The LOQ for imazapyr was 0.5 mg/kg.

Table 1 Recovery results obtained for the determination of imazapyr by the method M3023

Commodity	Fortification level (mg/kg)	N	Recovery (%)	Mean recovery (%)	Reference Method
Grass, forage	0.5	2	81, 85	83	IZ-244-011

	1.0	2	82, 85	84	
	5.0	2	81, 87	84	
	50	2	86, 86	86	

USE PATTERN

The Meeting received labels from Brazil and the USA. The authorized uses relevant to the supervised residue trials data submitted to the current Meeting are summarized in Table 2.

Table 2 Registered uses of imazapyr relevant to the residue evaluation by the current Meeting

Crop	Country	Formulation		Application				PHI, days
		Type	Conc. of imazapyr	Method	Rate kg ai/ha	Volume L/ha	No. max	
Pulses								
Soya bean (imidazolinone-tolerant)	Brazil	WG	525 g/kg	Ground application	0.042-0.053	100-200	1	60
				Aerial application	0.042-0.053	40-50	1	
Straw, fodder and forage of cereal grains and grasses (including buckwheat fodder)								
Bermudagrass and Bahiagrass	USA	SL	278 g/L	Ground application [a]	0.035-0.84[b]	47-935	1	7[c]
				Aerial application [a]	0.035-0.84[b]	19-281	1	7[c]

[a] Spot applications: may not exceed more than 1/10 of the area to be grazed or cut for hay.

[b] Rate per treated hectare

[c] Do not cut forage grass for hay for 7 days after application. There are no grazing restrictions.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on imazapyr supervised field trials for the following crops.

Group	Commodity	Table
Pulses	Soya bean (dry)	Table 3
Straw, fodder and forage of grasses	Grasses	Table 4

Imazapyr formulation was applied by foliar treatment. Each of the field trial sites generally consisted of an untreated control plot and a treated plot. Residues, application rates and spray concentrations have generally been rounded to two significant figures.

Residue values from the trials, which have been used for the estimation of maximum residue levels, STMRs and HRs, are underlined.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Date of analyses and duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except when residues were found in samples from control plots. Residue data are not corrected for percent recovery.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Most field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Pulses

Soya bean (dry)

The 2013 Meeting received supervised residue trials on imidazolinone-tolerant soya bean conducted in Brazil, which were summarized in the Evaluation of the 2013 JMPR. Table 3 was reproduced to add information related to the application of imazapyr.

Straw, fodder and forage of grasses

Fourteen field trials were conducted in the USA to determine the residue level of imazapyr on grasses. The SL formulation was applied once as broadcast foliar application. Samples of forage were collected at 0 (pre-treatment), 0.1, 7, 14, 28 and 56 days after application. Hay samples were collected on the same day as forage and left to dry before being sampled. Residue concentrations were not adjusted for moisture content and expressed on as received basis.

The Method M 3023 was used for analysis of imazapyr residues in grass forage and hay samples quantifying the analyte by capillary electrophoresis with an LOQ of 0.50 mg/kg.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In Processing

The Meeting had received information on the fate of imazapyr residues during the processing of soya bean seeds in 2013. Processing factors were calculated for imazapyr residues in soya bean seeds.

Raw agricultural commodity (RAC)	Processed commodity	Calculated processing factors*	PF (Mean or best estimate)
Soya bean seeds	Crude oil	< 0.005, < 0.006, < 0.008, < 0.01, < 0.06, < 0.07	< 0.009
	Meal	0.91, 1.0, 1.2, 1,2, 1.3, 1.3, 1.5, 1.8	1.3
	Aspirated grain fractions	0.04	0.04
	Hulls	0.54, 0.79	0.67

APPRAISAL

Imazapyr is a broad-spectrum herbicide in the imidazolinone family. It was evaluated in the 2013 JMPR for the first time for toxicology and for residues. The 2013 JMPR allocated an ADI of 0–3 mg/kg bw; an ARfD was unnecessary. It also determined that the definition of the residue was imazapyr for plant and animal commodities (for compliance with MRLs and for estimation of dietary intake). It recommended maximum residue levels for various commodities.

The 2013 JMPR received and considered the plant metabolism study and supervised residue trials on imidazolinone-tolerant soya beans; analytical methods, storage stability studies and processing studies on soya beans. However, at the time of the 2013 JMPR, no GAP had been approved for soya beans, transgenic or not. Due to the lack of an approved GAP, it was not possible for the Meeting to estimate maximum residue level for soya beans.

Imazapyr was included on the priority list by the CCPR at its Forty-sixth Session in 2014 for evaluation for additional MRLs by this Meeting. The current Meeting received information on analytical methods, use pattern and supervised residue trials to support estimation of maximum residue levels for soya beans and grasses.

Methods of analysis

The Meeting received information on the analytical method used for the determination of imazapyr residues in grass forage and hay. Samples were fortified with imazapyr at 0.5–50 mg/kg and analysed by capillary electrophoresis or LC-MS. The analytical method was validated; the LOQ was 0.5 mg/kg.

The freezer storage stability studies were reported on maize (grain, forage and fodder) and soya bean (seeds and processed fractions) samples in 2013. Storage stability results indicated that imazapyr residues were stable for at least 10 months in soya bean seed, at least 3 months in soya bean processd fractions (laminated soya bean, meal and oil) and at least 27 months in maize (grain, forage and fodder).

Residues resulting from supervised residue trials on crops

The 2013 Meeting received supervised trial data for the foliar application of imazapyr on soya bean (imidazolinone-tolerant) from Brazil and the current Meeting received supervised trial data on grasses from the USA.

Labels were available from Brazil and the USA describing the registered uses of imazapyr.

Soya bean (dry)

Supervised trials were conducted on imidazolinone-tolerant soya bean in Brazil.

The GAP on imidazolinone-tolerant soya bean of Brazil is a foliar application at a maximum rate of 0.053 kg ai/ha with a PHI of 60 days.

Imazapyr residues in soya bean seeds from independent trials in Brazil matching GAP were (n=12): < 0.05, 0.07, 0.11, 0.35, 0.48, 0.55, 0.83, 1.0, 1.3 (3) and 3.0 mg/kg.

Based on the residues for soya bean from trials in Brazil, the Meeting estimated a maximum residue level and an STMR value for imazapyr in soya bean seeds of 5 and 0.69 mg/kg respectively.

Animal feedstuffs

Straw, fodder and forage of grasses

Data were available from supervised trials on grasses in the USA.

The GAP on grasses in the USA is a spot application at a maximum rate of 0.84 kg ai per treated hectare with a PHI of 7 days for hay and no PHI for forage. The spot applications must not exceed more than 1/10 of the area to be grazed or cut for hay.

The trials were conducted with the broadcast foliar application to the whole trial area but the application does not correspond to the GAP. Therefore, the Meeting decided to use a factor of 0.1 to account for the difference between the application in the trials and that in the GAP for the estimation of a maximum residue level.

Calculated residues of imazapyr in forage of grasses were: 2.8, 3.3, 3.6, 3.7, 3.8, 4.4, 5.0, 5.4, 6.1, 6.5, 6.6, 6.8, 7.5 and 9.7 mg/kg.

Based on the calculated residues for forage grasses, the Meeting estimated a median residue value and a highest residue value for imazapyr in forage of grasses of 5.2 and 9.7 mg/kg, respectively on an “as received” basis.

Calculated residues of imazapyr in hay of grasses were: 0.15, 1.0, 1.1, 1.2 (3), 1.3 (2), 1.8, 1.9, 2.0, 2.2, 2.4 and 2.5 mg/kg.

Based on the calculated residues in hay grasses, the Meeting estimated a median residue value of 1.3 mg/kg, a highest residue value of 2.5 mg/kg on an as received basis and after correction for an average 88% dry matter content, estimated a maximum residue level of 6 mg/kg for imazapyr in hay of grasses.

Fate of residues during processing

Residues in processed commodities

The fate of imazapyr residues has been examined in soya bean seeds in processing studies. Estimated processing factors and the derived STMR-Ps are summarized in the Table below.

Processing factors, STMR-P for food and feed

Raw agricultural commodity (RAC)	Processed commodity	Calculated processing factors*	PF (Mean or best estimate)	RAC STMR (mg/kg)	STMR-P (mg/kg)
Soya bean seeds	Crude oil	< 0.005, < 0.006, < 0.008, < 0.01, < 0.06, < 0.07	< 0.009	0.69	0
	Meal	0.91, 1.0, 1.2, 1,2, 1.3, 1.3, 1.5, 1.8	1.3		0.897
	Aspirated grain fractions	0.04	0.04		0.0276
	Hulls	0.54, 0.79	0.67		0.462

* Each value represents a separate study. The factor is the ratio of the residue in processed commodity divided by the residue in the RAC.

Residue in animal commodities

Farm animal dietary burden

The Meeting estimated the dietary burden of imazapyr in farm animals on the basis of the diets listed in Appendix IX of the FAO Manual 2009. Calculations derived from highest residue, STMR (some bulk commodities) and STMR-P values provide estimations of levels in feed suitable for estimating MRLs, while calculations from STMR and STMR-P values for feed is suitable for estimating STMR values for animal commodities. The percentage dry matter is taken as 100% when the highest residue levels and STMRs are already expressed on a dry weight basis.

Estimated maximum and mean dietary burdens of farm animals

Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are provided in Appendix IX of the FAO manual. The calculations were made according to the animal diets from US-Canada, EU, Australia and Japan in the Table (Appendix IX of the FAO manual).

Since the GAP for grasses is only registered in the USA, median residue value and highest residue value in forage of grasses are used only for the calculation of dietary burden in US-Canada.

Livestock dietary burden, imazapyr, ppm of dry matter diet								
	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0.61	0.40	1.7	1.0	2.8	1.5	1.7	1.2
Dairy cattle	18a	9.6bc	2.0	1.2	2.0	1.2	2.3	1.3
Poultry – broiler	0.43	0.43	0.57	0.57e	0.37	0.37	0.38	0.38
Poultry – layer	0.43	0.43	0.68d	0.54	0.37	0.37	0.33	0.33

[a] Highest maximum cattle dietary burden suitable for MRL estimates for mammalian meat, fat, edible offal and milk

[b] Highest mean cattle dietary burden suitable for STMR estimates for mammalian meat, fat and edible offal

[c] Highest mean dairy cattle dietary burden suitable for STMR estimates for milk

[d] Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat, fat, edible offal and eggs

[e] Highest mean poultry dietary burden suitable for STMR estimates for poultry meat, fat, edible offal and eggs

Farm animal feeding studies

The 2013 JMPR received a lactating dairy cow feeding studies using imazapyr, which provided information on likely residues resulting in animal commodities and milk from imazapyr residues in the animal diet.

A poultry feeding study was not submitted as the expected residues of imazapyr in poultry feed were low. A poultry metabolism study at a dose rate of 9.7 ppm imazapyr in feed demonstrated that there was very low transfer to eggs and tissues with all residues of imazapyr less than 0.01 mg/kg.

Animal commodities maximum residue levels

For MRL estimations, the residue in the animal commodities is imazapyr.

Residues in tissues and milk at the expected dietary burden for dairy cattle are shown in the Table below. The mean estimated residue in milk was calculated using the residue values of day 3 to the final day.

	Feed level (ppm) for milk residues	Residues (mg/kg) in milk	Feed level (ppm) for tissue residues	Residues (mg/kg) in			
				Muscle	Liver	Kidney	Fat
MRL beef or dairy cattle							
Feeding study	58	0.013	58	< 0.05	< 0.05	0.36	< 0.05
Dietary burden and residue estimate	18	0.004	18	< 0.05	< 0.05	0.11	< 0.05
STMR beef or dairy cattle							
Feeding study	58	0.010	58	< 0.05	< 0.05	0.25	< 0.05
Dietary burden and residue estimate	9.6	0.001	9.6	< 0.05	< 0.05	0.041	< 0.05

For beef and diary cattle, the calculated maximum dietary burden is 18 ppm dry weight of feed.

Based on the highest estimated residue in milk (0.004 mg/kg), the Meeting estimated a maximum residue level of 0.01 (*) mg/kg in milk. The Meeting confirmed the previous recommendation for milks.

Based on the highest estimated residue in kidney (0.11 mg/kg), the Meeting estimated a maximum residue level of 0.2 mg/kg in mammalian edible offal to replace the previous recommendation for mammalian edible offal of 0.05 (*) mg/kg.

Based on the mean estimated residues in kidney, the Meeting estimated an STMR value of 0.041 mg/kg in edible offal.

In the lactating dairy cow feeding study, imazapyr residues in meat and fat were less than the LOQ (0.05 mg/kg) at the dose level of 58 and 157 ppm. The mean cattle dietary burden of 9.6 ppm is still lower than the both dose level.

The Meeting confirmed the previous recommendations for mammalian meat and fat.

The maximum dietary burden for broiler and layer poultry is 0.68 ppm and is lower than the dose level in the laying hen metabolism study of 9.7 ppm. In the metabolism study, in which imazapyr equivalent to 9.7 ppm in the diet was dosed to laying hens for 7 consecutive days, no residues of imazapyr exceed 0.01 mg/kg were detected in tissues and eggs.

The Meeting confirmed the previous recommendations for poultry meat, fat, edible offal and eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed in Annex 1 are suitable for estimating maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant and animal commodities (for compliance with the MRL and for estimation of dietary intake): *Imazapyr*

The residue is not fat soluble.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
MO 0105	Edible offal (mammalian)	0.2	0.05*	0.041	
AS 0162	Hay or fodder (dry) of grasses	6		1.3	2.5
VD 0541	Soya bean (dry)	5		0.69	
OC 0541	Soya bean oil, crude		0		
	Forage of grasses			5.2	9.7
	Soya bean asp gr fn [a]			0.028	
AB 0541	Soya bean hulls			0.46	
AB 1265	Soya bean meal			0.9	

[a] aspirated grain fractions

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of imazapyr were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the 2013 JMPR and the current Meeting (Annex 3 to the 2015 Report). The ADI is 0–3 mg/kg bw and the calculated IEDIs were 0% of the maximum ADI (3 mg/kg bw). The Meeting concluded that the long-term intakes of residues of imazapyr, resulting from the uses considered by current JMPR, are unlikely to present a public health concern.

Short-term intake

The 2013 JMPR decided that an ARfD is unnecessary. The Meeting therefore concluded that the short-term intake of residues of imazapyr is unlikely to present a public health concern.

IMIDACLOPRID (206)

First draft prepared by Makoto Irie, Ministry of Agriculture, Forestry and Fisheries, Tokyo, Japan

EXPLANATION

Imidacloprid is a systemic insecticide which has been used widely in many crops for years. It was first evaluated by JMPR in 2001 (T) and 2002 (R). An ADI of 0-0.06 mg/kg bw and an ARfD of 0.4 mg/kg bw was established. The compound was evaluated for residues in 2006, 2008 and 2012. In 2002 the Meeting agreed that the residue definition for compliance with MRLs and for estimation of dietary intake for plant and animal commodities should be the sum of imidacloprid and its metabolites containing the 6-chloropyridinyl moiety, expressed as imidacloprid. It was listed by the 46th Session of CCPR (2014) for the evaluation of 2015 JMPR for additional MRLs.

The residue studies were submitted by the manufacturer and member countries for additional MRLs for stone fruit, olive, curly kale, soya bean, tea, goji (China) and basil (Thailand).

RESIDUE ANALYSIS

Analytical methods

Samples of cherries, plum and peach were fortified with an equimolar solution of imidacloprid, desnitro imidacloprid (WAK4140, M09), olefin imidacloprid (WAK3745, M06), 5-hydroxyl imidacloprid (WAK4103, M01) and 6-chloronicotinic acid (6-CNA, M14), and were analysed for combined residues of those compounds by GC-MS using a modification of the Bayer Method 00200-reformated, Report No 102624-R1 dated 02/23/94 (see JMPR 2002, 2006 and 2012). At the LOQ of 0.05 mg/kg (expressed as imidacloprid), the recoveries were 98±12% for cherries, 92, 104, 115% for plum and 93±18% for peach.

The Meeting received information on the analytical method (Method 00834) for the determination of imidacloprid residues as well as the total residue of imidacloprid (including parent and all metabolites containing the 6-chloropyridinyl moiety) in plant materials (Schöning, 2003: MR-122/03).

Imidacloprid and related metabolites are extracted with a mixture of methanol/water (3/1, v/v) in the presence of diluted sulphuric acid (10%). Oil samples are dissolved in n-hexane and the residues are extracted twice with water. For the determination of the imidacloprid, an aliquot of the extract is partitioned against cyclohexane/ethyl acetate (1/1, v/v) using a Chromabond XTR column (diatomaceous earth). The organic solution is redissolved in acetonitrile/water (2/8, v/v + 2 mL/L formic acid). Quantitation is performed by reversed phase HPLC-MS/MS. For determination of the total residue of imidacloprid, a corresponding aliquot of the extract is evaporated to the aqueous remainder and dissolved in water. Imidacloprid and all metabolites containing the 6-chloropicolyl moiety are oxidised with alkaline $KMnO_4$ to yield 6-CNA. Following acidification and subsequent neutralisation of the excess oxidant, the 6-CNA is extracted from the aqueous solution using *tert*-butylmethylether (MTBE). The ether phase is dried, the solvent is evaporated and the remainder dissolved in acetonitrile/water (2/8, v/v + 2 mL/L formic acid). These solutions are subjected to analysis by HPLC-MS/MS.

The recoveries for imidacloprid ranged from 83 to 112% at fortification levels of 0.01 and 1.0 mg/kg. The mean recoveries for the parent compound were between 89 and 110% with relative standard deviations (RSD) up to 11.6%. The recoveries for the total residue of imidacloprid fortified as parent compound ranged from 75 to 102% at fortification levels of 0.05 to 2.0 mg/kg. The mean recoveries for the parent compound were between 77 and 93% with RSD values up to 6.1%. The recoveries for the total residue of imidacloprid fortified as a mixture of 6-CNA and desnitro-imidacloprid (1:1, w/w) ranged from 64 to 108% at fortification levels of 0.0567 to 1.134 mg/kg parent equivalents. The mean recoveries for the metabolite mixture were between 73 and 97% with relative standard deviations up to 16%. The LOQ is 0.01 mg/kg for imidacloprid and 0.05 mg/kg for total residue of imidacloprid, expressed as imidacloprid.

The method as modified in 00834/M001 (Schöning, 2004: MR-153/03) contains no changes in the analytical procedure compared to the original method 00834 but it incorporates an internal standard procedure to the method. Method 00834/M001 was validated for the determination of residues of imidacloprid parent compound as well as the total residue of imidacloprid (including parent and all metabolites containing the 6-chloropyridinyl moiety) in plant materials. The recoveries for imidacloprid ranged from 80 to 104% at fortification levels of 0.01 and 2.0 mg/kg (mean recoveries: 88 to 99%, RSDs: 1.5 to 7.4%). The recoveries for the total residue of imidacloprid ranged from 66 to 106% at fortification levels of 0.05 (0.0567 mg/kg as mixture of 6-CNA and desnitro metabolite (1:1, w/w) calculated as imidacloprid) to 2.0 mg/kg (mean recoveries: 75 to 101%, RSDs: 1.1 to 9.8%).

The analytical method 00834/M002 (Schöning, 2010: MR-09/169) was developed for the determination of residues of imidacloprid, 5-hydroxyl imidacloprid (WAK4103, M01) and olefin imidacloprid (WAK3745, M06) in plant materials. Imidacloprid and its metabolites are extracted from tomato (fruit), bean (bean with pod), orange (fruit), rape (seed), cereals (grain) and tobacco (green leaf and dried leaf) with methanol/water (3/1, v/v) using a blender. After filtration an aliquot of the extract was evaporated to the aqueous remainder and further the stable isotopically labelled analytes are added for tomato (fruit), bean (bean with pod), orange (fruit), rape (seed), cereals (grain) and tobacco (green leaf). Parts of the solutions are transferred into an HPLC vial and subjected to reversed phase HPLC-MS/MS in the positive ion mode without further clean-up. Recoveries were determined at fortification levels of 0.01 mg/kg (LOQ level, 0.05 mg/kg for tobacco), and 0.10 mg/kg (0.5 mg/kg for tobacco) (each compound expressed as parent equivalent). Mean recoveries for each fortification level ranged from 70 to 107% with RSD up to 12% for all matrices.

The supplemental method 00300/E007 (Schöning, 2010: MR-158/00) has no changes in the analytical procedure compared to the original method 00300. The method was validated for additional matrices of olive fruit, grape pomace and cacao bean. For imidacloprid, recoveries were determined by spiking control samples with imidacloprid at fortification levels of 0.01 and 0.20 mg/kg. The recoveries were in the range from 68 to 110%, the mean recoveries for each matrix ranged from 74 to 90% with a mean RSD ranging from 3.3 to 17.3%. For the total residue of imidacloprid, recoveries were determined by spiking control samples with imidacloprid (fortification levels of 0.05 and 0.5 mg/kg) or with a mixture of 6-CNA and desnitro imidacloprid (0.02 mg/kg each corresponding to 0.0567 mg/kg calculated as imidacloprid). The recoveries were in the range from 64 to 98%, the mean recoveries for each matrix ranged from 70 to 96% with a mean RSD ranging from 2.2 to 12%.

The results for olive are summarized in Tables 1 and 2.

Table 1 Recovery results obtained for the determination of imidacloprid from olive and its processed commodities

* Mixture of 6-CNA (0.02 mg/kg) and desnitro metabolite (0.02 mg/kg), (1/1, w/w) calculated as imidacloprid

The Meeting has received information on the analytical method (NY/T 1275-2007) for the detection, quantitative analysis and confirmation of imidacloprid residues in fresh and dried goji berries (Niu, 2014: IG-01).

Imidacloprid is extracted from goji samples by homogenizing with acetonitrile. After adding sodium chloride, the sample is shaked and centrifuged. An aliquot is concentrated, and purified by solid phase extraction using amino cartridges. Imidacloprid residues were analysed by reversed-phase HPLC-UV (275 nm). The method was validated in fresh or dried goji samples. Control samples were spiked with a standard solution of imidacloprid at fortified level of 0.02, 0.05 and 0.1 mg/kg, and recoveries of imidacloprid with this method ranged from 69–87% (mean: 72–84% with RSD of 2.6–3.5%) in fresh goji samples, while recoveries ranged from 76–100% (mean: 79–100% with RSD of 0–11%) in dried goji samples. The LOQ is 0.02 mg/kg for both matrices.

Table 3 Recovery results obtained for the determination of imidacloprid residue from goji berries

	0.05	5	70 – 100	85	11	
	0.10	5	76 – 82	79	3.0	

The Meeting has also received information on the analytical method (NT-001-P04-01) used for the determination of residues of imidacloprid in soya bean matrices (seed, forage, hay, meal, hull, refined oil, defatted flour and aspirated grain fractions) (Gould *et al*., 2005: 201591).

This analytical method is based on earlier methods 00200 and 00834 and is designed to make use of the equipment and techniques available at the analytical laboratory. The total residue of imidacloprid is analysed by a common moiety method and quantified by using isotopically-labelled internal standards and HPLC-MS/MS. The method is validated by measuring the concurrent recoveries of each analyte (imidacloprid, desnitro imidacloprid, 5-hydroxy imidacloprid, olefin imidacloprid, and 6-CNA) individually in separate control samples of soya bean seed, forage, and

hay, as well as processed commodities of meal, hull, refined oil, defatted flour and aspirated grain fractions. Additionally, the method is further validated by measuring the concurrent recoveries of an imidacloprid/desnitro mixture (1:1, w/w) in these same matrices at various fortification levels. The validation was performed concurrently during the studies RANTY002 and RANTY003-1 (see Table 4).

* The fortification level given is the total mg/kg of both analytes in the mixture.

The analytical method 01389 was developed for the determination of residues of imidacloprid, its 2 metabolites 5-hydroxy imidacloprid and olefin imidacloprid, and of the total residue of imidacloprid determined as 6-CNA in/on plant materials (Richter, 2014: P 3009 G). Imidacloprid and its metabolites are extracted from whole orange fruit, tomato fruit, wheat grain, dry beans, olive fruit, tea (green tea and black tea), hop cones (green and dried), tobacco (green leaves and fermented tobacco), coffee (green beans and roasted coffee), and cocoa (green beans and roasted beans) with methanol/water (3/1, v/v). For the individual analytes, an aliquot of the extract is cleaned-up with liquid/liquid SPE. For the common moiety analysis, an aliquot of the extract is made by alkaline oxidation under reflux and liquid/liquid partition. Final extracts of both branches are subjected to reversed phase HPLC-MS/MS.

The LOQ (expressed as imidacloprid equivalents) for each analyte is 0.01 mg/kg. For dried, fermented and roasted difficult matrices (dried hop cones, fermented tobacco leaves, roasted cocoa beans, roasted coffee beans, black tea) the LOQ increased to 0.05 mg/kg, because validation attempts for dried hop cones and roasted coffee beans at 0.01 mg/kg failed. For the total residue of imidacloprid, the LOQ is 0.05 mg/kg for all matrices.

Table 5 Recovery results obtained for the determination of imidacloprid from tea (green tea and black tea)

6-chloronicotinic acid	0.05 0.50	5 5	74 – 95 69 – 84	82 75	10 8.1

Stability of pesticide residues in stored analytical samples

The storage stability of imidacloprid and various important metabolites was tested in various plant and animal materials. Tests on animal samples were carried out to assess the stability of the total residue. For plants, tests were carried out to assess the stability of the total residue and on plants to assess the stability of residues of the active substance and of the total residue. The results indicate that imidacloprid and the tested metabolites are stable for a minimum of approximately 2 years in plants and for at least 1 year in animal commodities (see JMPR 2002, 2006, 2008 and 2012).

The Meeting has received data on the storage stability of imidacloprid, 5-hydroxy imidacloprid and olefin imidacloprid in various plant matrices for a period of 36 months (Schoening and Diehl, 2014: MR-09/182, P642094733). Samples of wheat (grain), orange (fruit), tomato (fruit), bean (seed) and rape seed were fortified with imidacloprid and its metabolites 5-hydroxy imidacloprid and olefin imidacloprid at a level of 0.1 mg/kg. The samples stored at an average temperature of -18°C or below were analysed at the nominal storage interval of 0, 30, 90, 180, 360, 540, 720, 900 and 1080 days.

At each storage interval imidacloprid and its metabolites 5-hydroxy and olefin were determined in the stored control samples and in the stored spiked samples according to the analytical method 00834/M002. Procedual recovery experiments at fortification levels of 0.10 mg/kg (0.01 mg/kg for 0 day storage interval) were also performed for each analyte at each storage interval. For all matrices the LOQ was 0.01 mg/kg for imidacloprid and its metabolite 5-hydroxy and olefin expressed as imidacloprid equivalent.

Storage stability results indicated that residues of imidacloprid and its metabolites 5-hydroxy imidacloprid and olefin imidacloprid were stable for at least 36 months under freezer conditions at about -18°C or below in wheat (grain), orange (fruit), tomato (fruit), bean (seed) and rape seed.

The Meeting has also received data on the storage stability of imidacloprid, olefin imidacloprid and 6-CNA in basil for a period of 9 months. Samples were fortified with imidacloprid, olefin imidacloprid and 6-CNA at a level of 0.50 mg/kg. The samples stored at -20°C were analysed at the storage interval of 0, 3, 6 and 9 months.

Imidacloprid, olefin imidacloprid and 6-CNA were determined in the control samples and in the stored fortified samples according to the analytical method 01389.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on imidacloprid supervised field trials for the following crops.

Group	Commodity	Table
Stone fruits	Cherries	Table 11
	Plum	Table 12
	Peach	Table 13
Assorted tropical and sub-tropical fruits–edible peel	Olive	Table 14–16
Leafy vegetables	Kale	Table 17
Fruiting vegetables, other than Cucurbits	Goji berry	Table 18
Pulses	Soya bean	Table 19
Herbs	Basil	Table 20
Teas	Tea	Table 21, 22
Legume animal feeds	Soya bean fodder and forage	Table 23

Imidacloprid formulations were applied by foliar treatment. Each of the field trial sites generally consisted of an untreated control plot and treated plots. Residues, application rates and spray concentrations have generally been rounded to two significant figures.

Residue values from the trials, which have been used for the estimation of maximum residue levels, STMRs and HRs are underlined.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Date of analyses and duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except when residues were found in samples from control plots. Residue data are not corrected for percent recovery.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Most field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Stone fruits

Cherries

Twelve residue trials for cherries were conducted in the USA (Dorschner, 2002: 111045). The 192 g/L SC formulation was applied five or six times as foliar spray at application rates 0.11-0.13 kg ai/ha. The total residue of imidacloprid was determined according to method 102624-R1 (based on the method 00200). The LOQ was 0.050 mg/kg.

Plum

Eight residue trials were conducted in the USA on plums according to the US GAP (Dorschner, 2002: 111044). The 192 g/L SC formulation was applied 5 times at the rate of 0.11 kg ai/ha with an application interval of 8-12 days. The total residue of imidacloprid were quantified with method 102624-R1 (based on the method 00200) at an LOQ of 0.05 mg/kg.

Peach

Sixteen side-by-side residue trials were conducted in the USA on peaches according to the US GAP (Harbin & Woodard, 2000: 109238). The 192 g/L SC formulation was applied 3 times at the rate of 0.11 kg ai/ha with application intervals of 7 days. Two different application scenarios (concentrated and dilute spraying) were tested within the same location. The total residue of imidacloprid were quantified with method 102624-R1 (based on the method 00200) at an LOQ of 0.05 mg/kg.

Olives

Eight trials on olives were conducted in Spain, Portugal, Italy and Greece (Schöning & Berkum, 2009: RA-2032/07, Schöning, Reneke & Krusell, 2011: 08-2001). The 200 g/L OD formulation was applied 5 times as a low pressure bait application with 0.020 kg ai/ha, corresponding to a concentration of 0.02 kg ai/hL and a spray volume of 100 L/ha. Only the south side (25% of the whole trees) was treated but samples were taken randomly from the whole trees. The application rate was related to the size of the plot and not just to the area actually treated. At each application the additive Buminal (hydrolyzed protein) was used (1.5%). The application intervals were 9 to 13 days.

All trials were analysed for imidacloprid parent compound and the total residue of imidacloprid according to method 00834/M001. Additionally, the samples taken in 2008 were analysed for imidacloprid parent compound and the metabolites 5-hydroxy imidacloprid and olefin imidacloprid according to method 00834/M002 (not be shown in Table 5).

Eight trials on olives were conducted in Spain, Italy, Portugal and Greece (Anderson & Eberhardt, 2002: RA-2065/00, Schöning, 2002: RA-2034/01). The 200 g/L SL formulation was applied twice as a spray application with 0.10 kg ai/ha, corresponding to a concentration of 0.0125 kg ai/hL and a spray volume of 800 L/ha. The application intervals were 28 to 32 days.

Fruits taken at day 0 at and the PHI of 28 days after the last application were analysed for parent compound whereas fruits of all sampling dates were analysed for the total residue of imidacloprid. Both analytes were either analysed according to method 00300/E007 or method 00834.

Kale

Four trials were conducted on curly kale in Spain and Italy (Schmeer, Krusell & Bauer, 2010: 08-2029, Ballesteros, 2011: 09-2002). The OD formulation containing 75 g/L imidacloprid and 10 g/L deltamethrin was applied twice as a spray application with 0.094 kg ai/ha, corresponding to a concentration of 0.012–0.016 kg ai/hL and a spray volume of 600–800 L/ha. The application interval was 13–18 days.

The samples were analysed for the parent imidacloprid and its metabolites 5-hydroxy imidacloprid and olefin imidacloprid according to method 00834/M002. The total residue of imidacloprid was determined as 6-CNA common moiety according to method 00834/M001.

Goji berry

Six trials were conducted on goji in China, using the EC formulation containing 50 g/L imidacloprid. The EC formulation was applied with three foliar applications at a concentration of 0.005 kg ai/hL. The application interval was 10 days.

After fresh goji were collected from field trial, 5 g potassium carbonate (0.5% of the weight of fresh goji sample) was added per 1000 g sample, then well mixed and stood for 30 min. The sample was dried in sunshine or under blast drying under 45-50°C. The water content of goji is 70-80%. So the weight of dried goji is about 20-30% of that before drying.

The analytical method NY/T 1275-2007 & GB/T 23201-2008 was used to determine the residue of imidacloprid on goji. The LOQ was 0.02 mg/kg.

Pulses

Soya bean (dry)

Twenty-one field residue trials were carried out with imidacloprid in soya beans in the USA and Canada using the 480 g/L SC formulation (Mackie, 2006: RANTY002). Soya bean seeds were treated at a rate of 0.125 kg ai/100 kg seed. The growing soya bean plants were subsequently treated with three foliar applications at a target rate of 0.053 kg ai/ha for a total seasonal application of 0.16 kg ai/ha. In each of the 21 residue trials, the treated plot was divided in two sub-plots A and B; from sub-plot A, forage and hay was harvested, and from sub-plot B, soya bean seeds. The application intervals, once foliar treatment was initiated, generally ranged between 5 and 7 days.

The analytical method NT-001-P04-01 (common moiety method) was used to determine the total residue of imidacloprid in soya bean seeds.

Herbs

Basil

Four field residue trials were carried out with imidacloprid in basil in Thailand using the 700 g/kg WG formulation. The growing basil plants were treated with two foliar applications at a target concentration of 0.042 kg ai/hL. The application intervals were 7 or 8 days.

The on-line multi residue methods applied for the determination of imidacloprid residues was based on extraction with a mixture of acetone, dichloromethane and sodium chloride water solution. The concentrated extract is cleaned up on silica gel column and detection with HPLC-MS/MS (Steinwandter, 1985). The LOQ for imidacloprid was 0.01 mg/kg. The total residue of imidacloprid (6-CNA common moiety analysis) was determined according to method 01389. The LOQ for total imidacloprid was 0.05 mg/kg.

Tea, Green, Black

A total of eight trials (four decline and four harvest trials) were conducted at four different trial locations during the dry season (Manikandan, 2015: RANTN021). Four trials were conducted in spring and the other remaining four trials in autumn. Imidacloprid 700 g/kg WG formulation was applied in a spray application once at 0.40 kg ai/ha. In decline trials tea shoots (two to three leaves and a bud) were harvested 0, 3, 7 and 10 days after the application. In three of them duplicate composite samples were taken and in one decline trial only single samples were taken. In harvest trials, tea shoots were harvested immediately after the application and 7 days thereafter. In all the decline and harvest trials a portion of the tea shoots harvested 7 days after application was used to manufacture green and black tea.

For green tea production, tea shoots comprising of two to three leaves and bud harvested from experimental plots were subjected for steaming for about 10 min. Then the leaves were allowed to cool down to room temperature and subjected to CTC (Crush, Tear and Curl) manufacturing process. The tea leaves were dried for about 20 min in a fluidized bed drier, and cooled to ambient temperature.

For black tea production, the tea leaves were spread to a thickness of about 6.4 cm in a miniature withering trough and allowed to wither for 15-16 hours. The withered leaves were put into a rolling machine and rolled. The rolled leaves were then passed through a CTC machine. Afterwards, the tea was fermented at a humidity of 90%. The fermented tea was dried in a fluid bed drier. The dried tea was allowed to cool at ambient conditions.

All samples were analysed for imidacloprid parent compound and its metabolites and the total residue of imidacloprid according to method 01389. The LOQ was 0.01 mg/kg for imidacloprid in fresh and green tea leaves and 0.05 mg/kg in black tea. The LOQ of the total residue of imidacloprid was 0.05 mg/kg in all sample materials.

Legume animal feeds

Soya bean fodder and forage (green)

Twenty-one field residue trials were carried out with imidacloprid in soya beans in the USA and Canada using the 480 g/L SC formulation (Mackie, 2006: RANTY002). Soya bean seeds were treated at a rate of 0.125 kg ai/100 kg seed. The growing soya bean plants were subsequently treated with three foliar applications at a target rate of 0.053 kg ai/ha for a total seasonal application of 0.16 kg ai/ha. Sample materials were forage and hay. In each of the 21 residue trials, the treated plot was divided in two sub-plots A and B; from sub-plot A, forage and hay was harvested, and from sub-

plot B, soya bean seeds. The application intervals, once foliar treatment was initiated, generally ranged between 5 and 7 days.

The analytical method NT-001-P04-01 (common moiety method) was used to determine the total residue of imidacloprid in soya bean forage and hay.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In Processing

The Meeting has received information on the fate of imidacloprid residues during the processing of plum, olive, soya bean seeds and tea. Processing factors have been calculated for imidacloprid residues in olive, soya bean seeds and tea.

The processing trials for cherry and peach were submitted in 2002.

Plum

The trial was conducted in the USA on plums according to the US GAP (Dorschner, 2002: 111044). The 192 g/L SC formulation was applied 5 times at the rate of 0.11 kg ai/ha with an application interval of 8-12 days. The plums were taken to a commercial drier and dried for 25.5 hours. The total residue of imidacloprid were quantified with method 102624-R1 (based on the method 00200) at an LOQ of 0.05 mg/kg.

Table 24 Imidacloprid residues in processed commodities of plum from supervised trials

country, year (variety)	Application			DALA Days	Commodity	Residues, mg/kg

Portion analysed: Fruit without pit and stem

Olive

Processing studies for olive were conducted in Germany to determine the concentration of residues of imidacloprid in/on olive fruits and processing products of olive (Schöning and Eberhardt, 2002: RA-3034/01, Schoening, *et al*., 2003: RA-3155/02). The SL formulation containing 200 g/L of imidacloprid was sprayed twice to olive trees with an application rate of 0.10–0.11 kg ai/ha, corresponding to a concentration of 0.013 kg ai/hL and a spray volume of 800–904 L/ha. The olives were harvested after two spray applications of the SL formulation in Spain, Italy, Greece and Portugal (RA-2034/01 and RA-2155/02). Samples in 2001 were taken from the treated and the control plots on day 6 or 7 after the last treatment, while in 2002, at day 28 or 30. The samples from the treated plots were processed. Imidacloprid and the total residue of imidacloprid were analysed according to methods 00300/E007, 00300/E010 and 00834. The LOQ was 0.01 mg/kg for imidacloprid. For the total residue of imidacloprid the LOQ was 0.2 mg/kg for press cake and 0.05 mg/kg for all other sample materials.

Preparation of washed olives, washing water, press cake, separation water and crude oil

The olives were washed in standing water, one part of the olives was weighed and stored deep-frozen. The remaining part of the washed olives was crushed into olive pulp using a cutter. After addition of NaCl (1%, w/w), the olive pulp was pressed to obtain press cake and a water/oil emulsion. A sample of press cake was taken. The water/oil emulsion was separated into crude oil and separation water using a centrifuge; both fractions were taken for analysis.

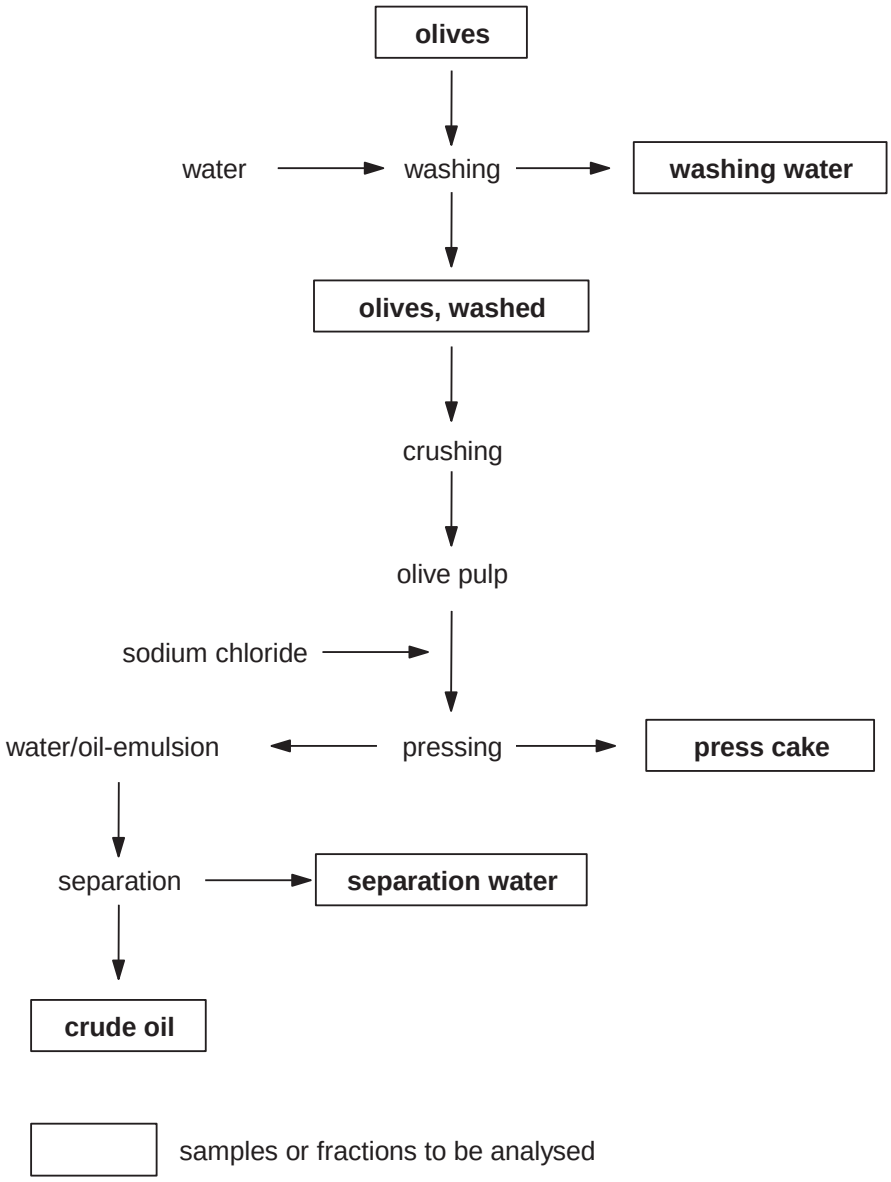

Figure 1 Flow chart of the preparation of washed olive, washing water, press cake, separation water and crude oil

Preparation of refined oil

The crude oil was preclarified by heating, removal of precipitated compounds and one part of the oil was taken for analysis. The remaining part of the preclarified oil was neutralized. After neutralisation, one part of the neutralised crude oil was taken for analysis.

The subsequent processes (bleaching, filtration and steaming) were all carried out in a vacuum. A sample of refined oil was taken for analysis

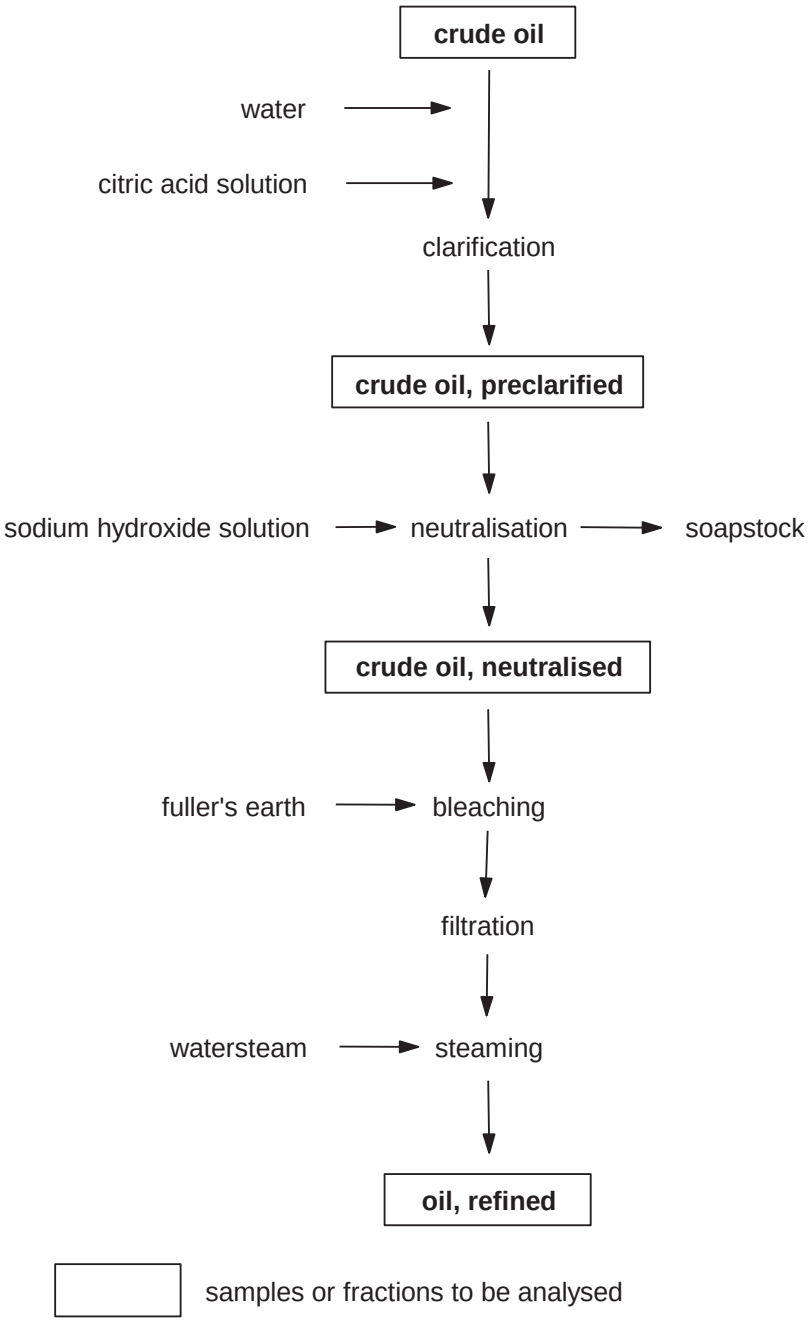

Figure 2 Flow chart of the preparation of refined oil

Soya bean seeds

A field trial was conducted to measure the magnitude of imidacloprid residue on soya beans treated with three foliar applications of the SC formulation containing 480 g/L of imidacloprid at a target rate of 0.263 kg ai/ha/application with 7 days between applications. Each application was made at a concentrated spray volume, 160–170 L/ha. The treatment rate is equivalent to a 5× the maximum recommended label use rate on soya beans. Single control and treated samples of soya bean seed were collected at normal commercial harvest (BBCH 89), corresponding to a 20-day PHI. Soya bean seed was processed into the commodities of meal, hulls, refined oil, and defatted flour. Aspirated grain

fractions were also collected. Processing was performed using procedures which simulated commercial processing practices (Krolski, 2006: RANTY003).

The total imidacloprid residue was quantitated as 6-chloronicotinic acid (6-CNA) by HPLC-MS/MS using isotopically labeled internal standards (method NT-001-P04-01). Method validation and concurrent recoveries were performed to demonstrate acceptable method performance. The LOQ for the total residue of imidacloprid was 0.05 mg/kg in soya bean seed, 0.10 mg/kg in soya bean refined oil, 0.20 mg/kg in soya bean meal, hulls, and defatted flour, and 30 mg/kg in soya bean aspirated grain fractions.

Preparation of aspirated grain fractions

After determining the moisture content of soya bean (RAC), the samples were dried to a moisture content of 10–13%. The samples were then placed in a dust generation room and moved in the system. Aspiration was used to remove light impurities. The light impurities were classified by sieving.

Preparation of hull, meal, defatted flour and refined oil

Soya beans were fed to a disc mill to crack the hull and liberate the kernel. After hulling, the material was passed through an aspirator to separate hull and kernel. The kernel material was flaked and heated. After expansion, the collets were dried and promptly taken for solvent extraction. The material was washed several times with hexane. Then the defatted flakes were ground and screened to produce defatted flour and the crude oil was heated for hexane removal and afterwards alkali refined. The refined oil was bleached and deodorised.

Tea

Two processing trials were performed in southern India with the imidacloprid 700 g/kg WG formulation. The formulation was applied once at a triple rate of 1.2 kg ai/ha. Tea shoots (two to three leaves and a bud) harvested 7 days after the application were used to manufacture green and black tea. Green and black tea was further processed into infusion using household practices whereas the preparation of instant tea simulated the industrial practice (Manikandan, 2014: RANTN021).

Preparation of infusion

100 g of green or black tea were infused into 5 L of boiling water for approximately 10 min. Infusion solution (liquid part) was separated with a sieve from wastes (infused tea). Wastes were weighed and discarded.

Preparation of instant tea

Two 0.5 L infusion solution subspecimens were collected and deep-frozen (below -18 °C). The Brix degree of the infusion solution was measured. The dry matter of solution determined by its Brix degree was increased with an addition of food additive to obtain between 8 to 9%. The pH of this preparation was measured and corrected with an addition of citric acid to obtain between a pH of 3.0 to 3.2. Afterwards the solution was placed in a vacuum chamber, where the water frozen in the solution was evaporated through sublimation.

All samples were analysed for imidacloprid parent compound and its metabolites and the total residue of imidacloprid according to method 01389. The LOQ was 0.01 mg/kg for imidacloprid in processed commodities (green and black tea infusion and instant green and black tea). The LOQ of the total residue of imidacloprid was 0.05 mg/kg in all sample materials.

APPRAISAL

Imidacloprid is a systemic insecticide which has been used widely in many crops for years. It was first evaluated by JMPR in 2001 (T) and 2002 (R). An ADI of 0–0.06 mg/kg bw and an ARfD of

0.4 mg/kg bw were established. The compound was evaluated for residues in 2006, 2008 and 2012. In 2002 the Meeting agreed that the residue definition for compliance with MRLs and for estimation of dietary intake for plant and animal commodities should be the sum of imidacloprid and its metabolites containing the 6-chloropyridinyl moiety, expressed as imidacloprid. It was listed by the Forty-sixth Session of CCPR (2014) for the evaluation of 2015 JMPR for additional MRLs.

The residue studies were submitted by the manufacturer and member countries for additional MRLs for stone fruit, olive, curly kale, soya bean, tea, goji berry (China) and basil (Thailand).

Methods of analysis

The Meeting received information on analytical methods used for the determination of imidacloprid residues in samples derived from supervised trials on olive, kale and soya bean (dry). Samples were fortified with imidacloprid and its metabolites desnitro-imidacloprid and 6-chloronicotinic acid. Imadacloprid and all metabolites containing 6-chloropyridinyl moiety were oxidised with alkaline $KMnO_4$ to yield 6-chloronicotinic acid. The 6-chloronicotinic acid was extracted from the aqueous solution using *tert*-butylmethylether (MTBE) and analysed by HPLC-MS/MS. The LOQ was 0.05 mg/kg (expressed in parent equivalents) for the commodities mentioned above.

The analytical method was developed for the determination of residues of imidacloprid, its 2 metabolites 5-hydroxy imidacloprid and olefin imidacloprid, and for the total residue of imidacloprid determined as 6-chloronicotinic acid in tea. Imidacloprid and its metabolites were extracted from tea (green tea and black tea) with methanol/water (3/1, v/v). For the individual analytes, an aliquot of the extracts was cleaned-up with liquid/liquid SPE. For the common moiety analysis, an aliquot of the extracts was made by alkaline oxidation under reflux and liquid/liquid partition. Final extracts of both branches were subjected to reversed phase HPLC-MS/MS. The LOQ (expressed as imidacloprid equivalents) for the total residue of imidacloprid was 0.05 mg/kg.

The Meeting received information on the analytical method for the determination of imidacloprid residues in fresh and dried goji berries. Imidacloprid was extracted from goji berries with acetonitrile. After adding sodium chloride, an aliquot was concentrated and purified by solid phase extraction using amino cartridges. Imidacloprid residues were analysed by reversed-phase HPLC-UV (275 nm). The LOQ was 0.02 mg/kg for both matrices.

The Meeting received data on the storage stability of imidacloprid, 5-hydroxy imidacloprid and olefin imidacloprid in various plant matrices. Storage stability results indicated that residues of imidacloprid and its metabolites 5-hydroxy imidacloprid and olefin imidacloprid were stable for at least 36 months under freezer conditions at about -18 °C or below in wheat (grain), orange (fruit), tomato (fruit), bean (seed) and rape seed.

Residues resulting from supervised residue trials on crops

The Meeting received supervised trial data for the foliar application of imidacloprid on cherries, plum, peach, olive, kale, goji berry, soya bean, basil and tea. Residue trial data was made available from Canada, China, India, Southern Europe, Thailand and the USA.

Labels were available from China, Italy, Japan, Spain, Thailand and the USA describing the registered uses of imidacloprid.

Stone fruits

The 2002 JMPR evaluated residue supervised trials data for imidacloprid on sweet cherries, plums, peaches and nectarines conducted in southern Europe. New residue data were submitted to the current Meeting for cherries, plums and peaches.

Cherries

Data were available from supervised trials on cherries in the USA.

The GAP of the USA is foliar applications of 0.056-0.11 kg ai/ha at a maximum rate of 0.56 kg ai/ha per year with a PHI of 7 days.

Imidacloprid residues in whole fruits of cherries from independent trials in the USA matching GAP were (n=8): 0.24, 0.36, 0.41, 0.53, 0.57, 0.63, 1.4 and 2.5 mg/kg.

Based on the residues for cherries from trials in the USA, the Meeting estimated a maximum residue level of 4 mg/kg, an STMR value of 0.55 mg/kg and an HR value of 2.5 mg/kg for the cherries subgroup. The Meeting withdrew the previous recommendation for Cherry, Sweet.

Plums

Data were available from supervised trials on plums in the USA.

The GAP of the USA is foliar applications of 0.056–0.11 kg ai/ha at a maximum rate of 0.56 kg ai/ha per year with a PHI of 7 days.

Imidacloprid residues in fruits without stone of plums from independent trials in the USA matching GAP were (n=8): 0.082, 0.095, 0.15, 0.22, 0.34, 0.39, 0.42 and 0.67 mg/kg.

Since the weight of stone does not significantly affect the residue level in plum fruits, the Meeting agreed to use the residues in the edible portion of plums to estimate a maximum residue level.

Based on the residues in the edible portion of plums from trials in the USA, the Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR value of 0.28 mg/kg and an HR value of 0.70 mg/kg (based on a highest residue of duplicate samples) for imidacloprid in the plums (including prunes) subgroup, to replace the previous recommendation for plums (including prunes).

Peaches

Data were available from supervised trials on peaches in the USA.

The GAP in the USA is foliar applications of 0.056-0.11 kg ai/ha at a maximum rate of 0.34 kg ai/ha per year with a PHI of 0 days.

Imidacloprid residues in whole fruit peaches from trials in the USA, matching GAP, were (n=8): 0.10, 0.25, 0.28, 0.34, 0.37, 0.38 (2) and 0.77 mg/kg.

Based on the residues for peaches from trials in the USA, the Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR value of 0.355 mg/kg and an HR value of 0.77 mg/kg for imidacloprid in the Peaches (including nectarine and apricots) subgroup. The Meeting withdrew the previous recommendations for peach, nectarine and apricot.

Olives

Data were available from supervised trials on olives from Southern Europe.

The GAP of Italy is for a foliar application at a maximum concentration of 0.013 kg ai/hL, with a PHI of 28 days. Imidacloprid residues in olives, from trials in Southern Europe matching GAP, were (n=8): 0.12, 0.23, 0.26, 0.28, 0.43, 0.61, 0.77 and 0.81 mg/kg.

The GAP of Spain is a maximum of four foliar applications at a maximum rate of 0.02 kg ai/ha with a PHI of 7 days. Imidacloprid residues in olive from independent trials in Southern Europe matching GAP were (n=8): < 0.05, 0.11, 0.14, 0.22, 0.49, 0.63, 0.71 and 1.1 mg/kg.

Based on the residues for olive from trials with the highest residue levels matching Spanish GAP, the Meeting estimated a maximum residue level of 2 mg/kg, an STMR value of 0.355 mg/kg and an HR value of 1.1 mg/kg for imidacloprid in olives.

Kale

Data were available from supervised trials on curly kale in Italy and Spain.

The GAP of Italy is a maximum two foliar applications at a maximum rate of 0.094 kg ai/ha with a PHI of 7 days.

Imidacloprid residues in curly kale from independent trials in Italy and Spain matching GAP were (n=4): 1.0, 1.1, 1.5 and 2.0mg/kg.

Based on the residues for curly kale from trials in Italy and Spain, the Meeting estimated a maximum residue level of 5 mg/kg, an STMR value of 1.3 mg/kg and an HR value of 2.0 mg/kg for imidacloprid in kale.

Goji berry

The GAP of China is a maximum three foliar applications at a maximum concentration of 0.005 kg ai/hL with a PHI of 3 days. Six trials were conducted on goji berries in China in 2010 with foliar treatment by 3 × 0.005 kg ai/hL. Samples were taken at 1–21 days after the last treatment. The data were submitted as separate trials but the analyte was parent imidacloprid only.

As the residue definition of imidacloprid is the sum of imidacloprid and its metabolites containing the 6-chloropyridinyl moiety, expressed as imidacloprid, the Meeting could not estimate a maximum residue level for imidacloprid in goji berry.

Soya bean (dry)

Data were available from supervised trials on soya bean in the USA.

The GAP on soya bean of the USA is seed treatment at a maximum rate of 0.125 kg ai/100 kg seed, and/or maximum three foliar applications at a maximum rate of 0.053 kg ai/ha with a PHI of 21 days.

Imidacloprid residues in soya bean seeds from independent trials in the USA matching GAP were (n=20): 0.035, 0.050, 0.052 (2), 0.094, 0.11, 0.18, 0.19, 0.21, 0.38 (2), 0.43, 0.48, 0.61, 0.62, 0.63, 0.67, 0.73 and 1.5 (2) mg/kg.

Based on the residues for soya bean from trials in the USA, the Meeting estimated a maximum residue level of 3 mg/kg and an STMR value of 0.38 mg/kg for imidacloprid in soya bean seed (dry).

Basil

Data were available from supervised trials on basil in Thailand.

The GAP of Thailand is foliar applications when the crop is infested at a maximum concentration of 0.042 kg ai/hL with a PHI of 7 days.

Imidacloprid residues in fresh basil from independent trials in Thailand matching GAP were (n=4): 4.3, 4.9, 5.1 and 6.5 mg/kg.

Based on the residues for basil from trials in Thailand, the Meeting estimated a maximum residue level of 20 mg/kg, an STMR value of 5.0 mg/kg and an HR value of 7.3 mg/kg (based on a highest residue of replicate samples) for imidacloprid in basil.

Tea, Green, Black

Data were available from supervised trials on tea in India.

The GAP on tea of Japan is a foliar application at a maximum concentration of 0.01 kg ai/hL with a PHI of 7 days.

Imidacloprid residues in green tea from independent trials in India matching Japanese GAP were (n=8): 2.9 (2), 3.0, 5.5, 7.3, 11, 12 and 23 mg/kg.

Imidacloprid residues in black tea from independent trials in India matching Japanese GAP were (n=8): 2.7 (2), 3.3, 5.1 (2), 12 (2) and 28 mg/kg.

The samples of green tea and black tea were produced from fresh tea leaves harvested 7 days after application at the same plot.

The Meeting recognized that the residue populations from trials on green tea and black tea were not different according to statistical tests (Mann-Whitney U-test). The Meeting agreed to use highest residues of green tea and black tea samples in each trial to estimate a maximum residue level for tea, green and black.

The residues in green tea and black tea were in rank order (n=8): 2.9, 3.0, 3.3, 5.5, 7.3, 12 (2) and 28 mg/kg.

Based on the residues for green tea and black tea from trials in India, the Meeting estimated a maximum residue level of 50 mg/kg and an STMR value of 6.4 mg/kg for imidacloprid in tea, green and black.

Animal feedstuffs

Soya bean fodder and forage (green)

Data were available from supervised trials on soya bean in the USA.

The GAP on soya bean in the USA isa seed treatment at a maximum rate of 0.125 kg ai/100 kg seed, and/or maximum three foliar applications at a maximum rate of 0.053 kg ai/ha for forage grass for hay.

Imidacloprid residues in soya bean forage from independent trials in the USA matching GAP were (n=21): 1.1, 1.6, 1.8, 2.1 (2), 2.4, 2.6, 2.7, 3.0, 3.1, 3.2, 3.5 (2), 3.8 (2), 3.9, 4.1, 4.2, 4.4, 4.6 and 6.5 mg/kg.

Based on the trials for soya bean forage from trials in the USA, the Meeting estimated a median residue value and a highest residue value for imidacloprid in soya bean forage of 3.2 and 6.5 mg/kg, respectively as received basis.

Imidacloprid residues in soya bean hay from independent trials in the USA matching GAP were (n=21): 4.0, 4.5, 5.7, 6.5, 7.5, 8.5, 9.1, 9.2, 9.4, 9.6, 9.9, 11, 13 (2), 14, 15 (2), 18, 21 (2) and 22 mg/kg.

Based on the residues in soya bean hay from trials in the USA, the Meeting estimated a median residue value of 9.9 mg/kg, a highest residue value of 22 mg/kg on an as received basis and after correction for an average 85% dry matter content, estimated a maximum residue level of 50 mg/kg for imidacloprid in soya bean hay.

Fate of residues during processing

Residues in processed commodities

The fate of imidacloprid residues has been examined in plum, olive, soya bean seeds and tea processing studies. Estimated processing factors and the derived STMR-Ps are summarized in the Table below.

Processing factors, STMR-P for food and feed

Raw agricultural commodity (RAC)	Processed commodity	Calculated processing factors*	PF (Mean or best estimate)	RAC STMR (mg/kg)	STMR-P (mg/kg)	RAC HR (mg/kg)	HR-P (mg/kg)
Cherry	Canned fruit	< 0.56, < 0.56, < 0.63 < 0.63	< 0.60	0.55	< 0.33	2.5	<1.5
Plum	Dried (prunes)	3.1	3.1	0.28	0.87	0.70	2.2
Peach	Canned fruit	< 0.38	< 0.38	0.32	< 0.12	0.77	< 0.092
	Jam	< 0.38	< 0.38		< 0.12		
Olive	Crude oil	< 0.19, < 0.36, < 0.23, < 1.0, 0.12	0.12	0.36	0.04		
Soya bean seeds	Refined oil	< 0.24	< 0.24	0.38	< 0.09		

Raw agricultural commodity (RAC)	Processed commodity	Calculated processing factors*	PF (Mean or best estimate)	RAC STMR (mg/kg)	STMR-P (mg/kg)	RAC HR (mg/kg)	HR-P (mg/kg)
	Meal	0.86	0.86		0.33		
	Aspirated grain fractions	160	160		61		
	Hulls	0.72	0.72		0.27		
Green tea	Infusion	0.024, 0.025	0.025	6.4	0.16		
	Instant	0.24, 0.25	0.25		1.6		
Black tea	Infusion	0.017, 0.023	0.02	6.4	0.13		
	Instant	0.19, 0.28	0.24		1.5		

* Each value represents a separate study. The factor is the ratio of the residue in processed commodity divided by the residue in the RAC.

The Meeting estimated a maximum residue level of 5 mg/kg (1.5 × 3.1 = 4.65 mg/kg) for dried plums.

Residue in animal commodities

The 2015 JMPR evaluated residues of imidacloprid in soya bean (dry), which is listed in the OECD feeding table. The Meeting noted that the estimation did not result in a significant change of the dietary burdens of farm animals. The previous recommendations of maximum residue level for animal commodities were maintained.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed in Annex 1 are suitable for estimating maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant and animal commodities (for compliance with the MRL and for estimation of dietary intake): *Sum of imidacloprid and its metabolites containing the 6-chloropyridinyl moiety, expressed as imidacloprid*

CCN	Commodity	Recommended Maximum residue level (mg/kg)		Recommended Maximum residue level (mg/kg)	HR or HR-P mg/kg

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of imidacloprid were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the 2002, 2006, 2008, 2012 and current Meeting (Annex 3). The ADI is 0–0.06 mg/kg bw and the calculated IEDIs were 2–5% of the maximum ADI (0.06 mg/kg bw). The Meeting concluded that the long-term intake of residues of imidacloprid, resulting from the uses considered by the current JMPR, were unlikely to present a public health concern.

Short-term intake

The International Estimated Short-Term Intakes (IESTI) of imidacloprid were calculated for food commodities and their processed commodities using HRs/HR-Ps or STMRs/STMR-Ps estimated by the current Meeting (Annex 4). The ARfD is 0.4 mg/kg bw and the calculated IESTIs were a maximum of 10% of the ARfD. The Meeting concluded that the short-term intake of residues of imidacloprid, when used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

LAMBDA-CYHALOTHRIN (146)

First draft prepared by Makoto Irie, Ministry of Agriculture, Forestry and Fisheries, Tokyo, Japan

EXPLANATION

Lambda-cyhalothrin consists of two of the four enantiomers of cyhalothrin. It was first evaluated by JMPR in 1984 (T, R) and periodic re-evaluation conducted in 2007 (T) and 2008 (R). A group of ADI for cyhalothrin and lambda-cyhalothrin was established as 0–0.02 mg/kg bw and an ARfD was estimated at 0.02 mg/kg bw. In 2008 the Meeting agreed that the residue definition for compliance with MRLs and for estimation of dietary intake for plant and animal commodities should be cyhalothrin, sum of isomers. It was listed by the 46th Session of the CCPR (2014) for the evaluation by the 2015 JMPR for additional MRLs.

The residue studies were submitted by the manufacturer and member countries for additional MRLs for basil (Thailand) and coffee.

RESIDUE ANALYSIS

Analytical methods

The Meeting received information on the analytical method (POPIT MET.044 Rev.31) for the determination of residues of lambda-cyhalothrin in plant materials (Reigada, 2009).

Lambda-cyhalothrin is extracted from samples with acetone/hexane (1:1 v/v). For coffee, deionised water is added to achieve phase separation and the upper (organic) phase is removed and evaporated to dryness. The evaporated residue is diluted with hexane and purified with a silica SPE column. The solvent is evaporated and the residue is dissolved in the internal standard (dicyclohexyl phthalate) and quantification was achieved by GC-ECD.

The LOQ is 0.01 mg/kg for lambda-cyhalothrin in coffee beans.

Table 1 Recovery results obtained for the determination of lambda-cyhalothin from coffee beans

Commodity	Fortification level (mg/kg)	N	Recovery range (%)	Mean recovery (%)	% RSD
Coffee beans	0.01 0.1	7 5	79–97 83–110	89 100	7.6 13

Stability of pesticide residues in stored analytical samples

Information on the freezer storage stability of lambda-cyhalothrin residues in plant commodities was submitted to the 2008 JMPR. Lambda-cyhalothrin residues were stable in the commodities apple and cabbage for 16 months and were stable for 26 months in peach, cabbage, pea, potato, rape seeds, wheat grain, sugar beet roots and cotton seed.

The periods of freezer storage between sampling and analysis for the residue trials of coffee beans submitted to the current Meeting were covered by the period of the freezer storage stability studies.

USE PATTERN

The Meeting received labels from Brazil and Thailand. The authorised uses relevant to the supervised residue trials data submitted to the current Meeting are summarized in Table 2.

Table 2 Registered uses of lambda-cyhalothrin relevant to the residue evaluation by the current Meeting

Crop	Country	Formulation		Application					PHI, days
		Type	Conc. of lambda-cyhalothin	Method	kg ai/ha	kg ai/hL	L/ha	No. max	
Seed for beverages and sweets									
Coffee	Brazil	CS	50 g/L	Foliar	0.005		100–150	2	1 (45 days interval)
Herbs									
Basil	Thailand	CS	25 g/L	Foliar		0.0025		[a]	7

[a] Apply when infested

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on lambda-cyhalothrin supervised field trials for the following crops.

Group	Commodity	Table
Seed for beverages and sweets	Coffee beans	3
Herbs	Basil	4

The lambda-cyhalothrin formulation was applied by foliar treatment. Each of the field trial sites generally consisted of an untreated control plot and treated plot. Residues, application rates and spray concentrations have generally been rounded to two significant figures.

Residue values from the trials, which have been used for the estimation of maximum residue levels, STMRs and HRs are underlined.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Date of analyses and duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except when residues were found in samples from control plots. Residue data are not corrected for percent recovery.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Most field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Seed for beverages and sweets

Coffee beans

Four residue field trials for coffee were carried out in Brazil (Marconi, 2009: M09068). Coffee plants were treated twice with the 50 g/L CS formulation at a rate of 0.005 kg ai/ha. The first application was done 50 days before harvest time followed by one application 45 days after the first application. The water volume used was 250 L/ha.

Coffee cherries were collected 0, 1, 7, 14 and 21 days after the last application. After collection, coffee cherries were placed in the sun to dry and coffee beans were separated from the shells with electric machinery. Residues of lambda-cyhalothrin in green coffee beans were determined according to the method POPIT MET.044 Rev31. The LOQ was 0.01 mg/kg.

[a] Code of BBCH scale

Herbs

Basil

Four field residue trials were carried out with lambda-cyhalothrin on <u>basil</u> in Thailand using the 25 g/L CS formulation. The basil plants were treated with two foliar applications at a target concentration of 0.025 kg ai/hL. The application interval was 6 or 7 days. The residue analysis was performed within 24 hours after sample collection.

The on-line method applied for the determination of lambda-cyhalothrin residues was based on extraction with a mixture of acetone, dichloromethane and sodium chloride water solution. The concentrated extract is cleaned up on silica gel column and detection with GC-ECD (Steinwandter, 1985). The recoveries for lambda-cyhalothrin ranged from 86–114% at fortification level of 0.02 mg/kg, 85–105% at 0.05 mg/kg, 94–110% at 0.1 mg/kg and 91–98% at 1.0 mg/kg. The LOQ for lambda-cyhalothrin was 0.01 mg/kg.

APPRAISAL

Lambda-cyhalothrin consists of two of the four enantiomers of cyhalothrin. It was first evaluated by JMPR in 1984 (T, R) and subsequently under the periodic re-evaluation programme in 2007 (T) and 2008 (R). A group ADI for cyhalothrin and lambda-cyhalothrin was established at 0–0.02 mg/kg bw and a group ARfD, 0.02 mg/kg bw. In 2008 the Meeting agreed that the residue definition for compliance with the MRL and for estimation of dietary intake for plant and animal commodities should be cyhalothrin, sum of isomers. It was listed by the Forty-sixth Session of the CCPR (2014) for the evaluation by the 2015 JMPR for additional MRLs.

The residue studies were submitted by the manufacturer and member countries for additional MRLs for basil (Thailand) and coffee.

Methods of analysis

The Meeting received new information on the analytical method (POPIT MET.044 Rev.31) for the determination of residues of lambda-cyhalothrin in plant materials including coffee beans. Lambda-cyhalothrin is extracted from samples with acetone/hexane (1:1 v/v). For coffee beans, deionised water is added to achieve phase separation and the upper (organic) phase is removed and evaporated to dryness. The evaporated residue is diluted with hexane and purified with a silica SPE column. The solvent is evaporated and the residue is dissolved in the internal standard (dicyclohexyl phthalate) and quantification is achieved by GC-ECD. The LOQ is 0.01 mg/kg for lambda-cyhalothrin in coffee beans.

For the determination of lambda-cyhalothrin in basil, a method[2] available from the scientific literature was used. The recoveries for lambda-cyhalothrin in basil tested concurrently with the analysis of trial samples ranged between 85 and 114%. The LOQ is 0.01 mg/kg for lambda-cyhalothrin in basil.

[2] H. Steinwandter, 1985, Universal 5-min on-line method for extracting and isolating pesticide residues and industrial chemicals

Residues resulting from supervised residue trials on crops

The Meeting received supervised trial data for the foliar application of lambda-cyhalothrin on coffee and basil. Residue trial data was made available from Brazil and Thailand.

Labels were available from Brazil and Thailand describing the registered uses of lambda-cyhalothrin.

Coffee beans

Data were available from supervised trials on coffee in Brazil.

The GAP of Brazil is maximum two foliar applications at a maximum rate of 0.005 kg ai/ha with a PHI of 1 day.

Lambda-cyhalothrin residues in green coffee beans from independent trials in Brazil matching GAP were (n=4): < 0.01 (4) mg/kg.

Based on the residues for coffee beans from trials in Brazil, the Meeting estimated a maximum residue level of 0.01 (*) mg/kg and an STMR value of 0.01 mg/kg for lambda-cyhalothrin in coffee beans.

Basil

Data were available from supervised trials on basil in Thailand.

The GAP of Thailand is foliar applications when crop is infested at a maximum concentration of 0.0025 kg ai/hL with a PHI of 7 days.

Lambda-cyhalothrin residues in basil from independent trials in Thailand matching GAP were (n=4): 0.08, 0.17, 0.20 and 0.37 mg/kg.

Based on the residues for basil from trials in Thailand, the Meeting estimated a maximum residue level of 0.7 mg/kg, an STMR value of 0.19 mg/kg and an HR value of 0.40 (based on a highest residue of replicate samples) mg/kg for lambda-cyhalothrin in basil.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels assessed were suitable for estimating maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant and animal commodities (for compliance with the MRL and for estimation of dietary intake): *Cyhalothrin, sum of isomers*

The residue is fat soluble.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
HH 0722	Basil	0.7		0.19	0.40
SB 0716	Coffee beans	0.01*		0.01	

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of lambda-cyhalothrin were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the 2008 JMPR and the current Meeting (Annex 3). The ADI is 0-0.02 mg/kg bw and the calculated IEDIs were 2-9% of the maximum ADI (0.02 mg/kg bw). The Meeting concluded that the long-term intakes of residues of

lambda-cyhalothrin, arising from the uses considered by the current Meeting, are unlikely to present a public health concern.

Short-term intake

The International Estimated Short-Term Intakes (IESTI) of lambda-cyhalothrin were calculated for food commodities and their processed commodities using HRs/HR-Ps or STMRs/STMR-Ps estimated by the current Meeting (Annex 4). The ARfD is 0.02 mg/kg bw and the calculated IESTIs were a maximum of 2% of the ARfD. The Meeting concluded that the short-term intake of residues of lambda-cyhalothrin, when used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

LINDANE (048)

The first draft was prepared by Professor Arpad Ambrus, Hungarian Food Chain Safety Office, Budapest, Hungary

EXPLANATION

Lindane was first evaluated by the Joint Meeting in 1966 (T,R). It had been last re-evaluated within the periodic review programme in 2002 (T) and 2003 (R). The Meeting agreed that the definition of the residue for compliance with MRLs and for estimation of dietary intake should be: lindane, for both plant and animal commodities. The residue is fat-soluble.

Since lindane was currently listed in Annex A of the Stockholm Convention by which Parties must take measures to eliminate the production and use of such chemicals, and there was no information on existing national registrations for lindane uses, the 46th CCPR (2014) requested a periodic review in 2015 to convert the existing CXLs for sweet corn, cereals, eggs, pountry and meats into Codex EMRLs.

Lindane has no use for crop protection. According to the Stockholm Convention, as a specific exemption, it may be used as a human health pharmaceutical for control of head lice and scabies as second line treatment (decision SC-4/15 under the Stockholm Convention

Subsequently, monitoring data were submitted by EFSA for the period of 2009-2013, the GEMS Food programme (2000-2011) In addition, individual residue data were provided by the Netherlands, and summarized results from India and the USA.

IDENTITY

Common name	Lindane;(for material containing ≥99% gamma stereoisomer)
Chemical name	
IUPAC:	1α,2α,3β,4α,5α,6β-hexachlorocyclohexane (gamma stereoisomer)
CAS:	(1α,2α,3β,4α,5α,6β)-hexachlorocyclohexane (gamma stereoisomer)
Other names	Gamma-BHC; Gamma-HCH;
CAS number:	58-89-9 (for the gamma isomer)
CIPAC Code:	488
Molecular formula:	$C_6H_6Cl_6$
Molecular weight:	290.82984 g/mol
Structural formula:	
PHYSICAL AND CHEMICAL PROPERTIES

The physical and chemical properties, metabolism and environmental fate were evaluated by the 2003 JMPR as part of the periodic review programme.

METHODS OF RESIDUE ANALYSIS

Analytical methods

Lindane is typically analysed with multi residue procedures enabling detection of a large number of samples whose pesticide treatment history is usually unknown. In the screening procedure the emphasis is to detect residues which are around the legal limit; achieving the lowest detectable concentration is not of the primary goal.

No analytical methods were referenced in the submissions of monitoring data. The reported LOQ values varied to a large extent in case of individual commodities and among commodities. The reported ranges of LOQs, where available, are mentioned together with the results of monitoring data. If the LOQ exceeded the present CXL values, for the evaluation of data, the residues were taken as non-detected.

Similarly, no information was provided on the design of sampling programmes or on the size of samples collected. In view of the very large number of samples analysed, the potential deviation from the principles of random sampling or the size of samples do not affect the applicability of the data for estimation of EMRLs.

RESIDUES IN FOOD IN COMMERCE OR AT CONSUMPTION

Residue data derived from the European monitoring programmes

For the period of 2009-2013, the European Food Safety Authority (EFSA) provided approximately 25000 monitoring results on lindane residues in unprocessed food products reported by EU Member States, as well as Norway and Iceland for the products for which currently Codex has established CXLs. The tested products were obtained from more than 60 different countries. However, the majority of the results (approximately 24,000 samples) refer to samples originating from the reporting countries. More specifically, the samples originated from Germany (5,261), the United Kingdom (2,508), Ireland (2,180), Denmark (,1856), France (1,738), Spain (1,385), Romania (1,336) and Poland (1,049); for the remaining testing countries the number of samples analysed amounted to less than 1000. The data compilation includes data on all sampling strategies (surveillance data and data reflecting targeted sampling strategies).

It is noted that no specific results for straw and fodder (dry) of cereal grains are available in the EFSA pesticide monitoring database.

Barley

In total, 630 results on lindane in barley were submitted by 17 European reporting countries. The samples originated from 21 different countries. In none of the samples detectable residues at or above the LOQ were found (LOQ ranged from 0.002 mg/kg to 0.05 mg/kg).

Maize

In total, 642 results on lindane in maize were submitted by 15 reporting countries. The samples originated from 25 different countries. Detectable residues at or above the LOQ were found in none of the samples (LOQ ranged from 0.001 mg/kg to 0.1 mg/kg).

Oats

In total, 898 results on lindane in oats were submitted by 20 reporting countries. The samples originated from 26 different countries. None of the samples contained detectable residues at or above the LOQ (LOQ ranged from 0.001 mg/kg to 0.05 mg/kg).

Rye

In total, 1,658 results on lindane in rye were submitted by 21 reporting countries. The samples originated from 25 different countries. None of the samples contained detectable residues at or above the LOQ (LOQ ranged from 0.0004 mg/kg to 0.05 mg/kg).

Sorghum

In total, 36 results on lindane in sorghum were submitted by two reporting countries. The samples originated from three different countries. None of the samples contained detectable residues above the LOQ were found (LOQ ranged from 0.01 to 0.02 mg/kg).

Wheat

In total, 4942 results on lindane in wheat were submitted by 25 reporting countries. The samples originated from 45 different countries. In only one sample, originating from France, lindane was quantified above the LOQ (0.078 mg/kg). The LOQ values ranged from 0.001 mg/kg to 0.05 mg/kg.

Sweet corn (kernels)

In total, 424 results on lindane in sweet corn were submitted by 15 reporting countries. The samples originated from 27 different countries. None of the samples contained detectable residues at or above the LOQ (LOQ ranged from 0.002 to 0.02 mg/kg).

Milks

Altogether, 4,319 results of lindane residue data in milk of different species (cattle, sheep, goat and horses) were submitted by 25 reporting countries. The samples included only unprocessed, frozen and pasteurised milk. The samples originated from 28 different countries. The LOQ values ranged from 0.00004 to 0.001 mg/kg. It is noted that the results concerning 379 samples were reported on a fat basis. The detectable residues are summarized in Table 1.

Table 1 Lindane residues detected in milk samples.

Commodity	LOQ [mg/kg]	Expression of residues	Residue detected [mg/kg]
Cattle milk	0.00004	Whole product basis	0.00004, 0.00004,0.00004, 0.00008
	0.00005	Whole product basis	
	0.0001	Whole product basis	0.0001
		Fat basis	0.0006
Sheep milk	0.001	Whole product basis	0.002
Goat milk	0.0003	Whole product basis	0.0003
	0.0001	Whole product basis	0.0006

Meat (from mammals other than marine mammals)

Overall, 3,360 samples of meat and 2,657 samples of fat of mammals (swine, bovine, sheep, goat and equine) were analysed for lindane residues. These samples originated from 42 different countries and were tested by 27 EU countries. The LOQ values ranged from 0.0001 to 0.005 mg/kg. Overall, 40 samples contained measurable residues at or above the LOQ. For 2,957 meat samples the results were expressed on whole weight basis, which were converted to a fat basis by applying a default fat content of 20 % unless the actual fat content of the sample was reported. For 403 meat samples the results were expressed on a fat basis. It is noted that for 15 of the fat samples, where the results were reported on whole weight basis, a specific fat content was reported which was taken into account for the evaluation of the data.

[a:] Wpb: Whole product basis

Mammalian edible offal

In total, 680 results on lindane residues in mammalian edible offal of different species (swine, bovine, sheep, goat and equines) were submitted by 23 reporting countries. It is noted that for 71 samples the results were expressed on a fat basis. The samples originated from 25 different countries. The LOQ values ranged from 0.0001 to 0.02 mg/kg. All but four samples were free of detectable residues (residues below the LOQ). The only detectable residues were measured in one sample of sheep edible offal (0.018 mg/kg on fat basis) and in three samples of bovine liver (0.0008 mg/kg, 0.001 mg/kg, 0.002 mg/kg on fat basis).

Poultry meat

Overall, 1,760 samples of poultry (chicken, geese, duck, turkey, and Guinea fowl) meat and poultry fat were reported (700 samples of poultry fat and 1,060 samples of poultry meat). These samples originated from 32 countries and were taken in 23 countries. The LOQ values ranged from 0.00005 to 0.02 mg/kg. For 931 poultry meat samples the results were reported on whole product basis. Thus, the results had to be recalculated on a fat basis using a default fat content of 10 % unless the specific fat content of the sample was reported. The LOQ was 0.0005 when the following residues were detected on a fat basis: 0.0006 (2), 0.0007 (3), 0.0008, 0.0009, 0.001 (5), 0.002 (11), 0.004 (2). The residues measured on whole product basis were recalculated assuming 10% fat. They were: 0.001, 0.002 and 0.004 mg/kg.

Poultry offal

In total, 406 results of poultry offal were reported; 402 thereof concerned poultry liver. The results for 13 samples of poultry edible offal were reported on a fat basis; the specific fat content of the samples were also reported. The samples originated from 18 different countries and tested by 15 countries. The LOQ values ranged from 0.0005 to 0.01 mg/kg. Four samples of poultry liver were reported at or above the LOQ. They were on a fat basis: 0.0009, 0.001, 0.0045, 0.1 mg/kg

Eggs

Overall, 2,465 results of lindane in eggs of different species (chicken, duck and quail) were submitted by 26 reporting countries. The samples included only unprocessed, frozen and pasteurised eggs. These samples originated from 28 countries. For 261 samples the results were expressed on a fat basis. The detectable residues at or above the LOQ are summarized in Table 3. (LOQs ranged from 0.00008 to 0.05 mg/kg).

Table 3 Lindane resides detected in eggs

GEMS/Food data

The GEMS/Food data package contained 4,110 individual results collected during 2000-2011 in Australia, New Zealand, China HK SAR, Germany, Slovakia and Denmark.

The summary of relevant results is given in Table 4. In addition, the results of analysis of other commodities are given in Table 5.

Monitoring data from India

Monitoring data for lindane residues in cereals, eggs, poultry and meat obtained in India under "Monitoring of Pesticide Residues at National Level" during 2009-14 were reported in summarized form. They are shown in Tables 6 and 7.

Table 6 Summary results of monitoring lindane residues in cereals, meat and eggs in India

Year	Commodity	Number of samples	LOQ mg/kg	Detected residues [mg/kg]
2009-2014	Cereals (Rice & Wheat)	7650	0.01	0.01,0.02 (2), 0.04, 0.05, 0.06, 0.08, 0.16
	Meat & Eggs	2361	0.01	0

The Netherlands

Fifty seven positive results derived from monitoring programmes carried out between 2004–2013 were provided. The relevant commodities and the detectable residues found were: maize whole meal (0.003 mg/kg), maize grits (0.012 mg/kg), wheat wholegrain floor (0.003, 0.006 mg/kg). The total number of samples analysed were not reported.

United States

The Pesticide Data Program (PDP) is directed at raw agricultural products and various processed foods originated from domestic production and import. Although processed foods are also included, the emphasis is on the raw agricultural product, which is typically analysed as the unwashed, whole (unpeeled), raw commodity. In addition to monitoring foods for human consumption, FDA also samples and analyses domestic and imported animal feeds for pesticide residues (US FDA).

None of the 80,224 samples analysed between 2007–2012 contained detectable amounts of lindane in the commodities relevant to the present evaluation. Only 14 samples, comprising frozen potato, ginseng and ginseng products, chick pea, dried mushroom and panax root powder contained lindane residues in the range of 0.003 and 0.7 mg/kg.

APPRAISAL

Lindane was first evaluated by the Joint Meeting in 1966 (T, R). It had been last re-evaluated within the periodic review programme in 2002 (T) and 2003 (R). The Meeting established an ADI of 0-0.005 mg/kg bw and ARfD of 0.06 mg/kg bw. The Meeting agreed that the definition of the residue for compliance with MRLs and for estimation of dietary intake should be: lindane for both plant and animal commodities. The residue is fat-soluble.

Since lindane is currently listed in Annex A of the Stockholm Convention by which Parties must take measures to eliminate the production and use of the chemical, and there was no information on existing national registrations for lindane uses, the Forty-sixth Session of the CCPR (2014) requested a periodic review in 2015 to convert the CXLs into Codex EMRLs.

Monitoring data were submitted by the European Food Safety Authority (EFSA) for the period of 2009-2013 and from the GEMS/Food programme (2000-2011) to the Meeting. In addition, individual residue studies were provided by the Netherlands in processed maize and wheat, and summarized results from India and the USA.

Methods of residue analysis

Lindane can be recovered using numerous multi residue procedures. The sensitivity of the detection depends on the extraction and cleanup procedures, and the instrumentation available for qualitative and quantitative determination. No information was provided on the methods of analyses of samples for which lindane residues were reported. However, in the screening procedures, the objective is to detect residues which are around the legal limit, and to achieve the lowest concentration is not the primary goal. The reported LOQ values varied significantly in cases of individual commodities and among different commodities. The median reported LOQ values reported by EFSA and GEMS/Food were: cereal grains (0.01 mg/kg), mammalian and poultry meat (0.001 mg/kg), mammalian and poultry edible offal (0.001 mg/kg), milks (0.0004 mg/kg) and eggs (0.001 mg/kg). The Meeting assumed that these values can be realistically achieved applying current instrumental detection techniques and they were taken into consideration in estimation of EMRL values. If the LOQ exceeded the present CXL values, the reported <LOQ values were considered as non-detected.

Residues reported from monitoring programmes

The EFSA submitted the results of analyses of about 25,000 individual samples relevant to the present evaluation. The results originated from 60 different countries with the majority (96%) from the EU Member States, Iceland and Norway. In addition the Netherlands reported detected residues in some samples.

The GEMS/Food data package contained 4,110 individual results collected in Australia, New-Zealand, China HK SAR, Germany, Slovakia and Denmark. The data package included several commodities for which no CXL had been established. When sufficient numbers of results were available, these data were also considered for estimation of EMRLs.

India provided the summarized results of analyses of 7,650 cereal grain samples, including rice and wheat, and 2,361 meat and egg samples.

The summary results of the US FDA Pesticide Data Programme (2007-2012) were provided, which included over 80,000 residue measurements obtained from a large variety of commodities. None of the samples analysed between 2007 and 2012 contained lindane residues above the LOQ in the commodities relevant to the present evaluation.

The above data sets including the results of analyses of large numbers of samples did not indicate differences among geographical regions; therefore it was assumed that they provide information on the lindane concentration resulting from environmental contamination present around the world. Consequently, they were considered together for estimating EMRLs. According to previous practice of the JMPR, EMRLs should cover a minimum of 99 percentile of the relevant residue data population with a 99% probability (FAO Manual sub-chapter 6.11.2). To meet this criterion a

minimum of 459 valid results are required. For covering 99.9 percent of the likely residues present with 99 percent probability, 4,603 results would be needed.

Sweet corn

None of the 424 samples, reported by EFSA originating from 27 different countries, contained detectable lindane residues.

Using the mature maize residue data (642) as supporting evidence, the Meeting concluded that the database is sufficient to recommend an EMRL of 0.01 mg/kg for sweet corn kernels.

The Meeting withdraws its previous recommendation of 0.01(*) mg/kg.

Cereal grains

Individual residue analyses are available from European countries for barley (630), maize (642) oat (898), rye (1,658), sorghum (36), and wheat (4,942). Quantified residues were reported by France in wheat (0.078 mg/kg), and The Netherlands in whole maize flour (0.003 mg/kg), maize grits (0.012 mg/kg), and whole wheat flour (0.003 and 0.006 mg/kg). Of a total of 8,806 raw cereal grain samples, only one wheat sample (0.078 mg/kg) and one maize grit sample (0.012 mg/kg) contained residues above the current CXL of 0.01 mg/kg (0.022%). Based on this result it can be stated that at least 99.8% of the expectable residues are below the current CXL with a 99% probability. This conclusion is supported by the large number of results reported by India and USA.

The Meeting recommended an EMRL of 0.01 mg/kg for cereal grains.

The Meeting withdraws its previous recommendations of 0.01 (*) mg/kg for maximum residue levels in barley, maize, oats, rye, sorghum and wheat.

Straw and fodder of cereal grains

Based on the results reported by the 2003 JMPR (Pesticide Residues in Food - 2003 Evaluations Part I P583, pp 177) indicating similar, generally non-detected, residues in wheat grains, hay and straw, supported by the summarized US FDA data package, the Meeting concluded that residues above 0.01 mg/kg are unlikely to occur in straw and fodder, dry, from environmental contamination.

The Meeting recommended an EMRL of 0.01 mg/kg for straw and fodder of cereal grains.

The Meeting withdraws its previous recommendation of 0.01 (*) mg/kg.

Meat (from mammals other than marine mammals)

Overall, 3,360 samples of meat and 2,657 samples of fat of mammals (pig, cattle, sheep, goat and horse) were analysed for lindane residues. These samples, reported by EFSA, originated from 42 different countries. Overall, 40 samples contained residues at or above the LOQ. However, only one sheep fat sample contained residue (0.53 mg/kg) above the current CXL of 0.1 mg/kg (0.016%). The next two highest values were in swine meat (fat) 0.017 mg/kg and 0.015 in beef fat.

Sixteen mammalian meat samples reported from the GEMS/Food database contained non-detected residues

The Meeting concluded that the residue level reported is much lower than that which was reported at the time of the estimation of the current CXL of 0.1 mg/kg.

The Meeting recommended an EMRL of 0.01 mg/kg (fat) for meat (from mammals other than marine mammals)

The Meeting withdraws its previous recommendation of 0.1 mg/kg (fat).

Edible offal (mammalian)

Overall, 680 samples of mammalian edible offal of different species (pig, cattle, sheep, goat and horse) were analysed for lindane residues. These samples originated from 25 different countries.

Four samples contained residues but none of them exceeded the current CXL of 0.01 mg/kg. Three cattle liver samples contained residues (0.0008 mg/kg, 0.001 mg/kg, 0.002 mg/kg on a fat basis), and one sheep edible offal (0.018 mg/kg on a fat basis). The residues expressed on a whole product basis would be about 20 times lower.

The Meeting concluded that there was sufficient information to recommend an EMRL of 0.001 mg/kg for edible offal (mammalian).

The Meeting withdraws its previous recommendation of 0.01 (*) mg/kg.

Milks

Altogether 4,319 lindane residues in unprocessed, frozen and pasteurised milk samples of different species (cattle, sheep, goat and horses) were reported by EFSA. Overall, detected residues were ≥ LOQ (0.00004 (3), 0.00008, 0.0001, 0.0003, 0.0006 and 0.002 mg/kg on a whole product basis and 0.0006 mg/kg on a fat basis. None of them exceeded the current CXL.

Cattle (341) and goat (1) samples obtained from GEMS/Food database contained non-detected residues (< 0.002 mg/kg).

Based on the extensive data base, the Meeting recommended an EMRL of 0.001 mg/kg for milks.

The Meeting withdraws its previous recommendation of 0.01 (*) mg/kg.

Poultry meat

Overall, 700 samples of poultry fat and 1,060 samples of poultry meat (chicken, geese, duck, turkey, and Guinea fowl) were derived from 32 countries. The LOQ was 0.0005 when the following residues [mg/kg] were detected on a fat basis: 0.0006 (2), 0.0007 (3), 0.0008, 0.0009, 0.001 (5), 0.002 (11), 0.004 (2). The residues measured on a whole product basis were recalculated assuming 10% fat. The values were: 0.001, 0.002 and 0.004 mg/kg.

One chicken meat (fat) sample of the 15 poultry meat samples obtained from GEMS/Food database contained residues of 0.0034 mg/kg lindane. None of the samples contained residues above the current CXL. The results indicate that 99.5% of the samples would unlikely contain residues above 0.004 mg/kg (fat) in 99.9% of the cases.

Based on the data available the Meeting concluded that 0.005 mg/kg residue level would sufficiently cover the residues carried over from environmental contamination, and recommended it as the EMRL for poultry meat (on fat basis).

The Meeting withdraws its previous recommendation of 0.05 mg/kg.

Poultry, edible offal of

In total, 406 results of poultry offal were reported by EFSA of which 402 were poultry liver. Four samples contained detected residues. They were on a fat basis: 0.0009, 0.001, 0.0045, 0.1 mg/kg. The residues expressed on a whole product basis would be at least 20 times lower.

Based on the 406 residue dataset, it can be assumed that 99% of the sampled lot would contain less than 0.01 mg/kg lindane residues with at least 98% probability.

Based on the available data the Meeting recommended an EMRL of 0.005 mg/kg for poultry, edible offal.

The Meeting withdraws its previous recommendation of 0.01 (*) mg/kg.

Eggs

Altogether 2,665 residue determinations were conducted in eggs on a whole product or fat basis as reported by EFSA and obtained from the GEMS Food database. The samples originated from more

than 26 countries. Of the 2,665 samples only 2 (0.075%) contained residues (0.25 and 0.3 mg/kg) above the current CXL.

Based on the available data the Meeting recommended an EMR of 0.001 mg/kg for eggs.

The Meeting withdraws its previous recommendation of 0.01 mg/kg.

Fish and diadromous fish

Lindane residues were reported from the GEMS/Food data base. Residues were detected in 41 of 2,649 samples. They were in rank order: 0.0019, 0.0028, 0.0029 (6), 0.003, 0.0031, 0.0032 (6), 0.0033, 0.0036 (5), 0.0037 (2), 0.0038 (2), 0.004, 0.0042 (2), 0.0043 (2), 0.0045 (2), 0.0051 (2), 0.0063 (4), 0.0083 and 0.0095 mg/kg.

The Meeting considered that the residues in fish are a suitable indicator of environmental contamination. The Meeting concluded that the residue data on fish derived from the GEMS/Food database would provide sufficient basis (99.8% of residues with 99.5% probability) for estimation of likely maximum residue levels of lindane in fish.

Based on the data available the Meeting recommended an EMRL of 0.01 mg/kg for fish and diadromous fish.

RECOMMENDATION

The Meeting noted that there are no authorised uses of lindane for crop protection and withdraws its previous recommendations for maximum residue levels and recommends the following extraneous residue levels for use as EMRLs.

Definition of residue is unchanged.

Definition of reside for compliance with EMRLs and for estimation of dietary intake: lindane.

The residue is fat soluble.

		Estimated residue levels mg/kg			Recommendation [a]	
CCN	Commodity	EMRL [b]	*Median*	*Highest*	New	Previous

[a] Lindane was recently classified as 2A (Probable carcinogen) by IARC. Since lindane is listed in annex A of the Stockholm convention and should be eliminated from production and use no toxicological re-evaluation is requested.

[b] Extraneous Maximum Residue Limit (EMRL) is the maximum concentration of a pesticide residue arising from environmental sources due to former agricultural uses, not from the use of the pesticide directly or indirectly on the food or feed.

Estimation of dietary intake

Cereal grains

The median LOQ value reported for barley, maize, oats, rye, sorghum and wheat is 0.01 mg/kg. For dietary intake calculations the 2003 JMPR estimated an STMR and HR of 0.005 mg/kg based on the results of supervised trials. As the estimated EMRL is at the same level as the previous CXL value, the Meeting concluded that the best estimates of the STMR and HR for these commodities and sweet corn are those recommended by the 2003 JMPR.

Animal commodities

Based on animal feeding studies taking into account the expected residue levels in feed commodities deriving from the use of lindane, the 2003 JMPR recommended HR and STMR values for muscle (0.005 mg/kg and 0.0007 mg/kg), fat (0.06 mg/kg and 0.005 mg/kg) edible offal (0.002 mg/kg and 0.0002 mg/kg) from mammals other than marine mammals, and STMR of 0.0003 mg/kg for milks.

Based on the monitoring data, the current residue level in mammalian meat and poultry meat is 10 times lower; the Meeting applied the 10 times lower factor in the corresponding commodities, compared with those estimated by the 2003 JMPR.

The Meeting estimated highest and median residue values for muscle (0.0005 mg/kg and 0.00007 mg/kg), fat (0.006 mg/kg and 0.0005 mg/kg) edible offal (0.0002 mg/kg and 0.00002 mg/kg) from mammals other than marine mammals, and a median residue of 0.00003 mg/kg for milks.

The 2003 Meeting recommended HR and STMR values for poultry meat (0.001 mg/kg and 0.0006 mg/kg), poultry fat (0.016mg/kg and 0.008 mg/kg), eggs (0.002 mg/kg and 0.0007 mg/kg) and edible offal (0.001 mg/kg and 0.0004 mg/kg).

For poultry meat and edible offal the residue levels are about 5–10 times lower, respectively, than those estimated in 2003.

The Meeting estimated highest and median residue values for poultry meat (0.0001 mg/kg and 0.00006 mg/kg), poultry fat (0.0016 mg/kg and 0.0008 mg/kg), poultry edible offal (0.0002 mg/kg and 0.00008 mg/kg) and eggs (0.0002 mg/kg and 0.00007 mg/kg

The fish consumption data was provided by the GEMS/Food database. The long-term intake is 0.43 g/kg bw and the short-term intake (97.5^{th} percentile of 1,043 consumption days) is 10 g/kg bw. The short-term intake was calculated with the highest residue observed in fish (0.0095 mg/kg) and the long term intake was calculated with the median of LOQ values (0.0036 mg/kg) reported for analyses of fish samples.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of lindane were calculated for the 17 GEMS/Food cluster diets using STMRs estimated by the Meeting. The results are shown in Annex 3 to the 2015 Report.

The ADI is 0–0.005 mg/kg bw and the calculated IEDIs were 0–1% of the maximum ADI. The fish consumption contributes to < 0.001% of the max ADI. The Meeting concluded that the long-term intake of residues of lindane from the environmental contamination of commodities considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The ARfD is 0.06 mg/kg bw. The short-term intake calculated using the HR and STMR values estimated by the Meeting were 0% of the ARfD for children and the general population. The fish consumption contributes to 0.016% of the ARfD. The Meeting concluded that the short-term intake of residues of lindane from the environmental contamination of commodities considered by the JMPR is

LUFENURON (286)

The first draft was prepared by Mr Christian Sieke, Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

Lufenuron is an insect growth inhibitor that is active against larvae of Lepidoptera and Coleoptera. When ingested, lufenuron interferes with chitin synthesis, and prevents larvae from moulting. It was considered for the first time by the 2015 JMPR for toxicology and residues.

IDENTITY

ISO common name	Lufenuron
Chemical name	
IUPAC	(*RS*)-1-[2,5-dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)phenyl]-3-(2,6-difluorobenzoyl)urea
CA	N-[[[2,5-dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)phenyl]amino]carbonyl]-2,6-difluorobenzamide
CAS No.	103055-07-8
CIPAC No.	704
Structural formula	Molecular formula	$C_{17}H_8Cl_2F_8N_2O_3$
Molecular mass	511.15 g/mol

Lufenuron consists of a pair of enantiomers. A chiral centre exists at the 2-position of the hexafluoropropoxy side-chain. Lufenuron technical active ingredient is manufactured under non-stereospecific conditions giving a racemate (R:S 50:50).

Specifications

Specifications for lufenuron were not yet developed by FAO.

Environmental fate in soil

For the investigation of the environmental fate of lufenuron the Meeting received studies on soil photolysis, hydrolysis, aerobic soil metabolism and the behaviour in confined rotational crops.

Soil photolysis

The soil surface photolytic behaviour of lufenuron on moist and dry soil was investigated by Ellgehausen (1994, LUFEN_026) using [^{14}C]dichlorophenyl ring-labelled lufenuron.

Moist and dry soil was dosed with radio-labelled lufenuron at 5 µg/cm^2 (equivalent to 500 g ai/ha). The samples were irradiated continuously at 25 °C for up to 17 days. Samples were taken at 0, 5, 9, 14, 19 and 26 days. One dark control sample was prepared in parallel.

For analysis, the soil layer was extracted by shaking with acetone (twice) followed by a mixture of acetone:water (80:20 v/v). Following each extraction step, the samples were centrifuged and the supernatants combined. The supernatants were concentrated, partitioned with dichloromethane and the radioactivity in each phase quantified by LSC. Characterisation and quantification of the photo-degradation products was conducted by HPLC.

The percentage recovery of the applied radioactivity is presented in Tables 1 and 2 and ranged from 99.4–103.8%. The recovery from the dark control plates was > 99% at the end of the study.

Table 1 Distribution of Applied Recovery in dry soil after Continuous Irradiation and results of the dark control sample

In a second experiment conducted by Ellgehausen (1994, LUFEN_027) [^{14}C]difluorophenyl-labelled lufenuron was used to investigate its behaviour under soil photolysis. The experimental conditions and analytical methods were identical to the ones used in the previous study for the [^{14}C]dichlorophenyl-label, however only dry soil was investigated.

The percentage recovery of applied radioactivity is presented in the following table and ranged from 99.7 to 102.1%. The recovery from the dark control plates was 101% at the end of the study.

Table 3 Distribution of Applied Recovery in Dry soil after Continuous Irradiation

Degradate	Incubation period (hours)						Dark control
	0	120	292	309	381	453

[a] The values in this row have not been adjusted for the 1.1% present in the starting material

[b] At least five components, none of which exceeded 1.6% AR

The amounts of lufenuron recovered decreased very slowly from 94.2% AR to 84.0% AR after 18.9 days continuous irradiation. CGA149772, the difluorobenzamide metabolite, reached a maximum of 11.2% AR after 15.8 days then decreased to 7.1% AR at the end of the study. A maximum 6.3% of carbon dioxide was evolved.

Hydrolysis

The stability of lufenuron in sterile buffer solutions was investigated using [dichlororphenyl-^{14}C] and [difluorophenyl-^{14}C]-lufenuron (Ellgehausen, 1992, LUFEN_025).

The test compounds were incubated under sterile conditions in buffer solutions contained in brown glass test tubes. A range of pH (5, 7 and 9) and temperature (25 ºC) conditions were applied to both difluorophenyl-labelled and dichlorophenyl-labelled lufenuron. In addition, a few experiments were conducted under more extreme conditions (pH 1 and 13) and temperature (50 and 70 °C) although not every combination was tested. Lufenuron and its degradation products were partitioned with dichloromethane and the amounts in each phase quantified by LSC and HPLC. Degradates were characterized, after derivatisation where necessary, by MS or GC-MS.

For the samples incubated at 25 °C, both labels showed virtually no degradation at pH 5, 7 and 9. Over 93% of the initial radioactivity was recovered as unchanged lufenuron. Only at pH 9, minor amounts of CGA238277 (3.9% AR) and CGA224443 (1.8% AR) for the dichlorophenyl-label and CGA149776 (3.8% AR) for the difluorophenyl-label were found.

Under more extreme conditions the parent substance was stable at pH 1 and 70 °C, representing more than 90% of the radioactivity after up to 168 hours. At pH 9 an accelerated degradation was observed. An overview of the degradation for the dichlorophenyl-label is presented in Tables 4 and 5, while the difluorophenyl-label results are presented in Tables 6 and 7.

In the experiments conducted at a pH of 13 with up to 70 °C incubation temperature, lufenuron was completely degraded within the first 24 hours. The primary hydrolysis products formed were CGA239786 (up to 51% AR after 96 h) and CGA301020 (up to 19% AR after 32 h) for the [^{14}C]dichlorophenyl-label and CGA149776 (up to 49% AR after 2.5 h) for the [^{14}C]difluorophenyl-label.

Aerobic soil metabolism

In a first set of studies the aerobic soil metabolism of lufenuron was investigated in two microbial active soil types and in their sterilised form.

Moisture: 83.6% — Soil: Les Evouettes (loam, microbial active)

pH 6.8 — Organic carbon: 3.8%

Half-live (parent): 24 days two 1st order compartment model) — ^{14}C accountability: 80–103%

% lufenuron remaining: 1.8% after 361 days

% mineralisation: up to 58.6% after 361 days

% unextracted: up to 36.1% after 60 days

Metabolites	Max (% TRR)	Day
None		

The aerobic soil metabolism was also investigated in the same soil types as above without microbial activity (sterile soil). After up to 90 days only unchanged lufenuron was recovered for both radiolabels without significant mineralisation or an increase of unextracted residues.

In a second study Gonzalez-Valero (1991, LUFEN_030) investigated the degradation of [^{14}C]dichlorophenyl-lufenuron in two soil types.

Ref.: Gonzalez-Valero (1991, LUFEN_030)

Test material: [^{14}C]dichlorophenyl-lufenuron — Dose rate: 0.1 mg/kg dry soil

Duration: 149 days
Moisture: 40% MWC
pH 5.0
Half-live (parent): 83 days
% lufenuron remaining: 32.4% after 149 days
% mineralisation: 2.0% after 149 days
% unextracted: 24.6% after 149 days

Temp: 20 °C
Soil: Neuhofen (sand, sterilised)
Organic carbon: 1.78
^{14}C accountability: 95.4–101.5%

Metabolites	Max (% TRR)	Day
CGA238277	10.1%	82
CGA224443	32.8%	149

Ref.: Gonzalez-Valero (1991, LUFEN_030)

Test material: [^{14}C]dichlorophenyl-lufenuron Dose rate: 0.1 mg/kg dry soil

Duration: 100 days Temp: 20 °C

Moisture: 40% MWC Soil: Mosimann (sandy loam, sterilised)

pH: 7.3 Organic carbon: 1.08

Half-live (parent): 17 days ^{14}C accountability: 89.9–101.8%

% lufenuron remaining: 8.1% after 82 days

% mineralisation: 5.0% after 100 days

% unextracted: 56.8% after 100 days

Metabolites	Max (% TRR)	Day
CGA238277	31.8%	30
CGA224443	28.0%	61

The nature of the unextracted radioactivity was further investigated by van der Gaauw (2004, LUFEN_029). After 90 day incubation of two soil types (silt loam “Les Evouettes”; loamy sand “Collombey”) the samples were extracted with three different extractants: acetonitrile: water (4:1 v/v, “solvent”), 40 mM aqueous solution of hydroxypropyl-ß-cyclodextrin (“HPCD”) or 0.02 M aqueous calcium chloride solution ($CaCl_2$). The radioactive residues, CO_2 and biomass were investigated during the experiment. In the following table the mass balance for each of the soils and its extraction efficiencies are summarized:

Table 8 Mass balance of radioactivity in soil

		Recovered Radioactivity (% applied)				
Soil Type		Days after treatment / extraction system				
		0	90/solvent	90/HPCD	90/$CaCl_2$	121/solvent

In addition the influence of the application technique was investigated by Ellgehausen (1994, LUFEN_033). In this study [^{14}C]difluorophenyl ring-labelled lufenuron was applied at 0.1 mg/kg to a silt loam soil (60% MHC) under three test conditions involving surface treatment, incorporation and surface treatment following incorporation after 14 days. For each of the three conditions the remaining residues of the parent substance were measured.

In the following tables the mass balance and the recovered parent substance at various sampling intervals are summarized.

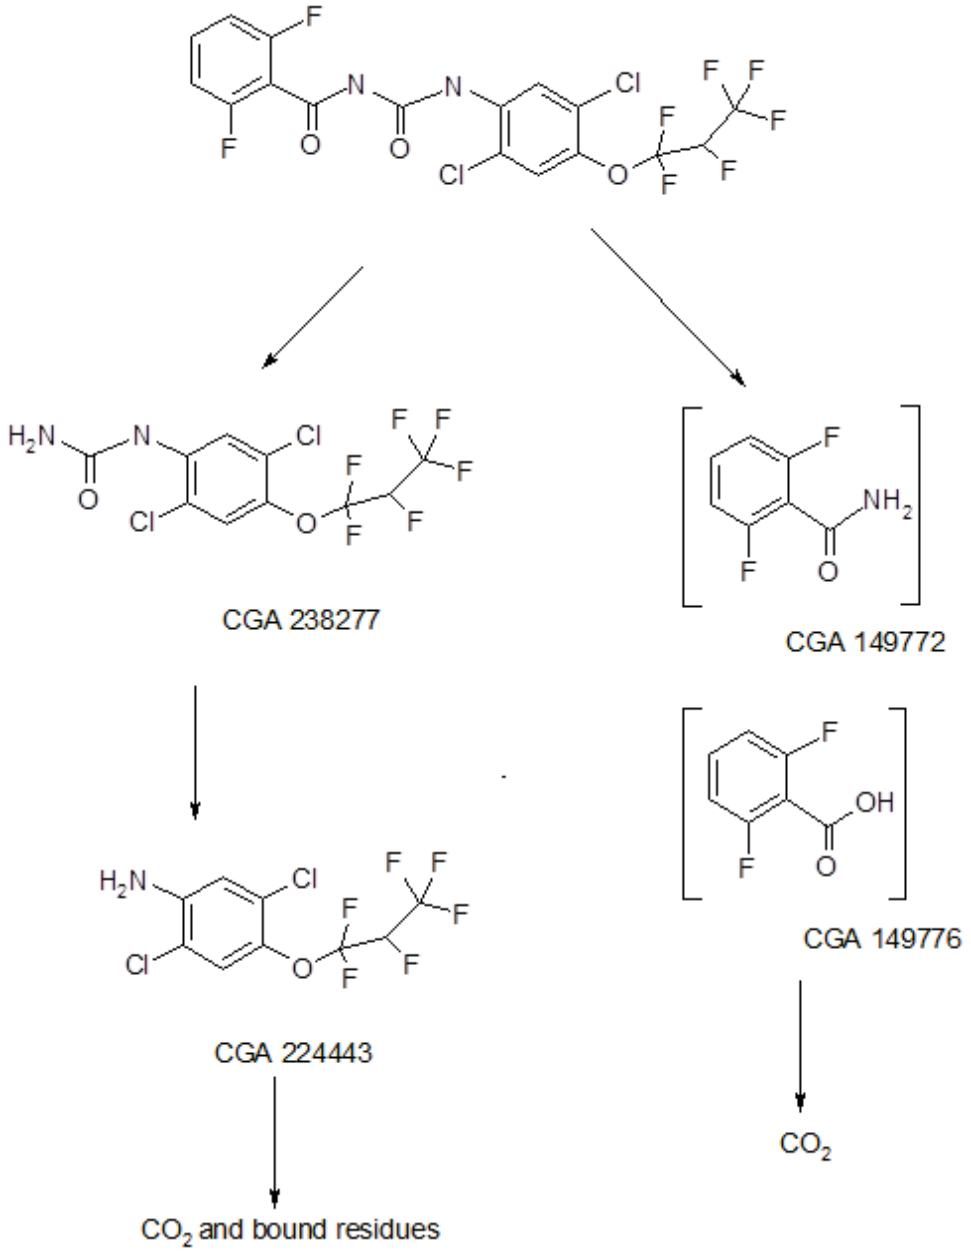

Figure 3 Proposed metabolic pathway of lufenuron in soil (aerobic)

Besides the parent substance the behaviour of the soil metabolite CGA149772 (2,6-difluorobenzamide) under aerobic conditions was investigated by Slangen (2003, LUFEN_034) in three different soil types using ^{14}C-phenyl ring-labelled CGA149772.

Soil was extracted by shaking with acetonitrile: acetic acid 98:2 following two more extractions with a mixture of acetonitrile: water 80:20 (v/v). Finally, the soil was extracted with water. The remaining soil debris was extracted with acetonitrile in a Soxhlet for six hours. All the supernatants were evaporated to aqueous and analysed by LSC followed by two different normal phase TLC methods and HPLC where possible. The sample of each soil type with the highest bound residue remaining after extraction was subjected to organic matter fractionation.

Soil degradation

The soil degradation of [^{14}C]dichlorophenyl-lufenuron and its primary metabolites CGA224443 and CGA238277 under varying moisture and temperature was investigated by Gonzalez-Valero (1991, LUFEN_031). A silt loam soil type (Les Evouettes) was incubated under different conditions described in the following table. For each condition, an amount of 0.1 mg ai/kg or 1 mg ai/kg soil was applied.

Table 13 Incubation conditions

Moisture content	Temperature (°C)	Concentration
30% field capacity	20	0.1 and 1.0 mg/kg
60% field capacity	20	0.1 and 1.0 mg/kg
60% field capacity	10	0.1 and 1.0 mg/kg

Based on these conditions, the following amounts of lufenuron, CGA224443 and CGA238277 were recovered.

The modelling of DT_{50}- and DT_{90}-values based on this study was conducted by Sapiets (2003, LUFEN_032). By using first-order compartment models (FOMC) the following values were estimated:

Table 17 Calculated DT_{50}- and DT_{90}-values for lufenuron, CGA224443 and CGA238277

Compound	Model	DT_{50} (days)	DT_{90} (days)
Lufenuron	FOMC	13.7	81.1
CGA238277	FOMC	12.8	42.5
CGA224443	FOMC	35.8	118.8

Plant metabolism

The fate of lufenuron in plants was investigated following foliar spray application of [dichlorophenyl-14C]- and/or [difluorophenyl-14C]-radiolabelled active substance to tomato, cabbage and cotton.

In all samples unchanged lufenuron was the only residue compound detected, mainly present on the surface of the treated plant parts. No significant translocation was observed after treatment or direct stem injection. After several weeks, an uptake of the residue in treated leaves was observed, however the extracts contained lufenuron solely. In very minor amounts CGA238277 was detected at levels of 3.3% TRR or less. A proposed metabolic pathway scheme is presented in Figure 4.

Tomato

The metabolism of lufenuron was investigated in tomatoes after three spray applications with [dichlorophenyl-^{14}C]-lufenuron by Stingelin (1992, LUFEN_019). Fruit bearing plants were treated with rates equivalent to 0.03 kg ai/ha per application with one week intervals. The plants were kept in protected environments. Samples were collected from the same four plants 1 h after the first treatment, and 1 h, 12 d and 28 d after the final application (dissipation experiment). Foliage and mature fruits of four additional plants were collected 28 days after the final treatment to investigate the distribution and degradation of lufenuron.

In a second experiment four single fruits were treated by injection of 34 µg lufenuron. The fruits were sampled after 18 and 33 days.

The tomato fruits were washed three times (1 minute) in acetone (250 mL) to solubilise surface radioactivity; the levels of radioactivity in the washing were determined by liquid scintillation counting (LSC). The washed tomato fruits were frozen and homogenised under liquid nitrogen and the total radioactive residues (TRR) determined by combustion and LSC.

Extraction of the radioactive residues in the homogenised plant material was carried out using methanol-water (80:20, v/v) for two hours. This procedure was repeated until the radioactivity of the last extract was less than 5% of the first extract (maximum five extraction steps). Any remaining residues were subjected to Soxhlet extraction and finally unextracted residues were determined by combustion.

Extracts and washings were analysed by thin layer chromatography. Reference markers were visualized under UV light and areas of radioactivity detected using a radiochromatogram camera.

In all fruit and leaves samples from the foliar spray experiments most of the radioactivity was recovered in the surface wash, presenting 74–100% of the TRR. Minor amounts were also recovered primarily by methanol/water extraction, adding to total recoveries of radioactivity of 96–118% TRR. Lufenuron was the major residue identified in the combined surface wash and extracts, representing 93–99% of the TRR. In the extracts of fruits sampled 28 DALT, traces of CGA238277 were identified at 0.2% of the TRR (see Tables 18 Table and 19).

In mature fruits receiving a direct injection of lufenuron the results were comparable, with 90–95% of the radioactivity identified as unchanged lufenuron. Again CGA238277 was identified in minor amounts up to 2% of the TRR, and 5% of the total radioactivity remained unextracted.

Table 18 Summary of the distribution of radioactivity and residual [dichlorophenyl-^{14}C]-lufenuron in tomato fruits (dissipation experiment)

Cabbage

Cabbage plants (white cabbage) in a greenhouse were treated by Krauss (1994, LUFEN_020) with three spray applications of 0.02 kg ai/ha each (0.06 kg ai/ha total) in two week intervals using [dichlorophenyl-^{14}C]-lufenuron. Samples were taken one hour after the first and last application, and at crop maturity, 28 days after the last application. At each sampling the heads were separated into old/wrapper leaves and remaining heads.

Homogenised plant material was extracted five times with methanol-water (80:20, v/v) or until the radioactivity of the last extract was less than 5% of first extraction. Further extraction of the plant material was carried out using Soxhlet extraction with methanol. The amount of radioactivity in extracts was determined using liquid scintillation counting (LSC) and by combustion LSC of solid materials.

The nature of the residues in cabbage extracts was elucidated using normal and reverse phase thin layer chromatography. Reference markers were visualised under UV light and areas of radioactivity detected using a radiochromatogram camera.

In cabbage samples most of the radioactivity was present in part of the heads directly affected by the spray solution. Whole cabbage and older leaves gave TRR levels between 0.5–1.8 mg eq/kg, while the inner head contained lower radioactive residues of 0.2–0.3 mg eq/kg, and 89–101% of the TRR were extracted by methanol/water. In the extracts, unchanged parent lufenuron was the only major residue representing 88–98% of the TRR. The only other metabolite identified was CGA238277, representing up to 3.3% of the TRR (see Table 20).

Cotton

The investigation on the metabolism of lufenuron in cotton under glasshouse conditions was reported in two studies. In the first study by Stingelin (1991, LUFEN_021) [dichlorophenyl-^{14}C]-lufenuron formulated as EC50 product was applied with three spray applications at a rate equivalent to 0.03 kg ai/ha (total seasonal application rate 0.09 kg ai/ha). The first application was made at the beginning of flowering and further applications made at 14-day intervals. Sampling of leaves took place 1 hour, 1 day, 3 and 7 days after the first application and 14 days, 28 and 84 days (maturity) after the last application. At maturity, plants were also separated into stalks, leaves (old and new), green bolls, hulls, fibre and seeds

In addition, four cotton plants were injected (into the stalks) with radiolabelled lufenuron (100 µg) dissolved in acetone (2 µL). Two further injections were made at 14-day intervals. Harvested cotton plants from the injection experiment were separated into similar components, i.e. stalks, (region of the injection and remainder) leaves (old and new), green bolls, hulls, fibre and seeds.

All plants were kept in plastic containers in greenhouse.

At each interval, from the foliar application, the leaves were washed three times with a mixture of acetone-water (50:50; v/v). The washed leaves were then homogenized in the presence of methanol water (80:20, v/v).

The components from the mature cotton plants were homogenized in the presence of “dry ice” or after freezing with liquid nitrogen; in the case of dry hulls the samples were homogenized in a mill. For extraction of the radioactive residues, the homogenised plant material was suspended in a mixture of methanol-water (80:20; v/v). This procedure was repeated until the radioactivity of the last extract was equal or less than 5% of the radioactivity contained in the first extract.

The amount of radioactivity in extracts and post-extraction solids was determined using liquid scintillation counting (LSC) and by combustion LSC. The nature of the residues in extracts was elucidated using silica gel 60 F thin layer chromatography. Reference markers were visualised under UV light (254 nm) and areas of radioactivity detected using a radiochromatogram camera.

In cotton leaves most of the residue was recovered in the surface wash, however at the end of the experiment (84 DALT) approximated half of the radioactivity was present in the washed leaf extracts. In total, the extraction rates of leaves and other plant parts was high, leaving less than 3% unextracted. In the combined extracts, unchanged lufenuron was the only

residue identified in leaves, stalks and hulls, representing 89–100% of the TRR. Fibre, seeds and bolls did not contain sufficient radioactivity for identification (TRR ≤ 0.001 mg eq/kg).

n.a.=Not analysed

The translocation experiment following stem injection showed that most of the applied radioactivity remained at the injection site (81.2% AR). Into close stalks (13.3% AR) and leaves (1.6-3.9% AR) a minor translocation was observed. In all samples the unchanged parent was the only residue identified (approximately 95–98% TRR).

In a second study conducted by Gentile (1991, LUFEN_022) cotton grown in greenhouse was treated with [^{14}C]difluorophenyl-lufenuron formulated as an EC50 product. Eight cotton plants were separately treated with three spray applications at a rate equivalent to 0.03 g ai/ha each (total seasonal application rate 0.09 g ai/ha). The first application was made at two months after sowing (no growth stage reported) and further applications made two and four weeks after the first application.

Sampling (three leaves from four plants) took place 2 hours after each application. At maturity, 52 days after the last application, plants were separated into stems, leaves (old and new), hulls, fibre and seeds.

At each interval from the foliar application, the leaves were washed twice with acetonitrile (surface wash). The washed leaves were then homogenized in the presence of acetonitrile-water (80:20, v/v). The unextracted radioactive residues were determined by combustion and liquid scintillation counting (LSC).

The components from the mature cotton plants were homogenized in the presence of liquid nitrogen. Radioactive residues in the homogenised plant material were extracted with acetonitrile-water (80:20, v/v). The procedure was repeated until the radioactivity of the last extract was equal or less than 5% of the radioactivity contained in the first extract. Residues remaining in the plant material were solubilised using Soxhlet extraction with acetonitrile. The amount of radioactivity in extracts was determined using liquid scintillation counting (LSC) and by combustion LSC in solid materials. The nature of the residues in extracts was elucidated using silica gel 60 F thin layer chromatography. Reference markers were visualised under UV light (254 nm) and areas of radioactivity detected using a TLC scanner.

In the leaves sampled at each interval at least 49% of the radioactivity was found in the surface wash. The total recovery of radioactivity was high, leaving less than 2% of the TRR unextracted. In the combined extracts unchanged lufenuron was the only residue identified, representing at least 92% of the TRR.

In other matrices (old leaves, stems, hulls and fibre) the methanol/water extract released the major part of the residue. Again, only unchanged lufenuron was present in the extracts at levels of 78.7–83.1% TRR. In seeds and new grown leaves the TRR was too low for further identification (0.003–0.005 mg eq/kg).

For a summary of the results please refer to Table 23.

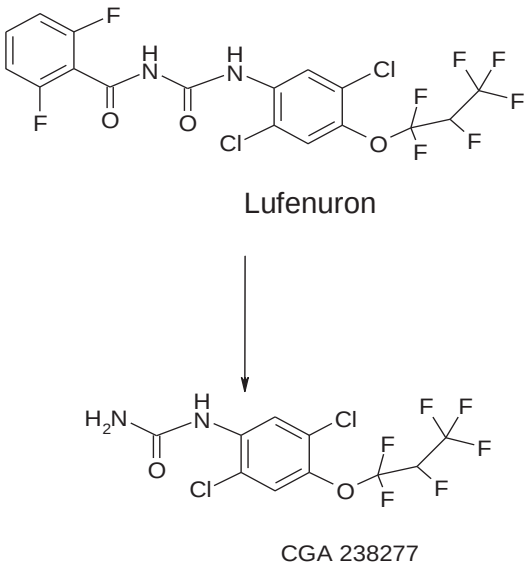

Figure 4 Proposed metabolic pathway of lufenuron in plants

Confined rotational crop studies

For the investigation of lufenuron in rotational crops two studies were conducted involving application of either [^{14}C]difluorophenyl- or [^{14}C]dichlorophenyl-lufenuron. The experiments using [^{14}C]difluorophenyl-lufenuron was conducted by Gentile (1992, LUFEN_023). Plant containers kept in a glasshouse received application to bare soil equivalent to 0.15 kg ai/ha. Lettuce, spring wheat, maize and carrots were planted in the treated soil 63 days after test substance application. Immature and mature samples of the crops were taken throughout the study and soil samples were taken at each sampling.

Fresh samples were homogenised in the presence of liquid nitrogen and dry plant parts, e.g. grain, were homogenised in a mill. For extraction of the radioactive residues the homogenised plant material was suspended in a mixture of acetonitrile-water (80:20; v/v). This procedure was repeated until the radioactivity of the last extract was equal or less than 5% of the radioactivity contained in the first extract. Non-extracted residues were solubilised using Soxhlet extraction with acetonitrile. The amount of radioactivity in extracts was determined using liquid scintillation counting (LSC) and by combustion LSC in solid materials.

The nature of the residues in extracts was elucidated using silica gel 60 F thin-layer chromatography. Reference markers were visualised under UV light (254 nm) and areas of radioactivity detected using a radiochromatogram camera.

The transfer of radioactivity into lettuce, wheat, maize and carrots grown as succeeding crops was very limited. In mature lettuce (126 d after treatment) the highest TRR levels of 0.047 mg eq/kg were found. 53% of the TRR was identified as unchanged parent (0.025 mg/kg). In other matrices only wheat straw (0.023 mg eq/kg, 0.007 mg lufenuron/kg) and immature carrots roots (0.023 mg eq/kg, no identification conducted) showed total radioactive residues above 0.01 mg eq/kg. No further identification was conducted for these matrices. In soil, nearly the entire extracted radioactivity was attributed to lufenuron. No further metabolites could be identified against the reference compounds CGA149772 or CGA149776.

In a second confined study in the field conducted by Stingelin (1992, LUFEN_024) [^{14}C]dichlorophenyl-lufenuron was applied to bare soil one at a rate equivalent to 0.13 kg ai/ha. After different plant-back intervals (PBI) lettuce (PBI 76 d), winter wheat (PBI 126 d), sugar beets (PBI 306 d) and maize (PBI 331 d) were planted/sown and grown to maturity. In addition soil samples from layers up to 30 cm depth were collected and analysed for residues.

Fresh samples were homogenised in the presence of liquid nitrogen and dry plant parts, e.g. grain, were homogenised in a mill. After homogenisation samples were combusted and the levels of radioactivity were measured by liquid scintillation counting (LSC).

None of the plant samples were extracted since the radioactive residues were < 0.01 mg/kg.

In soil samples most of the radioactivity was recovered in the first 5 cm soil layer (55–96% AR). At the end of the study (519 days after treatment) up to 27.9% AR moved into the 5–10 cm layer and up to 24.7% to the 10–20 cm layer. The transfer into even lower layers was minimal (< 7% AR). The analysis of the upper layers revealed lufenuron as the major residue. The only metabolites identified were CGA238277 and CGA224443, both not exceeding 0.014 mg eq/kg.

Animal metabolism

The Meeting received metabolism studies on laboratory animals, poultry and lactating goats using the difluorophenyl- and the dichlorophenyl-label of lufenuron.

The metabolism of lufenuron in livestock animals was minimal, showing only unchanged parent substance in all goat matrices. In poultry minor amounts of CGA149772 and CGA238277 were found in edible commodities, however at levels below 10% TRR or 0.01 mg eq/kg. Most of the radioactive residue was present in fat tissue, egg yolk and milk.

Laboratory animals

Lactating goats

The metabolic fate of lufenuron in lactating goats was investigated using [^{14}C]difluorophenyl- or [^{14}C]dichlorophenyl-lufenuron (Cameron, 1992, LUFEN_018 & Schulze-Aurich, 1992, LUFEN_017). The compound was administered to one lactating goat for each label in gelatine capsules at 5.4 ppm for the difluorophenyl-label (0.135 mg/kg body weight) and 6.0 ppm for the dichlorophenyl-label (0.15 mg/kg body weight) for ten consecutive days. Excreta and milk were collected daily. The animals were slaughtered approximately 24 hours after the last dose. Muscle, omental fat, peritoneal fat, liver, kidney, blood, bile and content of gastrointestinal tract/rumen were collected.

Radioactivity was measured by combustion and liquid scintillation counting. The composition of samples was investigated two months after sampling. Thin-layer chromatography was used to identify and characterize radioactive components in sample extracts.

The total recovery of the administered radioactivity was 95% for both labels. The majority of the radioactivity (73–74%) was found in the faeces. Radioactive residues in the edible tissues were 0.8–1.6% AR in muscle, 4.2–5.4% AR in fat, 0.28–0.3% AR in liver, 0.01–0.02% AR in kidney and 5.8–6.8% AR in milk. A summary of the recovered radioactivity is presented in Table 29.

Table 29 Radioactive residues in milk and tissues after oral administration of [^{14}C]difluorophenyl- (5.4 ppm) or [^{14}C]dichlorophenyl-lufenuron (6.0 ppm) for 10 consecutive days

7	0.878	0.892	0.850	1.049
8	0.998	0.940	1.037	0.798
9	1.001	0.979	0.711	0.790
10	0.997	0.706	0.786	0.791
11	0.690	–	0.674	–

For both labels unchanged lufenuron was the only residue in tissues and milk, representing 73–94% of the TRR. Highest concentrations were present in fat tissue and milk. No separation between milk fat and skim milk was conducted.

In goat faeces and urine the majority of the residue also comprised of lufenuron. Varying levels, depending on the sampling period, of CGA238277, CGA149772 and CGA149776 were also found.

For the composition of radioactive residues in milk and tissues please see Tables 31 and 32.

Laying hens

The metabolic fate of lufenuron was investigated using [^{14}C]difluorophenyl- or [^{14}C]dichlorophenyl-lufenuron (Cameron, 1992, LUFEN_016 & Schulze-Aurich, 1992, LUFEN_017). For each label the compound was administered in gelatine capsules to three laying hens at doses of 3.4 ppm for the difluorophenyl-label (representing 2.6 mg/kg body weight) and of 5.2 ppm for the dichlorophenyl-label (representing 3.5 mg/kg body weight) for fourteen consecutive days. Excreta and eggs were collected daily. The animals were slaughtered approximately 24 hours after the last dose. Muscle, skin with attached fat, peritoneal fat, liver, kidney and content of gastrointestinal tract were collected.

Radioactivity was measured by combustion and liquid scintillation counting. The composition of samples was investigated two months after sampling. Thin-layer chromatography was used to identify and characterize radioactive components in sample extracts.

The total recovery of the administered radioactivity was 75–79%. The majority of the radioactivity (54–62%) was found in the excreta. Radioactive residues in the edible tissues were 0.55–1.15% AR in lean meat, 5.1–9.9% AR in fat, 0.4–0.58% AR in liver, 0.07% AR in kidney and 8.7–9.6% AR in eggs. A summary of the recovered radioactivity is presented in Table 33.

Table 33 Radioactive residues in eggs and tissues after oral administration of [^{14}C]difluorophenyl- (3.4 ppm) or [^{14}C]dichlorophenyl-lufenuron (5.2 ppm) for 14 consecutive days

In eggs radioactive residues were mainly present in the egg yolk for both labels. A plateau was approximated at the end of the 14 days dosing period in the yolk while residues in egg white remained stable after more than 4 days. In the following table the total radioactivity recovered from egg white and egg yolk is summarized:

Table 34 Mean radioactive residues in hen egg following 14 consecutive doses of [^{14}C]dichlorophenyl or [^{14}C]difluorophenyl lufenuron to laying hens

14	0.002	6.470	0.008	8.479

For both labels unchanged lufenuron was the major residue in all tissues and eggs, representing at least 79.3% of the TRR. Highest concentrations were present in poultry fat and egg yolk.

The only other metabolites identified were CGA149772 for the difluorophenyl-label (egg white, 0.001 mg eq/kg, 17.3% TRR) and CGA238277 for the dichlorophenyl-label (kidney and egg white, < 0.001–0.028 mg eq/kg, 5.3–7% TRR).

In hen excreta > 90% TRR was extracted. Lufenuron was the major component of the residue, i.e. > 82%. No other component accounted for > 5% TRR, CGA238277 represented 3% TRR and CGA149776 for < 4.3% TRR.

For the composition of radioactive residues in eggs and tissues please refer to Tables 35 and 36.

RESIDUE ANALYSIS

Analytical methods

For lufenuron analytical methods were provided for plant and animal matrices. All plant matrices were validated with an LOQ of 0.01 mg/kg. For animal commodities a general LOQ of 0.02 mg/kg was validated.

The applicability of multi residue methods was confirmed on basis of DFG S19 for plant and animal matrices (LOQ 0.02 mg/kg for all commodities).

Plant materials

Method REM 118.01 (Altenburger, 1988, LUFEN_035; Clarke, 2004, LUFEN_036) and Method REM 118.07 (Clarke, 2005, LUFEN_037)

Lufenuron residues were extracted from plant material by maceration in the presence of methanol. The extract filtered and diluted with water and sodium chloride solution. Lufenuron is partitioned into hexane/diethyl ether (9/1; v/v); the organic phase is reduced in volume, redissolved in hexane, and "cleaned up" using solid phase extraction on a cyano SPE cartridge (REM 118.01 only). The concentration of lufenuron is determined using HPLC-UV detection at 255 nm (REM 118.01) and in the current version HPLC-MS/MS (REM 118.07).

Table 38 Recovery data for method REM 118.01 (HPLC-UV: 255 nm) and its modification REM 118.01 (LC-MS/MS: m/z: 509.1 → 326.0) measuring lufenuron in plant matrices

Method POPIT MET.015 (Anonymous, 2002, LUFEN_038)

Method POPIT MET.015 provides for the determination of lufenuron in coffee beans and soybeans. The frozen raw sample is prepared by milling the whole sample with dry ice until the complete homogenization. 10 g of the sample is homogenized with 80 mL of methanol by milling. An 8 mL aliquot of the sample is mixed with 8 mL of water, 4 mL of saturated sodium chloride solution, and 4 mL of hexane: ethyl ether (9:1) solution, for a final volume of 24 mL. The upper layer is transferred to another vessel, evaporated at 40 °C, and re-dissolved in 2.5 mL hexane. The sample is cleaned up by silica solid phase extraction (SPE). The sample solution collected is evaporated at 40 °C, and dissolved in 2 mL of hexane: isopropanol: methanol (90:5:5) solution. The final sample solution is analysed by LC UV (255 nm).

Table 39 Recovery data for method POPIT MET.015 in coffee and soybeans

Method POPIT MET.077.Rev05 (Anonymous, 2008, LUFEN_039)

Method POPIT MET.077 provides for the determination of lufenuron in cotton, coffee, sunflowers, peaches sugarcane and sugar cane litter. The frozen sample is prepared by milling the whole sample with dry ice until the complete homogenization. 5 g of the sample is homogenized with 40 mL of methanol by milling. An 8 mL aliquot of the sample is mixed with 8 mL of water, 4 mL of saturated sodium chloride solution, and 4 mL of hexane: ethyl ether (9:1) solution, for a final volume of 24 mL. The upper layer is transferred to another vessel. The clean-up is repeated and a 4 mL aliquot of the hexane: ethyl ether (9:1) solution is added to the remaining layer. The upper layer is combined with the initial extract. This extract is evaporated at 40 °C, and re-dissolved in 2.5 mL hexane. The sample is then cleaned up by silica solid phase extraction (SPE) and analysed by LC-MS/MS.

Method POP PAT 004 V01/V04 (Anonymous, 2010, LUFEN_040)

Method POP PAT 004 provides for the determination of lufenuron in maize and soy. The frozen raw sample is prepared by milling the whole sample with dry ice until homogenous. The sample is homogenized with 20 mL of methanol by milling. A 4 mL aliquot of the sample is mixed with 4 mL of water, 4 mL of saturated sodium chloride solution, and 4 mL of hexane: ethyl ether (9:1) solution, to a final volume of 16 mL. The upper layer is transferred to another vessel. The clean-up is repeated, and a 4 mL aliquot of the hexane:ethyl ether (9:1) solution is added to the remaining layer. The upper

layer is combined with the initial extract. The combined sample is evaporated at 40 °C, re-dissolved in 1 mL methanol and analysed by LC-MS/MS.

Multi-residue method DFG S19 (extended revision) (Anspach, 2002, LUFEN_042 & Schulz, 2003, LUFEN_043)

A method, based on the DFG S19 (extended revision) multi-method, for routine monitoring of lufenuron in samples of plant material has been validated.

Lufenuron residues are extracted using module E1 for orange and tomato, E2 for wheat grain followed by clean up procedures according to module GPC (gel permeation chromatography). All samples are analysed by high performance liquid chromatography with tandem mass spectrometric detection, HPLC-MS/MS (m/z: 509 → 326 & m/z: 509 → 175).

Animal materials

Method REM 118.04 (Tribolet, 1995, LUFEN_041)

REM 118.04 provides for the determination of lufenuron in tissues, fat and milk. Tissue samples are extracted by maceration (liver and kidney) or shaking (meat) with methanol. In the case of fat, the sample is melted and lufenuron residues are extracted by shaking with acetonitrile. The extract is filtered and the acetonitrile reduced in volume. The residue is re-dissolved in methanol.

Milk samples are diluted with acetonitrile to precipitate proteins, filtered and the acetonitrile reduced in volume. The residue is re-dissolved in methanol.

The extracts, for all commodities, are diluted with water and sodium chloride solution. Lufenuron is partitioned into hexane/diethyl ether (9/1; v/v) and the organic phase is reduced in volume, re-dissolved in hexane, and “cleaned up” using solid phase extraction on a silica gel cartridge.

The concentration of lufenuron is determined by HPLC-UV at 255 nm.

Table 43 Recovery data for method REM 118.04 in animal matrices

Matrix	Fortification level (mg/kg)	n	Recovery range (%)	Recovery, mean (%)	RSD (%)	Reference

Multi-residue method DFG S19 (extended revision) (Anspach, 2003, LUFEN_044 & Schulz, 2003, LUFEN_045)

A method, based on the DFG S19 (extended revision) multi-method, for samples of tissues, milk and eggs has been validated. For samples of milk, meat and eggs, samples are extracted with acetone. Water is added prior to extraction to maintain a ratio of 2/1 (v/v), taking into account the natural water content of the matrices. Ethyl acetate/cyclohexane (1/1; v/v) and sodium chloride are added and the mixture homogenised. An aliquot of the organic phase is applied and cleaned up using gel permeation chromatography. In the case of fat, samples are mixed with synthetic calcium silicate after addition of acetone and acetonitrile. An aliquot of the organic phase was cleaned up on gel permeation chromatography.

All samples were analysed for residues of lufenuron by high performance liquid chromatography with tandem mass spectrometric detection, HPLC-MS/MS (m/z: 509 → 326 & m/z: 509 → 175).

Stability of pesticides in stored analytical samples

Plant matrices

Tribolet (1993, LUFEN_046)

Samples of cotton seed, cabbage and orange were fortified with lufenuron at a concentration of 0.5 mg/kg and stored under –18 °C. The samples were stored in plastic and glass vessels, however no difference between both materials was observed. Samples were taken for analysis at intervals up to 24 months in parallel to freshly fortified samples to estimate the procedural recovery. Analysis of the samples was performed according to the method REM 118.01.

In the study report the results for the stored samples are only reported as percentage of the fortified level corrected by the procedural recoveries. No measured concentrations were described.

Table 45 Recovered lufenuron residues in stored plant commodities after storage up to 24 months (Tribolet, 1993, LUFEN_046)

Animal matrices

Tribolet (1995, LUFEN_047)

Storage stability of residues of lufenuron in bovine tissues and milk were conducted to support the data from the livestock feeding study. Samples of bovine muscle, liver, kidney, fat, milk and blood were fortified with lufenuron at a concentration of 0.2 mg/kg in tissues, 0.02 mg/kg in milk and 0.04 mg/kg in blood. Samples were stored at –18 °C for a period of 9 months, which covered the sample storage time in the study. Analysis of the samples (in triplicate) was performed according to the method REM 118.04.

USE PATTERN

Lufenuron is an insect growth inhibitor that is active against larvae of Lepidoptera and Coleoptera. It is used in a vegetable crops, oilseeds, root crops maize, sugarcane and coffee close to harvest.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue levels were reported as measured. Application rates were always reported as lufenuron equivalents. When residues were not detected they are shown as below the LOQ, e.g., < 0.01 mg/kg. Application rates, spray concentrations and mean residue results have generally been rounded to the even with two significant figures. HR and STMR values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. These results are underlined.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for% recovery.

Fate of residues in storage and processing

Nature of residue during processing

The hydrolysis of lufenuron under processing conditions was investigated by Grout (2003, LUFEN_100). [^{14}C]diflurophenyl and [^{14}C]dichorophenyl labelled lufenuron was incubated in aqueous buffer solutions at a nominal concentration of 5 mg/L under three sets of conditions, each designed to simulate an appropriate process: 90 °C (pH 4, 20 minutes) to simulate pasteurisation, 100 °C (pH 5, 60 minutes), to simulate boiling, baking and brewing, and 120 °C (pH 6, 20 minutes) to simulate sterilisation.

Total recovered radioactivity was measured for each test solution. Radioactive components were characterized by fractionation and co-chromatography with authenticated reference compounds using HPLC.

Residues after processing

The fate of lufenuron during processing of raw agricultural commodity (RAC) was investigated in tomatoes using important processing procedures. As a measure of the transfer of residues into processed products, a processing factor was used, which is defined as:

Processing factor=Residue in processed product (mg/kg) ÷ Residue in raw agricultural commodity (mg/kg)

If residues in the RAC were below the LOQ, no processing factor could be derived. In case of residues below the LOQ, but above the LOD in the processed product, the numeric value of the LOQ was used for the calculation. If residues in the processed product were below the LOD, the numeric value of the LOQ was used for the calculation but the PF was expressed as "less than" (e.g. < 0.5).

Tomato

A study on the behaviour of lufenuron during processing of tomatoes was conducted by Sole (2003, LUFEN_101). Tomatoes grown outdoor in Southern France were treated three times with 0.03 kg lufenuron/ha each at one week intervals. Samples were harvested 8 days after the last application. Tomatoes were used for the production of tomato juice, canned tomato and tomatoes puree. The field sample was split into subsamples processed multiple times for each commodity:

- The washed tomatoes were produced by washing for 2 minutes in cold running water.
- Tomato juice was produced by quartering and blanching the washed tomatoes followed by sieving to remove the peel and seeds (wet pomace). The raw juice was pasteurised (20 minutes at 99 °C).
- Tomato puree was produced by concentrating raw juice to approximately 30% dry matter and then pasteurising (20 minutes at 93–95 °C).
- Canned tomatoes were produced by blanching washed tomatoes to remove the peel. The peeled tomatoes and portion of tomato juice from the juicing process were then sterilised in tins.

Table 61 Summary of lufenuron residues in tomato and processed commodities from a trial conducted in Southern France (Sole 2003, LUFEN_101)

Commodity	Lufenuron in mg/kg	Processing factor	Median or best estimate processing factor
Fruits (RAC)	0.029	–	–
Raw juice	< 0.005, 0.005	< 0.17, 0.17	0.17

Residues in animal commodities

Farm animal feeding studies

For the estimation of residues of lufenuron in animal matrices one lactating cow feeding study and one steer feeding study were submitted to the Meeting.

Lactating cows

In the first study residues in lactating cows were investigated by Tribolet (1995, LUFEN_102). The dose rates were approximately 0, 39, 230 and 415 µg lufenuron/kg body weight/day (equivalent to nominal concentrations of 0, 0.82, 4.3 and 8.6 mg/kg in the daily feed).

The cows in the treatment groups were fed with the lufenuron twice daily with the active ingredient mixed with pelleted feed, for a period of 28–29 days. Milk samples were collected pre-treatment and throughout the dosing period. At Day 29–30 the cows were slaughtered and samples of muscle (tenderloin, round steak), liver, kidney and fat (omental and peri-renal) were taken for analysis.

Milk and tissues were extracted and analysed for lufenuron using method REM 118.04. The LOQ for milk, blood and tissues are 1 µg/L, 10 µg/L and 0.01 mg/kg respectively.

In the control group no detectable residues of lufenuron were found. The findings in milk and tissues are summarized in the following table.

Table 62 Residues of lufenuron in cow tissues and milk following administration of lufenuron at 0.82, 4.3 and 8.6 ppm in the diet

Steer

Residues of lufenuron in steer were also investigated by Tribolet (2000, LUFEN_103). Three groups of steers, Angus X Hereford, were used in this study, two treated and one control group. One group of three steers was dosed with capsules containing 0.2 mg lufenuron and a further treatment group of 12 steers were dosed with 10 mg of lufenuron. Each treatment group was dosed for 28 consecutive days. The dose rates were equivalent to nominal concentrations of 0.02 and 1 mg/kg in the daily feed (0.0006 and 0.031 mg/kg bw/day).

The lower dose group and three steers from the higher group were sacrificed 20–24 hours after the final dose and a further three steers were sacrificed at two week intervals, i.e. days 42, 56 and 70 after the commencement of dosing. At sacrifice, samples of blood, muscle (tenderloin, round steak), liver, kidney and fat (omental and peri-renal) were taken for analysis.

Tissues were extracted and analysed for lufenuron using method REM 118.04. The LOQ for blood and tissues are 2 µg/L, and 0.01 mg/kg respectively.

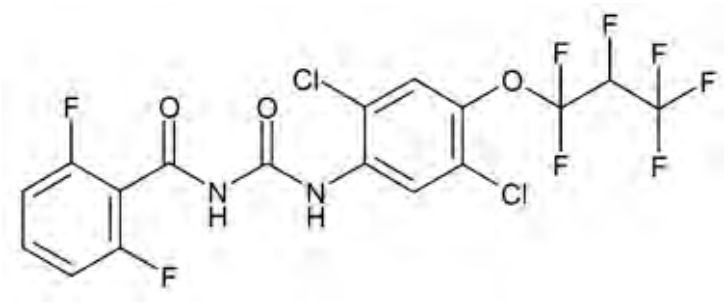
APPRAISAL

Lufenuron (ISO common name) is an insect growth inhibitor that is active against larvae of Lepidoptera and Coleoptera. When ingested, lufenuron interferes with chitin synthesis, and prevents larvae from moulting. It was considered for the first time by the 2015 JMPR for toxicology and residues.



The IUPAC name of lufenuron is (RS)-1-[2,5-dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)phenyl]-3-(2,6-difluorobenzoyl)urea and the CA name is N-[[[2,5-dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)phenyl]amino]carbonyl]-2,6-difluorobenzamide.

Lufenuron consists of a pair of enantiomers. A chiral centre exists at the 2-position of the hexafluoropropoxy side-chain. Lufenuron technical active ingredient is manufactured under non-stereospecific conditions giving a racemate (R:S 50:50).

The physical-chemical properties of lufenuron indicate low volatility and no accelerated photochemical degradation in water. The octanol-water partition coefficient, log $P_{ow,}$ is 5.12.

Lufenuron radio-labelled either in the dichlorophenyl- or difluorophenyl-moiety was used in the metabolism and environmental fate studies.

The following abbreviations are used for the metabolites discussed below:

CGA149776	2,6-Difluoro-benzoic acid	CGA149772	2,6-Difluoro-benzamide	CGA238277	2,5-Dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)-phenyl-urea	CGA224443	N-[2,5-dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)-benzenamine	CGA301018	no chemical name submitted	
Environmental fate in soil

The Meeting received information for lufenuron on soil photolysis, aqueous hydrolysis, aerobic soil metabolism and soil degradation.

Soil photolysis using [dichlorophenyl-^{14}C]-lufenuron and [difluorophenyl-^{14}C]-lufenuron revealed no significant degradation (84–99% parent remaining after 17 days of continuous irradiation).

Hydrolysis in aqueous solutions representative of environmental conditions (25 °C) showed virtually no degradation at pH 5, 7 and 9 within 5 days. Under more extreme conditions the parent substance was stable at pH 1 and 70°C, representing more than 90% of the radioactivity. At pH 9 an accelerated degradation was observed at 50 °C and 70 °C with 0–53% of the parent remaining after 1–5 days. Depending on the label the cleavage products CGA224443 and CGA238277 and its counterparts CGA149776 and 2,6-difluorobenzamide (CGA149772) were observed. In addition both labelled compounds produced CGA301018 by loss of fluoride and ring closure.

In the aerobic soil metabolism studies lufenuron was degraded with half-lives of 9–24 days in microbial active soil and 17–83 days in sterilised soil. Cleavage of the parent molecule was the primary degradation step, leaving CGA238277 and CGA224443 for [dichlorophenyl-^{14}C]-lufenuron. For [difluorophenyl-^{14}C]-lufenuron no metabolites were identified. Unextracted residues in soil at the end of the studies were between 25–79% of the AR. Mineralisation ranged up to 59% AR.

2,6-difluorobenzamide (CGA149772), which is a common soil metabolite to other active substances, e.g., diflubenzuron, was investigated separately for its behaviour in soil. Within 120 days it was completely degraded, leaving CGA149776 as its main degradate within the first two weeks. Afterward the radioactivity was further degraded and remained unextracted (up to 41% AR) or was mineralized (up to 65% AR).

The soil degradation of lufenuron and its metabolites CGA238227 and CGA224443 was also investigated on three different soils under laboratory conditions. Following 1st-order kinetic, DT_{50} and DT_{90} values of 13.7 d and 81.1d for lufenuron, 12.8 d and 42.5 d for CGA238277 and of 35.8 d and 119 d for CGA224443 were calculated, respectively.

In summary the Meeting concluded that lufenuron is moderately quickly degraded in soil under laboratory conditions, presumably by microbial activity. To assess the degradation behaviour under field conditions, field dissipation studies would be required. The residue is stable against photolysis and hydrolysis under environmental conditions, however at high temperature and basic conditions cleavage of the parent molecule was observed.

Plant metabolism

The Meeting received plant metabolism studies for lufenuron following foliar application of either [dichlorophenyl-^{14}C]-lufenuron or [difluorophenyl-^{14}C]-lufenuron in cabbage, tomato and cotton.

For cabbage the metabolism of lufenuron was investigated with [dichlorophenyl-^{14}C]-lufenuron only. Greenhouse plants received three spray applications equivalent to 0.02 kg ai/ha each in two week intervals. Samples were taken one hour after the first and last application, and at crop maturity, 28 days after the last application.

In mature cabbage heads TRR levels were 0.195 mg eq/kg (up to 1.8 mg eq/kg in withered leaves). 97.5% of the TRR (0.19 mg eq/kg) was recovered as unchanged lufenuron. In the head cabbage as well as in withered leaves, CGA238277 was identified at estimated levels of 0.6% and 3.3% of the TRR, respectively. The actual amounts were not measured in the TLC system used. No further metabolites were found.

For tomatoes the metabolism of lufenuron was investigated with [dichlorophenyl-^{14}C]-lufenuron only. Fruit bearing plants kept in a protected environment were treated with three sprayings equivalent to 0.03 kg ai/ha per application with one week intervals. Samples were collected directly

after the first application and up to 28 DALA. In parallel 34µg lufenuron was directly injected into single fruits, which were sampled after 18 and 33 days.

Directly after the last foliar application, TRR levels in fruits were 1.2 mg eq/kg, degrading to 0.69 mg eq/kg after 28 days. TRR levels found in additional samples at 28 DAT were 0.47 mg eq/kg for leaves and 0.44 mg eq/kg in mature fruits. Newly developed green fruits had much lower total radioactive residues of 0.03 mg eq/kg. In all fruits receiving a foliar treatment > 89% of the residue was recovered in the surface wash. Unextracted residues were generally low (< 0.6% TRR).

The identification of the radioactivity (combined surface wash and extract) showed unchanged lufenuron as the major residue in fruits and leaves (93–98% TRR). Only in one fruit sample collected 28 DAT, minor amounts of CGA238277 (0.2% TRR, 0.0013 mg eq/kg) were found.

In mature fruits receiving a direct injection of lufenuron, the results from the extracts were comparable to foliar treated fruits. 90–95% of the radioactivity was identified as unchanged lufenuron. CGA238277 was identified in minor amounts up to 2% of the TRR. 5% of the TRR remained unextracted.

For cotton grown under glasshouse conditions the metabolism was investigated in two studies using [dichlorophenyl-^{14}C]-lufenuron or [difluorophenyl-^{14}C]-lufenuron.

For [dichlorophenyl-^{14}C]-lufenuron cotton plants received three foliar sprayings equivalent to 0.03 kg ai/ha each at 14 day interval, beginning at flowering. Sampling of leaves took place 1 hour, 1 day, 3 and 7 days after the first application and 14 days, 28 and 84 days (maturity) after the last application. In addition, four cotton plants received three stem injections (100 µg lufenuron each) made at 14-day intervals.

TRR levels found were up to 4.9 mg eq/kg in the leaves, < 0.001 mg eq/kg in seeds, 0.092 mg eq/kg in hulls and 0.001 mg eq/kg in green bolls. In leaves the amount of radioactivity in the surface wash decreased from 98% TRR after application 1 to 43% TRR at maturity (84 DALA).

The identification of the radioactivity (combined surface wash and extracts) showed 89–100% of the TRR as unchanged lufenuron. No metabolites were identified. In seeds and green bolls TRR levels were too low for further identification. Unextracted residues did not exceed 3.3% of the TRR.

The stem injection showed that most of the applied radioactivity remained at the injection site (81.2% AR). Minor translocation was observed into adjected stalks (13.3% AR) and leaves (1.6–3.9% AR). In all samples the unchanged parent was the only residue identified (~95–98% TRR).

For [difluorophenyl-^{14}C]-lufenuron the use pattern was comparable to the other label, but only the foliar treatment experiment was conducted. Samples of mature plant parts were collected 52 DALA.

TRR levels found were up to 5.95 mg eq/kg in leaves (52 DALA), 0.69 mg eq/kg in hulls and 0.003 mg eq/kg in seeds. In the leaves the surface wash contained most of the residue with 96% TRR directly after treatment and 49–58% TRR at maturity (52 DALA).

The identification again revealed unchanged lufenuron exclusively, representing >92% of the TRR in leaves and 79–83% TRR in other matrices. The TRR found in seeds was too low for identification. No further metabolites were detected.

Two confined rotational crop studies for lufenuron were submitted

In the first study [difluorophenyl-^{14}C]-lufenuron was applied under protected conditions to bare soil at a rate equivalent to 0.15 kg ai/ha. Lettuce, spring wheat, maize and carrots were planted in the treated soil 63 days after test substance application. The transfer of radioactivity into succeeding crops was very limited. In mature lettuce (126 d after treatment) the highest TRR level of 0.047 mg eq/kg was found. 53% of the TRR was identified as unchanged parent (0.025 mg/kg). In other matrices only wheat straw (0.023 mg eq/kg, 0.007 mg lufenuron/kg) and immature carrots roots (0.023 mg eq/kg, no identification conducted) showed total radioactive residues above 0.01 mg eq/kg. No further identification was conducted for these matrices. In soil samples, nearly the entire extracted

radioactivity was attributed to lufenuron. No residue of CGA149772 or CGA149776 could be identified in any sample.

In a second confined study conducted under field conditions [dichlorophenyl-^{14}C]-lufenuron was applied to bare soil once at a rate equivalent to 0.13 kg ai/ha. After different plant-back intervals (PBI) lettuce (PBI 76 d), winter wheat (PBI 126 d), sugar beets (PBI 306 days) and maize (PBI 331 d) were planted/sown and grown to maturity. TRR levels in all plant samples was between < 0.001 mg eq/kg and 0.004 mg eq/kg, which was too low for further identification.

In summary lufenuron is deposited on the plant surface and slowly adsorbed by leaves following direct treatment. On the surface and in plant tissue, the active substance is the only residue present in major amounts. Minor amounts of CGA238277 were identified in cabbage and tomato (up to 3.3% TRR). All plant metabolism studies for lufenuron were conducted under protected conditions. However, since lufenuron is not subject to photolysis the residue pattern in plants grown under field conditions is expected to be similar. Also, two of three studies were conducted with [dichlorophenyl-^{14}C]-lufenuron only. Since nearly the entire applied radioactivity was recovered as unchanged parent compound in these studies, no investigations with a second label are considered necessary.

For rotational crops the transfer of residues into succeeding crops from soil is very limited and mostly resulted in TRR levels too low for identification. In soil and in crop samples subject to identification parent lufenuron was the major residue. No further metabolites were identified.

Animal metabolism

Information was available on metabolism of lufenuron in laboratory animals, lactating goats and laying hens. Studies on rats, mice and dogs were evaluated by the WHO Core Assessment Group.

For lactating goats two studies were conducted involving daily administration of either ^{14}C-difluorophenyl-labelled lufenuron at 5.4 ppm (0.135 mg/kg bw) or ^{14}C-dichlorophenyl-lufenuron at 6.0 ppm (0.15 mg/kg bw) for ten consecutive days. The animals were slaughtered approximately 24h after the last dose.

The total recovery of the administered radioactivity was 95% for both labels. The majority of the radioactivity (73–74%) was found in the faeces. Radioactive residues in the edible tissues were 0.8–1.6% AR in muscle (0.038–0.08 mg eq/kg), 4.2–5.4% AR in fat (0.82–2.4 mg eq/kg), 0.28–0.3% AR in liver (0.37–0.42 mg eq/kg), 0.01–0.02% AR in kidney (0.11–0.12 mg eq/kg) and 5.8–6.8% AR in milk (up to 1.0 mg eq/kg). A plateau in milk was observed after approximately one week.

In tissues and milk unchanged parent was the only residue identified for both radiolabels, representing 73–94% of the TRR. The remaining radioactivity remained unresolved in the TLC-System used (6.6–19% TRR) or was not extracted from the sample (0.6–8.9% TRR).

Also for laying hens two studies were conducted involving daily administration of either ^{14}C-difluorophenyl-labelled lufenuron at 3.4 ppm (2.6 mg/kg bw) or ^{14}C-dichlorophenyl-lufenuron at 5.2 ppm (3.5 mg/kg bw) for fourteen consecutive days. The animals were slaughtered approximately 24h after the last dose.

The total recovery of the administered radioactivity was 75–79%. The majority of the radioactivity (54–62%) was found in the excreta. Radioactive residues in the edible tissues were 0.55–1.2% AR in lean meat (0.1–0.24 mg eq/kg), 5.1–9.9% AR in fat (7.2–13 mg eq/kg), 0.4–0.58% AR in liver (0.83–1.5 mg eq/kg), 0.07–0.09% AR in kidney (0.52–0.74 mg eq/kg) and 8.7–9.6% AR in eggs (up to 0.016 mg eq/kg in egg white and 8.5 mg eq/kg in egg yolk). In eggs a plateau was observed after one week for ^{14}C-difluorophenyl-lufenuron while residues for ^{14}C-dichlorophenyl-lufenuron showed a slight increase until the end of dosing.

In tissues and eggs unchanged parent lufenuron was the predominant residue, representing 79–94% TRR in all matrices except egg white. For the difluorophenyl-label the cleavage product CGA149772 was the only metabolite detected, being present in egg white at 0.001 mg eq/kg (17.3% TRR). For the dichlorophenyl-label its counterpart CGA238277 was found in minor amounts in kidney (0.028 mg eq/kg, 5.3% TRR) and egg white (< 0.001 mg eq/kg, 7.0% TRR). The remaining

radioactivity remained unresolved in the TLC-System used (3–42% TRR) or was not extracted from the sample (2–11% TRR).

In summary the metabolic degradation of lufenuron in livestock animals is very limited, showing parent as the predominant residue in all matrices. Minor amounts of the cleavage products CGA149772 and CGA238277 were found in poultry kidney and egg white.

Methods of residue analysis

The Meeting received analytical methods for the analysis of lufenuron in plant and animal matrices. The basic principle employs extraction by homogenisation with methanol or water and partitioning against hexane: ethyl ether (9:1,v:v). Clean-up is normally achieved by C18 solid-phase extraction. Residues are determined by liquid chromatography (LC) in combination with UV (255 nm) or tandem mass spectroscopy (MS/MS). Mass-transitions are m/z 509.1 → 326 for quantification and m/z 509→ 175 for confirmation. The methods submitted are suitable for measuring residues with a LOQ of 0.01 mg/kg in high water, high oil and high starch matrices while acidic matrices were validated with a LOQ of 0.02 mg/kg.

For animal matrices the analytical methods were comparable, however silica gel SPE was used for clean-up instead. Validated LOQs were 0.001 mg eq/kg for milk, 0.01 mg/kg for liver and kidney, 0.02 mg/kg for meat and 0.1 mg/kg for fat.

The application of multi-residue methods was tested with DFG S19 for both plant and animal matrices. The method was shown suitable with a general LOQ of 0.02 mg/kg for lufenuron.

Stability of residues in stored analytical samples

The Meeting received information on the storage stability of lufenuron in plant and animal matrices stored at -18°C.

In plant matrices with high water, high acid and high oil content parent lufenuron was stable for at least 24 months. High starch matrices were not tested.

In animal matrices (bovine tissues and milk) no significant degradation was observed within 9 months. No storage stability data were provided for poultry matrices and eggs.

Definition of the residue

The fate of lufenuron in plants was investigated after foliar application to tomatoes, cabbage and cotton. In all crop samples investigated unchanged lufenuron was the only major residue present, representing 79–100% TRR. The residue was mainly present as a surface residue. No significant transfer into untreated plant parts was observed.

In confined rotational crop studies the overall uptake of radioactivity was very limited. Only parent lufenuron could be detected in collected plant samples.

The Meeting concluded that lufenuron is the relevant residue in all plant matrices for compliance with MRLs and for dietary intake purposes. Analytical multi-residue methods are capable of measuring lufenuron in all plant matrices.

Livestock animal metabolism studies were conducted on lactating goats (5.4–6.0 ppm) and laying hens (3.4–5.2 ppm).

In both species unchanged parent lufenuron was the only residue identified in major amounts, representing 73–94% of the TRR in all matrices. In goat matrices and milk no other metabolites could be detected. In poultry matrices minor amounts of the cleavage products CGA149772 and CGA238277 were found, representing up to 17% TRR in egg white but at low levels (0.001 mg eq/kg) and 5.3% TRR in kidney (0.028 mg eq/kg). No further metabolites were found in poultry matrices or eggs.

The Meeting concluded that parent lufenuron is the relevant residue in all animal matrices for compliance with MRLs and for dietary intake purposes. Analytical multi-residue methods are capable of measuring lufenuron in all animal matrices.

In all species residue concentrations in fat tissues or egg yolk were at least one order of magnitude higher than in muscle tissues or egg white. The log P_{ow} of lufenuron is 5.12. The Meeting decided that residues of lufenuron are fat soluble.

Definition of the residue for compliance with MRL and for dietary intake for plant and animal commodities: *lufenuron*

The residue is fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised trial data for applications of lufenuron on various vegetables crops as well as for soya beans, maize, sugarcane, cotton and coffee conducted in Brazil, China and Europe.

Cucumber

Lufenuron is registered in Spain for cucumbers under protected conditions at rates of 2 × 0.1 kg ai/ha with a PHI of 7 days. Supervised field trials from France, Greece and Spain according to this GAP and at rates up to +50% higher were submitted.

In protected cucumbers residues of lufenuron following GAP treatment (±25%) were (n=4): 0.01, 0.02, 0.06, 0.06 mg/kg.

The Meeting concluded that four supervised trials on cucumber approximating GAP are insufficient for an evaluation and decided to explore the proportionality approach using trials at +50% GAP rate. Since some of the trials according to GAP were also conducted at slightly elevated rates, all data are proportionally adjusted to the Spanish GAP rate of 0.1 kg ai/ha:

In protected cucumbers treated with 0.1 kg ai/ha lufenuron residues were (no scaling factor): 0.06 mg/kg.

In protected cucumbers treated with 0.11 kg ai/ha lufenuron residues were (scaling factor 0.91): 0.018 mg/kg (0.91×0.02 mg/kg).

In protected cucumbers treated with 0.12 kg ai/ha lufenuron residues were (scaling factor 0.83): 0.0083 and 0.05 mg/kg (0.83×0.01 mg/kg and 0.83×0.06 mg/kg).

In protected cucumbers treated with 0.15 kg ai/ha lufenuron residues were (scaling factor 0.66): 0.013(3), 0.02(3), 0.026 mg/kg (0.66×0.02 mg/kg(3), 0.66×0.03 mg/kg(3) and 0.66×0.04. mg/kg)

The combined total dataset for lufenuron in protected cucumbers was (n=11): 0.0083, 0.013(3), 0.018, 0.02(3), 0.026, 0.05 and 0.06 mg/kg.

The Meeting estimated a maximum residues level of 0.09 mg/kg and a STMR of 0.02 mg/kg for lufenuron in cucumber.

Melons, except watermelons

Lufenuron is registered in Spain for melons under protected conditions at rates of 3 × 0.1 kg ai/ha with a PHI of 7 days. Supervised field trials from Spain according to this GAP were submitted.

All samples were segmented and in some trials already separated into pulp and peel in the field, which is against the current Codex sampling procedure. However, lufenuron was not metabolized in plant metabolism studies, even after direct injection into tomato fruits. In addition simulated hydrolysis indicated no degradation at pH 7 or lower, which is representive of fruits and vegetables. The Meeting therefore concluded that segmentation of samples in the field did not influence the magnitude of residues. The Meeting also noted that no contamination of melon pulp with peel residues during separation occurred and decided to use the data for its assessment.

Some trials submitted involved a last sampling at 3 DALA which is shorter than the PHI of the Spanish GAP of 7 days. In plant metabolism studies lufenuron was a surface residue not subject to degradation or metabolism. Also, melons near maturity have already finalized their growth and are only subject to ripening. Therefore the Meeting concluded that no different residue populations have to be expected for melons within the last week before harvest when sampled at 3 or 7 DALA and decided to take samples collected after three days also into account for the assessment. This conclusion is supported by several decline studies from 0 to 10 DALA, indicating no constant decrease of the residue concentration but the usual sampling variation within the results.

In protected melons (whole fruits) residues of lufenuron were (n=6): 0.02, 0.03, 0.06, 0.09, 0.13, 0.19 mg/kg.

In the corresponding pulp samples, if measured, residues of lufenuron were (n=4): < 0.02(4) mg/kg.

For melon, except watermelons, the Meeting estimated a maximum residues level of 0.4 mg/kg, based on whole melon fruits, except watermelons and an STMR of 0.02 mg/kg, based on pulp data.

Peppers, sweet

Lufenuron is registered in Spain for sweet peppers under protected conditions at rates of 3 × 0.1 kg ai/ha with a PHI of 7 days. Supervised field trials on sweet peppers from Greece, Italy and Spain according to this GAP were submitted.

In protected sweet peppers residues of lufenuron following GAP treatment (±25%) were (n=6): 0.08, 0.13, 0.13, 0.17, 0.18 and 0.54 mg/kg.

The Meeting estimated a maximum residues level of 0.8 mg/kg and an STMR of 0.15 mg/kg for lufenuron in sweet peppers.

Tomato

Lufenuron is registered in Spain for tomatoes under protected conditions at rates of 3 × 0.1 kg ai/ha with a PHI of 7 days. Supervised field trials on tomatoes from Greece, Spain and Switzerland according to this GAP were submitted.

In protected tomatoes residues of lufenuron following GAP treatment were (n=13): 0.02, 0.04, 0.04, 0.05, 0.06, 0.08(4), 0.09, 0.1, 0.11 and 0.24 mg/kg.

The Meeting estimated a maximum residues level of 0.4 mg/kg and an STMR of 0.08 mg/kg for lufenuron in tomatoes.

Sweet corn

The Meeting received supervised field trail information on sweet corn, however no corresponding GAP was made available to the Meeting and therefore no recommendation was made.

Soya beans

Lufenuron is registered in Brazil for soya beans at maximum rates of 2 × 0.02 kg ai/ha with a PHI of 35 days. Supervised field trials on soya beans from Brazil at exaggerated rates (3.8 times higher) and a higher number of treatments (four instead of two) were submitted.

In soya beans residues of lufenuron after exaggerated treatment were (n=3): < 0.01(3) mg/kg

The Meeting concluded that under consideration of the exaggerated treatment regime involved, the seeds being protected by the pod during applications and the non-systemic properties of the active substance observed in plant metabolism studies, no finite residue following treatment at GAP rate have to be expected. The Meeting estimated a maximum residues level of 0.01* mg/kg and an STMR of 0 mg/kg for lufenuron in soya beans (dry).

Potatoes

Lufenuron is registered in Brazil for potatoes at rates of 4 × 0.04 kg ai/ha with a PHI of 14 days. Supervised field trials from Brazil matching the GAP were submitted.

In potato tubers residues of lufenuron after treatment according to GAP were (n=4): < 0.01(4) mg/kg

Taking into account the non-systemic properties of the active substance, the Meeting concluded that residues in tuber above the LOQ are unlikely to occur and estimated a maximum residues level of 0.01* mg/kg and an STMR of 0.01 mg/kg for lufenuron in potatoes.

Maize

Lufenuron is registered in Brazil for maize at maximum rates of 2 × 0.01 kg ai/ha with a PHI of 35 days. All supervised field trials on maize submitted were sampled at significantly longer DAT intervals than the PHI.

The Meeting concluded that the data submitted for lufenuron in maize is insufficient for a recommendation.

Sugar cane

Lufenuron is registered in Brazil for sugar cane at rates of 2 × 0.02 kg ai/ha with a PHI of 14 days. Supervised field trials from Brazil matching the GAP were submitted.

In sugar cane residues of lufenuron after treatment according to GAP were (n=4): < 0.01 and 0.02(3) mg/kg

The Meeting concluded that the data submitted for lufenuron in sugar cane is insufficient for a recommendation.

Cotton

Lufenuron is registered in China for cotton at rates of 2 × 0.045 kg ai/ha with a PHI of 28 days. Supervised field trials from China according to this GAP were submitted, however the trial description did not included information on the stage of boll opening for cotton plants.

In cotton seeds residues of lufenuron after treatment according to GAP were (n=4): < 0.05(4) mg/kg

The Meeting concluded that the stage of boll opening is a sensitive parameter for residues following foliar application. Without this type of information, a set of four field trials in not considered sufficient for estimating maximum residue levels in cotton seed. Supportive information from plant metabolism studies cannot be taken into account as the active substance was applied before boll opening in these studies.

Coffee

Lufenuron is registered in Brazil for coffee at rates of 2 × 0.04 kg ai/ha with a PHI of 7 days. Supervised field trials from Brazil matching the GAP were submitted.

In coffee beans (dry processed) residues of lufenuron after treatment according to GAP were (n=4): < 0.01(3) and 0.01 mg/kg

The Meeting concluded that the data submitted for lufenuron in coffee is insufficient for a recommendation.

Fate of residues during processing

The Meeting received information on the hydrolysis of radio-labelled lufenuron as well as processing studies using unlabelled material in tomatoes.

In a hydrolysis study using [dichlorophenyl-^{14}C]-lufenuron or [difluorophenyl-^{14}C]-lufenuron, typical processing conditions were simulated (pH 4,5 and 6 with 90°C, 100°C and 120°C for 20, 60 and 20 minutes). No significant degradation of the parent was observed. For pH5 with 100°C for 60min a minor formation of CGA224443 and CGA149772 (up to 6.9% of the applied radioactivity) was observed.

The fate of lufenuron residues has been examined simulating household and commercial processing of tomatoes. Estimated processing factors for the commodities considered at this Meeting are summarized below.

Raw commodity	Processed commodity	Lufenuron		
		Individual processing factors	Mean or best estimate processing factor	STMR-P in mg/kg
Tomato (STMR: 0.08 mg/kg)	Juice, raw	<0.17, 0.17	0.17	0.014
	Puree	0.79, 0.83, 0.86.0.9	0.85	0.068
	Paste	0.83, 1.1	0.97	0.078
	Canned/preserve	<0.17(4)	0.17	0.014
	pomace, wet	7.9, 7.9, 8.6, 9.7	8.3	0.66

Residues in animal commodities

Farm animal feeding studies

The Meeting received feeding studies involving lufenuron on lactating cows and steers.

Three groups of lactating cows were dosed daily at levels of 0.82, 4.3 and 8.6 ppm in the diet for 28 consecutive days. Milk was collected throughout the whole study and tissues were collected on day 29 within 24 hrs after the last dose.

In milk residues of lufenuron were 0.16 mg/kg, 0.99 mg/kg and 2.5 mg/kg for the low, middle and high dose group, respectively. Skim milk and cream were analysed individually, showing residues of 0.006, 0.038 and 0.054 mg/kg for skim milk and 3.1, 24 and 32 mg/kg for cream.

In tissues mean concentrations of lufenuron with increasing dose rate were 0.03, 0.17 and 0.43 mg/kg in muscle, 0.06, 0.37 and 0.77 mg/kg in liver, 0.03, 0.22 and 0.36 mg/kg in kidney and 0.73, 4.5 and 8.0 mg/kg in fat.

In the steer study three groups of Angus steers were dosed 0.02 or 1 ppm in the diet for 28 consecutive days. Animals were sacrificed 24h after the last administrations (day 28).

Mean lufenuron residues in the low and high-dose animals were < 0.01 and < 0.01 mg/kg in muscle, < 0.01 and 0.023 mg/kg in liver, < 0.01 and 0.026 mg/kg in kidney and 0.036 and 0.23 mg/kg in fat, respectively.

Estimated maximum and mean dietary burdens of livestock and animal commodities maximum residue levels

Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6. The calculations were made according to the livestock diets from US-Canada, EU, Australia and Japan in the OECD Table (Annex 6 of the 2006 JMPR Report).

	Livestock dietary burden, lufenuron, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max.	mean	max.	mean	max.	mean	max.	mean
Beef cattle	0.02	0.02	0.34	0.34	0.02	0.02	none	none
Dairy cattle	0.02	0.02	0.34 [a]	0.34 [b]	0.02	0.02	none	none
Poultry - broiler	none	none	0.01	0.01	none	none	none	none
Poultry - layer	none	none	0.01 [c]	0.01 [d]	none	none	none	none

[a] Highest maximum beef or dairy cattle burden suitable for MRL estimates for mammalian meat and milk

[b] Highest mean beef or dairy cattle burden suitable for STMR estimates for mammalian meat and milk
[c] Highest maximum broiler or laying hen burden suitable for MRL estimates for poultry products and eggs
[d] Highest mean broiler or laying hen burden suitable for STMR estimates for poultry products and eggs
none - no relevant feed items

Animal commodities maximum residue levels

For beef and dairy cattle a maximum and mean dietary burden of 0.34 ppm was estimated. Two feeding studies on lactating cows and steers were submitted. Since no accumulation of residues in steers compared to dairy cows was observed, the Meeting decided to base its recommendations for mammalian products on the lactating cow feeding study, generally showing higher residues at identical intake levels.

Lufenuron feeding study	Feed level	Total residue				
	(ppm)	(mg/kg) in milk	(mg/kg) in muscle	(mg/kg) in kidney	(mg/kg) in liver	(mg/kg) in fat
Maximum residue level: dairy cattle						
Feeding study (HR for each dose group, except for milk)	0.82	0.16 (cream: 3.1)	0.04	0.04	0.07	1.2
Dietary burden and residue estimate	0.34	0.066 (cream: 1.2)	0.017	0.017	0.029	0.5
STMR dairy cattle						
Feeding study (Mean for each dose group)	0.82	0.16 (cream: 3.1)	0.03	0.03	0.06	0.73
Dietary burden and residue estimate	0.34	0.066 (cream: 1.2)	0.012	0.012	0.025	0.3

The Meeting estimated STMR values of 0.012 mg/kg for muscle, 0.025 mg/kg for edible offal (based on liver) and 0.3 for fat. Corresponding maximum residue levels were estimated at 0.04 mg/kg for edible offal, mammalian (based on liver) and 0.7 mg/kg for meat (based on the fat) and mammalian fat.

For milk, an STMR and a MRL of 0.066 mg/kg and 0.1 mg/kg were estimated, respectively. Based on the data for cream, the Meeting also estimated an STMR and MRL of 1.2 mg/kg and 2 mg/kg for lufenuron in milk fat, respectively.

For poultry a maximum and mean dietary burden of 0.01 ppm was estimated. No farm animal feeding studies were provided for poultry. Therefore the Meeting decided to make its recommendations based on the ^{14}C-difluorophenyl-labelled poultry metabolism study which showed higher residues than the corresponding ^{14}C-dichlorophenyl-labelled experiment.

Lufenuron feeding study	Feed level	Total residue				
	(ppm)	(mg/kg) in eggs	(mg/kg) in muscle	(mg/kg) in kidney	(mg/kg) in liver	(mg/kg) in fat
Mean and maximum residue level: poultry						
^{14}C-difluorophenyl-labelled metabolism study	3.4	2.5 [a]	0.196	0.588	1.34	9.15
Dietary burden and residue estimate	0.01	0.01	0.0006	0.0017	0.004	0.027

[a] In the metabolism study egg white and egg yolk were analysed separately. To estimate residues in whole eggs, an average ratio of 65% egg white and 35% egg yolk was taken into account: 0.65 × 0.003 mg eq/kg in egg white + 0.35 × 7.18 mg eq/kg in egg yolk=2.5 mg eq/kg in whole eggs

The Meeting estimated STMR values of 0.01 mg/kg for eggs, 0.0006 mg/kg for poultry meat, 0.004 mg/kg for poultry edible offal of (based on liver) and 0.027 mg/kg for poultry fat. Corresponding maximum residue levels for lufenuron were estimated at 0.02 mg/kg for eggs, poultry meat and edible offal of and at 0.04 mg/kg for poultry fat.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed in Annex 1 were suitable for estimating maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with MRL and for dietary intake purposes for plant and animal commodities: *Lufenuron*

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
VC 0424	Cucumbers	0.09		0.02

	Tomato wet pomace			0.66	

FURTHER WORK OR INFORMATION

- Poultry feeding study

DIETARY RISK ASSESSMENT

Long-term intake

The evaluation of lufenuron has resulted in recommendations for MRLs and STMRs for raw and processed commodities. The International Estimated Daily Intakes for the 17 GEMS/Food cluster diets, based on this years estimated STMRs, were in the range 0–4% of the maximum ADI of 0.02 mg/kg bw. The results are shown in Annex 3 to the 2015 Report.

The Meeting concluded that the long-term intake of residues of lufenuron from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

For short-term intake, an ARfD was considered unnecessary. The Meeting concluded that the short-term intake of lufenuron residues from uses considered by the Meeting is unlikely to present a public health concern.

PYRIMETHANIL (226)

The first draft was prepared by Ms Monique Thomas. Pest Management Regulatory Agency, Canada

EXPLANATION

Pyrimethanil, an anilinopyrimidine fungicide was evaluated for the first time by the 2007 JMPR, where an ADI of 0–0.2 mg/kg bw was established and an ARfD was deemed unnecessary. At this Meeting, maximum residue levels were recommended for a limited number of uses where GAP information was available.

The residue definitions for pyrimethanil are:

- For plant products (compliance with MRLs and dietary risk assessment)—*pyrimethanil*
- For milk (compliance with MRLs and dietary risk assessment)—sum of pyrimethanil and 2-anilino-4,6-dimethylpyrimidin-5-ol, expressed as pyrimethanil
- For livestock tissues, excluding poultry (compliance with MRLs and dietary risk assessment)—sum of pyrimethanil and 2-(4-hydroxyanilino)-4,6-dimethylpyrimidine, expressed as pyrimethanil

New GAP information, freezer storage stability studies and supervised residue trials on cane berries, bush berries and greenhouse cucumbers were provided to the current Meeting.

METHODS OF ANALYSIS

Residue trial samples from the EU were analysed using gas chromatography with mass selective detection (GC-MS) method DGM C05/98-0, which was previously evaluated by the JMPR in 2007. The North American trial samples were analysed using a similar method with minor adaptations (LC-MS/MS instead of GC-MS), in order to simplify the clean-up procedure (no hexane partition and no SPE purification step). In the case of cucumbers, an Evolute ABN SPE was used instead of a Silica SPE. The method has a demonstrated LOQ of 0.05 mg/kg.

Stability of pesticide residues in stored analytical samples

The storage stability data from the 2007 JMPR cover a diverse range of crops (apples, grapes, tomatoes, lettuce, carrots, dry peas, peaches, and plums) and demonstrated stability of pyrimethanil for up to 12 months. The samples from the submitted cane berry and bush berry supervised residue trial studies were stored for periods less than 12 months. Therefore, the current Meeting concluded that the available data is sufficient to cover the storage intervals from the berry crop field trials.

Although the stability of residues of pyrimethanil in cucumber is covered by the 12 month storage interval for the high-water content commodity group, as determined during the 2007 JMPR, the current Meeting noted that concurrent storage stability data provided with the cucumber supervised residue trials also demonstrated stability of pyrimethanil residues up to 4.5 months (the period for which the samples were stored) in greenhouse cucumbers.

The 2015 Meeting received freezer storage stability data investigating the stability of pyrimethanil in almond nutmeat and in wheat matrices.

Control samples of almond nutmeat were fortified at 0.50 mg/kg with pyrimethanil and stored in a freezer at –20 °C. Samples from Day 0 were analysed immediately after fortification, followed by time periods of 1, 3, 6 and 12-months. At each time period, a control, two freshly fortified controls, and two aged fortifications were analysed for residues of pyrimethanil.

Control samples of wheat forage, straw and grain were fortified at 0.50 mg/kg with pyrimethanil in glass jars and were stored in a freezer at –20 °C. Samples from day 0 were analysed immediately after fortification, followed by time periods of 1, 3, 6, 12, 18 and 24-months. At each time period, a control, two freshly fortified controls, and two aged fortifications were analysed for residues of pyrimethanil.

The GC-MS method DGM C05/98-0 was used to analyse residues of pyrimethanil in almond and wheat matrices.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received new information on supervised field trials involving foliar applications of pyrimethanil to the following crops.

Crop	Field/Greenhouse	Treatment Type	Countries	Table
Raspberries	Field	foliar (spray)	USA, Germany	3, 4
Blackberries	Field	foliar (spray)	USA	3
Blueberries	Field	foliar (spray)	USA	5
Cucumbers	Greenhouse	foliar (spray)	USA, CAN	6
Cucumbers	Greenhouse	foliar (spray)	France, Italy, Spain, Greece	7

Berries and other small fruits

Results from supervised residue trials on cane berries (blackberries and raspberries), and on bush berries (blueberries) conducted in the USA and raspberries conducted in Germany were provided to the Meeting.

Cane berries (blackberries and raspberries)

Five supervised field trials were conducted in the USA (2007) on cane berries (two trials on raspberries and three trials on blackberries). The blackberries and raspberries analysed in this study were held in frozen storage for a maximum of 11.6 months prior to analysis using the adapted analytical method DGM C05/98-0 by LC/MS/MS. The reported LOQ was 0.05 mg/kg. Berry samples

fortified with 0.05–9 mg/kg pyrimethanil were within the acceptable range of 70–120%, with a relative standard deviation of less than 20%.

[a] Both treatments were made on the same days, rendering the trials dependent.

Raspberries

Five supervised field trials were conducted in Germany (1999–2000) on raspberries.

The raspberries were held in frozen storage for a maximum of 259 days prior to analysis using the GC/MS Method DGM C05/98-0. The reported LOQ was 0.05 mg/kg. Raspberry samples fortified with 0.05–5 mg/kg pyrimethanil were within the acceptable range of 70–120%, with a relative standard deviation of less than 20%.

[a] Last applications were made 25 days apart, rendering the trials independent

[b]Application and sampling before the beginning of ripening (BBCH 79). It is not compatible with a DALT = 0 (no marketable fruit available). This value is then excluded.

Bush berries (highbush blueberries)

Eight supervised field trials were conducted in the USA (2007) on highbush blueberries. The highbush blueberries analysed in this study were held in frozen storage for a maximum of 11.4 months prior to analysis using the adapted analytical method DGM C05/98-0 by LC/MS/MS. The reported LOQ was 0.05 mg/kg. Blueberry samples fortified with 0.05–6 mg/kg pyrimethanil were within the acceptable range of 70–120%, with a relative standard deviation of less than 20%.

Greenhouse Cucumbers—North America

Five greenhouse trials were conducted in Canada and the USA (2010–2011) on cucumbers.

The cucumber samples analysed in this study were held in frozen storage for a maximum of 4.6 months prior to analysis using the adapted analytical method DGM C05/98-0 by LC/MS/MS. The reported LOQ was 0.05 mg/kg. With the exception of one recovery of 68%, cucumber samples fortified with 0.05–5 mg/kg pyrimethanil were within the acceptable range of 70–120%, with a relative standard deviation of less than 20%.

Greenhouse Cucumbers—Southern Europe 1997–1998

Nine greenhouse trials were conducted in the EU (1997–1998) on cucumbers.

The cucumber samples analysed in this study were held in frozen storage for a maximum of 6 months prior to analysis using the validated GC/MS method DGM C05/98-0. The reported LOQ was 0.05 mg/kg. With the exception of one recovery of 65%, cucumber samples fortified with 0.05–0.50 mg/kg pyrimethanil were within the acceptable range of 70–120%, with a relative standard deviation of less than 20%.

APPRAISAL

Pyrimethanil, an anilinopyrimidine fungicide, was evaluated for the first time by the 2007 JMPR, where an ADI of 0–0.2 mg/kg bw was established and an ARfD was deemed unnecessary. It was listed by the Forty-sixth Session of the CCPR (2014) for the evaluation by the 2015 JMPR for additional MRLs. New GAP information, freezer storage stability studies and supervised residue trials on cane berries, bush berries and greenhouse cucumbers were provided to the current Meeting

Residue definitions are:

- For compliance with the MRL and for dietary intake estimation for plant commodities: pyrimethanil
- For compliance with the MRL and for dietary intake estimation for milk: sum of pyrimethanil and 2-anilino-4,6-dimethylpyrimidin-5-ol, expressed as pyrimethanil
- For compliance with the MRL and for dietary intake estimation for livestock tissues (excluding poultry): sum of pyrimethanil and 2-(4-hydroxyanilino)-4,6-dimethylpyrimidine, expressed as pyrimethanil

The residue is not fat-soluble.

Stability of pesticide residues in stored analytical samples

Based on the storage stability data submitted, the Meeting concluded that no significant dissipation of pyrimethanil residues was observed in almond nutmeat after 12 months of storage or in wheat straw, forage and grain after 24 months of storage.

Results of supervised residue trials on crops

The Meeting received new supervised trial data for foliar applications of pyrimethanil (SC formulations) on cane berries (blackberries and raspberries), bush berries (blueberries), and greenhouse cucumbers.

Berries and other small fruits

Results from supervised field trials on blackberries, raspberries, and blueberries conducted in North America were provided to the Meeting, including raspberry data from Germany.

Cane berries (blackberries and raspberries)

Results from supervised field trials on blackberries and raspberries conducted in the USA and trials on raspberries conducted in Germany were provided to the Meeting.

A total of four independent supervised trials were conducted in the USA on blackberries and raspberries according to the critical GAP of Canada for cane berries (blackberries and raspberries) which allows a maximum of 2 applications of 0.8 kg ai/ha/application, and a PHI of 0 day.

Residues of pyrimethanil matching the Canadian GAP were: 1.86, 2.13, 2.62 and 8.38 mg/kg.

A total of five independent supervised trials were conducted in Germany on raspberries according to the Poland critical GAP for raspberries which allows a maximum of 3 applications of 0.8 kg ai/ha/application, and a PHI of 3 days.

Residues of pyrimethanil in raspberries matching the Poland GAP were: 0.78; 2.40; 3.02; 3.37 and 6.95 mg/kg.

The Meeting agreed to use the data set according to the Canadian GAP and estimated a maximum residue level of 15 mg/kg and an STMR of 3.02 mg/kg from the German trials for cane berries.

Bushberries-Blueberry

Results from supervised field trials on highbush blueberries conducted in the USA were provided to the Meeting.

A total of eight independent supervised trials were conducted in the USA on highbush blueberries according to the critical GAP in Canada for bush berries which allows a maximum of 2 applications of 0.8 kg ai/ha/application, and a PHI of 0 day.

Residues of pyrimethanil in highbush blueberries conducted in North America matching the GAP were: 1.12, 1.40, 1.89, 2.00, 2.11, 2.14, 2.27, and 5.13 mg/kg.

The Meeting estimated a maximum residue level of 8 mg/kg and an STMR 2.06 mg/kg for pyrimethanil on blueberries.

Greenhouse cucumbers

Results from supervised field trials on greenhouse cucumbers conducted in North America and Southern Europe were provided to the Meeting.

In the absence of a North American GAP for greenhouse cucumbers, the Meeting did not consider the USA and Canada trials in estimating a maximum residue level.

A total of nine independent supervised trials were conducted in Southern Europe on greenhouse cucumbers according to the critical GAPs in Greece, Italy, and Spain which allow a maximum of 3 applications of 0.8 kg ai/hL/application, and a PHI of 3 days.

Residues of pyrimethanil in greenhouse cucumbers matching the Southern EU GAP were: 0.10; 0.12; 0.16; 0.19; 0.24; 0.25; 0.29; 0.32; and 0.37 mg/kg.

The Meeting estimated a maximum residue level of 0.70 mg/kg and an STMR of 0.24 mg/kg for residues of pyrimethanil in greenhouse cucumbers.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue levels and for IEDI assessment.

Definition of the residue for compliance with the MRL and for the estimation of dietary intake for plant commodities: *pyrimethanil.*

Definition of the residue for compliance with the MRL and for dietary intake estimation for milk: sum of pyrimethanil and 2-anilino-4,6-dimethylpyrimidin-5-ol, expressed as pyrimethanil.

Definition of the residue for compliance with the MRL and for dietary intake estimation for livestock tissues (excluding poultry): sum of pyrimethanil and 2-(4-hydroxyanilino)-4,6-dimethylpyrimidine, expressed as pyrimethanil.

The residue is not fat soluble.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	New		
FB 0264	Blackberries	15		3.0	
FB 0020	Blueberries	8		2.1	
VC 0424	Cucumbers	0.7		0.24	
FB 0272	Raspberries	15		3.0	

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes of Pyrimethanil for the GEMS/Food 17 cluster diets, based on estimated STMRs were 0% of the maximum ADI of 0.2 mg/kg bw. The Meeting concluded that the long-term intake of residues of pyrimethanil from uses considered by the current Meeting is unlikely to contribute to the overall intake and will not present a public health concern.

Short-term intake

The 2007 JMPR determined that no ARfD was considered necessary. Therefore the short-term intake of pyrimethanil residues from uses considered by the current Meeting is unlikely to present a public health concern.

QUINCLORAC (287)

First draft was prepared by Dr Anita Stromberg, National Food Agency, Uppsala, Sweden

EXPLANATION

Quinclorac (ISO common name) is a quinone carboxylic herbicide used to control annual grass and broadleaf weed species in barley, canary seed, rape seed (canola), non-crop areas, pasture, rhubarbs cranberry, rice, sorghum and wheat. The herbicide has an auxin activity similar to that of indolylacetic acid and belongs to the auxin-type class of herbicides that includes the phenoxy-acids, benzoic acids and pyridine compounds.. The use of quinclorac results in the rupture of the cell membranes due to overstimulation of the growth of the plant. Quinclorac is mainly adsorbed via the root system and partly through foliage, mainly for the pre- and post-emergence control of *Echinocloa* spp, but also other weeds like *Aeschynomene* spp., *Sesbania* spp., and *Ipomoea* spp. occurring in direct-seeded and transplanted rice. Quinclorac was scheduled by the 46h session of the CCPR (2014) as a new compound for consideration by the 2015 JMPR.

IDENTITY

ISO common name	Quinclorac
Chemical name, IUPAC	3,7-dichloroquinoline-8-carboxylic acid
Chemical name, CA	3,7-dichloro-8-quinoline carboxylic acid
CIPAC No.	493
CAS No.	84087-01-4
Structural formula	Molecular formula	$C_{10}H_5Cl_2NO_2$
Molecular mass	242.1 g/mol

	Half life = ca. 100 days (nonsensitized, sterile solution, calculated for continuous illumination) Half life = ca. 43 days (sensitized , sterile solution, calculated for continuous illumination) Experimental setup: solution in water (sterile), pH 7, 25°C, simulated sunlight at 805 w/m², for 660 h over 35 d (15 h light, 9 h dark, illuminated at weekends). Result: Half life > 30 days (dark control solution, non-sensitized, sterile, see hydrolysis) The results were used to extrapolate the half life values above. Half -life > 30 days (dark control solution, non-sensitized sterile)		US-EPA Assessment guidelines, Subdiv. N, 161-2 (1982)	JMPS, Quinclorac 2002 Evaluation report 493/2002

Hydrolysis of quinclorac

A hydrolysis study was carried out by Hassink, J (2005/1016370). Quinclorac at a concentration of 29.9 µg/L was investigated in aqueous solution at pH 4, 5, 7 and 9 at 25 ºC. Samples were taken 0, 2, 7, 9, 11, 14, 21 and 30 days after treatment and analysed using LC/MS.

A summary of the results is presented in the table below.

Table 1 Summary of hydrolysis of quinclorac at pH 4, pH 5, pH 7 and pH 9 at 25ºC

DAT [a]	pH4		pH5		pH7		pH9	
	µg/L	%[b]	µg/L	%[b]	µg/L	%[b]	µg/L	%[b]

Formulations

Quinclorac is applied as a single active ingredient in different formulations.

Table 2 Available formulations of containing quinclorac as active ingredient

Formulation	Content of active ingredient
WP (wettable powder)	50% w/w
WG (wettable granules)	75% w/w
SC (suspension concentrates)	250 g/L
SL (soluble concentrates)*	180 g/L
FL (liquid flowable)*	40% w/w
DF (dry flowable)*	75% w/w

* Formulation in registered label presented to the 2015 JMPR Meeting

METABOLISM AND ENVIRONMENTAL FATE

Metabolism studies were conducted using 2, 3, 4-[^{14}C]-quinclorac (quinolone-label, Fig. 3) or 3-[^{14}C]-quinclorac (quinolone-label, Fig 2). In strawberry the [^{14}C]-quinclorac (quinolone-label, Fig. 3) was used. The position of the labels for both substances is presented in the following figures:

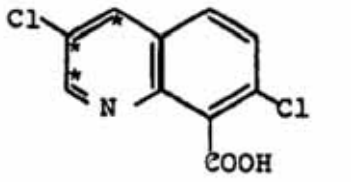

Figure 1 2, 3, 4-[^{14}C]-quinclorac

*location of the radiolabel

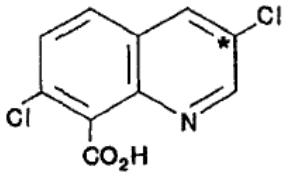

Figure 2 3-[^{14}C]-quinclorac

*location of the radiolabel

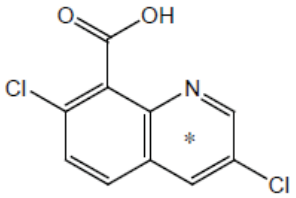

Figure 3 [^{14}C]-quinclorac

*location of the radiolabel

Chemical names, structures and code names of metabolites and degradation products of quinclorac are presented in the table below.

Table 3 Known metabolites of quinclorac from studies provided in animal, plants and soil matrices

Codes	Molecular formula and Nominal mass	Structure	Occurrence
BH 514-Me Reg. No. 161555 Quinclorac methyl ester SES218	$C_{11}H_7Cl_2NO_2$ methyl-3,7-dichloroquinoline-8-carboxylate 255		rats[1] canola sorghum rotational crops (mustard green, turnip, barley) soil (terrestrial aerial metabolism)
BAS 514 H M1 glucuronide (glucuronic acid) conjugate Quinclorac glucose conjugate	419		rat[1] goat hen wheat strawberry

Codes	Molecular formula and Nominal mass	Structure	Occurrence
BH 514-2-OH 2 -hydroxyquinclorac	$C_{10}H_5Cl_2NO_2$ 3,7-dichloro-2-hydroxyquinoline-8-carboxylic acid 258		soil (terrestrial metabolism)
BH 514-1 3-chloroquinoline-8-carboxylic acid	$C_{10}H_6ClNO_2$ 3-chloroquinoline-8-carboxylic acid 207.6		soil (aquatic metabolism)

Animal metabolism

The Meeting received metabolism studies on laboratory animals, poultry and lactating goats using the 2, 3, 4-[^{14}C]-quinclorac (quinoline label).

Laboratory animals

Rats

In rats given 2, 3, 4-[^{14}C]-quinoline labelled quinclorac orally absorption was rapid and accounted for at least 85.5% given a single administration of low and high doses (15 mg/kg and 600 mg/kg bw, respectively). The maximum plasma concentration of radioactivity was reached approximately 30 minutes after administration of the low or high dose. The half life in plasma was 3-4 hours for the low dose and 12-13 hours for the high dose. Radioactivity was widely distributed throughout the body. Elimination of radioactivity was mainly via urine (> 91%) for both female and male rates, while faecal excretion ranged from 0.7 to 3.7% of the dose. The bile was a minor route of excretion of the low dose but was found to be a significant route after administration the high dose (600mg/kg). Minor radioactivity was excreted in the faeces of intact rats dosed at this level, indicating that the greater part of the biliary excreted radioactivity was reabsorbed and eliminated via urine.

Biotransformation of quinclorac was minimal. The parent and one metabolite (a glucuronide of quinclorac) was identified in the urine. The metabolism of quinclorac was characterized in the bile where > 18 minor (< 10% TRR) metabolites were identified. The metabolism is characterized by two primary reactions; nucleophilic substitution of the chlorine atom at the isocycle with glutathione and formation of an arene oxide intermediate followed by reactions with glutathione to form S-conjugates and/or by addition of water to form hydroxylated derivatives. Metabolite M1 (glucuronic acid conjugates of quinclorac) was the major metabolite identified in the liver and kidney

Livestock

Lactating goats

The kinetic behaviour and the metabolism of 2, 3, 4-[^{14}C] quinclorac was investigated by Hawkins *et al.* (1986, BASF 86/0434, 1987 BASF 86/0473).

One lactating goat (47 kg) was dosed orally daily for five days with 34 mg radiolabelled quinclorac per kg bodyweight/day (1600 mg/animal/day, equivalent to 800 ppm in the diet). The goat was sacrificed 6 hours after the last dose. Milk, plasma, urine and faeces were collected during the whole dosing period. After sacrifice liver, kidney, fat and loin muscle were sampled.

Analysis of the total radioactive residue (TRR) was carried out using combustion and or liquid scintillation counting (LSC). In total 66.7% of applied radioactivity was recovered in the experiment. The relatively low recovery of applied radioactivity is explained by unabsorbed radioactivity within gastrointestinal tract due to the termination of the sacrifice of the animal relatively early, 6 hours after the final dose. The passage time of material within the GI tract of ruminants can be up to 72 hours. The GI tract was not analysed for TRR. Excretion of radioactivity in

urine, faeces and milk accounted for 63.0%, 3.7% and 0.003%, respectively of the total dose up to 6 hours after the final dose.

The TRR found in organs and tissues were about 0.2% of the applied radioactivity, with levels being highest in kidney (10.3 mg eq/kg) followed by liver (2.13 mg eq/kg), fat (subcutaneous: 0.78 mg eq/kg, omental 0.14 mg eq/kg) and muscle (leg: 0.19 mg eq/kg, loin: 0.16 mg eq/kg). In milk the TRR level increased from 0.034 mg eq/kg directly after the first administration up to 0.055 mg eq/kg after two days, then down to 0.032 mg eq/kg at day three and back to 0.056 mg eq/kg day, a plateau level was thus not reached. The TRR levels found are summarized in Table 4. The radioactivity in milk over time is presented in table 5.

Table 4 TRR in goats milk and tissue after daily oral administration for five days with 2, 3, 4-^{14}C-quinclorac at 34 mg/kg bw/ day (equivalent to 800 ppm in the diet) 6 h after sacrifice.

96-102	0.056		0.056

***** Refers to morning following the afternoon collection immediately prior to the next dose..

Milk (day 2, PM) was mixed with methanol to precipitate the proteins. After centrifugation the methanolic extracts were reduced by evaporation and mixed with 1 M HCl. The extract was fractionated by column chromatography (C-8, octylsilane). The column was washed sequentially with 1 M HCl and hexane followed by elution with ethyl acetate. The ethyl acetate extracts were evaporated to dryness and reconstituted in methanol.

Liver and kidney samples were homogenized and extracted with 1 M HCl/ethyl acetate (1:10, v/v) for 10-20 min followed by centrifugation. The ethyl acetate extracts were evaporated to dryness and reconstituted in methanol.

Fat and muscle samples were extracted with water/ethanol (1:9, v/v) and 1 M NaOH , followed by extraction with methanol. Both extracts were combined, concentrated by evaporation and mixed with 1 M HCl. The extract was fractionated as described for milk.

The extraction efficiency was generally > 90% TRR except in muscle where it was 83% TRR. In muscle tissue 17% TRR (mg eq/kg not given) of the residue was not extracted and attempts to further extract this solid material was not performed. Identification of the radioactivity in extracts and column fractions was done using TLC in five different solvent systems. The reference substance used was the parent quinclorac which was confirmed on TLC plates by the quenching of UV fluorescence at 254 nm.

Quinclorac is not significantly metabolized in the goat. Parent quinclorac was present at levels >80% TRR in milk, liver and kidney. The metabolite M1 (glucuronic acid conjugate of the parent) was present at levels of 4.0% TRR in milk and at 4.7% TRR in kidney. Three other unidentified fractions (R01, R03 and R05) were found at levels of 0.4–5.4% TRR in milk, liver and kidney.

Since the methods used to extract the residues included 1 M HCl, it is not clear whether parent compound represents parent only or includes parent released from conjugates and whether the M1 is the fraction of conjugates that remained uncleaved.

Table 6 Characterization and identification of compounds in milk, tissues and urine of the lactating goat after administration of 2, 3, 4-^{14}C-quinclorac at 34 mg/kg bw/day (800 ppm in the diet)

Laying hens

The kinetic behavior and the metabolism of 2, 3, 4-^{14}C-quinclorac in laying hens was investigated by Hawkins et al. (1986, BSF 1986/5003). Seven birds (366-372) were selected from a group of 15 birds based on egg laying records. These hens (1.8–2.4 kg) were orally dosed once for five days with 33–44 mg radiolabelled quinclorac per kg body weight per day (80 mg/bird/day) corresponding to 800 ppm in the diet (based on a food consumption of 100 g/day). Excreta and eggs were collected daily during the dosing period. The number of laid egg varied significantly from hen to hen. For example two birds did not lay any eggs during the study, and for two of the birds all eggs were broken and no eggs collected during the sampling time point. The birds were sacrificed 6 hours after the last dose and liver ,kidney, muscle, skin with underlying fat were collected. Blood samples were collected just prior to sacrifice and separated by centrifugation into plasma and cells.

Total radioactivity was measured in excreta, eggs and tissues using combustion and/or LSC. The TRR levels found in tissues and eggs (in concentration and per eggs) are summarized in Tables 7 and 8. Excretion of radioactivity in excreta was 87.5–95.1% of the applied radioactivity up to 6h after the final dose. The total radioactive residue (TRR) were highest in the kidney (0.77–88.98 mg eq/kg), followed by liver (0.26–10.53 mg eq/kg), plasma (0.14–13.50 mg eq/kg), whole blood (0.09–9.41 mg eq/kg), skin/fat (0.23–7.2 mg eq/kg and leg muscle (0.05–3.95 mg eq/kg). Plasma levels and tissue concentration obtained at sacrifice, 6 hours after the final dose, showed considerable inter-animal variation.

In eggs the TRR levels increased from 0.06 mg eq/kg one day after first administration up to an average plateau of 0.18–0.65 mg eq/kg after four days. Levels showed a wide variation as also found in plasma and tissue. One bird reached a plateau of 1.06 mg eq/kg after three days, while two other birds reached a plateau after two days (1.21 and 0.27 mg eq/kg.

Eggs excluding shells

ns no eggs laid during this period

B eggs laid but broken by the bird and included with excreta

* Hen 272 laid two eggs on day 5

Samples of excreta, eggs, liver, breast muscle and skin/fat were further analysed for the composition of the radioactivity. Excreta were mixed with methanol and the methanolic supernatant was collected after centrifugation.

Whole egg homogenates from birds 367 (day 2), 369 (day 4) and 372 (day 3) were mixed with methanol and the protein precipitate removed by centrifugation. The methanol extracts were reduced by evaporation and acidified with 1 M HCl. The extract was fractionated by column chromatography (C-8, octylsilane). The column was washed sequentially with 1 M HCl and hexane followed by elution with ethyl acetate. The ethyl acetate extracts were evaporated to dryness and reconstituted in methanol.

Birds 367 and 372 had the highest tissue concentration of radioactivity and were selected for extraction. Liver samples were extracted with 1M HCl/ethyl acetate (1:10, v/v). After centrifugation, the remaining solids were extracted again with ethyl acetate. Both extracts were combined. Muscle and skin/fat samples were extracted with methanol/water (1:1) with a few drops of 1 M NaOH per 10 mL. After centrifugation, the remaining solids were extracted again with methanol. Both extracts were combined, reduced by evaporation, acidified with 1 M HCl and fractionated by column chromatography as for eggs.

Identification of the radioactivity in all extracts was done using TLC in five different solvent systems. The reference substance used was the parent quinclorac which was confirmed on TLC plates by the quenching of UV fluorescence at 254 nm.

Extraction efficiency varied from bird to bird but were generally around 90% for excreta, liver, breast muscle and skin/fat (Table 9). The unextracted residues in eggs were rather high from 10.5–21.1% of TTR in the egg tissue.

Besides the parent quinclorac (levels > 78% TRR in tested matrices) the only identified metabolite was M1 (glucuronic acid conjugate of the parent). M1 co-chromatographed with the major radioactive component in the bile of rat. In the rat study this metabolite was identified as the glucuronic acid conjugate of parent by enzymatic cleavage, followed by MS analysis. The combined concentration of M1 and fractions R01-1 and R01-3 was a maximum of 3% TRR in the tissues and not detected in eggs. Another fraction R01-5was present at levels from 0.3–3.7% TRR in eggs and tissue. In eggs (excluding shells) 10.5–21.1% of the residue was not extracted.

Since the methods used to extract the residues included 1 M HCl, it is not clear whether parent compound represents parent only or includes parent released from conjugates and whether the M1 is the fraction of conjugates that remained uncleaved.

Plant metabolism

The Meeting received plant metabolism studies after foliar application of ^{14}C-radiolabelled active substances to rice, wheat, rape seed (canola), sorghum and strawberry. In these studies 2, 3, 4-[^{14}C]-quinclorac (quinoline label) or 3-[^{14}C]-quinclorac (quinoline label) were used.

Rice

In a study reported by Wood (1988, Ref. BASF 88/5059) one foliar application of 2,3,4-^{14}C-quinclorac was made to paddy rice plants. The experiments were performed on plants grown in a growth chamber and in the field. These plants were treated at 1.5 kg ai/ha at the 4 leaf stage (~ BBCH 14) and were grown in pots containing a mixture of loam compost and peat moss. The field plants (variety Starbonnet) were treated at 0.84 kg ai/ha at 3-5 leaf stage (~BBCH 15-16) under unflooded conditions in a sandy loam soil. Seven days later a permanent flood was established for the field plants. Whole plants (forage) were harvested from the field plots 28 days after treatment and mature grain and straw samples were taken from the growth chamber plants (97 days after treatment) and field grown plants (118 days after treatment).

Analysis of the TRR was done using combustion and LSC. An overview of the TRR levels found in collected samples is presented in Tables 10 and 11 below. Only rice grain and straw from the growth chamber and rice forage and grain from the field treatment were analysed further.

Radioactivity in rice straw and forage was easily extracted with organic solvents. Straw samples were homogenized and 92% TRR was extracted with acetone /water (6:4, v/v). The extract was evaporated, acidified with HCl and residues were partitioned overnight between diethyl ether (87% TRR) and water (4.9% TRR). The diethyl ether fraction was analysed by TLC.

Forage samples were homogenized and 92% TRR was extracted with acetone/water (1:1, v/v) and acetone/water (6:4, v/v). The extract was evaporated and acidified with HCl. The residues in the aqueous extract were exhaustively partitioned between dichloromethane (87% TRR), ethyl acetate (2.4% TRR) and water (4.9% TRR). The dichloromethane and ethyl acetate extracts were combined, evaporated to dryness and redissolved in acetone for TLC analysis.

Radioactivity in rice grain was extracted poorly with organic solvents. When the grain was first dissolved in boiling water and then acidified or refluxed with 1 M HCl, the residues could be easily extracted with organic solvents. Grain samples from growth chambers were refluxed with water

for 2 hrs, acidified with HCl and residues were partitioned for 8 hrs into diethyl ether (97% TRR). The diethyl ether extract was partitioned with 1 M NaOH, whereby the oil remained in the diethyl ether and the residues transferred into the aqueous phase. The combined aqueous extracts were acidified with HCl and partitioned with diethyl ether. The diethyl ether extract (94% TRR) was evaporated to near dryness and then diluted with methanol for TLC analysis.

Field grain samples were first extracted with hexane (1.9% TRR) to remove the oils. Remaining solids were air dried and solubilized by reflux with 1 M HCl. Boiling acid was used to avoid frothing and to avoid emulsion problems during extraction. Residues were partitioned between diethyl ether (58% TRR), ethyl acetate (25% TRR) and water (15% TRR). The combined diethyl ether and ethyl acetate extracts were concentrated to near dryness and diluted with methanol for TLC analysis.

Organic fractions were analysed by TLC. An overview of the composition of the residue is presented in Table 11. Nearly all the radioactivity in all parts of the rice plant could be accounted for as unchanged parent up to the final harvest. Metabolites were not further characterized. The identification of the parent was performed by derivatization of quinclorac to its methyl ester and analysis with GC-MS.

Grain samples required boiling water or boiling 1 M HCl to allow extraction of the residues with organic solvents. This suggests that quinclorac is bound to the grain matrix and the quinclorac identified is actually quinclorac released from conjugates. Forage and straw were easily extracted with organic solvents, therefore the quinclorac identified in forage and straw is likely the unchanged parent compound.

Wheat

In a study reported by Ellenson, J, L (1996a, BASF 1996/5 197) one foliar application of 3-^{14}C quinclorac was applied at 3-5 leaf stage to wheat plants grown in a greenhouse at 1 × 0.125 kg ai/ha

and at 1 × 0.500 kg ai/ha. Plants (variety Katepwa) were grown in pots containing silt loam. Forage was sampled at 37 DAT when plants were in early to late boot stage and mature wheat grain and straw were sampled at 92 DAT.

Analysis of the TRR was carried out using combustion and LSC. The TRRs found in the samples collected amounted to 3.26 and 13.14 mg eq/kg at the two application rates in forage. In the straw 1.86 mg eq/kg was detected at the low application rate and 8.16 mg eq/kg at the high application rate. TRR for the grain were 1.13 mg eq/kg at the low application rate and 3.94 mg eq/kg at the high application rate samples. An overview of the TRR levels found in collected samples is presented in Table 12.

In forage, straw and grain 85–95% TRR was extracted with acetone/water (2:1, v/v). A further 3.3–12% TRR could be released by hydrolysis with 0.1 M NaOH. Identification of residues in the acetone/water fraction in straw was based upon retention time comparison with known standards and/or determination with HPLC-MS. Separation and isolation of specific radioactive residues from the straw samples was accomplished using semi-preparative and analytical HPLC methods coupled with fraction collection. Identification and characterization of residues in forage and grain acetone/water fractions were derived from HPLC retention time comparison with residues isolated from the higher application straw. An aliquot of the acetone/water extract was treated by base hydrolysis (pH 13, 100 °C, 2 hrs) to cleave any conjugates present in the extract and the extract was re-analysed by HPLC-MS.

In forage, parent residues accounted for 24% TRR (0.78 mg eq/kg) in the low application rate and 45% TRR (5.92 mg eq/kg) in the high rate samples. A total of 9.8% TRR (0.32 mg eq /kg) in the low application rate and 6.4% TRR (0.84 mg/kg) in the high application rate forage were associated with hydroxyquinclorac conjugates. Other metabolites identified at levels <5% TRR were quinclorac conjugates and hydroxyquinclorac. Unidentified components were <5% TRR (0.16 mg/kg) for the low application rate or 6.93%TRR (0.91 mg/kg) for the high application rate.

In grain, parent residues accounted for 62% TRR (0.69 mg eq/kg) in the low application rate grain, and 68% TRR (2.68 mg eq/kg) in the high rate samples. A total of 4% TRR (0.14 mg eq/kg) in the high application rate grain was assigned to hydroxyquinclorac conjugates. Unidentified components were none > 2.11% TRR (0.024 mg eq/kg) for the low application rate or 3.47%TRR (0.14 mg eq/kg) for the high application rate.

In straw, parent accounted for 12% TRR (0.22 mg eq/kg) in the low application rate samples and 22% TRR (1.83 mg eq/kg) in the high application rate samples. Additional residues at 13.7% TRR (0.26 mg eq/kg) in the low application rates samples and 12.6% TRR (1.02 mg eq/kg) in the high application rate were assigned to hydroxyquinclorac conjugates. Unidentified compounds were none > 7.07% TRR (0.13 mg eq/kg) for the low application rate samples or 7.71%TRR (0.63 mg eq/kg) for the high application rate.

A more detailed fractionation of the high application rate straw were generally in agreement with the simpler profile determined by HPLC analysis of the soluble residues only. Individual residues identified during analysis of the high application rate straw sample included the parent 23% TRR, a glucose conjugate of hydroxyquinclorac (~6% TRR), and hydroxyquinclorac (~3% TRR). The hydroxyquinclorac was not the 2-OH quinclorac identified in the soil degradation studies. Mass spectral analysis also indicated the presence of small (<1% TRR) amounts of possible malonate esters of parent and/or hydroxyquinclorac. A relatively large portion of TRR (20% or 1.6 mg/kg in the 4× sample) was associated with high molecular weight species that are presumed to be natural products.

Base hydrolysis (pH 13, 100 °C, 2 hrs) of the entire homogenized forage, straw and grain samples did not release any compounds beyond what was already identified.

The results indicate that the residues in wheat primarily consist of unchanged parent compound. Low levels of hydroxyquinclorac are formed by oxidative hydroxylation of the ring structure of the parent compound. Both quinclorac and hydroxyquinclorac can be metabolized to glucose conjugates. A less prevalent metabolic pathway may involve esterification of the parent at the carboxyl group.

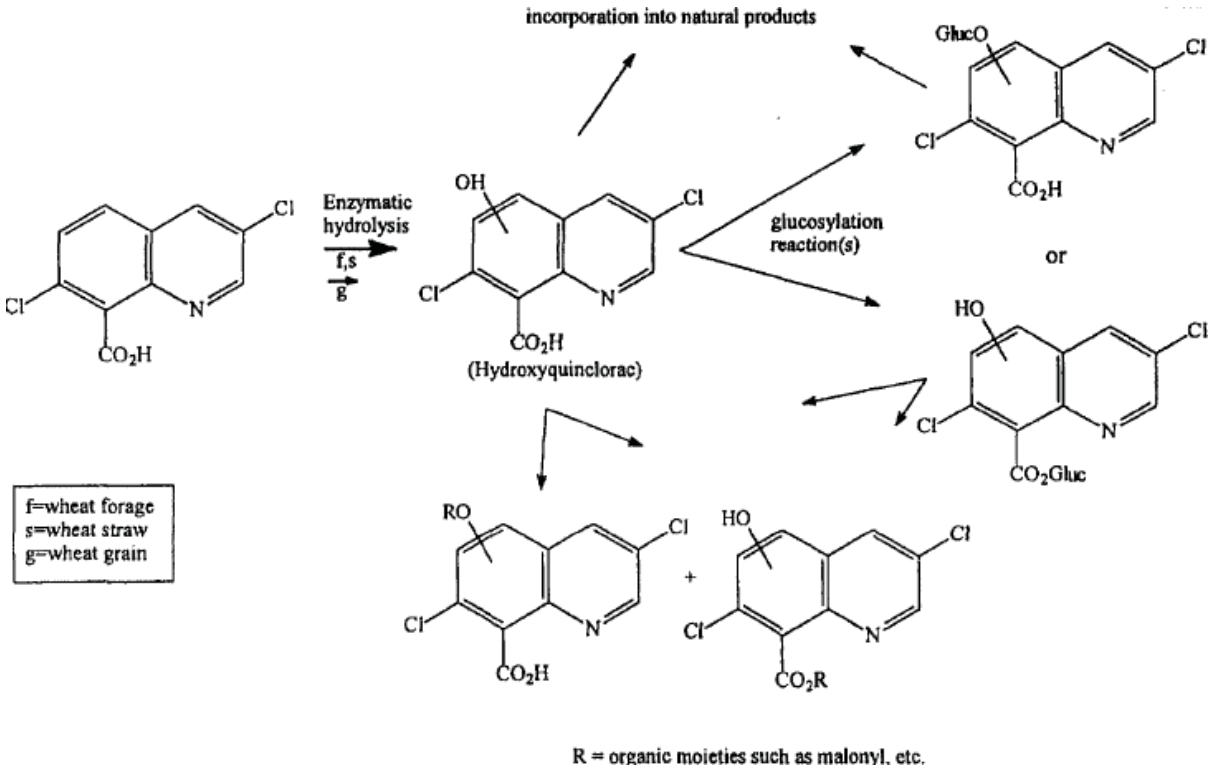

Figure 6 Proposed metabolic pathway of quinclorac in wheat

Sorghum

In a metabolism study reported by Ellenson J, L, (1993, Ref 1993/5088) 3-^{14}C-quinclorac was applied pre-emergent outdoors to the soil followed by a post-emergence treatment when sorghum plants were 15–25 cm tall. The pre-emergence treatment was 0.525 kg ai/ha and the post-emergence was 0.504 kg ai /ha (total 1.03 kg ai/ha) with an interval of 25 days. The plants (variety G820) were grown in a field plot with loamy sand soil in North Carolina, USA.

Analysis of the TRR was carried out using combustion and LSC. Residue analysis was done on forage sampled 25 days after the last treatment and on grain and fodder sampled 95 days after the last treatment. The TRRs for these samples amounted to 4.01 mg eq/kg in forage, 0.87 mg eq/kg in fodder and 0.83 mg eq/kg in grain.

Sorghum forage was extracted with acetone/water and the filtrate was further extracted with ethyl acetate. Sorghum fodder samples were extracted with acetone/water and the filtrate was subsequently extracted with hexane, dichloromethane and ethyl acetate. Sorghum grain samples were extracted with acetone/water and the filtrate was subsequently extracted with hexane, dichloromethane and ethyl acetate and refluxed with HCl.

Remaining solids were subjected to refluxing with NaCl solution (10 g/L) for 2 hr to determine radioactivity incorporated into water soluble polysaccharides, boiling with EDTA (5 g/L) for 1 hr to determine incorporation in peptic polysaccharides, with 1.25 M NaOH (50 g/L) for 6 hr at 80 °C to determine incorporation in hemicellulose I, with sodium chlorite ($NaClO_3$, 10 g/L at room temperature) for 3 hr to determine incorporation in lignin and with 6 M NaOH (240 g/L) for 6 hr to determine incorporation in hemicellulose II.

Extracts were analysed by radio TLC. Quinclorac was confirmed using methylation to its methyl ester and determined by GC-ECD. The presence of quinclorac methyl ester was also separately confirmed by two dimensional TLC.

An overview of the TRR levels found in collected samples and the composition of the residue is presented in Tables 13–15. In all samples unchanged quinclorac was the major residue being present at levels of 73.4% TRR in forage, 21.5% TRR in fodder and 73.5% in grain. This residue included the parent compound that was released from remaining solids (4% in grains to 9% TRR in forage and fodder). The only other metabolite identified was quinclorac methyl present at 3.6% TRR in forage, 5.9% in fodder and 1.7% in grain. In spite of substantial alkaline extraction procedure, a large amount of unidentified residues was present in forage and fodder in organic and aqueous fractions, maximum 18.7% TRR (0.75 mg eq/kg in forage and 52.4% TRR (0.46 mg eq/kg) in fodder. The majority of the released residue from the remaining solids was in the polysaccharide fraction ($NaCl/H_2O$) or the hemicellulose fraction (1 M NaOH).

The results indicate that extraction with acetone/water is very effective for the sorghum forage and grain, but less so for the fodder. An additional 24% TRR could be extracted from the remaining fodder solids after addition of NaOH. The current analytical method incorporates an alkaline extraction step.

Rape seed (canola)

In a study reported by Parker 1998a (BASF 1998/5180) one foliar application of 3-^{14}C quinclorac was made post emergence (30 days after sowing at 5th true leaf stage) at 0.2 kg ai/ha. The experiment was performed in a growth chamber on a *brassica rapa v*ariety "Horizon" grown on a sandy loam. By simulation of a North American climate during summer it was possible to cultivate oil seed within 90 days. Whole plants were harvested 1 and 29 days after treatment. Seed and straw were harvested 60 days after treatment.

Analysis of the TRR was carried out using combustion and SC. An overview of the TRR levels found in collected samples is presented in Table 16. Forage was not further characterized.

Homogenized samples of oilseed rape seeds or straw were subsequently extracted with acetone/phosphate buffer pH 7 (50:50, v/v). Rape seeds were further extracted with 0.1 M NaOH at room temperature (mild alkaline hydrolysis) and 0.1 M NaOH at 100 °C (harsh alkaline hydrolysis). Organic solvents extracted 84–87% TRR from seed and straw, while an additional 6.9% and 5.2% TRR could be extracted from the seeds by mild and harsh alkaline hydrolysis (Table 17). After centrifugation, each extract was partitioned between an aqueous and organo-soluble fraction (Table 18). Extracts and solids were analysed by (combustion) LSC.

[a] Partitioned into hexane at pH 7 (37.1% TRR quinclorac methyl) and into dichloromethane at pH 2 (38.5%, contains 37.1% TRR quinclorac parent)

[b] Partitioned into ethyl acetate at pH 2

[c] Partitioned into dichloromethane at pH 2

Identification and characterization of residues in rape seed was based upon retention time comparison with standards for parent and quinclorac methyl and by confirmation using HPLC-MS/MS. An overview of the composition of the residues in collected samples is presented in Table 19.

In rape seed a total of 37.1% TRR (0.176 mg eq/kg) was identified as the parent quinclorac and 37.1% TRR (0.176 mg eq/kg) was identified as a methyl ester. Quinclorac methyl, in the acetone/phosphate buffer extract partitioned into hexane at pH 7, while the quinclorac parent partitioned into dichloromethane at pH 2. The remainder of the extracts (17.4% TRR) represents a multitude of minor discrete residues and was characterized as organo soluble or aqueous-soluble. The post extraction solids accounted for 2.7% TRR (0.013 mg eq/kg).

For straw, the organo soluble fractions consisted of two major fractions containing quinclorac and quinclorac methyl ester, and at least two minor fractions. A minor peak at approximately 25 min. corresponded to a minor peak seen in the seed samples. No quantitative data are indicated in the report. The post extraction solids from straw containing 12.2% TRR (0.078 mg eq/kg) were not further analysed as it was concluded that rape seed straw not is a feed item.

Strawberry

In a study reported by Walsh, K (2015, BASF/029602-1, report 029602-1) mature strawberry plants were individually treated with one foliar spray application of ^{14}C-quinclorac at 1.120 kg ai/ha at growth stage BBCH 73 61 days prior to the third sampling. The fruits were harvested 21, 37 and 61 days after treatment (DAT). All mature fruit was collected and approximately 2-3 leaves from each plant. At the third and final harvest, all the remaining leaves and immature green strawberry fruits were collected.

Foliage was surfaced washed with ethanol prior to homogenization. Homogenized samples of both fruits and foliage were extracted with ethanol/water. The post extracted solids (PES) were combusted and further extracted using a Soxhlet apparatus. Acid hydrolysis of pooled extracts was done with 12 N hydrochloric acid and 2 hours incubation at 37 °C. Extracts and PES were analysed by LSC, and concentrated extracts were analysed on HPLC to determine the TRR and the nature of major terminal residues. The identity was confirmed by LC-MS/MS. An overview of the residues and fractions found in collected samples is presented in tables below.

In foliage, parent quinclorac accounted for 67.4% TRR (10.43 mg eq/kg) at first harvest 21 DAT and at 57.4% TRR (4.36 mg eq/kg) at the last harvest 61 DAT. Conjugated quinclorac (M1) released by acid hydrolysis was identified from 26.8%TRR (4.19 mg eq/kg) at first harvest and at 28.6%TRR (2.27 mg eq/kg) in the last harvest. As the parent is an acid it is possibly a glucose ester conjugate. A minor polar metabolite was present from 1.8% (0.27 mg eq/kg) at first harvest 21DAT to 5.8% TRR (0.47 mg eq/kg) at last harvest 61 DAT. Post extracted (non-characterized) solids went from 4.5% TRR (0.7 mg eq/kg) at the first harvest to 8.1% TRR (0.67 mg eq/kg) at the last harvest. Quinclorac methyl ester was not detected in the foliage.

In fruit, parent quinclorac accounted for 78.8% TRR (9.13 mg eq/kg) at first harvest and at 50.8% TRR (1.69 mg eq/kg) at third harvest. Conjugated quinclorac (M1) released by acid hydrolysis went from 10.7%TRR (1.26 mg eq/kg) at first harvest to 47.3%TRR (1.57 mg eq/kg) in the last harvest. Quinclorac methyl ester accounted for 9.6% TRR (1.13 mg eq/kg) at first harvest, to 4.9% TRR (0.42 mg eq/kg) at second harvest and was not detected at the last harvest. Level of post extracted (non-characterized) solids was below 10% TRR throughout the study.

Environmental fate in soil

For the investigation of the environmental fate of quinclorac the Meeting received one study on hydrolysis, one on photolysis, two on terrestrial and aquatic soil metabolism and one on field dissipation. In the studies, 2, 3, 4-[^{14}C]-quinclorac (quinoline label) or 3-[^{14}C]-quinclorac (quinoline label) were used.

The characteristics of the soils used in the experiments are presented in the table below.

*Soil classification system not stated

Photolysis on soil

The photodegradation of quinclorac was investigated by Wood, N and Winkler, V (1991, BASF 1991/5005) with 3-[^{14}C]-quinclorac in soil (15% sand, 65% silt and 20% clay). Irradiated soil layers were exposed to light from a xenon lamp, filtered to remove light with wavelengths < 290 nm, in a 12 hour light/ 12 hour dark cycle. Test systems were maintained at 26ºC during irradiated periods and 18 ºC during dark periods. The test system was continually aerated with a stream of moistened, CO_2 free, air, and the outgoing air connected to traps for the collection of $^{14}CO_2$. Total recoveries were generally in the range of 93–106% of the % AR.

Under the conditions of the test quinclorac degraded slowly in irradiated samples, with a half-life (DT_{50}) of 162 days; polar metabolites were identified but each to an extent less than 10% AR. In dark control samples the degradation of quinclorac was very slow, with DT_{50} of 529 days.

Soil metabolism

The aerobic soil metabolism was investigated in aquatic and terrestrial soil systems using quinoline [2, 3, 4-^{14}C]- or [3-^{14}C] labelled quinclorac.

In the terrestrial and aquatic soil metabolism study conducted by Clark, J (1987, BASF 1987/5040) [2,3,4-^{14}C]- quinclorac was applied to two silt loam soils from Savoy, IL (USA) and Greenville, MS (USA) and two aquatic water and soil systems from rice fields near Davis, CA, USA and Greenville, MS, USA, see Table 22. The studies were performed prior to GLP being required, but were performed in accordance with US EPA guideline 162-1. Applications were made at a concentration of 0.5 mg/kg, and 5.0 mg/kg corresponding to field application rates of 0.375 kg ai/ha and 3.750 kg ai/ha respectively.

The terrestrial soil test systems were maintained in the dark at 23 ºC, and the moisture adjusted at the start of the study to 40% of the maximum water holding capacity (mWHC). Reaction

flasks with gas outlets to allow CO_2 free air to pass into the bottom and out at the top of the cylinders were used in the experiment. Soil, 500 g for the 0.5 ppm rate and 200 g for the 5 ppm rate. was placed in the flasks and an acetone solution (0.4 mg/g of soil) of quinclorac was added.

The aquatic soil test systems were conducted in a growth chamber in the dark (temperature not given). 250 mL flasks contained approximately 100 g of sediment and 100 mL of water collected from the rice field simultaneously with the sediment. The flasks were connected via tubing to allow the flasks to receive a stream of CO_2 free air and an exit containing scintillation cocktail to capture $^{14}CO_2$. In both the aerobic and the anaerobic experiments, the application of 0.5 mg/kg and 5 mg/kg of quinclorac was added to the water and the water added to each flask containing the sediment.

The individual test systems were continually aerated with a stream of moistened, CO_2 free air, and the outgoing air connected to traps for the collection of $^{14}CO_2$. Single samples for the 0.5 mg/ kg studies were taken after application and at seven further sample times including at the study termination 12 months after application. For the 5 mg/kg studies samples were collected at 5 sample times from 1 month to 12 months after application. In the aerobic aquatic soil studies water was decanted and analysed by LSC. Soil samples were frozen at -20 ºC following collection until they were analysed.

Soil samples were extracted at room temperature with water and 0.1 N NaOH. The aqueous extracts were partitioned with ethyl acetate. The extracted soil was then refluxed with 0.1 N NaOH, neutralized with HCl, and partitioned with ethyl acetate.

All extracts were radio-assayed, with residual soil combusted and analysed by LSC to determine radioactive mass balances. TLC was used for identification and quantification, with confirmation by HPLC using eight synthetized standards.

An overview of radioactive residues extracted from terrestrial and aquatic soil systems are presented in tables below.

*3-chloro-8-quinolilne carboxylic acid

Quantified characterization data of extracted residues is not presented in the reports. It is stated with regard to the terrestrial soil samples that the TLC profiles on total extracted residues in both soils indicated no degradation of quinclorac 120 days after treatment. After one year incubation, traces of metabolite BH 514-1 (3-chloro-8-quinolilne carboxylic acid) was reported to have been observed in the soil.

In the aquatic anaerobic and aerobic systems (Table 25) extraction data 180 days after the application of quinclorac show small differences in the distribution of residues in the different fractions.

In the aerobic aquatic system, with an application rate of 0.5 mg/kg, it is stated in the report that samples displayed mainly unchanged quinclorac after 1 year. In the same system (Table 26) at an application rate (AR) of 5 mg/kg (corresponding to 3.75 kg ai/ha) to sediment and water of a silty loam (rice field) quinclorac degraded slowly to the metabolite BH 514-1 (3-chloro-8-quinolilne carboxylic acid) at a maximum concentration of 55.7% AR 180 days after treatment. Three additional metabolites were detected each present at less than 10% AR and not further characterized. The half-life (DT_{50}) of quinclorac in this system was 4.7 months and for the metabolite BH 514-1 7.4 months. Under anaerobic conditions at the 5 mg/kg level, the same metabolites were formed but at a slower rate, there was a 50% conversion of quinclorac to BH 514-1 within one year.

In an aerobic soil metabolism study conducted by Goetz AJ (1993, BASF 1993/5074) [3-^{14}C]-quinclorac was applied to a clay soil from Holly Springs, NC, USA, and to a loamy sand soil from Leland, MS, USA (Table 22 beginning of chapter). Applications were made at concentrations of 5.3 mg/kg dry soil to the clay soil, and 5.5 mg/kg dry soil to the loamy sand soil, corresponding to field application rates of 3.975 kg ai/ha and 4.125 kg ai/ha respectively. Soil samples from loamy sand and a clay soil were extracted by shaking and/ or refluxing borate buffer and additionally by refluxing in sodium hydroxide if required.

Radioactivity in the extracts was quantified by LSC, with residual soil combusted and analysed by LSC. HPLC was used for characterization and quantification of extracted radioactivity. Analytical standards were used for quinclorac, BH 514-1 (3-chloro-8-quinolilne carboxylic acid), BH 514-2-OH (2-hydroxyquinclorac) and BH 514-Me (quinclorac methyl ester).

The extractability and characterization of the extracted residues in the organic extracts is presented in tables below. Additional residues present in the sodium hydroxide fractions are presented in brackets.

Table 27 Extractability and distribution of radioactive residues after incubation of 5.5 mg/kg (corresponding to 3.98 kg ai/ha) of [3-^{14}C quinclorac dry loamy sand soil (81.0% sand, 13.0% silt, 6.0% clay)

***** The radioactivity found in the different fraction reported does not always add up to exact TTR

** Additional residues from the extraction with methanol/ammonium hydroxide following reflux in sodium hydroxide are presented in brackets.

The radioactive residues extracted from soil by refluxing with sodium hydroxide solution are considered bound. The residues associated with the humic material increased with time and at 364 days after treatment accounted for 1.1 and 5.5% TRR in the loamy sand and clay soil. The majority of the residues extracted from the humic material by sodium hydroxide were quinclorac.

The residues extracted from the borate buffer solution are considered as available residues**.** Under the condition of the study quinclorac degraded with half-lives (DT_{50}) of 391 days in a loamy sand and 168 days in a clay, forming the metabolites BH 514-2 –OH (2-hydroxyquinclorac) at a maximum concentration of 12% AR and the metabolite BH 514-Me (quinclorac methyl ester) at a maximum of 7.8% AR. Other metabolites were identified at levels well below 10% AR throughout the study and not further characterized.

Field dissipation study

The dissipation of quinclorac in a loamy sand soil was investigated at one site in Kansas USA by Jackson, S *et al* (1997, BASF 1996/5205). Quinclorac was applied with two applications of 2.8 kg ai/ha to bare soil. One application of was made in autumn (October 1994) and the other at summer (June 1995).

Soil samples were taken at day 0 to approximately 540 days after the first application at a maximum depth of 1.22 m. Samples were separated into 15 cm segments (table below) and three samples were analysed per segment. The samples were extracted with 0.1 N NaOH followed by acidification and partitioning with methylene chloride/ ethyl acetate. An aliquot of the organic extract was dried and reconstituted in HPLC mobile phase and analysed by LC/MS/MS. The LOQ for the summed residue was 0.01 mg/kg. Quinclorac methyl ester was extracted from soil with methylene chloride, ethyl acetate and methanol. The extract was dried, re-constituted in HPLC mobile phase, and analysed by LC/MS/MS.

Soil characteristics and residue concentrations of quinclorac and the metabolites BH 514-2-OH and BH 514-Me are presented in tables below.

Table 29: Soil characteristics for soil used for a field dissipation study for quinclorac

Soil characteristic	Soil depth (cm)						
	0-15	15-30	30-45	45-61	61-76	76-91	91-107
% sand	84	84	88	94	94	94	90

texture	loamy soil	loamy soil	loamy soil	sand	sand	sand	sand

Residue values were determined at each sampling interval in (15 cm) segments to a depth of up to 121 cm. Based on the distribution and magnitude of concentrations, ca. 89% of the quinclorac was observed in the topsoil (0–30cm) with 74% in the 0–15 cm segment and 15% in the 15–30 inch segment. At the exaggerated use rate of this study (2 × 2.8 kg ai/ha) some movement to lower depth segments was observed with 7% in the 30-46 cm segment, 2% in the 46-61 cm segment, 1% in the 61-76 cm segment, and < 1% in all lower depths. Metabolite BH 514-2-OH was observed primarily in the topsoil (91%) with 32% in the 0–15 cm segment and 59% in the 15-30 cm segment. The remainder (9%) was observed in the 30–46 cm segment. Metabolite BH 514-Me was only observed in topsoil with ca. 84% in the 0–15 cm segment and 16% in the 15–30 cm segment.

Table 30 below shows total residues from quinclorac during the 540 day study detected from samples taken to a maximum depth of 1.22 m.

The maximum observed concentrations of the two metabolites were 3.6% for BH 514-2-OH (2-hydroxyquinclorac quinclorac) and 1.1% for BH 514-Me (quinclorac methyl ester). DT_{50} and DT_{90} for quinclorac were 126 days and > 360 days following the first application (winter), and 8 days and 26 days following the second application (summer).

Long-term soil accumulation studies were not submitted to the Meeting.

Confined rotational crop studies

The metabolism of [2, 3, 4-^{14}C]-quinclorac was investigated by Winkler, V and Brown M (1987, BASF 1987/5037) in the rotational crops wheat, mustard greens, turnips, sorghum and soya bean from two consecutive (first (120 days after treatment) and second (360 days after treatment) rotations. A replanting of a crop just after harvest (30 days) was not considered necessary as in good agricultural practice a new crop is never planted 30 days after harvesting of a rice crop. The first (autumn) rotational crops were wheat, mustard green and turnips, the second (annual) rotational crops were sorghum, mustard green, soya beans and turnip.

Quinclorac was applied to flooded and non-flooded rice (primary crop) at a rate of 0.84 kg ai/ha in Mississippi, USA. Rice was planted approximately one month prior to application.

The formulation was applied to one plot under flooded conditions and to another plot under non-flooded conditions; seven days later, permanent flood conditions were established on this plot. After mature harvest of rice, the soil was “worked and prepared” before first rotational crops were planted less than one month after the rice harvest (120 DAT) followed by the second rotational crops 360 DAT. The study was ended 474 days after the application of quinclorac.

Table 31 Physiochemical properties of the soil

Soil type	pH	OM%	Sand %	Silt	Clay	Field moisture	CEC meq/100g
Silty clay	6.5	2.2	9.6	40.4	50.0	21.69	33.18

Soil and plant samples were collected. Soil samples were extracted with distilled water following centrifugation. Residual soil was re-suspended in 0.1N NaOH and refluxed, centrifuged and analysed by combustion to determine $^{14}CO_2$ content. Plant samples were extracted with aqueous acetone, concentrated into the aqueous phase, acidified and extracted with ethyl ether. Soya bean and wheat seeds were defatted with hexane, hydrolysed with 1N HCl and extracted with ethyl ether. Soya bean was also further extracted by 1% NaCl reflux, EDTA reflux, 5% NaOH extraction and finally 1% sodium chlorite treatment for three hours at 80 °C. The extracted residues were derivatized using diazomethane before TLC analysis using authentic standards for parent quinclorac and the metabolite BH 514-1 (3-chloro-8-quinoline carboxylic acid) which was found as a major metabolite (55.7% AR) in the aquatic soil degradation systems.

The non-flooded treatment gave the highest residues in soil and in crops. In the following table the TRRs found in soil samples (silty clay) in the first 1–10 cm from non-flooded treatments are summarized.

Table 32 Total radioactive residues (mg/kg ^{14}C-quinclorac equivalents) in the first 10 cm of a silty clay soil (non-flooded)

Days after treatment	Total TRR	Water extract	0.1N NaOH Extract	Unextracted	Unextracted % TRR	% material balance
0	0.424	0.365	0.094	0.022	5	116

474	0.059	0.005	0.025	0.028	45	99

Water extracted residues is considered as free and available to the plant, while generally sodium hydroxide extracts are ionic and covalent bound residues**.** The total radioactive residues decreased from an initial level of 0.4 ppm to 0.056 ppm one day after application, and remained relatively constant at that level through the 474 days study.

The table below summarizes the uptake of radioactive residues in different rotational crops and their matrixes.

*The first (fall) rotational crops were wheat, mustard green and turnips, the second (annual) rotational crops were sorghum, mustard green, soya beans and turnip.

**sampling days for first and second rotational crop

In the first rotational crops as well as the second rotational crops, the residues found were higher from crops grown under non-flooded conditions. Uptake of residues was observed in both first and second rotational crops. For the first rotational crops maximum uptake was 0.028 mg eq/kg for leafy vegetable (mustard plant), for small grain (wheat seed) 0.025 mg eq/kg and for root and tuber vegetable (turnip plant) 0.012 mg eq/kg. For the second rotational crops maximum uptake was 0.014 mg eq/kg for leafy vegetable (mustard top) for small grain (soya bean seed) 0.017 mg eq/kg and for root and tuber vegetable (turnip root) 0.02 mg eq/kg.

The methylated extracted residues were identified as mainly total quinclorac and trace amounts of the metabolite BH 514-1 (3-chloro-8-quinoline carboxylic acid).

The table below quantifies the total radioactive residues found in the different rotational crops and their matrixes.

Table 34 Extraction of ^{14}C-quinclorac from mustard, wheat and soya bean samples

Quinclorac was the only major residue (>10% TRR but less than 0.05 mg eq/kg) detected in the examined rotated crops. The metabolism of quinclorac by soya bean was different from mustard and wheat due to that as much as 62% TRR (0.01 mg eq/kg) was found in soya bean seed as insoluble residues in the marc. Further extraction of the marc revealed radioactive residues in protein, carbohydrate and lignin fractions according to table below.

Table 35: Characterization of ^{14}C-quinclorac residues in soya bean

The metabolism of [3-^{14}C]-quinclorac was investigated by Nelsen, J (1992, BASF 1992/5044) in rotational crops mustard green, turnip and barley from one rotational interval (120 days). 3-^{14}C-quinclorac was applied as a spray pre-emergence and 25 days later post-emergence to sorghum plants. Treatment levels were 0.527 kg ai/ha pre-emergence and 0.504 kg ai/ha post-emergence. Sorghum plants were harvested 95 days after the post-emergence treatment. Approximately 120 days after the post-emergence treatment, mustard, turnip and barley seed were planted. Rotational crops were harvested at maturity. Barely forage was harvest 205 days after treatment.

Crop samples were treated with 0.1N NaOH or 0.1N NH_4OH and then extracted with acetone. The filtrate was subsequently acidified, concentrated, the pH adjusted to 8 and then diluted with water and extracted with dichloromethane. The water layer was further extracted with dichloromethane or refluxed with HCl. All subsamples of marc were subjected to refluxing with sodium chloride to determine radioactivity incorporated into water soluble polysaccharides, with EDTA to determine peptic polysaccharides, with sodium hydroxide to determine hemicellulose I or II and with sodium chlorate to determine lignin.

Total radioactivity was determined by combustion analysis and LSC. The nature of the residues was determined by fractionation and TLC using quinclorac, BH 514-1 (3-chloro-8-quinilone carboxylic acid) and their respective methylated samples as reference standards.

In the table below the extracted and identified radioactivity residue found at harvest in the different rotated crop matrixes is presented.

Table 36: Identification and characterization of radioactive residues in rotational crops (1st rotation, 120 days) following application of [3-^{14}C]-quinclorac to sorghum crop at a total rate of 1.0131 kg ai/ha

*The TRR identified in the different fractions does not always sum up to the TRR in the combustion analysis.

** TLC was not performed on these samples

The parent quinclorac was a major residue in all matrices and the metabolite BH 514-Me (quinclorac methyl ester) a minor metabolite (3-4% TRR) in mustard green and turnips.

Field rotational crop study

Magnitude of quinclorac residues in rotational rape seed (canola) was investigated by Barney, WP (1993, BASF 1993/5157) in a field trial in Canada. Rape seed was planted in the same plot as barley which had been grown and treated the previous year with quinclorac in a single broadcast post emergence application at the rate of 0.2 kg ai/ha.

Rape seed samples (four replicates) were harvested at maturity and stored frozen until analysis within 5 months. Samples were analysed for quinclorac with method A8902 using GC/EDC detection. The method was validated to a LOQ of 0.05 mg/kg for oil seed and the method recovery was at fortification level 0.05 mg/kg was 96% (n=1) and at fortification level 0.5 mg/kg 82% (n=1).

Table 37 Residues from quinclorac in rotating seed from plots where barley was grown previous year and treated with 0.2 kg ai/ha

Location	Application			Residues				Trial
Year (variety)	kg ai/ha	no	Growth stage	matrix	PHI	Total quinclorac (mg/kg)	mean mg/kg	Reference

ANALYTICAL METHODS

The meeting received analytical method description and validation data for quinclorac and its metabolite quinclorac methyl ester. Most matrices are validated with a LOQ of 0.05 mg/kg for both analytes, however in strawberry and oil seeds the analytes were validated also with a LOQ of 0.01 mg/kg. A summary of the analytical methods for plant and animal commodities is provided below.

Table 38 Overview of analytical methods used for the quantification of quinclorac residues in plant and animal matrices

Method (analytes)	Matrix	Extraction	Clean-up	Detection, LOQ
Method 268 Quinclorac	Animals (eggs, milk, muscle, kidney, fat, liver)	Acetone/sodium solution, acidify and partition with ethyl acetate, and derivatized with diazomethane.	filtration and C-18 SPE column	GLC-ECD SE 54 capillary column at 270-350°C, Quantification by external standards. Quinclorac-Me LOQ, 0.05 mg/kg
Method 268-1 amendment Quinclorac	Animals (eggs, milk, muscle, kidney, fat, liver)	Acetone/sodium solution, acidify and partition with dichloromethane, and derivatized with diazomethane.	filtration and amino SPE column	GLC-ECD SE 54 capillary column at 270-350°C, Quantification by external standards. Quinclorac-Me LOQ, 0.05 mg/kg
Method M829/A Quinclorac	strawberry and high water fruit crops	Acetic acid in acetonitrile in the presence of magnesium sulfate and sodium chloride		LC-MS/MS using a C18 analytical column. Quantification is made using internal standard The quinclorac ion transition 242→224 is used for quantification and the ion transition m/z 244-226 is used for confirmation. LOQ 0.01 mg/kg
Method A8902 Quinclorac	Rice (grain and straw rough rice, rice hulls, brown rice, rice bran, milled rice) Sorghum forage grain and stover.	Acetone /0.1 M NaOH solution acidify and partitioned with dichloromethane, and derivatized with diazomethane.	filtration and by solid phase extraction (silica gel column)	The methylated samples are analysed by GC-EDC at 300°C using a DB17 fused silica column at 200ºC and an electron capture detector (GC-ECD). Quantification by external standards. Quinclorac-Me LOQ 0.05 mg/kg
Method D9708 Quinclorac	Sorghum forage, grain and stover Validation data for	Acetone /0.1 M NaOH acidify and partitioned with dichloromethane, diluted with sodium	filtration and by using quaternary amine SPE column	HPLC-MS/MS using a Betasil C18 column Quantification by

				confirmation. The quinclorac methyl ester ion transition m/z 256→224 is used for quantification and the ion transition m/z 256→161 is used for confirmation LOQ 0.05 mg/kg for both analytes
Method R0036 Quinclorac and Quinclorac methyl ester	rape seed, rape oil	Plant material: *Quinclorac* acetone/sodium solution, acidify and partition with dichloromethane. *Quinclorac methyl ester* acetone. The centrifuged sample is saturated with sodium chloride and extracted with dichloromethane. Oil: *Quinclorac* hexane followed by acetonitrile/sodium hydroxide *Quinclorac methyl ester* hexane and acetonitrile/water and methanol. The centrifuged samples is saturated with sodium chloride, acidified and extracted with dichloromethane.	Not necessary using HPLC-MS/MS and the instruments high degree of specificity	HPLC-MS/MS using an Atlantis T3 column. The quinclorac ion transition m/z 242→224 is used for quantification and the ion transition m/z 242→161 is used for confirmation. The quinclorac methyl ester ion transition m/z 256→224 is used for quantification and the ion transition m/z 256→161 is used for confirmation LOQ 0.01 mg/kg for both analytes.

Animal commodities

For quantification of parent quinclorac in animal commodities method 268 was developed and validated by Mayer, F (1988, BASF 88/0542).

Method 268 (animal matrices)

The analytical method 268 was described and validated for parent quinclorac by Mayer, F (1988 a, BASF 88/0542) for cow and chicken tissues, milk and eggs. Homogenised samples (20g) were extracted with acetone/0.1 N NaOH (15:10, v/v) for 5 min followed by acidification with sulphuric acid. After centrifugation, the remaining solids were extracted again with acetone/0.1 N sulphuric acid (50:50 v/v). Both extracts were combined and the interferences were removed by clean-up on an Extrelut column, followed by $NaHCO_3$/ethyl acetate partition at pH =8. The extract was acidified to pH 2 and quinclorac was partitioned into ethyl acetate. After clean-up with C18 modified silica, quinclorac was derivatized (methylated) with diazomethane and determined by GC-ECD using a derivatized external standard. Confirmation was obtained by HPLC-UV or GC MS at m/z 224, 226, 255, 257. The reported LOQ was 0.05 mg/kg. Validation results are shown in Table 39

Method 268/1, amendment to method 268 (animal matrices)

In the amended method 268/1 by Mayer, F (1989 BASF/10911) the same procedure was followed except that quinclorac was partitioned into dichloromethane, cleaned using amino SPE and eluted with citrate buffer /dichloromethane.

Independent laboratory validation (ILV) studies for the method were not presented to the Meeting.

Table 39 Recovery data for determination of quinclorac in animal matrices

A radiovalidation of the method 268 was conducted by Mayer F (1988 b BASF/10179) with samples from muscle, skin with fat, liver, kidney and eggs from the hen metabolism study. The total radioactive residues were determined by combustion LSC and thereafter analysed in duplicate according to method 268. All fractions containing the parent compound were analysed by LSC. Concurrent recoveries verified on non-radiolabelled control samples ranged between 66–88%. Extraction efficiency in the different hen matrices varied from 91–98% TRR. Quinclorac as quantified by method 268 accounted for 60–81% TRR. This is slightly lower than the amounts found in the metabolism study, where 78–92% TRR could be assigned to parent. Losses mainly occurred during C18 clean-up due to irreversible adsorption to the column.

Table 40 Radiovalidation for hen matrices using method 268

Matrix	TRR mg/kg	Total extracted %TRR [a]	Parent %TRR method 268 (B)	Parent mg/kg method 268	Parent %TRR metabolism study (C)	Trueness ratio B:C	Concur recovery

[a] Extraction using acetone/0.1 M NaOH and acetone; 0.1 M sulfuric acid (method 268)

A radiovalidation of the method 268 was conducted by Mayer, F (1989 BASF/5001) with samples from muscle, fat, liver, kidney and milk from the goat metabolism study. The total radioactive residues were determined by combustion LSC and thereafter analysed in duplicate according to method 268 and 268/1. All fractions containing the parent compound were analysed by LSC. Extraction efficiency in the different goat matrices varied from 72 to 104% TRR. Concurrent recoveries verified on non-radiolabelled control samples ranged between 54–77% for method 268. Quinclorac as quantified by method 268 accounted for 42–88% TRR, this is lower than the amounts found in the metabolism study, where 81–96% TRR could be assigned to parent. Losses mainly occur during C18 clean-up due to irreversible adsorption to the column. When the clean-up procedure was changed, as in method 268/1, concurrent recoveries improved to 66–96%. Quinclorac as quantified by method 268 accounted for 61–85% TRR, this is lower than the amounts found in the metabolism study, where 81–96% TRR could be assigned to parent.

Plant commodities

Strawberry

The analytical (enforcement) (method M829/A was developed by White, G (2015, J20044) for the determination of quinclorac in strawberry representing a high water content crop. Residues of quinclorac are extracted from plant matrices by sonication with 1% acetic acid in acetonitrile in the presence of magnesium sulfate and sodium chloride. Following centrifugation, samples are diluted with 0.1% formic acid and analysed by LC-MS/MS. The determination of the residues is calculated using matrix matched standards employing triphenyl phosphate (TPP) as the internal standard. The quinclorac ion transition 242→224 is used for quantification and the ion transition m/z 244-226 is used for confirmation. LOQ is 0.01 mg/kg.

The applicability of the method was confirmed in an independent laboratory by Moinuddin, A (2015, JRF/228-2-13-10872). In both laboratories parent quinclorac were analysed with validated LOQ of 0.01 mg/kg in strawberry see Table 46).

Rice

The analytical method A8902 was validated for parent quinclorac by Single, YM (1989 BASF 5007) for residues in rice grain and straw with an LOQ of 0.05 mg/kg. The residues are extracted from 5–10 g plant materials. Samples are soaked in 0.1 N sodium hydroxide for 1 hr prior to extraction with acetone (acetone/0.1 M NaOH, 10:15, v/v). After centrifugation in the presence of Celite, the extract was acidified with sulfuric acid and the acetone was removed by evaporation at 50 °C. The extract was adjusted to pH 8 by $NaCO_3$ and partitioned with dichloromethane to remove matrix impurities. The aqueous phase was acidified and residues were partitioned into dichloromethane. After filtration and cleaning by SPE (silica gel column) quinclorac residues were derivatized (methylated) with diazomethane and determined by GC-ECD. Quantification is performed using a derivatized external standard. Residues are expressed as quinclorac.

Independent laboratory validation (ILV) studies for the method were not presented to the Meeting.

A radiovalidation of the method A8902 was conducted by Single Y (1989 BASF 5006) with samples from rice grain, straw and forage from the rice metabolism study. The total radioactive residues were determined by combustion LSC and thereafter analysed in duplicate according to method A8902. All fractions containing the parent compound were analysed by LSC. Extraction efficiency in the different rice matrices were 88% for the grain, 90% for the straw and 84% for the forage. Average concurrent recoveries verified on non-radiolabelled control samples for rice grain were 87% for method A8902. Quinclorac as quantified by method A8902 accounted for 69–77% TRR, this is lower than the amounts found in the metabolism study, where 85–94% TRR could be assigned to parent.

Table 42 Radiovalidation for rice using method A8902

Matrix	TRR mg/kg	Total extracted %TRR [a]	Parent %TRR method A8902 (B)	Parent mg/kg method A8902	Parent %TRR metabolism study (C)	Trueness ratio B:C	Concur recovery

[a] Extraction with 0.1 N NaOH in acetone as for method A8902

Wheat

The analytical method D9708/1 was validated for parent quinclorac in wheat (forage, grain, straw, flour and bran) with an LOQ of 0.05 mg/kg by Guirguis M, and Riley M (1998 BASF/5095**).** The residues were extracted from 5–10 g plant material. Samples were soaked in 0.1 N sodium hydroxide for 1 hr prior to extraction with acetone (acetone/0.1 M NaOH, 10:15, v/v). After centrifugation an aliquot of the extract was acidified with HCl to pH < 2 and evaporated at 50 °C to remove the acetone. The residues in the extract were partitioned into dichloromethane. The dichloromethane was evaporated to dryness and redissolved in 0.0025 M NaOH (pH 9–11). After cleaning using a quaternary amine SPE column, the solution was analysed for quinclorac by HPLC-MS/MS using ion transition 240→196 for quantification and using external standards. Validation data for the method is presented in Table 46

The applicability of method D9708/2 for determination of quinclorac in wheat grain was confirmed in an independent laboratory by Li F and Patel D (2013 a, BASF/7000579). Parent quinclorac was analysed with validated LOQ of 0.05 mg/kg Table 46.

Sorghum

The analytical method D9708 was validated for the determination of parent quinclorac in sorghum commodities by Haughey D, *et.al.* (1998, BASF/5081). The residue was extracted from ≥ 0.9 kg plant material. Further description as for wheat D9708/1.

The analytical method D9708 was validated for the determination of parent quinclorac in forage, grain and fodder by Versoi, P. et al (1996/5136). The residue was extracted from >2 kg plant material. Further description is as for rice A9002.

Rape seed

The analytical method D9806 was validated for rape seed by Guirguis M and Riley M (1998 BASF/5184) for the determination of quinclorac methyl in rape seed and oil (canola). Seed samples (10 g) were extracted with acetone. An aliquot of the extract is evaporated to dryness and redissolved in hexane. Oil samples (2g) are dissolved in hexane. Hexane solutions from seeds or oil are partitioned twice with 95% acetonitrile/water (2:1, v/v)/5% methanol. The samples are cleaned-up using C18 SPE columns. The eluates are evaporated to dryness and redissolved in HPLC mobile phase. The samples are analysed for quinclorac-methyl by HPLC-MS/MS. The ion transition m/z 255→224 is used for quantification. Quantification is performed using external standards.

The analytical method D9708/1 for the determination of quinclorac and analytical method D9806 for determination of quinclorac methyl ester were validated for oilseed rape seed by Guirguis M, (1998/ BASF 5174).

The applicability of the method D9708/2 for determination of parent quinclorac and method D9806/2 for determination quinclorac methyl ester was confirmed in an independent laboratory for wheat grain and rape seed (canola) by Li F, and Patel D 2013a BASF/7000579). Quinclorac and quinclorac methyl ester were analysed with a validated LOQ of 0.05 mg/kg.

Recovery data are presented in table below.

Table 43 Procedural recovery for quinclorac with method D9708/2

A radiovalidation of the method D9708/1 (quinclorac) was conducted by Parker 1998a (BASF 1998/5180). Analytical method D9708/1 was used to quantify quinclorac in the rape seed from the rape seed metabolism study and 45.3% TRR (0.218 mg/kg) accounted for parent quinclorac. Compared to the metabolism study, where 37.1% TRR (0.176 mg/kg) accounted for parent quinclorac after extraction with acetone/buffer pH 7, the analytical method results in higher residue levels for the parent compound. This can be explained by the partial conversion of quinclorac methyl back to parent as a result of the alkaline extraction conditions (acetone/0.1 M NaOH) used in the analytical method. The conversion percentage was determined by fortifying control samples with 0.5 mg/kg quinclorac methyl and analysing the rapeseed by method D9708/01 (for parent quinclorac). The conversion averaged 25.2% for four samples with a range of 15.8–32.6%. Method D9708/1 is therefore not suitable for determination of parent quinclorac.

A radiovalidation of the method D9806 (quinclorac methyl) was conducted by Parker 1998a (BASF 1998/5180). Analytical method D9806 was used to quantify quinclorac methyl in the rape seed from the rape seed metabolism study and 30.3% TRR (0.144 mg/kg) accounted for quinclorac methyl. Compared to the metabolism study where 37.1% TRR (0.176 g/kg) accounted for quinclorac methyl, the analytical method results are within acceptable levels.

The analytical (enforcement) method R0036 was validated by Malinsky, D, S (2013 BASF 7002468) for the determination of quinclorac and quinclorac methyl ester residues in rape seed and oil. Validation data for the method is presented in Table 45.

Parent quinclorac residues in/on plant samples (5 g each) are extracted using acetone/0.1 N NaOH (3:1, v/v). After centrifugation, residues in an aliquot of sample extract are cleaned up by liquid-liquid partitioning in which residues are diluted with water and saturated NaCl solution, concentrated to remove the acetone, and partitioned against dichloromethane, which is discarded. The residues in the aqueous phase are then acidified (pH ~2–3) with concentrated formic acid, partitioned into dichloromethane, and evaporated to dryness. The residues are re-dissolved in a final volume of acetonitrile:water (10:90, v/v), filtered, and analysed by HPLC-MS/MS.

From oil samples (5 g each), parent quinclorac residues are extracted with a mixture of hexane, acetonitrile:0.1 N NaOH (1:1, v/v), and methanol. After centrifugation, residues in the aqueous acetonitrile layer are diluted to volume with acetonitrile:0.1 M NaOH (1:1, v/v). An aliquot of the extract is concentrated to remove the acetonitrile, and residues in the aqueous remainder are then subjected to extensive liquid-liquid partitioning, finally into dichloromethane, the combined extracts of which are evaporated to dryness. The residues are re-dissolved in acetonitrile:water (10:90, v/v), filtered, and then analysed by HPLC-MS/MS.

Residues of quinclorac methyl ester in/on canola seed samples (5 g each) are extracted with acetone. An aliquot of extract is evaporated to dryness, and the residues are redissolved, and subjected to liquid-liquid partitioning, in saturated NaCl solution and dichloromethane. The residues in an aliquot of the dichloromethane layer are evaporated to dryness, re-dissolved in methanol:water (1:1, v/v), filtered, and then analysed by HPLC-MS/MS.

From oil samples (5 g each), quinclorac methyl ester residues are extracted with a mixture of hexane, acetonitrile:water (2:1, v/v), and methanol. The residues in the aqueous acetonitrile layer are diluted with acetonitrile:water (2:1, v/v), an aliquot is taken, further diluted with methanol-water (1:1, v/v), filtered, and analysed by HPLC-MS/MS.

Quantification is performed using external standards. Quinclorac is quantified using m/z 242→224 for quantification and m/z 242→161 for confirmation. Quinclorac methyl is quantified using m/z 256→224 for quantification and 256→161 for confirmation. LOQ is 0.01 mg/kg for both analytes.

Acceptable linearity was observed within the 0.01–0.25 ng/mL standard range and the two mass transitions for each analyte ($r = \geq 0.9976$). No interfering peaks were found at the retention times for these analytes. Matrix effects on the detector response were less than 20%); therefore, the validation samples were analysed only using solvent-based calibration standard solutions. Further validation results are shown in Table 45.

The applicability of the method was confirmed in an independent laboratory by Schmitt J.L (2013 a, BASF/7002603). In both laboratories parent quinclorac and quinclorac methyl ester were analysed with validated LOQ of 0.01 mg/kg. Validation results are shown in table below.

A radiovalidation study showed that extraction with acetone/0.1 M NaOH converts quinclorac-methyl partly into parent compound. For this reason, the parent is overestimated in samples containing quinclorac-methyl ester. Methods D9708/1 (quinclorac) and R0036 (quinclorac) use acetone/0.1 M NaOH and are therefore not suitable for the determination of parent compound in oilseed rape seed and possibly other pulses and oilseeds, where the quinclorac methyl ester can be expected to be present.

Soil

The method A8903 was validated by Mayer, F et al (1989, BASF 1989/5017) for analysis of quinclorac and its metabolite BH 514-1 (3-chloro-8-quinolinecarboxylicacid) in soil. Residues of quinclorac are extracted from soil (25 g) with sodium hydroxide followed by acetone/aqueous solution and then acidified with concentrated sulphuric acid and extracted with dichloromethane.

The samples are analysed by high performance liquid chromatography with ultra-violet detected (HPLC-UV) at 230 nm, using Nucleosil 100-5-C18 column (50 mm × 4.6 mm −pre-column and 250 mm × 4.6 mm main column) and a waters Guard-Pak Pre-column with gradient elution using mobile phases of acetonitrile/water/acetic acid. Quantification is performed using external standards. Limit of quantification was 0.05 mg/kg for both analytes.

Recovery data generated from samples fortified at the LOQ and from samples fortified at 10 × LOQ are presented in the table below.

Table 47 Recovery data for quinclorac and BH 514-1 (3-chloro-8-quinolinecarboxylicacid) in soil

Test	Analyte	No of tests	mean (%)	SD (±)	CV (%)
87101	Quinclorac	5	85	6	7

87125	Quinclorac	6	81	6	7
	BH 514-1	6	70	6	9
87098	Quinclorac	10	76	7	9
	BH 514-1	8	59	4	7

For the analysis of quinclorac and its metabolites BH 514-2-OH (2-hydroxyquinclorac) and (BH 514-ME) (quinclorac methyl ester) in soil the method D9513 was validated by Jordan J (1996, BASF 1996/5149). The extraction of quinclorac and BH 514-2-OH from soil samples (10g) are first extracted with sodium hydroxide acidified and partitioned with 8:2 methylene chloride/ethyl acetate. The metabolite BH 514-ME is converted to parent quinclorac and is analysed as parent equivalents in the method. For the determination of BH 514-ME soil samples are extracted in a mixture of methylene chloride, ethyl acetate and methanol.

The final quantitative determination of quinclorac, BH 514-2-OH and BH 514-ME is made by LC/MS/MS using multiple reaction monitoring. The LOQ for each metabolite is defined as the lowest fortification that was successfully run through the method. For this method it is 10 ppb. The average

recoveries for BAS 514 was 85.3% +/- 3.6 (n=6) for the shake extraction method and 95.3% +/- 7.7% for the reflux extraction. The average recoveries for BH 514-2-OH was 81.7% +/- 4.5% (n=6) for the shake extraction and 83.6% +/- 8.4% (n=13) for the reflux extraction. The average recovery for BH 514-ME is 89.3% +/- 3.3% (n=13).

Stability of residues in stored analytical samples

Plant matrices

Storage stability of quinclorac was investigated in rice (grain and straw) and sorghum (forage, hay, grain, silage and fodder) matrixes up to 38 months by Burkey, J (1994, BASF/5015) in wheat up to 26 months by Burkey, J (1996, BASF/5110) and in cranberry up to 14 months by Barney, WP, Homa K (2010, BASF /7018348).

Homogenized samples of rice, sorghum and wheat were fortified individually at levels of 1 mg/kg for quinclorac and stored frozen. Bulk control matrix was placed into storage simultaneously. At each sampling interval, two fortified samples and control samples were removed from the freezer. Subsequently, two control samples of each sampling material were freshly fortified with quinclorac 1 mg/kg to determine the procedural recovery.

For cranberry triplicate untreated field samples were individually fortified with quinclorac at 0.5 mg/kg (10 × method LOQ). At two time intervals three fortified and one control samples freshly fortified with 0.5 mg/kg were prepared to test procedural recovery.

The analytical method A8902 was used to determine quinclorac total in all matrixes. The samples (10g) were soaked in a 0.1N sodium hydroxide solution and extracted with acetone. Samples were then acidified, extracted with dichloromethane and derivatized with diazomethane. Quantification of samples was done using a calibration curve for quinclorac. The LOQ was 0.05 mg/kg.

The storage stability of quinclorac and the metabolite BH514-Me (quinclorac methyl ester) in rape seed (seed, meal and oil) up to 671 days was investigated by Saha, M (2013, BASF/7000581).

Samples from a field trial of homogenized seed, meal and oil were individually fortified with 1 mg/kg quinclorac and quinclorac methyl ester respectively and stored frozen. At each sampling interval two fortified samples and three control samples were removed from the freezer. Two of the control samples were fortified with 1.0 mg/kg each analyte. The modified versions of analytical methods D9708/1 and D9806 were used to determine quinclorac and quinclorac methyl ester.

Residues of parent quinclorac in/on seed and meal samples (10 g each) were extracted were soaked in a 0.1N sodium hydroxide solution and extracted with acetone. Samples were then acidified, extracted with dichloromethane.

Residues of quinclorac methyl ester in/on seed and meal samples (10 g each) were extracted with acetone partitioned with dichloromethane/methanol and water. Quantification was performed using external standards.

The residues were analysed by LC-MS/MS. The MS/MS detection in the positive ionization mode was used to monitor ion transition from m/z 242-160.8 for quinclorac and m/z 256 to 224 for quinclorac methyl ester. The LOQ was 0.05 mg/kg

In the following tables the recovered residues in stored samples are summarized

Table 48 Storage stability of quinclorac in plant commodities fortified at level of 1 mg/kg

Animal matrices

For animal matrices no procedural recovery studies (with fortified samples) for storage stability were provided. The maximum storage time for hen was eggs were 90 days and tissue 74 days and for lactating goat milk 31 days, subcutaneous fat 58 days, peritoneal fat 56 days and muscle 51 days.

USE PATTERN

Quinclorac is registered for uses in berries and other small fruits stalk and stem vegetables, cereal grains and rape seed in a number of countries. Information on GAP with supporting labels from Canada and USA was provided to the Meeting. Quinclorac is a systemic herbicide with uptake through roots and foliage and used to control annual grass and broadleaf weeds. Its mode of action is overstimulation of growth resulting in the rupture of the cell membranes.

Table 50 Registered uses quinclorac from labels provided.

Crop	Country	Application details					Comments
		Method	Rate; kg ai/ha min.-max. (max. kg ai/ha /season)	Crop growth stage at last treatment	No (interval in days)	PHI	Restrictions

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials involving quinclorac for the following crops.

Group	Crop commodity	Portion of commodity to which MRL apply	Countries	Table No
FB, Berries and other small fruits	Cranberry	Whole commodity after removal of caps and stems	USA	51
VS, Stalk and stem vegetables	Rhubarb	Whole commodity after removal of obviously decomposed or withered leaves	USA	52
GC, Cereal grain	Rice	Whole commodity	USA	53-55
	Wheat	Whole commodity	Canada, USA	56-58
	Sorghum	Whole commodity	USA	59-60
SO, Rapeseed	Canola	Whole commodity	Canada, USA	61

Conditions of the supervised residue trials were generally well reported in detailed field reports. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Residue levels are reported as measured, when residues were not detected they are shown as below the LOQ (e.g. < 0.01 mg/kg). Residue data are recorded unadjusted for % recovery.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from supervised trials. Data of analysis or duration of residue samples storage were also provided. Residues values from trials conducted according to a maximum registered GAP with supporting trials have been used for the estimation of maximum residue levels. The results included in the evaluation of the MRL, STMR and HR is underlined.

Cranberry

To determine magnitude of residue of quinclorac in cranberry five supervised field trials were conducted in USA (Massachusetts Wisconsin and Oregon). Quinclorac was applied as two post-emergence ground broadcast applications each at 0.28 kg ai/ha using a SL formulation. All applications contained crop oil concentrate as spray adjuvant.

Duplicate cranberry fruit samples were collected and stored frozen (< -27 °C) until homogenization. Frozen samples were processed in presence of dry ice. Upon grinding, all samples were subsampled. Samples were analysed for quinclorac using GC/EDC detection. The LOQ was of 0.05 mg/kg and average recovery, 86 ± 14% (n=14).

The method validation recoveries of quinclorac at 0.05, 0.5, 0 5 mg/kg was 86 ± 14% (n=12). Concurrent recoveries ranged from 72% to 104% (average 83 ± 13 (n=8). The limit of storage stability for quinclorac in rhubarb petioles were 385 days. The maximum storage time for samples (from sampling to extraction) was 334 days. The storage period is covered by the storage stability studies (385 days).

Results from residues in cranberry fruit are presented in the table below.

Table 51 Residues of quinclorac residue in cranberry fruit following two post-emergence foliar broadcast applications with an SL formulation.

Rhubarb

To determine magnitude of residue of quinclorac in rhubarb four field trials were conducted in USA (Michigan and Oregon). Quinclorac was applied as two post-emergence ground broadcast applications each at 0.42 kg ai/ha and a ~ 30 days interval. All applications contained crop oil concentrate as spray adjuvant**.**

Duplicate samples of rhubarb petioles were collected and stored frozen (< -15°C) until homogenization. After processing the samples were returned to frozen storage until analysis within 357 days. Samples were analysed for quinclorac according to method A8902 using GC/EDC detection. Method validation recoveries of quinclorac at 0.05, 0.5, 0 5 mg/kg were in 88 ± 12% (n=9). Concurrent recoveries ranged from 80% to 117% (average 98 ± 9 (n 13). The maximum storage time of samples (from sampling to extraction) was 357 days. The storage period is covered by the storage stability studies (385 days).

Results from residues in rhubarb fruit are presented in the table below.

Rice

Results from supervised trials from USA on rice were provided to the Meeting.

To compare aerial and ground application a total of nine field trials were performed during growing season 1988 in USA (California, Texas, Arkansas, Louisiana and Mississippi) using a WP formulation. In all trials except two conducted in California, quinclorac was applied to a non-flooded rice field.

Single rice grain samples were homogenized and straw samples were pre-cut, ground and stored at -5 °C until analysis within 4–5 months. Samples were analysed for quinclorac by method A8902 using GC/ECD detection. The LOQ was 0.05 mg/kg and the average recovery were 88±14% (n=21) for grain and 94±15% (n=21) for the straw.

PHI = Pre-harvest interval

To determine magnitude of residues of quinclorac in rice, field trials were performed during growing season 1996 in USA (Texas, Arkansas, Louisiana, Mississippi, Missouri, and Texas) using a DF formulation. In all trials quinclorac was applied as a single post-emergence ground spray to flooded (paddy field) rice fields. All applications contained crop oil concentrate as spray adjuvant.

Duplicate samples of rice grain and straw were sampled and kept at < -10 °C until they were homogenized at room temperature (grain) and in dry ice (straw) and then returned to frozen storage until analysis within 5 months. The storage period is covered by the storage stability studies (38 months). Samples were analysed for quinclorac by method A8902 using GC/EDC detection. The LOQ was 0.05 mg/kg and the average recoveries were 82±13% (n=26) for grain and 84±14% (n=24) for the straw.

Results from residues in rice grain are presented in Table 54 and from straw in Table 55.

Trial 96165 is missing

To determine the influence of the formulation on the residues in rice grain five supervised trials were conducted during the growing season 2009 in USA (Arkansas and Louisiana). Each trial consisted of side-by-side tests comparing the dry flowable (DF) and the soluble liquid (SL). The rice was irrigated according to typical commercial practices for paddy-grown rice

Duplicate samples were sampled and maintained frozen until analysis within 7.7 months. Samples were analysed for quinclorac method D9708/1 using LC- MS/MS. The LOQ was 0.05 mg/kg and the average recovery was 94% (n=2).

PHI = Pre-harvest interval

Wheat

Results from supervised trials from Canada and USA on wheat were provided to the Meeting.

To determine magnitude of residues of quinclorac in spring wheat field trials were performed during growing season 1998 in Canada (Alberta, Manitoba, Saskatchewan). At each trial four different treatments were applied each including quinclorac. One treatment was only quinclorac and the other three were with quinclorac plus one or more tank mix partner. In all trials quinclorac was applied as a single broadcast post-emergence spray 75 days prior to harvest. Forage was sampled 9 to 16 days after treatment

Duplicate samples of wheat forage, grain and straw were sampled and stored frozen (<-15 °C) until they were homogenized and until analysis within 7 months. The storage period is covered by the storage stability studies (26 months). Samples were analysed for quinclorac by method A8902 using GC/ECD detection. The LOQ was 0.05 mg/kg and the average recovery were 85±14% (n=8) for forage, 80±9% (n=6) for grain and 103±1 7% (n=7) for the straw.

Results from residues in wheat grain are presented in Table 56 and from forage and straw in Tables 64-5.

PHI = Pre-harvest interval

To determine magnitude of residues of quinclorac in spring wheat field trials were performed during growing season 1998 in USA (Minnesota, Montana, North Dakota, Oregon, South Dakota and Washington) using a DF formulation. In all trials quinclorac was applied as a single broadcast post-emergence spray 70–74 days prior to harvest. All applications contained crop oil concentrate as spray adjuvant.

Samples of wheat forage (duplicate), grain (single) and straw (triplicate) were sampled and stored frozen (< -10 °C) until they were homogenized and until analysis within 27 months. Samples were analysed for quinclorac by method A8902 using ECD detection. The LOQ was 0.05 mg/kg and the average recoveries were 78±12% (n=15) for forage, 83±11% (n=12) for grain and 75±7% (n=12) for the straw.

Results from residues in wheat grain are presented in Table 57 and from forage and straw in Tables 64-5.

To determine magnitude of residues of quinclorac in spring wheat field trials were performed during growing season 1998 in Canada (Alberta, Manitoba, Saskatchewan) using a DF formulation. In all trials quinclorac was applied as a single broadcast post-emergence spray 90-76 days prior to harvest for grain and straw and . All applications contained crop oil concentrate as spray adjuvant.

Samples (four replicates) of wheat forage (duplicate), grain (single) and straw (triplicate) were sampled and stored frozen (< -5 °C) until they were homogenized and analysed within 8 months. Samples were analysed for quinclorac by method A8902 using GC/ECD detection. . The LOQ was 0.05 mg/kg and the average recoveries were 89±15% (n=17) for forage, 88±18% (n=24) for grain and 83±9% (n=18) for the straw.

Results from residues in wheat grain are presented in Table 58 and from forage and straw in Table 63

Sorghum

Results from supervised trials from USA on sorghum were provided to the Meeting.

To determine magnitude of residues of quinclorac in sorghum field trials were performed during growing season 1995 in USA (Kansas, Nebraska, Oklahoma and Texas) using a DF formulation. In all trials quinclorac was applied as a single broadcast post-emergence spray. All applications contained crop oil concentrate as spray adjuvant.

Duplicate samples of sorghum grain and straw were sampled and kept at < -10 °C until they were homogenized in room temperature (grain) and in dry ice (straw) and then returned to frozen storage until analysis within 12 months. The storage period is covered by the storage stability studies (38 months). Samples were analysed for quinclorac by method A8902 using GC/ECD detection. The LOQ was 0.05 mg/kg and the average recoveries were for trials 94200-94203; 79±17% (n=10) for forage, 81±10.1% (n=10) for grain and 85±11% (n=7) for the fodder and for trials 9766-97270; 84±21% (n=3) for forage, 96±9.4% (n=3) for grain and 93±21.5% (n=3) for the fodder.

Results from residues in sorghum grain are presented in Table 59 and from forage and straw in Table 66.

To determine the influence of the formulation on the residues in sorghum grain five supervised trials were conducted during the growing season 2009 in USA (Arkansas and Louisiana). Each trial consisted of side-by-side tests comparing the dry flowable (DF) and the soluble liquid (SL). The rice was irrigated according to typical commercial practices for paddy-grown rice

Duplicate samples were sampled and maintained frozen until analysis within 7.7 months. Samples were analysed for quinclorac using method D9708/1 using LC- MS/MS. LOQ was 0.05 mg/kg and the average recovery was 94% (n=2).

PHI = Pre-harvest interval

Rape seed

To determine magnitude of residue of quinclorac in rape seed seventeen supervised field trials were conducted in Canada (16) and USA (1). Quinclorac was applied as a single post-emergence broadcast application.

Duplicate rape seed samples were collected and stored frozen (< -10 °C) until homogenization. After homogenization samples were returned to frozen storage until analysis within 6 months for quinclorac and 12 months for quinclorac methyl ester. The storage period is covered by the storage stability studies (22 months) for both analytes. Samples were analysed for quinclorac according to method D9708/1 with LOQ of 0.05 mg/kg and average recovery of 75±13% (n=13) and for quinclorac methyl ester according to method D9806 with LOQ of 0.05 mg/kg and average recovery of 92±15% (n=9).

Results from residues in rapeseed (canola) grain are presented in table below.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In storage

Storage stability of quinclorac in sorghum starch was investigated up to 20 months by Brukey, J and Stewart J (1997/5046).

Control sorghum starch samples from study 1994/5104 study were fortified with 1.0 mg/kg quinclorac. The fortified samples were stored frozen (<-5 ºC) for a period of 20 months. Duplicate samples were analysed for total quinclorac using Method A8902 at 1 day and then 7, 17 and 20 months after the initial fortification.

Table 67 Storage stability of quinclorac in sorghum starch

Storage periods (months)	Procedural recovery % AR (mean)	Residues remaining % AR mean
0	na*	89, 88 (89)
7	98, 101 (100)	92, 95 (94)
14	72, 77 (75)	69, 80 (75)
20	89, 87 (88)	81, 86 (84)

* Data not available. The 0 day analysis, was extracted the day after fortification.

Nature of residue during processing

The hydrolysis of quinclorac during processing condition was investigated by Kennan, D and Brusky, M (2014 BASF/700909). ^{14}C-quinclorac was applied directly to a target concentration of 30 µg/mL to buffer solutions of pH 4, 5 and 6. Incubation was done at three representative sets of hydrolysis conditions: 90 °C, pH 4 for 20 minutes (pasteurization); 100 °C, pH 5 for 100 minutes (boiling) and 120 °C, pH 6 for 20 minutes (sterilization).

Parent compound and potential hydrolysis products were quantified by LSC and identified by HPLC using a radioactive detector (HPLC-RAD) and three replicates per sample. Quinclorac reference standard was chromatographed at the beginning of each sampling set. Material balance was established for each set of hydrolysis conditions. In the following tables recovered radioactivity is summarized.

Table 68 Hydrolysis of quinclorac under simulated processing conditions expressed as % TRR

Incubation time (minutes)	Hydrolysis conditions	Recovered % AR (average)	Quinclorac (average)	Total other (average)
0	pH 4, 90 °C	98.8, 98.9, 99.6 (99.1)	97.2, 97.1, 98.3 (97.5)	1.7, 1.9, 1.3 (1.6)
20		99.6, 100.2, 99.4 (99.7)	98.1, 98.6, 96.7 (97.8)	1.9, 1.6, 2.7 (2.1)

20		29.8, 30.0, 20.8 (29.9)	28.9, 29.6, 29.2 (29.2)	0.6, 0.6, 0.8 (0.7)
0	pH 6, 120 °C	29.8, 29.8, 29.8 (29.8)	28.6, 29.2, 29.4 (29.1)	1.2, 0.6, 0.4 (0.7)
20		30.6, 30.6, 30.5 (30.6)	30.0, 29.7, 30.1 (29.9)	0.5, 0.9, 0.4 (0.6)

Within pH 4 and pH 5 none of the individually degradates exceeded 3.0% applied radioactivity (AR). Within pH 6 individual degradate did not exceed 4% AR. Therefore the products were not further analysed.

Residues after processing

The fate of quinclorac and its metabolite quinclorac methyl ester during processing of raw agricultural commodity (RAC) was investigated in rice, wheat, and sorghum and rape seed. As a measure of the transfer of residues into processed products, a processing factor (PF) was used, this is defined as:

$$PF = \frac{\text{Total residue in processed products (mg/kg)}}{\text{Total residue in raw agriculture commodity (mg/kg)}}$$

If residues in the RAC were below the LOQ, no processing factor could be derived.

Rice

In one field trial conducted in Texas and reported by Single, YH (1989, BASF/5003) rice samples were taken from field plots treated with a single foliar application of 1.68 kg ai/ha (3N GAP rate) and a pre-harvest interval of 79 days. The samples were harvested at normal maturity and then processed into hulls and brown rice which was further processed into bran and white milled rice indicating that it is polished milled rice

The milling process was designed to simulate commercial processing. The rough rice was shelled to remove hulls. The remaining brown rice was milled to remove the bran and to yield white milled rice. The processed fractions were homogenized and stored frozen. Rough rice was analysed 12 months after storage followed by the processed fraction 13 months after harvest.

All samples (10g) were analysed for quinclorac according to method A8902. The method is designed to determine residues of quinclorac expressed as its methyl ester. The LOQ was 0.05 mg/kg. Spiked samples were run concurrently and the overall average recovery was 82±11% (n=23). In the following table the residues found in the processed commodities are summarized.

Table 70 Residues of quinclorac in rice and rice processed products

Commodity	Residues (mg/kg)	Mean residues (mg/kg)	Processing factor
Rice grain	0.43, 0.46	0.45	-
Hulls	0.50, 0.45	0.48	1.07
Brown rice	0.47, 0.45	0.46	1.02
Rice bran	1.4, 1.2, 1.5, 1.3	1.35	3
Milled rice	0.33, 0.35	0.34	0.76

Residues in the hulls have been corrected for the control baseline. None of the other results were corrected for control or recovery values.

Wheat

In two independent field trials conducted in USA and reported by Burkey, JD and Riley, M (1994, BASF/5093) samples of spring wheat were taken from plots treated with three post emergence broadcast applications of quinclorac each at 0.56 kg ai/ha (6× GAP rate). The treatments were made in a sequence within growth stage BBCH 22–49 (from tillering to first awn visible). The samples (control and treated) were harvested at normal maturity (57–58 days after the last application) and then processed.

The spring wheat grain was first dried and cleaned to separate husks and other impurities from the grain. The seed were then conditioned by adding tap water to adjust the moisture content to 16%. The milling process followed. For analysis, samples of whole wheat, bran, middlings, shorts, low grade flour and patent flour was collected.

Samples were analysed for quinclorac according to method A8902. The LOQ was 0.05 mg/kg. Spiked samples were run concurrently and the overall average recovery was 76±9% (n=14). In the following table the residues found in the processed commodities are summarized.

Table 71 Residues of quinclorac in wheat and wheat processed products

Location, year	No	kg ai/ha total	DALT*	Commodity	Residues (mg/kg)	average mg/kg	PF calculated
Minnesota 1990	3	1.68	57-58	Wheat grain	0.21, 0.20	0.21

				Patent flour	0.53, 0.57	0.55	0.56

DALT= days after last treatment

PF = processing factor

In one field trial in spring wheat conducted in USA and reported by Versoi, PL (1996, BASF/5208) samples of spring wheat were taken from plots treated with one pre emergence broadcast applications of quinclorac at 1.4 kg ai/ha (5× GAP rate). The treatment was made on bare soil on the date the wheat seed was later planted. Grain samples (control and treated) were collected as raw agricultural commodity at normal maturity 103 days post application and then processed.

The spring wheat grain was first dried and cleaned to separate husks and other impurities from the grain. 50 kg of cleaned grain from untreated control sample and 19 kg of treated grain were removed for germ recovery process. The yield of grain from treated plots was reduced due to the extreme rate of application. The 50 kg sample was divided into 25 kg batches. The entire sample of treated wheat and each batch of untreated control was lightly ground and separated over a 12 mesh screen. The resulting material was screened over a 46 mesh screen. The material that passed through the 46 mesh screen was discarded. The material that remained on the screen contained the germ fraction. The endosperm fragments were separated from the germ fraction by bulk density. The entire wheat germ samples recovered was stored frozen. The original plan for processing is presented below. Due to the low supply of treated grain, residues were only measured in the germ fraction.

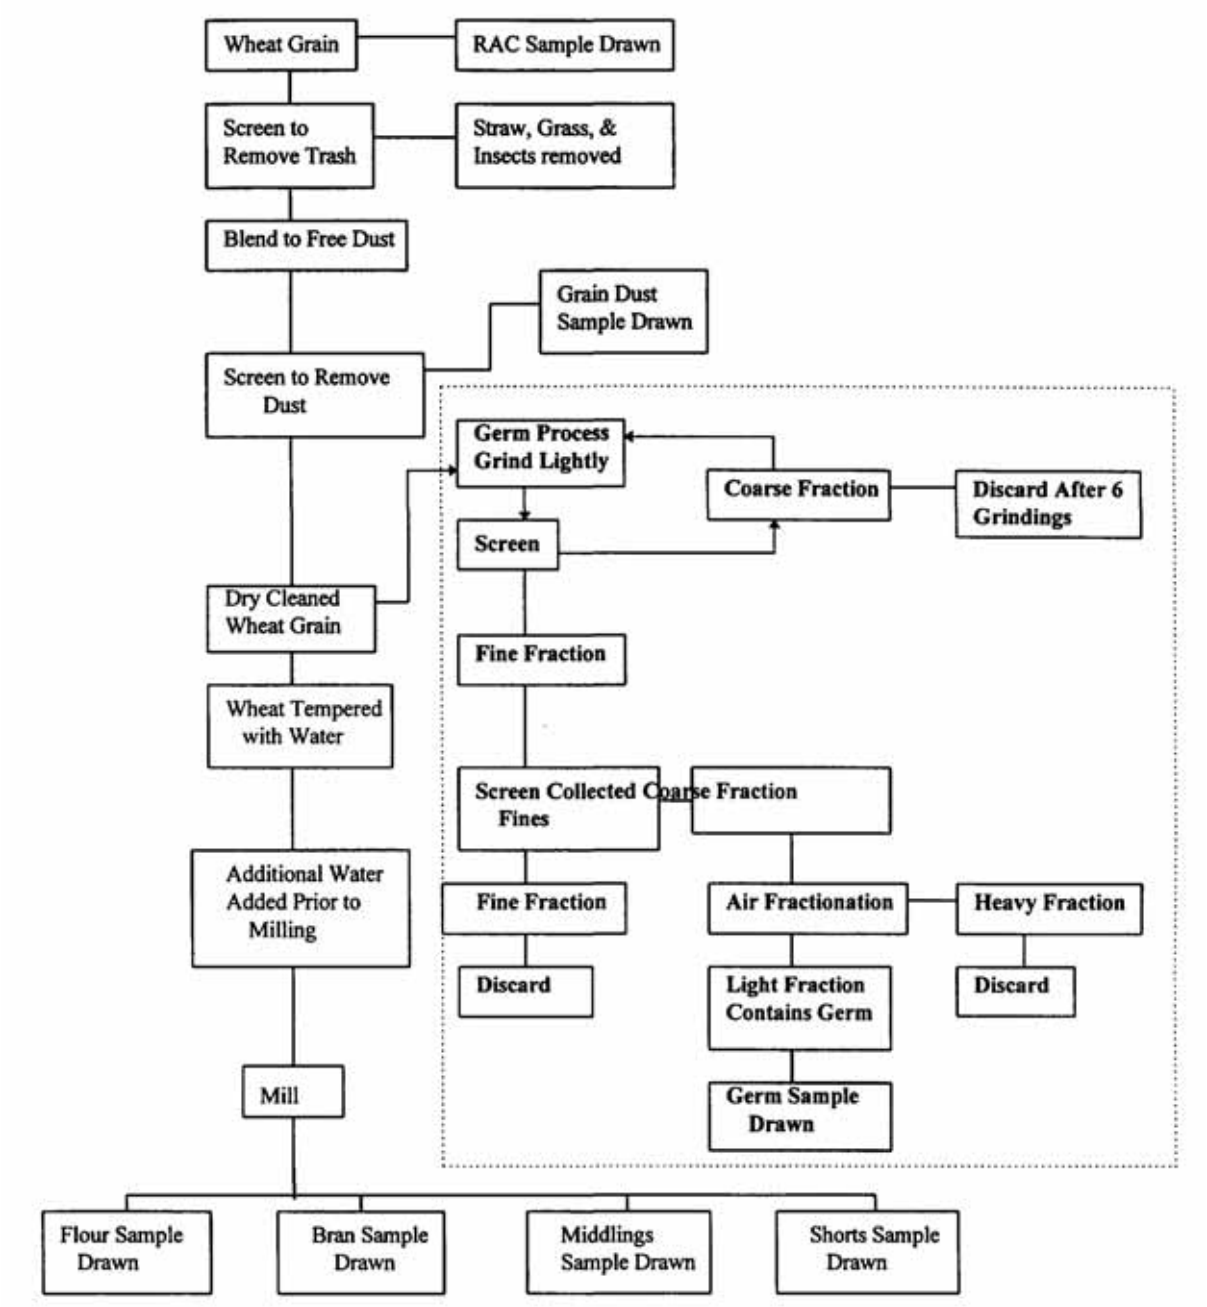

Figure 10 The original plan for processing into wheat germ

Samples were analysed for quinclorac according to method A8902. The LOQ was 0.05 mg/kg. Spiked samples were run concurrently and the overall average recovery was 79±7% (n=5). In the following table the residues found in the wheat germs are summarized.

Table 72 Residues of quinclorac in wheat and wheat germs

Commodity	Residues (mg/kg)	Mean residues (mg/kg)	PF
Wheat grain	0.221, 0.221	0.221	-
Germ	0.544, 0.683	0.614	2.8

PF = processing factor

Rape seed (canola)

In two independent field trials in rape seed one conducted in Canada and the other in USA reported by Guirguis, M (1998, BASF/5093) samples of rape seed were taken from plots treated with 0.1 kg ai/ha (1× GAP rate), 0.5 kg ai/ha and control plots. The application was a broadcast spray made to the crop 60 days, before the rape seed was harvested and then processed.

The rape seed was dried at 54–71 °C to a moisture content of 7–10%. After aspiration separating light impurities, the sample is screened to separate large and small foreign particles (screenings) from the canola. The conditioned and cleaned oil seeds were flaked and pressed yielding crude oil, press cake (meal), refined oil and soap stock.

Whole seed were flaked with a gap setting of 4–5 mm. The flakes were heated to 82–99 °C and pressed to liberate most of the crude oil. Residual crude oil remaining in the solid material (press cake) exiting the expeller was extracted with the solvent hexane.

The press cake was placed in stainless steel batch extractors and submerged in 43–52 °C solvent (hexane). After 30 minutes, the hexane was drained and fresh hexane added to repeat the cycle two more times. After the final draining, warm air was forced through the extracted press cake to remove residual hexane.

The miscella (crude oil and hexane) was passed through a Precision Scientific Recovery unit to separate the crude oil and hexane. The crude oil was heated to 73–90 °C for hexane removal. The crude oil recovered from the expeller and solvent extraction was combined and refined. Before refining the crude oil was pre-treated with phosphoric acid. Refining is performed according to AOCS method Ca9a52. After refining, the refined oil and soap stock are collected.

Residues of quinclorac and quinclorac methyl ester (BH 514 ME) were determined in rape seed, meal and refined oil.

Samples (duplicate) were analysed for quinclorac according to method D9708/1 (LC-MS/MS) and for quinclorac methyl ester by the method D9806 (LC-MS/MS). The LOQ was 0.05 mg/kg for each analyte. Spiked samples were run concurrently for each analyte and the recovery for each of them ranged in rape seed, meal, and oil from 69–110%. In the following table the residues found processed products are summarized.

Table 73 Quinclorac resides in rape seed, meal and refined oil

PF = processing factor

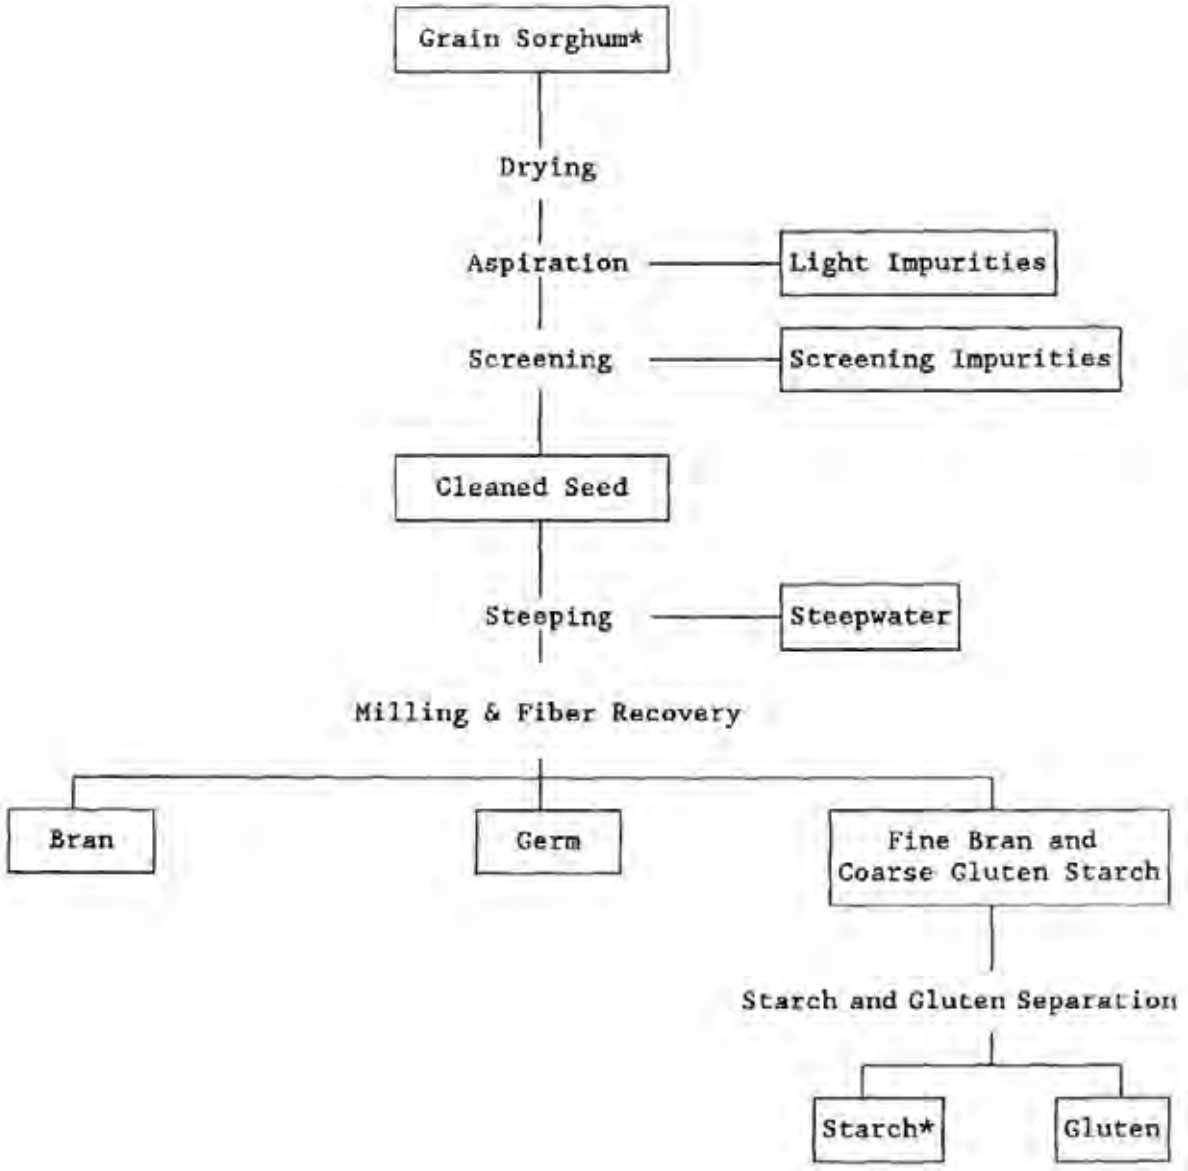
Sorghum

In two independent field trials conducted in USA and reported by Burkey, JD and Riley, M (1994, BASF 1994/5104) samples of sorghum grain were taken from plots treated with a pre-emergence application of 1.12 kg ai/ha followed by two sequential broadcast post emergence applications of 0.84 kg ai/ha. The applications were broadcast spray made when the sorghum was 3 to 5 leaf stage and again at the 8–10 leaf stage. Samples of sorghum grain were taken at normal maturity which was 89 days or 106 days after the last application and then processed.

The sorghum grain was dried until moisture content was 13% or less. After drying the grain was cleaned from light impurities (aspiration) and screened for large impurities (screening).

For dry milling of grain into flour, the hulls were first separated (decorticated) and then ground with a 2 mm screen and passed through a sifter

For wet milling of grain into starch, the cleaned grain was conditioned by steeping in a stainless steel tank with water, sodium bisulfite, and lactic acid at 50 °C. The steeped grain was ground, a majority of the germs were removed, the stock solution was passed over a shaker equipped with a 610µ (0.6 mm) screen. The material collected after screening was passed through a mill with 6 mm screen. The milled product was washed in a shaker equipped with a 43µ (0.043 mm) screen. The remaining process water with gluten and starch fraction was separated by centrifugation. The resulting fractions were starch, gluten and process water.



*fraction analysed

Figure 11 Flow chart of wet milling sorghum grain into flour and starch

Samples (duplicate) were analysed for quinclorac residues according A8902 (derivatized extracts analysed by GC). The LOQ was 0.05 mg/kg. Spiked samples were run concurrently and the average recoveries were 86% (n=2) for the grain, 81% (n=2) for the flour and 79% (n=2) for the starch. In the following table the residues found processed products are summarized.

Table 74 Quinclorac resides) in sorghum grain, flour and starch

RESIDES IN ANIMAL COMMODITES

Farm animal feeding studies

For the estimation of residues of quinclorac in animal matrices laying hen and lactating cow feeding studies was submitted to the Meeting. Storage stability data was not provided in the studies.

Poultry

The magnitude of the residue of quinclorac has been studies in laying hens by Mayer, F (1989, BASF 89/5024)(Method 268). Adult hens (15 birds per diet group divided in 3 subgroups with five birds each, one control with four to three birds) were exposed for 28 consecutive days to levels of 1 ppm (1 × dose group), 10 ppm (10 × dose group) and 100 ppm feed/day (100 × dose group) corresponding to approximately (0.07, 0.7 and 7 mg/kg bw/day

Eggs were collected during the whole dosing period. At sacrifice (day 28) samples of muscles, skin and subcutaneous fat, heart, gizzard, liver and kidney were sampled.

Eggs and tissues were analysed for the parent using method no 268. The LOQ was 0.05 mg/kg for the parent. The limit of detection was (LOD) was 0.01 mg/kg. The maximum storage time under frozen conditions was 90 days for eggs and 74 days for tissues.

In the following table the residues from eggs are summarized. Prior to dosing of quinclorac eggs collected contained no detectable residues of quinclorac. The results for those samples are not presented.

Table 76 Residues of quinclorac in eggs of laying hens after daily administration of quinclorac for 28 days

Lactating cows

Residues in lactating cows were investigated by Mayer F (1989 BASF 89/5025)(Method 268). Fifteen lactating Friesian dairy cows, three cows/treatment group, were dosed orally, via capsule, for 28

consecutive days with quinclorac either 0 ppm (control), 1 ppm (1 × dose group), 10 ppm (10 × dose group), 50 ppm (50 × dose group) or 500 ppm (500 × dose group) corresponding to approximately 0.002 mg/kg bw, 0.02 mg/kg bw, 0.09 mg/kg bw and 0.9 mg/kg bw, respectively.

Milk was collected twice daily. On day 29 after the administration of the first dose, the animals were sacrificed and liver, kidney, muscle, omental fat, and subcutaneous fat were collected for analysis. The maximum storage time under frozen conditions was for milk 31 days, subcutaneous fat 58 days, peritoneal fat 56 days and muscle 51 days.

Milk and tissues were analysed for the quinclorac using BASF method no 268. The LOQ was 0.05 mg/kg. The LOD was 0.01 mg/kg.

Quinclorac residues in milk are presented in the following table:

Table 79 Residues* of quinclorac in milk after daily oral administration of quinclorac for 28 days

National residue definitions

Country	MRL-compliance	Dietary intake	Exceptions/comment
Australia	quinclorac	quinclorac	
Canada	quinclorac	quinclorac	For rape seed quinclorac + quinclorac methyl ester
Europe	not registered	not registered	Import tolerance for rice: quinclorac
Korea	quinclorac	quinclorac	Import tolerance for rape seed: quinclorac + quinclorac methyl ester
Japan	quinclorac + quinclorac methyl ester for crops	quinclorac + quinclorac methyl ester for crops	
Japan	quinclorac for terrestrial animal	quinclorac for terrestrial animal	
USA	quinclorac	quinclorac	For rape seed quinclorac +quinclorac methyl ester expressed as quinclorac

APPRAISAL

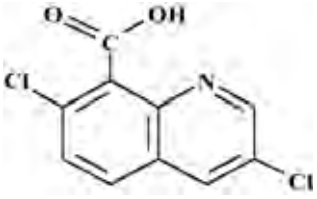
Quinclorac is a systemic herbicide with uptake through roots and foliage and used to control annual grass and broadleaf weeds. Quinclorac mode of action is similar to phenyl herbicides as it imitates the plant growth hormone auxin. The use of quinclorac results in the rupture of the cell membranes due to overstimulation of the growth of the plant.

It was scheduled by the Forty-sixth Session of the CCPR (2014) as a new compound for consideration by the 2015 JMPR. The manufacturer submitted studies on metabolism, analytical methods, supervised trials, processing, storage stability, environmental fate in soil and rotational crop studies.

Quinclorac is registered for uses in berries and other small fruits stalk and stem vegetables, cereal grains and rape seed in Australia, Canada, China, Republic of Korea, South America and USA. Information on GAP with supporting labels from Canada and USA was provided to the Meeting.

Chemical name

Quinclorac: 3,7-dichloroquinoline-8-carboxylic acid
Structural formula:



Metabolites referred to in the appraisal with codes:

BH 514-Me Quinclorac methyl ester SES218	 methyl-3,7-dichloroquinoline-8-carboxylate
BAS 514 H M1 glucuronide (glucuronic acid) conjugate	BH 514-2-OH 2 -hydroxyquinclorac	 3,7-dichloro-2-hydroxyquinoline-8-carboxylic acid
BH 514-1 3-chloroquinoline-8-carboxylic acid	 3-chloroquinoline-8-carboxylic acid

Animal metabolism

The Meeting received metabolism studies on laboratory animals, poultry and lactating goats using 2, 3, 4-[^{14}C]-quinclorac (quinoline label).

In rats quinclorac is widely distributed in the body, with highest concentrations of radiolabel present in the blood, kidney and plasma. The labelled material was excreted primarily via urine (50-90% in 24 hours). Absorbed quinclorac was metabolized to only a limited extent, with unchanged parent compound representing approximately 80% of the excreted radiolabel. The major bio-transformation product was quinclorac glucuronide conjugate at approximate 5% of the administrated dose.

One lactating goat received five daily doses of ^{14}C- quinclorac at a rate equivalent to 800 ppm in the diet (34 mg/kg bw). The animal was sacrificed approximately 6 h after the last dose.

A total 67% of the applied radioactivity was recovered. Excretion of radioactivity in urine and faeces accounted for 63 and 3.7% respectively of the total dose. In milk 0.003%, in liver 0.12% and kidney 0.1% of the administrated dose was recovered. The extraction efficiency using 1 M HCl) was generally > 80% TRR in muscle and liver. In milk and kidney it was above 95% TRR.

In milk the TRR levels reached a plateau after 48 hrs. Residues found in tissues at sacrifice were 0.16 to 0.19 mg eq/kg in muscle, 0.14 and 0.78 mg eq/kg in fat (omental and subcutaneous respectively), 10 mg eq/kg in kidney and 2.1 mg eq/kg in liver. Muscle and fat were not analysed

further. In milk, liver and kidney, parent quinclorac was the major residue at 86, 81 and 86% TRR respectively. Metabolite (M1) identified as the glucuronic acid conjugate of the parent was found at 4.0% TRR in milk and at 4.7% TRR in kidney.

Seven laying hens (1.8–2.4 kg) were orally dosed once daily for five days with 33–44 mg radiolabelled quinclorac per kg body weight per day corresponding to 800 ppm in the diet. The animals were sacrificed after 6 hours after the last dose. The major part of the radioactivity was recovered in the excreta (93%).

Extraction efficiency (including 1 M HCl) was generally above 80% for excreta, liver, breast muscle and skin. In eggs the TRR levels increased from < 0.06 mg eq/kg one day after first administration up to a plateau of 1.2 mg eq/kg after three days; however levels of TRR showed wide variation in eggs. TRR levels in tissues were 1.1–1.8 mg eq/kg in muscle (breast and leg respectively), 2.0 mg eq/kg in skin/fat, 3.7 mg eq/kg in kidney and 20 mg eq/kg in liver. The unextracted residues were from 2.0–21.1% of TTR.

Parent quinclorac was the major residue in poultry tissues and eggs (78–92% of the TRR). The only metabolite identified was M1, present up to 3% TRR in a combined concentration with two other fractions.

In summary from data presented quinclorac is not significantly metabolized in animals. Parent quinclorac is the major residue found in tissues, milk and eggs, making up from 78–92% TRRs, with the only identified metabolite being M1 present at low levels (< 5% TRR) and also identified in the rat. Since the extraction methods used for lactating goat and poultry tissues included 1 M HCl, it is not clear whether parent compound represents parent only or includes parent released from conjugates and whether the M1 is the fraction of conjugates that remained uncleaved.

Plant metabolism

The Meeting received plant metabolism studies for quinclorac following pre- and/or post-emergent foliar application of 2,3,4-^{14}C-quinclorac to rice, or with 3-^{14}C-quinclorac to wheat, rape seed sorghum and strawberry.

Rice plants were treated in the growth chamber with one foliar application at 1.5 kg ai/ha, and with one application at 0.84 kg ai/ha in the field at the 4 and 3-5 leaf stage, respectively. Samples were collected from whole plant (28 days after application), straw (97 days after application) and grain (97 and 118 days after application from growth chamber and field respectively). Total radioactive residues were 0.49 mg eq/kg from whole plant, 13 mg eq/kg from straw and 1.5 mg eq/kg and 0.12 mg eq/kg from grain in growth chamber and field respectively. Extraction rates were in general above 80% TRR.

Quinclorac was the major residue identified (85–94% TRR) in rice straw, whole plant, and grain in growth chamber and the field. Since rice grain was extracted by reflux with 1 M HCl, the quinclorac detected in rice grain might be released from conjugates. Metabolites present at low levels were not identified.

Wheat plants were treated in the greenhouse with one foliar application of 0.125 kg ai/ha or 0.5 kg ai/ha at the 3–5 leaf stage. Samples were collected of forage (early to late boot stage, 37 days before harvest), straw and grain (92 days after application). Total radioactive residues following the low application rate were 3.3 mg eq/kg (forage), 1.9 mg eq/kg (straw) and 1.1 mg eq/kg (grain) and following the high application rate were 13 mg eq/kg (forage), 8.2 mg eq/kg (straw) and 3.9 mg eq/kg in grain. Extraction with acetone/water and subsequent treatment with NaOH for forage, grain and straw in general was above 80% TRR.

In all plant parts parent quinclorac was the major residue identified at 24% and 45% TRR in forage, 12 and 22% TRR in straw and 62 and 68% TRR in grain from low and high application rate respectively. Metabolites characterized as hydroxyquinclorac conjugates were present in forage at 6.8% TRR (0.22 mg/kg) in the low application rate and 6.4% TRR (0.84 mg/kg) in the high application rate, straw at 14% TRR (0.26 mg eq/kg) and 13% TRR (1.83 mg eq/kg), in grain at 4%

TRR (0.05 mg eq/kg) and 4%TRR (0.14 mg eq/kg) in low and high rate application respectively. Other metabolites identified in forage and straw were quinclorac conjugates and hydroxyquinclorac, each < 5% TRR.

Sorghum plants were grown outdoor and treated with a pre-emergence spray application to the soil followed by a foliar treatment (post-emergence) when sorghum plants were 15–25 cm tall. The pre-emergence treatment was 0.525 kg ai/ha and the post-emergence at 0.504 kg ai /ha (total 1.03 kg ai/ha. Residue analysis was done on forage (whole plants) collected at 25 days after the last treatment and on mature fodder and grain collected at 95 days after last treatment.

Extraction with acetone/water and subsequent treatment with HCl were in general above 80% TRR for forage, grain and straw. In all plant samples, unchanged parent quinclorac was the major residue being present at levels of 73% TRR (2.9 mg eq/kg) in forage, 22% TRR (0.19 mg eq/kg) and 74% (0.61 mg eq/kg) in grain. This residue included the quinclorac that was released from remaining solids (4% in grains to 9% TRR in forage and fodder) under hydrolysis conditions. The only other metabolite identified was quinclorac methyl ester present at 3.6% TRR in forage, 5.9% in fodder and 1.7% in grain. A large amount of unidentified residues was present in forage and fodder in organic and aqueous fractions, maximum 19% TRR (0.75 mg eq/kg in forage and 52% TRR (0.46 mg eq/kg) in fodder.

Rape seed plants were grown in a growth chamber and treated with one foliar post emergence application of 0.2 kg ai/ha at 30 days after sowing at 5th true leaf stage. Whole plants were sampled 1 and 29 days after treatment. Seed and straw were sampled 60 days after treatment. Extraction with acetone/ phosphate buffer and subsequent treatment with 0.1M NaOH was above 90% TRR in seed and straw.

Residues in seed were identified as parent quinclorac at 37% TRR (0.18 mg eq/kg) and the quinclorac methyl ester 37% TRR (0.18 mg eq/kg). Metabolites characterized as ‘aqueous soluble’ were present at 8.7% TRR (0.042 mg eq/kg) and those characterized as ‘organo soluble’ were found at 8.6% TRR (0.041 mg eq/kg). Residues in straw (0.64 mg eq/kg) and forage (0.68 mg eq/kg) were not further identified

Strawberry plants were grown outdoor and treated with one foliar post-emergence application at growth stage BBCH 73 (seeds clearly visible). The treatment rate was 1.12 kg ai/ha. Foliage and fruits were sampled at three harvest times 21, 37 and 61 days after treatment.

In foliage, unchanged parent quinclorac accounted for 67% TRR (10 mg eq/kg) at first harvest 21 DAT and at 57% TRR (4.4 mg eq/kg) at the last harvest 61 DAT. Conjugated quinclorac released by acid hydrolysis ranged from 27%TRR (4.2 mg eq/kg) at first harvest to 29%TRR (2.3 mg eq/kg) in the last harvest. Extraction efficiency was above 90% TRR in fruit and foliage.

In fruit, unchanged parent quinclorac accounted for 79% TRR (9.1 mg eq/kg) at first harvest and at 51% TRR (1.7 mg eq/kg) at third harvest 61 DAT. Conjugated quinclorac released by acid hydrolysis increased from 11%TRR (1.3 mg eq/kg) at first harvest to 47%TRR (1.6 mg eq/kg) in the last harvest. Quinclorac methyl ester accounted for 9.6% TRR (1.1 mg eq/kg) at first harvest, to 4.9% TRR (0.42 mg eq/kg) at second harvest and was not detected at the last harvest.

In summary the Meeting concluded that in cereals (rice, wheat and sorghum), and in strawberry quinclorac is not significantly metabolized and parent quinclorac including conjugates is the major residue > 80% TRR in both food and feed matrices. A number of identified quinclorac conjugates were identified in amounts below 5% TRR in cereals and up to 47% TRR in fruit. Quinclorac levels reported in cereal metabolism studies may already include the quinclorac released from conjugates. Other metabolites were not found in tested crop matrices above 10% TRR except quinclorac methyl ester which was found at 37% TRR (0.18 mg eq/kg) in rape seed. Quinclorac methyl ester was found as a minor metabolite in strawberry fruit at a maximum of 9.6% TRR (1.1 mg eq/kg), in sorghum at a maximum of 1.7% TRR (0.014 mg eq/kg) and in forage at 3.6% TRR (0.14 mg eq/kg).

Environmental fate in soil

The Meeting received studies on hydrolysis, photolysis, terrestrial and aquatic soil metabolism and field dissipation for the investigation of the environmental fate.

In the photolysis study it was shown that quinclorac degraded slowly with a half-life of 162 days. The soil hydrolysis study showed that quinclorac was stable during the testing period 30 days and at the temperature 25 °C.

In aerobic soil metabolism studies in silt loam soils under laboratory conditions and an application rate of 0.375 kg ai/ha, quinclorac degraded slowly; no degradation was indicated 120 days after treatment. In another study at an application rate of 3.9 to 4.1 kg/ha, the half-life (DT_{50}) for quinclorac was estimated at 391 days in loamy sand and 168 days in a clay soil. In this study two major soil metabolites were detected; 2-hydroxyquinclorac, at a maximum of 12% AR and quinclorac methyl ester at a maximum of 7.8% AR. Other metabolites were present at levels below 10% AR.

In one tested aerobic aquatic system (rice field) at an application rate 3.75 kg ai/ha, quinclorac degraded to the metabolite 3-chloro-8-quinolilne carboxylic acid (BH 514-1) up to a maximum of 55.7% AR. Three additional fractions were present (not characterized) but present at less than 10% AR. The half-life of quinclorac in this system was 4.7 months and for the metabolite 3-chloroquinoline-8-carboxylic acid, 7.4 months. Under anaerobic conditions at the same application rates the same metabolites were formed but at a slower rate; there was 50% conversion of quinclorac to 3-chloroquinoline-8-carboxylic acid.

In one field dissipation study using a loamy sand soil, quinclorac was applied to bare soil with two applications of 2.8 kg ai/ha. DT_{50} and DT_{90} values for parent quinclorac were 126 days and > 360 days respectively following the first application (autumn), and DT_{50} and DT_{90} of 8 days and 26 days respectively following the second application (summer). The maximum of the two metabolites were less than 5% TRR. The results indicate that quinclorac is tightly bound to the loamy sand soil.

One confined rotational metabolism study from crops rotated after flooded and non-flooded rice grown on silty clay was available. Quinclorac [2, 3, 4-^{14}C] was applied to flooded and non-flooded rice (primary crop) at a rate of 0.84 kg ai/ha in Mississippi, USA. After harvest of mature rice, the first rotational crops (wheat, mustard green and turnips) were planted 120 DAT followed by the second crops (sorghum, mustard green, soya beans and turnip) 360 DAT. The extractable radioactive residues were analysed for quinclorac and the metabolite 3-chloroquinoline-8-carboxylic acid (BH 514-1).

For the first rotational crops, maximum TRRs were 0.028 mg eq/kg for mustard plant, wheat seed, 0.025 mg eq/kg and turnip plant, 0.012 mg eq/kg. For the annual rotational crops, maximum TRRs were 0.014 mg eq/kg for mustard top, soya bean seed 0.017 mg eq/kg and for root and turnip root, 0.02 mg eq/kg. The metabolism of quinclorac by soya bean was qualitatively similar, although up to 62% TRR (0.01 mg eq/kg) was not extractable.

Quinclorac was the only major residue (>10% TRR but less than 0.05 mg eq/kg) detected in the examined rotational crops. Furthermore in the first rotational crops as well as the second rotational crops, TRRs were higher from crops grown under non-flooded conditions.

Another confined rotational metabolism study with one interval (120 days) was also available from crops planted after sorghum. Treatment levels to sorghum plants with 3-^{14}C-quinclorac were 0.53 kg ai/ha pre-emergence and 0.50 kg ai/ha post-emergence giving a total of 1.03 kg ai/ha (2 times GAP). The rotational crops mustard green, turnip and barley were planted 120 days after the last treatment of sorghum. The parent quinclorac was the major (up to 0.1 mg/kg) residue in all matrices. Quinclorac methyl ester was a minor metabolite below 5% in mustard green, turnip roots, and barley.

One field rotational crop study with rape seed planted after barley treated at 0.2 kg ai/ha the previous year was available. The application rate was below -25% critical GAP for cereals (0.29 kg ai/ha, wheat). The residues in rape seed at harvest analysed for parent quinclorac were below the LOQ of 0.05 mg/kg.

In the confined rotational studies, uptake of quinclorac and quinclorac methyl ester was observed in both first and second rotational crops. Residues were no more than 0.01 mg/kg (0.012 mg eq/kg) at the GAP rate.

In summary quinclorac is persistent in some soils and the amount, dependent on the season; residues from quinclorac in rotational crops may be found but generally at levels <.05 mg/kg.

Methods of residue analysis

The Meeting received analytical methods for the analysis of quinclorac residues in plant and animal matrices.

The extraction in lactating goat and laying hen was with acetone/0.1M NaOH. After clean-up, residues of parent quinclorac are determined by GC-ECD. The method is suitable for measuring residues of quinclorac in animal commodities with a LOQ of 0.05 mg/kg. It is not clear whether identified quinclorac represents quinclorac only or also includes quinclorac released from conjugates by the alkaline extraction method used.

The extraction in strawberry was with 1% acetic acid, in rice and wheat with acetone/0.1 M NaOH, in rape seed with acetone. After clean-up, residues of parent quinclorac in wheat, sorghum, rape seed, and strawberry were determined by HPLC-MS/MS or GC-ECD. Methods used for analysis of quinclorac in cereals may hydrolyse any quinclorac conjugates present. The LOQ ranged between 0.01–0.05 mg/kg.

The metabolite quinclorac methyl ester identified as a metabolite in rape seed and sorghum matrices is extracted with acetone and after clean-up determined by HPLC-MS/MS. The LOQ was 0.05 mg/kg.

A radiovalidation study showed that extraction with acetone/0.1 M NaOH converts quinclorac methyl ester partly into parent compound. For this reason, the parent is overestimated in samples containing quinclorac methyl ester. Methods D9708/1 (quinclorac) and R0036 (quinclorac) use acetone/0.1 M NaOH and are therefore not suitable of the determination of parent compound in oilseed rape seed and possibly other pulses and oilseeds, where the quinclorac methyl ester can be expected to be present.

In summary analytical methods are available for determining parent quinclorac in plant (cereals and fruit) and animal (lactating goat and hen) matrices and for the quinclorac methyl ester in plant (fruit and sorghum) matrices. However the methods for animal and cereal commodities use a hydrolysis step; indicating that the quinclorac residues measured may actually include quinclorac released from conjugates. Current analytical methods presented for oil seed rape are likely to overestimate quinclorac residues as the determination of quinclorac may also include some of its methyl ester.

Stability of residues in stored analytical samples

The Meeting received information on the storage stability of quinclorac and quinclorac methyl ester in plant matrices. Quinclorac (> 80% of spiked levels remained) was stable in rice and sorghum matrices for 38 months, in wheat grain for 26 months, and in cranberry fruit for 14 months. For quinclorac and quinclorac methyl ester no significant degradation was observed within 22 months in oilseed meal and oil.

For animal matrices no storage stability studies were provided.

Definition of the residue

In wheat and rice the parent quinclorac is the major residue present (above 80% TRR). Glucose conjugates, hydroxylated conjugates of quinclorac and hydroxyquinclorac were identified as minor metabolites (< 10% TRR) in wheat. In sorghum parent was also the major (> 73% TRR) residue present. The metabolite quinclorac methyl ester was also present (< 6% TRR) in sorghum.

In rape seed besides the parent, the metabolite quinclorac methyl ester was found as a significant metabolite (37%TRR).

In strawberry the parent quinclorac was the major residue present (> 98% TRR). Quinclorac methyl ester accounted for 9.6% TRR in fruit at the first harvest and was not detected in the third harvest

In rotational crop studies including mustard, barley and turnip in first rotation, uptake of residues identified as quinclorac (major) and quinclorac methyl ester (minor) was observed when analysed and resulted in residues near the LOQ at GAP rate.

Thus based on available metabolism data parent quinclorac is the major residue in examined crops. The metabolite quinclorac methyl ester was a significant residue in rape seeds and was a minor residue in other primary and subsequent rotational crops analysed.

Analytical methods are available for determining parent quinclorac in plant (cereals and fruit) and quinclorac methyl ester in fruit and sorghum matrices.

Current analytical methods determining quinclorac and quinclorac methyl ester in rape seed is not suitable as they overestimate the level of parent present.

Taking into account that the methodology measuring quinclorac is also accounting for conjugates derived from hydrolysis during the extraction process, and that quinclorac is the major residue measured in plants, the Meeting decided that the residue definition should be as follows:

Definition of the residue for compliance with MRL for plant commodities: Quinclorac plus quinclorac conjugates

The Meeting noted that quinclorac methyl ester has a toxicological potency up to 10 times that of quinclorac and decided to include it in the residue definition for dietary intake.

Definition of the residue for estimating dietary intake for plant commodities: Quinclorac plus quinclorac conjugate plus quinclorac methyl ester expressed as quinclorac

In calculating residue values for dietary intake estimation the Meeting agreed to use the following formula: residues = (quinclorac +conjugate) + 10 × quinclorac methyl ester.

In lactating goat the major residue was quinclorac and the highest residues were found in liver and kidney with small amounts of other metabolite also found (less than 5% TRR).

For laying hen, the available data show that quinclorac is the only major residue in tissues and eggs.

In both species, measurement of the parent in the metabolism studies probably also includes conjugates of quinclorac as the extraction method used strong acid or alkali. This conclusion is supported by partitioning of residues in the animal feeding studies where quinclorac residues are more than ten times higher in fat tissue compared to muscle tissue.

The Meeting noted however that quinclorac residue was more than ten times higher in fat tissue compared to muscle tissue.

For quinclorac, a log Kow of -0.72 at pH 7 was reported suggesting residues of free quinclorac are water soluble.

The fact that the residue is generally found in the fat suggests that the actual tissue residue is not the parent molecule but may be a fatty acid conjugate of quinclorac.

Based on the above the Meeting decided the residue definition for compliance with MRLs and estimating the dietary intake should be as follows:

Definition of the residue for compliance with MRL and estimating the dietary intake for animal commodities: Quinclorac plus quinclorac conjugates.

The residue is fat soluble

Results of supervised residue trials on crops

Quinclorac is registered for use as a herbicide in many countries. The Meeting received supervised trial data for foliar application of quinclorac to rice, wheat, rape seed, sorghum, cranberry and rhubarb. The trials were conducted in USA and Canada. Frozen samples from the trials presented are covered by storage stability studies. The residue trials did not measure the methyl ester required for estimating dietary intakes.

The Meeting noted quinclorac methyl ester in oilseed equal level to quinclorac in the rape metabolism study and for cereals and fruit at levels up to10 percent of the parent, and agreed to use to the following formula to estimate levels for use in dietary intake calculations:

Plants except oilseed:

HR/STMR = (quinclorac + conjugate) + 10 x 0.1 (quinclorac + conjugate) = 2 × (quinclorac + conjugate)

Oil seed:

HR/STMR = (quinclorac + conjugate) + 10 x (quinclorac + conjugate) = 11 × (quinclorac + conjugate)

Cranberry

Data from supervised trials on cranberry from USA were presented to the Meeting. The critical GAP in USA is two foliar post-emergent applications of 0.28 kg ai/ha, with a 30 day interval and a PHI of 60 days.

In four independent trials from USA matching the critical GAP residues of quinclorac in cranberry fruit for MRL estimation were (n=4): 0.16, 0.17, 0.18, 0.67 mg/kg. The highest residue of 0.68 mg/kg was measured in an individual cranberry sample.

Residues for dietary intake estimation in cranberry fruit were (n=4): 0.32, 0.34, 0.36 and 1.34 mg/kg

Based on a data set from USA the Meeting estimated a maximum residue level, an STMR value and an HR value for quinclorac in cranberry fruit of 1.5 mg/kg, 0.35 mg/kg and 1.36 mg/kg, respectively.

Rhubarb

Data from supervised trials on rhubarb from USA were presented to the Meeting. The critical GAP in USA is two foliar post-emergence applications of 0.42 kg ai/ha, with a 30 day interval and a PHI of 30 days.

In three independent trials from USA matching the critical GAP residues in rhubarbs for MRL estimation were (n=3) 0.11, 0.18, 0.21 mg/kg. The highest residue of 0.23 mg/kg was measured in an individual rhubarb sample.

Residues for dietary intake estimation in rhubarbs were (n=3): 0.22, 0.36 and 0.42 mg/kg.

Based on a data set from USA the Meeting estimated a maximum residue level, an STMR value and an HR value for quinclorac in rhubarb of 0.5 mg/kg, 0.36 mg/kg and 0.46 mg/kg, respectively.

Rice

Data from supervised trials on rice from USA were presented to the Meeting. The critical GAP in USA is one application of 0.29-0.54 kg ai/ha and a PHI of 40 days. The use can be soil application, pre-planting or pre-emergence (dryland rice) or post-emergence broadcast application after the 2-leaf stage (but before heading) on dryland and water seeded rice. Only six trials matched the GAP and an estimation of maximum residue level was not made.

Wheat

Data from supervised trials on wheat from USA and Canada were presented to the Meeting. The critical GAP in Canada is one post-emergent foliar application of 0.135 kg ai/ha and a PHI of 80 days. Only six trials matched the GAP and an estimation of maximum residue level was not made.

Sorghum grain

Data from supervised trials from USA were presented to the Meeting. The critical GAP is one application pre- and /or post-emergence (at maximum 12 cm height limit) as long as the seasonal maximum amount of 0.7 kg ai/ha is not exceeded. The maximum post-emergent application rate is 0.56 kg ai/ha. The trials did not match the critical GAP and an estimation of maximum residue level was not made.

Rape seed (canola)

A registered use with a supporting label from Canada was presented with one foliar application at 2-6 leaf stage of 0.1 kg ai/ha and a PHI of 60 days. Data from seventeen independent supervised trials from Canada (16) and USA (1) supporting this GAP were presented to the Meeting.

The analytical method used in the trials method D9708/1 for determining quinclorac and method D9806 for determining quinclorac methyl ester (BH514-Me) overestimates the level of the parent. Therefore the trials cannot be used for estimating the maximum residue level.

Animal feeds

Strawberry and rhubarbs are not used as animal feeds.

Fate of residues during processing

The Meeting received information on the fate of incurred residues of quinclorac during the processing of rice, wheat, rape seed and sorghum. Supporting trials with matching GAPs were not available and therefore the studies were not considered by the current Meeting.

Residues in animal commodities

Farm animal feeding studies

The Meeting received feeding studies on residue levels of quinclorac plus quinclorac conjugates in laying hens and lactating cows.

For lactating cows three groups of were dosed daily at levels of 1, 10, 50, or 500 ppm in the diet (0.002, 0.02, 0.09 and 0.9 mg/kg bw) for 28 consecutive days.

In milk residues were only detected in the 500 ppm group. A plateau level was reached in this group after 4 days (mean: 0.032 mg/kg).

In muscle residues were only detected in the 500 ppm group, 0.01–0.037 mg/kg (mean: 0.027 mg/kg).

In fat two different tissues were analysed (peritoneal and subcutaneous fat). The highest residues were found in subcutaneous fat with < 0.01–0.013 (mean: 0.005 mg/kg) for the 1 ppm group, < 0.01 mg/kg for the 10 ppm group. In peritoneal fat with < 0.01–0.01 mg/kg for the 1 ppm group, < 0.01–0.023 mg/kg for the 10 ppm group.

In liver residues were < 0.01–0.01 mg/kg for the 1 ppm group, 0.01-0.02 mg/kg for the 10 ppm group.

In kidney residues were < 0.01–0.016 mg/kg for the 1 ppm group, 0.062-0.082 mg/kg for the 10 ppm group.

For laying hens three groups of animals were dosed with rates of 1, 10 and 100 ppm by dry weight in the feed (0.07, 0.7 and 7 mg/kg bw/day) for 28 consecutive days. Eggs were collected throughout the whole study and tissues were collected on day 29 after the last dose.

In eggs a clear plateau level was not reached in any dosing group. For the 1 and 10 ppm the residues were below 0.01 mg/kg during the whole experiment.

In dark and light muscle residues were 0.0–0.005 mg/kg (max mean: 0.002 mg/kg) for the 1 ppm group.

In skin + fat total residues in fat for the 1 ppm group was 0.0–0.018 mg/kg.

In liver residues were: 0.0–0.009 mg/kg for the 1 ppm group. In kidney residues were 0.002–0.059 mg/kg for the 1 ppm group.

Animal commodities residue levels estimation

Strawberry and rhubarbs are not used as animal feed and therefore estimation of residue levels was not made for animal commodities.

RECOMMENDATIONS

On the basis of the data from supervised residue trials the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for the IEDI and IESTI assessment.

Definition of the residue for compliance with MRL for plant commodities: quinclorac plus quinclorac conjugates

Definition of the residue for estimating dietary intake: quinclorac plus quinclorac conjugate plus quinclorac methyl ester expressed as quinclorac

Definition of the residue for compliance with MRL and estimating the dietary intake for animal commodities: quinclorac plus quinclorac conjugates

The residue is fat soluble.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
FB 0265	Cranberry	1.5		0.35	1.36
VS 0627	Rhubarb	0.5		0.36	0.46

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intake of quinclorac for the 17 GEMS/Food regional diets based on estimated STMRs were 0% of the maximum ADI of 0.4 mg/kg bw for the sum of quinclorac, its conjugates plus 10× quinclorac methyl ester, expressed as quinclorac (see Annex 3 of the 2015 Report). The Meeting concluded that the long-term dietary intake of residues of quinclorac is unlikely to present a public health concern.

Short-term intake

The International Estimated Short Intake (IESTI) for quinclorac was calculated for commodities for which STMRs or HRs were estimated and for which consumption data were available. The results are shown in Annex 4 to the 2015 Report. The ARfD for quinclorac, its conjugates plus 10 × quinclorac

methyl ester, expressed as quinclorac is 2 mg/kg bw and the IESTIs varied from 0–1% of the ARfD for children and the general population.

The Meeting concluded that the short-term intake of residues of quinclorac when used in ways that have been considered by the JMPR is unlikely to present a public health concern.

SPIROTETRAMAT (234)

The first draft was prepared by Professor Arpad Ambrus, Hungarian Food Chain Safety Office, Budapest Hungary

EXPLANATION

The compound was evaluated by the JMPR for the first time in 2008. The Meeting established an ADI of 0–0.05 mg/kg bw per day and an ARfD of 1 mg/kg/bw and defined the residues as follow:

Residue for enforcement plant commodities: spirotetramat plus spirotetramat enol, expressed as spirotetramat.

Residue for dietary intake plant commodities: *spirotetramat plus the metabolites enol, ketohydroxy, enol glucoside, and monohydroxy, expressed as spirotetramat*.

Residue for enforcement and dietary intake animal commodities: *spirotetramat enol, expressed as spirotetramat*.

The residue is not fat soluble.

The Meeting estimated residue levels for a number of commodities. Additional residue data were evaluated by the 2011 Meeting. Subsequently, the recommendations, including several animal feed commodities, were adopted as Codex MRLs except those for strawberry, avocado and guava.

The manufacturer provided new supervised trial data in avocado, guava and sweet corn and corresponding labels for the evaluation by the 2015 JMPR.

METHODS OF RESIDUE ANALYSIS

Several analytical methods were developed for the residue analysis of spirotetramat in different matrices.

The analytical method 00857 used to measure residues of spirotetramat (STM) and its metabolites, STM-enol, STM-ketohydroxy, STM-mono-hydroxy and STM-enol-Glc was evaluated by the JMPR in 2008. This method was applied with minor modifications for determination of residues in guava, avocado and sweet corn on cob husk removed, sweet corn forage and fodder. The residues were extracted with an acidic acetonitrile/water mixture (4/1,v/v) filtered and quantitated by high performance liquid chromatography/triple stage quadrupole mass spectrometry (LC/MS/MS) using stable isotopically labelled internal standards. The individual analyte derived residues were converted to spirotetramat equivalents and summed up to yield the total residue of BYI08330 calc.1. Additionally the sum of spirotetramat and STM cis-enol was calculated. The limit of quantitation (LOQ) for each analyte was 0.01 mg/kg (expressed as parent equivalents), the LOQ for the total residue was 0.05 mg/kg and was 0.02 mg/kg for the sum of spirotetramat and BYI08330 enol.

The recoveries obtained during the validation of the method and analysis of supervised trial samples are summarized in Tables 1-6.

Stability of residues in stored analytical samples

Individual data on storage stability of spirotetramat and its metabolites were evaluated by the JMPR in 2008. No new information was provided.

The 2008 Meeting concluded that spirotetramat, when determined as the sum of spirotetramat and its enol, was stable (≥ 80% remaining) for 2 years in tomato, potato, lettuce, almond nutmeat, climbing French beans and tomato paste on various commodities stored frozen for intervals typical of storage prior to analysis. Considered alone, however, spirotetramat may show significant loss (to spirotetramat enol). Likewise, the metabolites spirotetramat enol, spirotetramat ketohydroxy, spirotetramat monohydroxy, spirotetramat enol Glc (glucoside) are stable.

No new information was provided.

USE PATTERN

The use patterns relevant for the residue data submitted for evaluation by the present meeting are summarized in Table 7. Spirotetramat 150 OD is an oil dispersible (OD) formulation containing 150 g ai/L; Spirotetramat 240 SC is a suspension concentrate (SC) formulation containing 240 g ai/L.

Table 7 Foliar spray application for spirotetramat on avocado, guava and sweet corn

Crop and/ country	Pests or Group of pests controlled	Formulation Type	Application					PHI (days)	Remarks:
			No. min max	Interval (min)	kg ai/hL min/ max	Water L/ha min/ max	kg ai/ha min/ max

Sweet corn Canada	Aphids	240 SC	3		0.0438		0.053-0.088	7/50[c]	/[b]

[a]: Do not graze or cut for stock food for 7 days after application

[b]: Max. annual rate 0.264 kg/ha

[c]: PHI is 50 days if the crop is being harvested for silage

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The residue trials were conducted with the two formulations OD 150 (150 g ai/L) and SC 240 (240 g ai/L). Trials were generally well documented with laboratory and field reports. Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Unless stated otherwise, residue data are recorded unadjusted for recovery.

Residues have generally been rounded to two significant figures or, for residues near the LOQ, to one significant figure. Residue values from the trials conducted according to GAP have been used for the estimation of maximum residue levels. Those results used for estimation of maximum residue levels and dietary intake calculations are underlined and double underlined, respectively.

Assorted tropical and sub-tropical fruits – edible peel

Guava

Four supervised field residue trials were conducted with spirotetramat on guava in Mexico in the growing seasons 2007/2008 (2) (Hoag, P.E. and Harbin, A.M. 2009) and 2011 (2) (Hoag, R.E., Fain, J. 2013). Each trial included several plots, where the application parameters varied (spray volume, SC or OD formulation, application rate). In total 13 plots were treated.

Three dilute or concentrated airblast applications of spirotetramat 150 OD were made to guava trees at a target rate of 0.15 kg ai/ha or 0.288 kg ai /ha/application. The actual application rates ranged from 0.147-0.153 and 0.274 to 0.309 g ai/ha/application. Side-by-side bridging trials conducted in 2008 and 2011 received three concentrated airblast applications of spirotetramat 240 SC or spirotetramat OD 150 at the same rate to confirm that the formulation type (OD or SC) does not have any effect on residue behaviour. Adjuvant Dyne Amic or Induce was included in all spray mixtures at a rate of 0.25% or 0.5%, respectively.

Samples of guava fruit were taken 1 and 3 days after last treatment in trials conducted during 2008 growing season. From the 2011 trials samples of guava fruit were taken on day 0, 1, 3, 7 and 12 (14) days after the last treatment. The two parallel samples of guava fruit were analysed using method 00857 with minor modifications. The maximum storage period of deep-frozen samples before analysis was 474 days (5.8 months), which is covered by the storage stability studies. Residues of spirotetramat (STM), STM cis-enol, STM cis-keto-hydroxy, BYI08330 monohydroxy, STM enol-glucoside were determined separately and each expressed as the parent compound. The sum of STM and cis-enol, as well as the sum of residues of STM and 4 metabolites were calculated and expressed as STM.

The full dataset on guava (including the two trials already described in 2010) is presented in Table 8.

Assorted tropical and sub-tropical fruits – inedible peel

Avocado

A total of 5 residue trials are available which were conducted with spirotetramat in avocado in the USA (2) (Hoag, P.E. and Harbin, A.M. 2009.), Chile (2) and Mexico (1) following three broadcast foliar spray applications (either diluted or concentrated spray) of spirotetramat. The nominal application rate per treatment was 0.288 kg ai/ha. Actual application rates for all plots ranged from 0.274 to 0.309 g ai/ha.

Side-by-side bridging plots were included that received three concentrated airblast applications of spirotetramat 240 SC at the rate of 0.288 to 0.272 kg ai/ha/application. The concentrated spray applications were made at spray volumes ranging from 364 to 686 L/ha and the dilute spray applications were made at spray volumes ranging from 1943 to 2839 L/ha. The intervals between applications ranged from 12 to 14 days. For all trials, the first application was made between BBCH 47 and 85. Adjuvant Dyne Amic or Induce was included in all spray mixtures at a rate of 0.25% or 0.5% respectively.

Samples of avocado fruit were taken 1 and 3 days after the last treatment. In one decline trial additional samples were taken on day 0, 5 and 7 days after the last application. The samples were analysed for the parent compound spirotetramat (STM) and its metabolites STM cis-enol, STM cis-keto-hydroxy, STM cis-enol-glucoside and STM 8330 cis-mono-hydroxy using method 00857 with the LOQ of 0.01 mg/kg for each analyte.

The maximum storage period of deep-frozen samples before analysis was 211 days which is covered by the storage stability studies reported by the previous Meeting.

Residue results are presented in Table 9.

Fruiting vegetables – other than cucurbits

Sweet corn

Eight trials on sweet corn were conducted in Canada during the 2009 growing season at about the maximum dose specified on the Canadian label (3 × 0.088 kg ai/ha at 7 days PHI and maximum seasonal rate of 0.264 kg ai/ha) (Lonsbary, S. 2011). Actual application rates ranged from 78 to 95 g as/ha/application, with re-treatment intervals of three to eight days and a PHI of 7 ± 1 days.

Seven trials on sweet corn were conducted in Australia during the growing season 2008 (1), 2009 (3) and 2010 (3) according to Australian label (2 × up to 0.072 kg ai/ha at 7 days interval and 7 day PHI) (Radunz, L. 2009. Radunz, L. 2010.). The actual application rates ranged from 0.015 to 0.08 kg ai/ha/application. The spray intervals between applications ranged from 6 to 9 days. A Hasten adjuvant was included in all spray mixtures at a rate of 0.5–1.0 L/ha.

Ear without husk and fodder samples were collected 6 to 9 days after the final application. Stover samples were collected 33 to 85 days after the last application, according to the normal harvest of stover.

Residues of spirotetramat and its four metabolites STM-enol, STM-ketohydroxy, STM-mono-hydroxy and STM-enol-glucoside (Glc) were analysed using method 00857, including minor modifications. For all analytes the limit of quantitation (LOQ) was determined to be 0.01 mg/kg.

The maximum storage period of deep-frozen samples before analysis was 552 days for Canadian trials and 253 days for Australian trials. These storage periods are covered by the previously reported storage stability studies.

The results are summarized in Tables 10 and 11.

Animal feed

Sweet corn forage, fodder and stover

The trial conditions are described under sweet corn. The results are summarized in Tables 12-14.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In storage

No data are available from the storage under warehouse conditions.

In processing

The effect of processing on spirotetramat residues have already been evaluated by JMPR in 2008. The meeting concluded that spirotetramat-enol was resistant to hydrolysis under all test conditions. Processing factors have been established for cooked bean (0.46), canned tomato (0.58) and canned cherries (0.47). In all these commodities the reduction of residues was observed. Similarly, it is expected that the residues will not concentrate in sweet corn.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Based on a dairy cattle feeding study and poultry metabolism study the 2008 JMR estimated residue levels in animal commodities. No new information was provided.

APPRAISAL

The compound was evaluated by the JMPR for the first time in 2008. The Meeting established an ADI of 0–0.05 mg/kg bw per day and an ARfD of 1 mg/kg/bw and defined the residues as follow:

Residue for enforcement plant commodities: spirotetramat plus spirotetramat enol, expressed as spirotetramat.

Residue for dietary intake plant commodities: *spirotetramat plus the metabolites enol, ketohydroxy, enol glucoside, and monohydroxy, expressed as spirotetramat*.

Residue for enforcement and dietary intake animal commodities: *spirotetramat enol, expressed as spirotetramat*.

The residue is not fat soluble.

Additional residue data were evaluated by the 2011 JMPR.

Spirotetramat was listed by the Forty-sixth Session of CCPR (2014) for the evaluation by the 2015 JMPR for additional MRLs. Supervised trials data were submitted for evaluation on avocado, guava and sweet corn for the evaluation by the 2015 JMPR.

Analytical methods

Analytical methods were evaluated by the 2008 and 2011 Meetings. Recovery data obtained from the analysis of avocado, guava and sweet corn and sweet corn fodder. The limit of quantification was 0.01 mg/kg for individual residues. The residues of individual analyte were expressed as spirotetramat equivalents and summed up to yield the total residue of spirotetramat plus enol (LOQ 0.02 mg/kg) and spirotetramat plus 4 metabolites (LOQ 0.05 mg/kg). The recoveries for individual residue components in the matrices tested 0.01 and 0.1 mg/kg or 1.0 and 10 mg/kg spike level and their relative standard deviations were within acceptable range.

Stability of analytes

Individual data on storage stability of spirotetramat and its metabolites were evaluated by the JMPR in 2008. The Meeting concluded that spirotetramat including its enol metabolite was stable (≥ 80% remaining) for about 2 years in tomato, potato, lettuce, almond nutmeat, climbing French beans and tomato paste. No new information was provided.

Residues resulting from supervised trials in crops

Results of new trials and some of the previously submitted ones on guava, avocado and sweet corn were evaluated by the present meeting. The sum of respective residues was expressed in spirotetramat equivalent.

Assorted tropical and sub-tropical fruits – edible peel

Guava

In 2008 and 2011, four residue trials in guava were conducted (including 13 plots) in Mexico. The trials were performed either with the OD 150 or the SC 240 formulation. The trials were conducted at two different application rates: 3× 0.288 kg ai/ha or 3× 150 kg ai/ha at spray intervals of 14 days. The US GAP permits 3 applications at 0.179 kg ai/ha rate at 14 days intervals with a PHI of 1 day. The results of supervised trials conducted in Mexico are evaluated against the US GAP.

The results indicate that the type of formulation and concentration of the spray solution did not affect the residue level. Therefore, the highest residues were selected from each set of trials.

The sum of residues of spirotetramat and its enol metabolite deriving from the 3 times 0.288 kg ai/ha nominal application rates at 1-3 days after last application were: 0.429, 0.660, 0.906 and 1.30 mg/kg.

Taking into account the nominal application rate of 288 g ai/ha and the USA GAP rate of 179 g ai/ha, the scaling factor is 179/228=0.6215. The residues scaled to match US GAP are in rank order: 0.27, 0.41, 0.56, and 0.81 mg/kg.

The sum of residues of spirotetramat and 4 metabolites are: 0.474, 0.79, 0.965 and 1.37 mg/kg.

The residues scaled to US GAP are: 0.29, 0.49, 0.60, and 0.85 mg/kg.

The Meeting estimated maximum residue level of 2 mg/kg, an HR of 0.85 mg/kg and an STMR residue of 0.55 mg/kg.

Assorted tropical and sub-tropical fruits – inedible peel

Avocado

The uses on avocado and the corresponding residue trials were previously submitted in 2010, but no recommendation could be made at that time. Subsequently, the GAPs of Chile and Mexico have been changed.

The use of spirotetramat in/on avocado is registered in the USA (3 applications of maximum 0.179 kg ai/ha at 14 days interval with a maximum seasonal rate of 0.44 kg ai/ha and PHI of 1 day), Chile (2 applications with a maximum seasonal rate of 0.8 kg ai/ha and PHI of 3 days) and Mexico (1 applications at maximum rate of 0.168 kg ai/ha and PHI of 1 day.

Five trials were conducted in USA, Chile and Mexico with nominal application rates of 0.288 kg ai/ha.

The critical GAP is from USA. The results of trials were evaluated based on the US GAP.

The highest sum of spirotetramat and enol from each replicate plots corresponding to this GAP are: 0.045, 0.11, 0.17, 0.20, 0.29 mg/kg.

Taking into account the targeted application rates of 0.288 and the maximum authorised rate of 0.179, the scaling factor is 0.179/0.288=0.6215.

The scaled residues in avocado fruits were in rank order: 0.028, 0.067, 0.106, 0.125, and 0.183 mg/kg.

For dietary intake assessment the sum of residues of spirotetramat and 4 metabolites was considered. They are in rank order: 0.055, 0.13, 0.20, 0.24, and 0.31 mg/kg.

The scaled residues in rank order are: 0.034, 0.080, 0.126, 0.147, and 0.193 mg/kg.

The highest residue observed in any single sample was 0.23 mg/kg.

The Meeting estimated a maximum residue level an STMR and HR of 0.4 mg/kg, 0.126 mg/kg and 0.23 mg/kg, respectively.

Sweet corn

Seven trials were conducted in Australia between 2008 and 2010 with applications close to Australian maximum GAP (2 times 0.072 kg ai/ha at 7 day intervals with a PHI of 7 days). One sample was taken from each plot.

In Australian trials the sum of spirotetramat and enol in ear without husk were: 0.056, 0.056, 0.1, 0.12, 0.12, 0.24 and 0.40 mg/kg.

For dietary intake assessment the sum of residues of spirotetramat and 4 metabolites was considered. They were in rank order: 0.12, 0.12, 0.18, 0.18, 0.18, 0.3 and 0.62.

Eight trials were conducted in Canada approximating maximum GAP which permits treatments with 3 × 0.088 kg ai/ha at 7 days intervals and a PHI of 7 days. Duplicate samples were taken in each trial.

Some Canadian trials were carried out at the same location, timing, dosage and equipment. The highest sum of spirotetramat and enol in ear without husk from the independent trials were: 0.040, 0.061, 0.235, 0.48 and 0.545 mg/kg.

For dietary intake assessment the sum of residues of spirotetramat and 4 metabolites was considered. They were in rank order: 0.071, 0.125, 0.31, 0.60 and 0.695 mg/kg.

The maximum residue in a single sample was 0.75 mg/kg.

Based on the Canadian trials reflecting maximum GAP, the Meeting estimated a maximum residue level of 1.5 mg/kg, and for dietary risk assessment an STMR residue of 0.31 mg/kg and an HR of 0.75 mg/kg.

Animal feed

Residue data on sweet corn forage and stover derived from supervised trials conducted in Australia and Canada were made available for evaluation. The trial conditions, reflecting maximum GAP are described under sweet corn.

The independent Canadian trials resulted in the following highest average residues:

Sum of spirotetramat and enol:

Sweet corn forage 7 days after last application: 0.027, 0.18, 0.18, 0.25 and 1.8 mg/kg.

Sum of residues of spirotetramat and 4 metabolites:

Sweet corn forage 7 days after last application: 0.06, 0.29, 0.32, 0.35 and 1.9 mg/kg.

The meeting estimated 0.32 mg/kg median and 1.9 mg/kg high residue for animal burden calculation.

In the independent Canadian trials 47–85 days after last application the residues in sweet corn stover were:

Sum of spirotetramat and enol: < 0.02, 0.023, 0.046, 0.11 and 0.41 mg/kg

Sum of residues of spirotetramat and 4 metabolites: < 0.05, 0.078, 0.10, 0.11, and 0.58 mg/kg.

In Australian trials 7 days after last application the sum of residues in/on sweet corn fodder was:

Spirotetramat and enol: 0.18, 0.2, 0.31, 0.28, 0.33, 0.5, 0.58 mg/kg.

Spirotetramat and 4 metabolites: 0.39, 0.47, 0.54, 0.57, 0.63, 1.0, and 1.36 mg/kg,

The Australian trials resulted in higher residues in sweet corn stover and fodder. Based on the Australian trials the Meeting estimated highest and median residues of 1.36 mg/kg and 0.57 mg/kg for sweet corn stover and fodder.

Farm animal feeding studies

Based on a dairy cattle feeding study and poultry metabolism study the 2008 JMPR estimated residue levels in animal commodities. No new information was provided.

Residues in animal commodities

The residues in sweet corn forage and stover do not increase the maximum animal burden that would affect the maximum, HR and median residue values estimated by the 2008 Meeting.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for dietary intake assessment.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
FI 0326	Avocado	0.4		0.126	0.23
FI 0336	Guava	2		0.55	0.85
GC 0447	Sweet corn	1.5		0.31	0.75

DIETARY RISK ASSESSMENT

Long-term intake

The ADI is 0–0.05 mg/kgbw. The long-term intake calculated for the commodities considered by the present meeting is 0% of maximum ADI and did not affect the previously made long-term dietary estimates. Hence, a new risk assessment was not necessary.

Short-term intake

The ARfD is 1 mg/kgbw. The estimated short-term intakes of avocado, guava and sweet corn are up to 1% 2% of ARfD for the general population and children.

The Meeting concluded that the short-term intake of residues of spirotetramat from the uses

TEBUCONAZOLE (189)

First draft prepared by Professor Eloisa Dutra Caldas, University of Brasilia, Brazil

EXPLANATION

Tebuconazole, a triazole fungicide, was last evaluated for residues in 2011 within the periodic re-evaluation program. It was listed by the 46th Session of CCPR (2014) for the evaluation of 2015 JMPR for additional data on residues. Residue data were submitted on banana and cucumber by the government of China, on ginseng by the government of Korea, and on asparagus, sunflower, onion, bulb and onion, green by the Government of the United States. The government of Korea also submitted storage stability and processing studies on ginseng.

METHOD OF ANALYSIS

The analytical method used to analyse fresh ginseng and processed products (dried and red ginseng and ginseng extracts) involves extraction with acetone, partition with chloromethane, cleaned up in a glass florisil column and quantification by GC-NPD. The method was satisfactorily validated for fresh ginseng at a LOQ of 0.03 mg/kg up to 0.5 mg/kg, and for processed commodities at a LOQ of 0.06 mg/kg up to 1 mg/kg (n=5, recovery in the range of 80–120% and CV< 10%).

Storage stability under frozen conditions

Samples of fresh and processed ginseng fortified with tebuconazole were stored at -20 °C up to 156 days (Kyung, 2014). The results are shown in Table 1.

Table 1 Stability of tebuconazole in samples of ginseng, stored at -20 °C

Matrix	Fortification level, mg/kg	Period of storage, days	Mean % remaining; n=5	Coefficient variation, %
Fresh ginseng	0.3	42	88.7	2.1
		52	74.7	2.5
Dried ginseng	0.6	142	101	2.4
		41	80.0	1.3
Red ginseng	0.6	156	80.4	3.0
		32	91.6	3.6
Water extract of dried ginseng	0.6	121	89.4	6.9
		44	81.4	1.7
Water extract of red ginseng	0.6	96	90.6	1.4
		25	93.2	1.9

USE PATTERNS

Table 2 shows the critical registered uses of tebuconazole in China, Republic of Korea and USA for crops relevant to this submission.

Table 2 Use patterns of tebuconazole in China, Republic of Korea and USA

Crop	Country	Formulation	Application					PHI (days)
			Method	Max. rate, kg ai/ha	kg ai/hL	Number	Interval, days	
Asparagus*	USA		Foliar	0.2		3/season	14	100[a] or 180
Banana	China	ME/WP/WG	Foliar	0.27	0.03	3		42
		EC	Foliar	0.28	0.031	3		35
		EW	Foliar, bagged	0.25	0.025	3		14
Cucumber	China	SC	foliar	0.12		3	7-10	5
Ginseng	Rep. Korea	SC	foliar	0.13		3		21
Onion (dry bulb) and garlic	USA		Over/in furrow at planting	0.65		1/season	---	---
			Foliar	0.2		4/season	10-14	7

Crop	Country	Formulation	Application					PHI (days)
			Method	Max. rate, kg ai/ha	kg ai/hL	Number	Interval, days	
			In furrow plus two foliar [b]	0.65 +0.2		3/season	In furrow then 10-14	7
Onion (green)	USA		Foliar	0.2		4/season	10-14	7
Sunflower	USA		Foliar	0.2		max 0.49 kg ai/ha	14	50

* Apply to the developing ferns after harvest of spears is completed;

[a] in California;

[b] If over/in furrow treatment used, then only two foliar applications are allowed. Otherwise four foliar treatments maybe used.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

A total of 77 foliar supervised trials were conducted in China, Republic of Korea and USA. Trials conducted in Republic of Korea were not at GLP, but the report provided information on the field conditions and analytical method used in the study. Unless indicated, concurrent determinations of residues in untreated crops gave residues <LOQ. Residues of tebuconazole within 25% of GAP are underlined and were considered for estimation of STMR, HR and maximum residue levels. When residues in samples harvested at a later stage were higher than that at the critical PHI, they will be selected for the estimations.

Banana

A total of 22 foliar residue trials were conducted in banana (bagged and ungagged) in China in 2013. The samples were analysed by LC-MS/MS and validated at a LOQ of 0.01 mg/kg. The results are shown in Table 3.

Table 3 Results of residue trials conducted with tebuconazole in/on banana in China in 2013 using 3 applications of an EW formulation

Location	Banana variety	Application			Residues			Trial No.
		Method	kg ai/ha	kg ai/hL	Portion analysed	DAT, days	mg/kg

Processing studies

After rinsing with tap water, fresh ginseng was dried in hot air at 60 °C reaching a moisture content under 14% to yield dried ginseng. Washed fresh ginseng was steamed for 3 hours at 98 °C, dried at 65 °C to a moisture content of 50~55% and ground to yield red ginseng. Dried ginseng or red ginseng was cut into about 1 cm length and extracted three times in a refluxing extractor with water at 85 °C for about 18 hours. The water was evaporated reaching 72 °Brix to yield water extract of dried or red ginseng (Kyung, 2014). Residues in fresh and processed ginseng and the respective processing factors are shown in Table 10.

Table 10 Residues of tebuconazole in ginseng processed commodities and calculated processed factors

Matrix	Residues, mg/kg*	Processing factors	Residues, mg/kg*	Processing factors	Residues, mg/kg*	PF	Processing factors, best estimate underlined

*Three replicate plots in each field. All samples were analysed in triplicates.

APPRAISAL

Tebuconazole a triazole fungicide was last evaluated for residues in 2011 within the periodic re-review programme. It was listed by the Forty-sixth Session of CCPR (2014) for the evaluation in the 2015 JMPR for additional data on residues. Data was submitted for banana, cucumber, ginseng, asparagus, sunflower, onion bulb; and onion, green. The residue definition for plant commodities for enforcement and risk assessment purposes is tebuconazole. The ADI for tebuconazole is 0-0.03 mg/kg bw and the ARfD is 0.3 mg/kg bw.

Method of analysis and stability of residues

A GC-NPD analytical method was satisfactorily validated for the analysis of tebuconazole in fresh ginseng at a LOQ of 0.03 mg/kg up to 0.5 mg/kg and for processed commodities at a LOQ of 0.06 mg/kg up to 1 mg/kg.

Tebuconazole residues were shown to be stable under frozen conditions (at -20 °C) in fresh ginseng for at least 52 days; in dried ginseng for at least 142 days; in red ginseng for at least 96 days; and in ginseng water extracts for at least 121 days.

The sample storage period used in the trials for ginseng and other commodities evaluated by the present Meeting was within the storage period that guaranteed that the residues in the samples were not degraded.

Residues resulting from supervised trials

Banana

In China, the critical GAPs for tebuconazole in banana is 3 × 0.28 kg ai/ha and 35 days PHI for unbagged banana and 3 × 0.25 kg ai/ha and 14 days PHI for bagged banana.

In eleven trials conducted with unbagged banana in China according to GAP, residues in the whole fruit were 0.10, 0.13 (2), 0.17, 0.19, 0.20, 0.21, 0.37, 0.53, 0.54 and 0.74 mg/kg. Residues in the pulp were 0.02, 0.03, 0.05, 0.06, 0.07 (4), 0.09, 0.15 and 0.16 mg/kg.

In eleven trials conducted with bagged banana according to GAP, residues in the whole fruit were < 0.01 (5), 0.01, 0.03 (2), 0.09, 0.15 and 0.42 mg/kg. Residues in the pulp were < 0.01 (9), 0.04 and 0.10 mg/kg.

Residues from trials conducted with unbagged banana gave the highest residues. The Meeting estimated a maximum residue level of 1.5 mg/kg, a STMR of 0.07 mg/kg and a HR of 0.16 mg/kg for tebuconazole in banana. These estimates replace the previous recommendations for tebuconazole in banana.

Onion, bulb and shallots

In the USA tebuconazole can be applied in onion and shallots at 4 foliar applications at 0.19 kg ai/ha or one furrow at 0.65 kg ai/ha plus 2 foliar at 0.19 kg ai/ha. The PHI is 7 days for both. In eight trials conducted in USA at the foliar GAP, residues were < 0.05 (5). 0.06. 0.08 and 0.09 mg/kg. In five trials conducted using furrow plus foliar application, residues were < 0.02, 0.02, 0.04 (2), and 0.06 mg/kg.

The Meeting agreed that the foliar only trials gave the highest residues and estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.055 mg/kg and an HR of 0.09 mg/kg for tebuconazole in onion, bulb. These estimates replace the previous recommendation for tebuconazole in onion bulb.

The Meeting agreed to extrapolate this estimate to shallots.

Spring onion (Onion, green)

In the USA, tebuconazole can be applied in onions, green witht 4 foliar applications at 0.19 kg ai/ha and a 7 day PHI. In three trials conducted in the USA and Canada in 1999 at GAP, residues were 0.06, 0.10 and 0.80 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg, a STMR of 0.10 mg/kg and an HR of 0.8 mg/kg for tebuconazole in spring onion.

Cucumber

GAP for tebuconazole in cucumber in China is 3 × 0.12 kg ai/ha and 5 days PHI. In eight field trials conducted in the country according to GAP, residues were 0.02 (2), 0.03, 0.04, 0.06, 0.07, 0.09 and 0.11 mg/kg. In three protected trials residues were 0.03, 0.04 and 0.06 mg/kg.

Based on the residue data from field trials, the Meeting estimated a maximum residue level of 0.2 mg/kg, an STMR of 0.05 mg/kg and an HR of 0.11 mg/kg for tebuconazole in cucumber. These estimates replace the previous recommendations for tebuconazole in cucumber.

Ginseng

Six trials were conducted with tebuconazole in ginseng in Korea according to GAP (3 x 0.13 kg ai/ha; 21 days PHI). giving residues in fresh ginseng of 0.03 (2), 0.04, 0.06 (2) and 0.08 mg/kg. Three other trials conducted with 6 applications gave similar results.

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.05 mg/kg and an HR of 0.08 mg/kg for tebuconazole in ginseng.

Asparagus

In the USA the critical GAP for tebuconazole in asparagus is to apply up to 3 × 0.19 kg ai/ha to the developing ferns after harvest of spears is completed; the PHI is 100 days. In three trials conducted in USA at GAP gave residues of < 0.02 (3) mg/kg.

The Meeting estimated a maximum residue level of 0.02* mg/kg and an STMR and HR of 0.02 mg/kg for tebuconazole in asparagus.

Sunflower

In the USA tebuconazole can be applied to sunflowers at a maximum rate of 0.49 kg ai/ha with a 50 day PHI. In seven trials conducted in the USA at GAP residues were < 0.04 (6) and 0.04 mg/kg.

The Meeting estimated a maximum residue level of 0.1 mg/kg and an STMR of 0.04 mg/kg for tebuconazole in sunflower seed.

Fate of residues in processing

Nine processing studies were conducted with ginseng yielding dried ginseng (≤ 14% water content). red ginseng (50–55% water content) and water extracts of dried and red ginseng. Median processing factors were 2.5 for dried ginseng, 1.0 for red ginseng, 3.35 for dried ginseng extract and 1.87 for red ginseng extract.

Using the estimated maximum residue level and STMR for ginseng (0.15 and 0.05 mg/kg, respectively) and the processing factor for dried ginseng (2.5), the Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.125 mg/kg for ginseng, dried including red ginseng.

Using the processing factor for water extract of dried ginseng (3.35), the Meeting estimated a maximum residue level of 0.5 mg/kg and an STMR of 0.17 mg/kg for ginseng extracts.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for dietary intake assessment.

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous

DIETARY RISK ASSESSMENT

Long-term intake

The IEDI of tebuconazole based on the STMRs estimated by this and previous Meetings for the 17 GEMS/Food regional diets were 2–9% of the maximum ADI of 0.03 mg/kg bw (see Annex 3 of the 2015 Report). The Meeting concluded that the long-term dietary intake of residues of tebuconazole is unlikely to present a public health concern.

Short-term intake

An ARfD for tebuconazole is 0.3 mg/kg bw. The Meeting estimated the International Estimated Short-Term Intake (IESTI) of propiconazole for the commodities for which STMR, HR and maximum residue levels were estimated by the current Meeting. The results are shown in Annex 4. The IESTI represented a maximum of 5% of the ARfD. The Meeting concluded that the short-term intake of tebuconazole residues from uses considered by the current Meeting was unlikely to present a public health concern.

TRIFLOXYSTROBIN (213)

The first draft was prepared by Professor Arpad Ambrus, Hungarian Food Chain Safety Office, Budapest Hungary

EXPLANATION

Trifloxystrobin is a broad-spectrum contact fungicide for foliar application. It was first evaluated by the JMPR in 2004 (T, R) and 2012 (R). The 2004 Meeting established an ADI of 0–0.04 mg/kg bw and decided that ARfD was not necessary. The Meeting agreed that the residue definition for enforcement purposes for plant commodities should be trifloxystrobin per se, for animal commodities and dietary intake assessment the residue definition should be parent compound and CGA 321113 (expressed as trifloxystrobin equivalents).

Data on identity, formulations, physical and chemical properties, metabolism and environmental fate of trifloxystrobin were submitted to the JMPR in 2004. No new information was made available. Supervised trials data were submitted for a number of commodities for evaluation by the 2004, and 2012 JMPR.

Trifloxystrobin was listed by the 46th Session of CCPR (2014) for the evaluation by the 2015 JMPR for additional MRLs. Additional supervised trial data were submitted for evaluation on dry soya beans, lentils, chick peas and peas together with new data, which were not available in the first evaluation in 2004.

METHODS OF RESIDUE ANALYSIS

Analytical methods

The Meeting received descriptions and validation data for analytical methods for residues of trifloxystrobin (CGA 321113) and several other metabolites in different plant matrices.

The DFG method S19, evaluated in 2004, is suitable for enforcement. Analytical methods used in residue trials evaluated by the present Meeting are summarized below.

Method 00742 (Nuesslein, F 2002)

The method was developed and validated for the determination of residues of parent trifloxystrobin and CGA 321113 (metabolite) in/on sample materials of carrots, Brussels sprouts, cabbages, tomatoes, red peppers and lettuce. Both analytes were extracted from plant materials using a mixture of acetonitrile/water. After filtration and concentration to the aqueous remainder, the acidified crude extract was purified by liquid-liquid partition on a ChemElut cartridge, thereby partitioning the analytes in a mixture of cyclohexane / ethyl acetate. The residues were quantified by reverse-phase HPLC with Turbo-Ionspray MS/MS-detection. The limit of quantitation (LOQ) was 0.02 mg/kg in all matrices. Recoveries for trifloxystrobin ranged from 72 to 99% with mean values between 81 and 93% and relative standard deviations between 0.7 and 10.4%. In the case of CGA 321113, recoveries were between 71 and 103% with mean values between 83 and 100% and relative standard deviations between 0.6 and 8.1%. The repeatability was tested with carrots and tomatoes.

Supplement E001 for method 00742 (Nuesslein, F 2003)

The analytical method 00742 was validated for the determination of trifloxystrobin and CGA 321113 in additional plant materials. Recovery tests were performed at fortification levels of 0.02 mg/kg, 0.20 mg/kg and 2.0 mg/kg with the sample materials beans (beans with pods), broccoli (head), cauliflower (head), cherries (fruit), cucumbers (fruit), currants (fruit), leeks (shoots), melons (fruit, peel), plums (fruit) and strawberries (fruit, jam and preserves). The LOQ was 0.02 mg/kg in all matrices. Individual recovery rates of trifloxystrobin ranged from 68 to 103% with overall standard deviations (RSD) between 1.1 and 9.3%. In the case of CGA 321113, recoveries were between 81 and

101% with overall standard deviations (RSD) between 1.4 and 5.4%. The repeatability was tested successfully with cauliflower and strawberries.

Method 00765 (Sur, R 2003.)

The method was developed and validated to determine trifloxystrobin, its metabolite CGA 321113, and cyproconazole in/on cucumbers, green peppers, melons and tomatoes. The active substances and the metabolite were extracted twice from the sample material with an acetonitrile/water mixture. After filtration and dilution the extract solution was subjected to HPLC-MS/MS analysis for quantitation. For all three analytes two transitions are recorded. The LOQ for all analytes was 0.01 mg/kg. The method was validated by spiking control samples with the analytes at fortification levels of 0.01 and 0.1 mg/kg. The overall mean recovery for the quantifier transition was 99% (RSD 3.8%, n=32) for trifloxystrobin and 100% (RSD 2.7%, n=32) for CGA 321113. For the qualifier transition the overall mean recovery was 100% (RSD 4%, n=32) for trifloxystrobin and 96% (RSD 6.2%, n = 32) for CGA 321113. The repeatability was tested with melons and tomatoes.

Method 01013 (Brumhard, B and Stuke, S 2007.)

The method was developed for the determination of residues of trifloxystrobin and metabolite CGA 321113, and other actives substances and their metabolites in/on plant material (citrus fruit, pea green seed, wheat grain, rape seed, and corn green material). All analytes were extracted from plant materials using a mixture of acetonitrile/water. After filtration of the extract, the stable isotopically labelled analytes were added. The solution was made up to volume, diluted and subjected to reversed phase HPLC-MS/MS without a further clean-up step.

The LOQ for the determination of trifloxystrobin and CGA 321113 was 0.01 mg/kg in all matrices tested. The method was validated by spiking control samples with the analytes at fortification levels of 0.01 and 0.1 mg/kg. Mean recoveries for each fortification level and the overall mean recovery were within the 70–110% range for all matrices. The correlation between the injected amount of substance and the detector response was linear for solvent standards ranging from 0.005 to 50 µg/L. Possible matrix effects were eliminated by the internal standard procedure using isotopically stable labelled standards.

Apparent residues in control samples were below 0.3 × LOQ. Two MRM transitions were monitored and calculated for each analyte and each matrix tested. The HPLC-MS/MS method is highly specific and an additional confirmatory method is not necessary. The repeatability was tested successfully with all matrices. Relative standard deviations were below 20% for all analytes and sample materials. The method 01013 allows determination of trifloxystrobin-derived residues in crops with a LOQ of 0.01 mg/kg.

Method 01313 (Stuke, S 2013.)

The method was developed for the determination of residues of trifloxystrobin (CGA 279202) and metabolite CGA 321113, and their isomers CGA357262, CGA357261, CGA331409, and CGA373466 in/on corn green material, bean dry seed, wheat grain, rape seed, dried hops and orange fruit. All analytes were extracted from plant materials using a mixture of acetonitrile/water. After filtration by using celite and addition of ammonium acetate solution to adjust the pH, the extract was made up to volume, diluted and subjected to HPLC-MS/MS measurement. The LOQ for the determination of trifloxystrobin and CGA 321113 was 0.01 mg/kg in all matrices tested. The method was validated by spiking control samples with the analytes at fortification levels of 0.01 and 0.1 mg/kg (0.05 and 0.5 mg/kg in hops). Mean recoveries for each fortification level and the overall mean recovery were within the 70–110% range for trifloxystrobin and CGA 321113. The mean and the overall mean relative standard deviations at each fortification level were below 20%.

The results of the method validation were confirmed using a second and a third MRM transition for confirmation. The LOQ was 0.01 mg/kg for trifloxystrobin-derived residues.

Method 200177 (de Haan, RA 2002.)

The method was developed for the determination of trifloxystrobin and CGA 321113 in plant materials. The residues of trifloxystrobin and CGA 321113 were extracted from homogenised plant samples with acetonitrile/water (4 vol. + 1 vol.) in a blender. The suspension was vacuum filtered through a paper filter. The remaining solids were blended a second time with fresh solvent and filtered. The filtrates were combined and deuterated internal standard was added. The total volume was adjusted to 50 mL with acetonitrile/water (4 vol. + 1 vol.). A solid phase extraction was performed on a SPE column under slight vacuum. The column was rinsed with acetonitrile/water (4 vol. + 1 vol.) and the analytes were eluted with acetonitrile. The solution was evaporated to dryness, the dry residue was subsequently dissolved in acetonitrile/water (4 vol. + 1 vol.). The final determination was done with LC/MS/MS in the positive ion mode. The LOQ was 0.01 mg/kg.

The recovery values obtained during the validation of the above methods are summarized in Table 1.

Table 1 Recovery of trifloxystrobin and CGA321113 from different plant materials

Sample /method	Analyte	Spike level [mg/kg)	No of tests	Mean recovery [%]	RSD [%]
Method 00742 trifloxystrobin 409.2 →186.3 (145.2) amu; CGA 321113: 395.1→186.1 (145.2).

Stability of residues in stored analytical samples

Individual data on storage stability were evaluated by the 2004 JMPR. The results indicated that the residues of trifloxystrobin and CGA 321113 are stable under freezer storage conditions for at least 24 months (grapes, cucumbers, potato, and wheat grain, straw and whole plant) or 18 months (apple fruit, apple wet pomace, peanut nutmeat, peanut oil, and grape juice). No new information was provided.

USE PATTERNS

Various formulations of trifloxystrobin are registered for application in chickpeas, dry peas, lentils and soya (Table 2) for the control of various fungus diseases of Chickpea (Ch), dry peas (Dp), Lentils (L) and soya (S): *Alternaria* spp. (S), *Ascochyta lentis* (L), *Ascochyta pisi* (Dp), *Ascochyta rabiei* (Ch), *Botrytis cinerea* (CH, L), *Cercospora kikuchii* (S), *Cercospora sojina* (S), *Colletotrichum truncatum* (Ch,L,S), *Corynespora cassiicola* (S), *Diaporthe phaseolorum* (S), *Erysiphe diffusa* (S), *Macrophomina phaseolina* (S), *Microsphaera diffusa* (S), *Mycosphaerella pinodes* (Dp), *Phakopsora pachyrhizi* (S), *Phomopsis longicolla* (S), *Rhizoctonia solani* (S), *Sclerotinia sclerotiorum* (Ch, L, S), and *Septoria glycines* (S).

Table 2 Composition of trifloxystrobin formulations

Formulation	Active ingredient content
SC 500	375 g/L trifloxystrobin + 125 g/L prothionazole
SC 535	375 g/L trifloxystrobin + 160 g/L cyproconazole
EC 267.5	187.5 g/L trifloxystrobin + 80 g/L cyproconazole
SC 325	150 g/L trifloxystrobin + 175 g/L prothionazole
EC 250	125 g/L trifloxystrobin + 125 g/L propiconazole
SC 300	100 g/L trifloxystrobin + 200 g/L tebuconazole

[a] Do not apply within 7 days of cutting or swathing of the crop for forage

[b] Do not graze or feed soya bean forage or hay

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Numerous residue trials were performed according to GLP with different mixture formulations of trifloxystrobin.

Trials were generally well documented with laboratory and field reports. Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Control samples are indicated in the summary tables with a "c". Unless stated otherwise, residue data are recorded unadjusted for recovery. The averages of detected residues, used for estimation of residue levels, are double underlined.

Residues have generally been rounded to two significant figures or, for residues near the LOQ, to one significant figure. However, the calculations were made with Excel utilising all digits. Residue values from the trials conducted according to GAP have been used for the estimation of maximum residue levels. Those results included in the evaluation are underlined.

Pulses

Soya beans

Four field trials were conducted in Canada (Ardiel, KD 2007.) with application rates of two times 0.0625 kg trifloxystrobin/ha and sampling 19 or 21 days after the last application.

In 2003 a total of twenty residue trials were performed in the USA. Trifloxystrobin was applied three times at application rates of 0.086 to 0.095 kg trifloxystrobin/ha. Samples of soya bean (seed) were taken at days 19 to 24 after the last application. In 2005 an additional twenty residue trials were conducted in the USA. Trifloxystrobin was applied three times at application rates of 0.122 to 0.134 kg ai/ha. Samples of soya bean (seed) were taken at days 19 to 23 after the last application.

The residues of trifloxystrobin and CGA 321113 were determined according to method 200177. The LOQ was 0.01 mg/kg.

Altogether 16 trials were reported from Brazil according to the Brazilian use patterns with two applications up to 0.075 or four applications up to 0.06 kg trifloxystrobin/ha and a PHI of about 30 days. The LOQ was 0.01–0.02 mg/kg (Anon. 2010, Anon. 2012a, 2012b, Resende, G 2011, Santiago, L 2012a, 2012b, Galhiane, MS and de Sousa, SL 2006a, Galhiane, MS and de

Sousa, SL 2006b, Galhiane, MS and de Sousa, SL 2006c, Galhiane, MS and de Sousa, SL 2006d, Galhiane, MS and de Sousa, SL 2006e, Galhiane, MS and de Sousa, SL 2006f.).

The results of the trials are summarized in Tables 4–6.

[a] Residues were measured in dry seeds

Beans and Peas (dry)Green beans

Nine field trials were conducted in Canada in 2012 with trifloxystrobin in/on dry beans (Milo, J and Harbin, A 2013a.) Two applications at 0.129 to 0.137 kg ai/ha were done with a spray interval of 10 to 14 days and a pre-harvest interval of 28 to 32 days.

Nine field trials were conducted in Canada in 2012 with trifloxystrobin in/on peas (Milo, J and Harbin, A 2013b.). Two applications at 0.108 to 0.135 kg ai/ha were done with a spray interval of 11 to 14 days and a pre-harvest interval of 29 to 31 days.

The residues of trifloxystrobin and CGA 321113 were quantified according to methods 00742, 00742/M001 and 01313 at a LOQ of 0.01 mg/kg.

The results are summarized in Tables 7 and 8.

TFS: trifloxystrobin

[a] Residues were measured in hay,

Fate of residues in storage and processing

The effect of processing on trifloxystrobin residues was investigated in soya beans in the USA. In one trial, three foliar spray applications at rates of 0.446–0.471 kg trifloxystrobin/ha were made to soya beans with a 8 to 9-day interval between applications. Soya beans were harvested at normal maturity at a 19-day after last application (Beedle, EC and Harbin, AM 2005b.). Subsamples of the soya bean seed were removed for analysis. The remainder of the soya bean seed was used to generate aspirated grain fractions and then processed into hulls, meal, and refined oil. Processing was performed using batch procedures that simulated commercial processing practices. The residues of trifloxystrobin and CGA 321113 were determined according to method 200177. The individual analyte residues were summed to give a total trifloxystrobin residue. The limit of quantitation (LOQ) for total trifloxystrobin residue was 0.01 mg/kg in soya bean seed, hulls, meal, and refined oil, and 0.10 mg/kg in soya bean aspirated grain fractions.

Table 13 Results of processing soya beans treated with trifloxystrobin

Crop Variety	Application			Portion analysed	Residues [mg/kg]

Residues in animal commodities

Dairy and poultry feeding studies were submitted for the 2004 JMPR review.

APPRAISAL

Trifloxystrobin was first evaluated by the JMPR in 2004 (T, R) and in 2012 (R). The 2004 Meeting established an ADI of 0–0.04 mg/kg bw and decided that ARfD was not necessary. The Meeting agreed that the residue definition for enforcement purposes for plant commodities should be trifloxystrobin per se, for animal commodities and dietary intake assessment the residue definition should be parent compound and CGA 321113 (expressed as trifloxystrobin equivalents) for plant and animal commodities.

Trifloxystrobin was listed by the Forty-sixth Session of CCPR (2014) for the evaluation by the 2015 JMPR for additional MRLs. Supervised trials data were submitted for evaluation on dry soya bean, lentil, chick pea and pea.

Analytical methods used for supervised trials were also provided.

Analytical methods

The Meeting received descriptions and validation data for analytical methods for residues of trifloxystrobin, CGA 321113 and several other metabolites in different plant matrices.

The plant materials are generally extracted with a mixture of acetonitrile/water. After filtration and concentration to the aqueous remainder, the acidified crude extract is purified, where necessary, by liquid-liquid partition. The residues are quantified by reverse-phase HPLC with MS/MS-detection. The average recoveries of trifloxystrobin and CGA 321113 and their relative standard deviations from test portions spiked at 0.01–2 mg/kg levels were for peas (100–101%, 3.1–4.7%) and soya beans (86–91%, 6.4, 19%). The limits of quantification ranged between 0.01–0.02 mg/kg.

The DFG method S19, evaluated in 2004, is suitable for enforcement.

Residues resulting from supervised trials on crops

The sum of trifloxystrobin and CGA 321113 was calculated and expressed as trifloxystrobin on the basis of the relative molecular masses. A conversion factor of 1.036 is required to express CGA 321113 as trifloxystrobin. As CGA 321113 does not generally constitute a significant proportion of the residue in crops, when the levels of trifloxystrobin or CGA 321113 were below the LOQ, their sum was calculated according to the method used by the 2004 JMPR.

Trifloxystrobin (mg/kg)	CGA 321113 (mg/kg)	Total (expressed as trifloxystrobin) (mg/kg)
< 0.01	< 0.01	< 0.01
< 0.01	0.011	0.021
0.10	< 0.02	0.10
0.92	0.16	1.1

In field trials duplicate samples were taken from each treated plot. Of the duplicate results the non-detected residues were disregarded in the calculation of average residue. As a conservative

approach, if the residues measured were 0.015 and < 0.01, the calculated average was taken as 0.015 mg/kg.

Pulses

Soya bean

The GAP in Canada allows maximum 2 times 0.0625 kg/ha treatment with a 20 day PHI. In 4 trials conducted according to GAP the residues in soya bean seeds were < 0.01 mg/kg (4).

The Brazilian GAP permits up to 4 treatments with 0.060 kg/ai/ha or 2 treatments with 0.075 kg ai/ha with a PHI of 20 days. Following treatment according to GAP the trifloxystrobin residues were below the LOQ (< 0.01 or < 0.02 mg/kg). CGA 321113 residues occurred in seven samples at 0.01–0.02 mg/kg level.

The US GAP permits 3 applications at rates between 0.0913–0.127 kg ai/ha and a PHI of 21 days. In 2003 a total of 20 trials were conducted in the USA applying trifloxystrobin three times at rates of 0.086–0.095 kg ai/ha. In addition, another 20 trials were performed in 2005 with application rates of 0.13 kg ai/ha and samples were taken at 21 days. Duplicate samples were taken from each site.

The US use patterns represent the critical GAP. The nominal application rates in US trials are within ± 25% of the GAP. The residues of parent compound in rank order were: < 0.01 (28), 0.01 (4), 0.012, 0.014, 0.016 (2), 0.021, 0.027, and 0.041mg/kg.

The sum of residues were in rank order: < 0.01 (24), 0.012 (4), 0.021 (2), 0.023 (2), 0.024, 0.025, .026, 0.027, 0.039, 0.043, 0.057 and 0.058 mg/kg.

The Meeting estimated a maximum residue level of 0.05 mg/kg for trifloxystrobin in soya beans, and an STMR residue of 0.01 mg/kg for the sum of trifloxystrobin and CGA 321113.

Beans and peas, dry

The use of trifloxystrobin in/on dry pea, chickpea and lentil is registered in Canada and the USA.

Nine trials were conducted on dry peas and nine trials on dry beans according the GAP in Canada (1-2 application with 0.132 kg ai/ha, the PHI is 30 days). Duplicate samples were taken at each sampling interval.

In beans, the average residues of trifloxystrobin at about 30 days were < 0.01 mg/kg in all (9) samples.

The sum of trifloxystrobin and CGA 321113 residues expressed as trifloxystrobin were in rank order: < 0.01 (5), 0.021 (2), 0.022, and 0.023 mg/kg.

In peas, the residues of trifloxystrobin at about 30 days were all < 0.01 mg/kg in all (9) samples.

The sum of residues of trifloxystrobin and CGA 321113 expressed as trifloxystrobin (mg/kg) at about 30 days were: < 0.01 (3), 0.021 (2), 0.022, 0.023, 0.027 and 0.033 mg/kg.

The use pattern is the same for beans and peas and the residues are not different. Consequently the residue datasets can be combined for mutual support.

The residues of trifloxystrobin in dry bean and pea seeds were < 0.01 mg/kg.

The sum of residues in beans and peas in rank order were: < 0.01 (8), 0.021 (4), 0.022, 0.023 (2), 0.025, 0.027 and 0.033 mg/kg.

As the use pattern for lentils is the same as for beans and peas, the Meeting decided that the database is sufficient for making recommendation for these three commodities.

The Meeting estimated a maximum residue level of 0.01* mg/kg and an STMR residue of 0.021 mg/kg for dry beans, lentils, and pea.

Animal feed

Soya bean forage and hay

Altogether 40 trials were conducted in USA in accordance with registered use patterns. Residues in forage and hay were measured and reported. However, grazing animals on soya bean fields or using forage and hay as animal feed are not permitted, therefore the results of trials were not evaluated.

Pea forage and hay

The average residues of trifloxystrobin and CGA 321113 measured in pea green materials (pea vine) obtained from trials conducted according to Canadian GAP are listed below.

Trifloxystrobin residues: 0.61, 0.78, 0.91, 0.92, 1.05, 1.10, 1.30, 1.50 and 1.95 mg/kg.

The sum of trifloxystrobin and CGA 321113 residues: 0.64, 0.81, 0.94, 0.95, 1.09, 1.15, 1.35, 1.54 and 1.98 mg/kg.

The Meeting estimated highest residue of 2 mg/kg and median residue of 1.1 mg/kg for the sum of trifloxystrobin and CGA321113 in pea vine for animal burden calculations.

The residues of trifloxystrobin and CGA 321113 (TFSA) measured in pea hay obtained from trials conducted according to Canadian GAP are listed below. Trifloxystrobin residues: 2.1, 3.0, 3.1, 3.3, 4.2, 5.3, 6.0, 6.7 and 6.8 mg/kg.

The sum of residues were in rank order: 2.2, 3.2, 3.3, 3.6, 4.5, 5.6, 6.3, 6.9 and 7.1 mg/kg

The Meeting estimated a maximum residue level of 17 mg/kg (dry weight) for peanut hay.

The Meeting estimated highest residue of 7.1 mg/kg and median residue of 4.5 mg/kg for the sum of trifloxystrobin and CGA321113 in pea hay for animal burden calculation.

Fate of Residues in Storage and Processing

Soya bean was treated with trifloxystrobin three times at a rate of 0.446–0.471 kg/ha and harvested 19 days after last application. The average total trifloxystrobin residue was 0.26 mg/kg in soya bean seed (raw agricultural commodity (RAC)), 18.2 mg/kg in soya bean aspirated grain fractions, 0.12 mg/kg in hulls, < 0.01 mg/kg in meal, and 0.03 mg/kg in refined oil. Concentration of the total trifloxystrobin residue was seen only in the soya bean aspirated grain fractions (processing factor about 70). No concentration of the total trifloxystrobin residue was seen in soya bean hulls, meal, or refined oil.

For the purpose of animal burden calculation, the Meeting estimated median residue of 0.7 mg/kg for aspirated grain fraction, 0.01 mg/kg for hull and < 0.0008 mg/kg for meal of soya bean.

Residues in animal commodities

Animal feeding studies were evaluated by the 2004 Meeting. Dairy cows were dosed with trifloxystrobin in capsules at the equivalent of 2, 5.9 or 21 ppm in the diet for 28–30 days. The residues measured in various samples are summarized below:

Sample	Day	Maximum trifloxystrobin residues (mg/kg)								
		Dose 2 ppm			Dose 5.9 ppm			Dose 21 ppm		
		Parent	321113	Total	Parent	321113	Total	Parent	321113	Total
Milk	26	-	-	-	-	-	-	< 0.01	< 0.01	< 0.02
Liver	28-30	< 0.02	< 0.02	< 0.04	< 0.02	< 0.02	< 0.04	< 0.02	0.09	0.11
Kidney	28-30	< 0.02	< 0.02	< 0.04	< 0.02	< 0.02	< 0.04	< 0.02	0.02	0.04
Perirenal fat	28-30	< 0.02	< 0.02	< 0.04				0,06	< 0.02	0.08
Omental fat	28-30	< 0.02	< 0.02	< 0.04	< 0.02	< 0.02	< 0.04	0.05	< 0.02	0.07
Round	28-30	-	-	-	-	-	-	< 0.02	< 0.02	< 0.04
Tenderloin	28-30	-	-	-	-	-	-	< 0.02	< 0.02	< 0.04

Laying hens were dosed at 1.5, 4.5 and 15 ppm level for 29 days. At the highest treatment level no residues (< 0.02 mg/kg) were detected in composite tissue samples of breast plus thigh, skin plus attached fat, peritoneal fat, liver and eggs.

The Meeting estimated the dietary burden of trifloxystrobin in farm animals on the basis of the diets listed in Annex 6 of the 2009 JMPR Report and using the estimated residues in livestock feed commodities evaluated by the present and previous Meetings.

	Trifloxystrobin animal dietary burden, ppm, of dry matter diet							
	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	2.17	1.15	26.6[a]	6.97[b]	8.24	5.00	4.53	0.84
Dairy cattle	2.79	1.27	23.2[c]	6.37[d]	8.21	4.11	2.11	0.43
Poultry - broiler	0.11	0.11	0.069	0.069	0.15	0.15	0.03	0.03
Poultry – layer	0.11	0.11	1.83[e]	0.78[f]	0.15	0.15	0.079	0.079

[a] Suitable for estimation maximum residue levels in meat

[b] Suitable for estimation of median residues in meat

[c] Suitable for estimation maximum residue levels in milk

[d] Suitable for estimation median residue levels in milk

[e] Suitable for estimation maximum residue levels in poultry meat and edible offal

[f] Suitable for estimation median residue levels in poultry meat and edible offal

The maximum dietary burden of beef cattle and dairy cattle is about 30% higher than the maximum feeding level of 21 ppm. The Meeting concluded that the residues observed at the highest feeding level can still be used as a basis for estimation of maximum residues in meat, offal and milk.

The Meeting concluded that the current Codex limits cover the residues derived from the uses of trifloxystrobin and maintains its previous recommendations.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed in Annex 1 to the Report were suitable for establishing maximum residue limits and for IEDI assessment.

CCN	Commodity Name	MRL, mg/kg proposed	previous	STMR or STMR-P mg/kg
VD0071	Beans, dry	0.01*		0.021
VD0533	Lentils	0.01*		0.021
VD4511	Pea, dry	0.01*		0.021
VD0541	Soya bean	0.05		0.01

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of trifloxystrobin were calculated for the 17 GEMS/Food cluster diets using STMRs and STMR-Ps estimated by the JMPR in 2004, 2012 and the current meeting. The results are shown in Annex 3 to the 2015 Report.

The ADI is 0–0.04 mg/kg bw and the calculated IEDIs were 1–4% of the maximum ADI. The Meeting concluded that the long-term intake of residues of trifloxystrobin from the uses considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The 2004 JMPR decided that it was unnecessary to establish an ARfD. The present Meeting therefore concluded that the short-term intake of trifloxystrobin residues is unlikely to present a public health.

PESTICIDES RESIDUES IN SPICES

The first draft was prepared by Professor Arpad Ambrus, Hungarian Food Chain Safety Office, Budapest Hungary

EXPLANATION

Establishing of maximum residue limits for spices was discussed by the CCPR at several occasions.

The 36th Session of CCPR decided (Alinorm 04/24A) to schedule the JMPR to review the monitoring data available for the elaboration of MRLs on spices for pesticides already in the Codex system. The Committee also recommended that governments and the spice trade industry continue to collect monitoring data for pesticides on spices on a regular basis, following agreed criteria and other JMPR guidelines on the conduct of selective surveys, in order to keep the database updated for future review.

Subsequently the 2004 JMPR developed the general principles for evaluation of monitoring data for recommending maximum residue levels, median and high residues depending on the number of residue data available for a given pesticide residue and commodity combination.

The Meeting recommended among others that:

- when no sample contained detectable residues the highest reported LOQ value was used as the maximum residue level and the high residue value. The median residue value was calculated from the reported LOQ values.
- when > 120 samples contained detectable residues, the sample size was sufficiently large to calculate the upper 95% one-tailed confidence limit of the 95th percentile of the population of residues, which should be used as maximum residue level.
- monitoring results should not be used for estimating maximum residue levels that reflect post-harvest use.

Detailed guidance on submission of monitoring data and designing selective field surveys for obtaining residue data in/on spices are given in the FAO Manual Chapter 3.6.

Based on the elaborated principles, the 2004 JMPR recommended maximum residue, median and high residue levels for roots and rhizomes (HS01193) and fruits and berries (HS0191) groups for a number of pesticides. Based on the monitoring data submitted by Thailand, the 2010 JMPR recommended additional maximum, median and high residue levels for a number of pesticide residues in/on fruit, berry, root and rhizome spices.

In accordance with the decision of the 46th Session of the CCPR, India submitted monitoring data from 2009-2014 for acetamiprid, imidacloprid, carbofuran, cypermethrin, lambda-cyhalothrin, phorate, profenofos and triazophos residues in fruit/berry (cardamom, black pepper) spices, and seed spices (cumin, fennel and coriander).

METHODS OF RESIDUE ANALYSIS

Cardamom and pepper

Blend cardamom/pepper sample (250 g) into a coarse powder. Water is added to a representative test portion and mixed. After addition of acetonitrile and mixing, the material was placed in the freezer at -18 ºC for 20 minutes. The sample was then treated with NaCl, shaken and then centrifuged. The supernatant organic layer was treated with Na_2SO_4, vortexed and centrifuged. The subsequent supernatant was then treated with PSA sorbent and anhydrous $MgSO_4$, vortexed and centrifuged. The supernatant was divided into two, one for LC-MS/MS and the other for GC analysis. The pesticide residues detected in GC are confirmed by GC-MS.

Seed spices

Modified QuEChERS multiresidue method was adopted for the extraction and clean-up of various pesticide residues from seed spices. A representative portion ground seed (20 g) was moistened with water followed by addition of acetonitrile. The extract was treated with sodium chloride for separation of acetonitrile layer which was then subjected to dispersive SPE clean-up using PSA, $MgSO_4$ and C_{18}. The residues were determined using GC-MS/MS and/or LC-MS/MS.

The recovery and limit of quantification (LOQ) of pesticides on spices are given in Table-1.

Table 1 Recovery and limit of quantification (LOQ) of pesticides in spices

Compound	Commodity	Spike level (mg/kg)	Recovery range (%)	LOQ (mg/kg)
Acetamiprid	Cardamom	0.1-1.0	84 -103	0.1
	Pepper	0.1-1.0	88-100	0.1
	Cumin, Coriander, Fennel	0.1-1.0	88-112	0.1
Imidacloprid	Cardamom	0.1-1.0	71-83	0.1
	Pepper	0.1-1.0	81-93	0.1

	Pepper	0.1-1.0	84-98	0.1
Lambda-cyhalothrin	Cardamom	0.1-1.0	91-102	0.1
	Pepper	0.1-1.0	95-107	0.1
Profenofos	Cardamom	0.1-1.0	93-105	0.1
	Pepper	0.1-1.0	94-108	0.1
	Cumin, Coriander, Fennel	0.1-1.0	90-110	0.1
Phorate	Cumin, Coriander, Fennel	0.1-1.0	88-102	0.1
Triazophos	Cardamom	0.1-1.0	92-99	0.1
	Pepper	0.1-1.0	88-107	0.1

Description of agricultural practices for growing spice producing plants

Cardamom, *Elettaria cardamomum* L. Maton, is mostly cultivated in the evergreen forests of Western Ghats of India. The crop is prone to infestation by diverse group of insect pests and diseases. Thrips and capsule borers are the major pests. On an average, farmers often apply pesticides every 15 to 18 days resulting in 18 to 25 sprays per year as against the recommended use of seven to eight treatments.

Pepper, *Piper nigrum* L is a native of South India. It is grown in the tropical regions. Pollu beetle, fungal Pollu and wilt disease are the limiting factors of pepper production in all the growing regions.

Cumin, coriander, and fennel are minor crops which are mainly cultivated in southern and western part of India. They are highly infested by aphid, thrips, cutworm, tobacco caterpillar and root knot nematodes. For the control of sucking pests like aphid and thrips, various pesticides are used as a foliar application. For the control of cutworm and tobacco caterpillar, profenofos is used, while phorate is used for the effective control of root knot nematode.

Information regarding harvesting, processing and storage of the spices

The cardamom is obtained by plucking the fruit or berry in the form of capsules from the spice crop. The sun dried or artificially dried capsules are then polished, graded and stored in polythene lined gunny bags or in wooden boxes in moisture free conditions.

Black pepper is produced from the still-green unripe drupes of the pepper plant. The drupes are boiled briefly in hot water, both to clean them and to prepare them for drying. The drupes are

dried in the sun or by machine for several days, during which the pepper around the seed shrinks and darkens into a thin, wrinkled black layer. The capsule of cardamom and unripe drupes for pepper are harvested up to 6 to 8 times a year.

Cumin and coriander are being harvested only once by separating the seeds from the dried spice-crop by using physical techniques. After removal of the physical impurities, the separated seeds are stored in gunny bags at room temperature. Aluminium phosphide is used for post-harvest protection.

The fennel seeds are obtained by drying matured inflorescence of the spice-crop under shade which are then stored in gunny bags at room temperature. The fennel is harvested up to 3 to 4 times a year.

RESULTS OF MONITORING PESTICIDE RESIDUES

Monitoring data were submitted from the period of 2009-2014. Cumin, fennel and coriander samples (250-500 g) were collected from the retail outlets. No information was provided on sampling of cardamom and black pepper.

Black pepper (HS 0790

Of the 284 samples analysed none of them contained residues at or above the 0.1 mg/kg limit of quantification.

Cardamom (HS 0775)

The residues detected are summarized in Table 2.

Coriander (HS0779)

Altogether 223 samples were analysed (positive results in brackets) for acetamiprid (0.02 mg/kg), imidacloprid (0), profenofos (0), phorate (0) and triazophos (0)

Fennel (HS 0731)

Altogether 255 samples were analysed (positive results in brackets) for acetamiprid (0.023, 0.03 mg/kg), carbofuran (0), imidacloprid (0.32), profenofos (0), phorate (0). and triazophos (0).

APPRAISAL

The Thirty-sixth Session of CCPR decided (Alinorm 04/24A) to schedule by the JMPR the review of the monitoring data available for the elaboration of MRLs on spices for pesticides already in the Codex system.

Subsequently the 2004 JMPR developed the general principles for evaluation of monitoring data for recommending maximum residue levels, median and high residues depending on the number of residue data available for a given pesticide residue and commodity combination.

In accordance with the decision of the Forty-sixth Session of the CCPR, India submitted monitoring data from 2009-2014 for several pesticide residues in cardamom, black pepper, cumin, fennel and coriander for review by the 2015 JMPR.

Sampling and analytical methods

Cumin, fennel and coriander seed samples (250–500 g) were collected from the retail outlets. No information was provided on sampling of cardamom and black pepper.

The residues in/on cardamom and black pepper were extracted with a mixture of acetonitrile/water. The dried extract was purified with a primary secondary amine (PSA) adsorbent in the presence of $MgSO_4$, and the residues were identified and quantified by GC-MS/MS or LC-MS/MS.

Seed spices were extracted with the mixture of acetonitrile/water and further determined with a modified QuEChERS multiresidue method using GC-MS/MS and/or LC-MS/MS.

For both methods, the recoveries were within the acceptable range, and reported LOQ was 0.1 mg/kg for all pesticide residue commodity combinations.

Agricultural practices for growing spice producing plants

Cumin, cardamom, coriander, pepper and fennel are minor crops which are mainly cultivated in the southern and western parts of India. The spices need to be protected against several pests and diseases which require repeated application of pesticides around the year.

The capsule of cardamom and unripe drupes for pepper are harvested up to 6 to 8 times a year. Cumin and coriander are harvested only once and fennel, up to 3 to 4 times.

No information was available on registered or approved uses or application conditions of the pesticides.

Principles of evaluation of residues derived from monitoring programmes

Principles for evaluation of monitoring data elaborated by the 2004 JMPR were followed:

- It is assumed that the laboratories reported only valid results. Therefore, all residue data are taken into account without excluding any value as an outlier.
- When residue values were reported as<LOQ, it does not necessarily mean that the sampled commodity was not treated with or exposed to the pesticide. While, it is unlikely that all the sampled commodities were treated with the pesticides looked for with the multi residue procedure, it cannot be assumed to be a 'nil' residue situation.
- When no sample contained detectable residues, the highest reported LOQ value is used as the maximum residue level. When justified based on the consumption, the high and median residue value are taken from the reported LOQ values.
- Distribution-free statistics are used in estimating the maximum residue level, covering the 95th percentile of the residue population at the 95% confidence level. Thus, the estimated maximum residue level encompasses at least 95% of the residues with 95% probability (in 95% of cases). To satisfy this requirement, a minimum of 58–59 samples is required. In such cases the uncertainty derived from the limited number of data points are taken into account in recommending maximum residue levels.
- When > 120 samples contain detected residues, the sample size is sufficiently large to calculate the upper 95% one-tailed confidence limit of the 95^{th} percentile of the population of residues, which should be used for estimation of maximum residue level after rounding up to the next value of the scale of expressing residues according to the OECD MRL calculator.
- Monitoring results are not used for estimating maximum residue levels that reflect post-harvest use.

Furthermore, the Meeting decided that:

Maximum residue levels would only be estimated for those pesticide residues which were determined according to the definition of residues for enforcement purposes. Consequently, the reported residues of carbofuran and imidacloprid were not considered.

Residues resulting from monitoring programmes

Black pepper

Of the 284 samples analysed for acetamiprid, cypermethrin, lambda-cyhalothrin, profenofos, and triazophos, none were found to contain residues at or above the LOQ of 0.1 mg/kg.

The Meeting concluded that the reported LOQ values are higher than those which can be obtained with current analytical methods. Consequently, the Meeting agreed there was no reason to revise its previous recommendations for maximum residue levels for cypermethrin, lambda cyhalothrin, profenofos and triazophos.

The Meeting estimated a maximum residue level and median residue of 0.1 mg/kg for acetamiprid.

Cardamom seed

Results of analyses of 487 samples were reported for acetamiprid, cypermethrin, lambda-cyhalothrin, imidacloprid, profenofos and triazophos.

No residues (< 0.1 mg/kg) of acetamiprid were detected.

Based on the results, the Meeting estimated a maximum residue and median residue of 0.1 mg/kg for acetamiprid.

Out of 487 samples 133 contained cypermethrin residues which were in rank order: 0.10, 0.11 (3), 0.12, 0.13, 0.14 (4), 0.16, 0.18 (2), 0.19 (3), 0.20 (3), 0.21, 0.22 (2), 0.23 (3), 0.24 (2), 0.25, 0.26 (4), 0.27, 0.28 (2), 0.29 (2), 0.30 (2), 0.31 (2), 0.32 (6), 0.34 (5), 0.35(4), 0.36, 0.37 (3), 0.38, 0.39 (2), 0.41 (2), 0.43 (2), 0.44 (4), 0.45 (2), 0.46, 0.47, 0.49, 0.50 (2), 0.52, 0.53 (2), 0.54 (2), 0.55 (2),0.56, 0.58 (2), 0.59 (2), 0.60, 0.63, 0.64, 0.65, 0.66, 0.69 (2), 0.70 (3), 0.71 (2), 0.73, 0.75 (2), 0.76, 0.77, 0.79, 0.81, 0.86, 0.87(2), 0.91,0.92, 0.93, 0.99, 1.03, 1.12, 1.16, 1.34, 1.41, 1.54, 1.62, 1.65, 1.67, 1.76, 1.85, 1.94, 1.98, 2.00, 2.24, and 2.97(2) mg/kg.

The upper 95% confidence limit of the detected residues is 2.24 mg/kg.

The Meeting estimated a maximum residue level of 3 mg/kg and a median residue of 0.43 mg/kg for cypermethrin which replaces its previous recommendations.

Out of 487 samples 146 contained lambda cyhalothrin residues which were in rank order: 0.10 (5), 0.11 (4), 0.12 (7), 0.13 (5), 0.14, 0.15 (4), 0.16 (3), 0.18 (3), 0.19 (7), 0.20 (6), 0.21 (5), 0.22, 0.23 (4), 0.24 (6), 0.25 (2), 0.26 (5), 0.27 (3), 0.28 (4), 0.29, 0.31 (2), 0.32 (3), 0.34 (5), 0.35 (3), 0.36 (2), 0.37 (3), 0.38, 0.40 (2), 0.41 (2), 0.42 (3), 0.43, 0.44, 0.45, 0.46, 0.49 (2), 0.50 (2), 0.51, 0.52 (3), 0.53, 0.54, 0.55, 0.57, 0.58 (2), 0.59, 0.61, 0.62 (2), 0.63, 0.67, 0.68, 0.69, 0.71, 0.73, 0.74 (2), 0.79, 0.82 (2), 0.86, 0.96, 0.99, 1.02, 1.04, 1.06, 1.20, 1.33, 1.87, 1.94, and 3.06 mg/kg.

The upper 95% confidence limit of the residues is 1.87 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg and a median residue of 0.28 mg/kg for cyhalothrin, which replaces its previous recommendations.

Out of 487 samples 68 contained profenofos residues which were in rank order: 0.10 (3), 0.11 (5), 0.12 (3), 0.13 (2), 0.14 (5), 0.16, 0.17, 0.19 (2), 0.21, 0.22 (3), 0.24 (2), 0.25, 0.27, 0.28, 0.29, 0.30 (3), 0.31, 0.32 (2), 0.34 (2), 0.36, 0.38, 0.39, 0.42 (2), 0.43, 0.44, 0.47 (2), 0.50 (2), 0.53 (2), 0.55, 0.63, 0.65, 0.66, 0.78, 0.79, 0.82, 0.91, 1.08, 1.19, 1.26, 1.54, 1.76, 1.9, and 3.06 mg/kg.

The 95th percentile of the residues is 1.4 mg/kg. The database is insufficient for calculation of the upper confidence limit.

Taking into account the limited database, the Meeting estimated a maximum residue level of 3 mg/kg and a median residue of 0.3 mg/kg for profenofos which replaces its previous recommendations.

Out of 487 samples 79 contained triazophos residues which were in rank order: 0.10, 0.11(2), 0.12(2), 0.14,0.15,0.16, 0.17 (4),0.19 (2), 0.21(5), 0.22, 0.23 (2), 0.25, 0.26, 0.28, 0.29 (3), 0.32, 0.33, 0.34, 0.37(2), 0.39(2), 0.40 (2), 0.43, 0.45 (3), 0.46, 0.47, 0.48, 0.49, 0.5 (2), 0.53 (2), 0.55 (2), 0.58, 0.59, 0.6, 0.61, 0.62, 0.63, 0.64, 0.69, 0.77, 0.82 (2), 0.84, 0.85 (2), 0.86, 1.06, 1.09, 1.11, 1.13, 1.34, 1.38,1.42, 1.49, 1.67, 1.68, 1.71, 2.30, and 3.64 mg/kg.

The 95th percentile of the residues is 1.7 mg/kg. The database is insufficient for calculation of the upper confidence limit.

Taking into account the limited database, the Meeting estimated a maximum residue level of 4 mg/kg and a median residue of 0.45 mg/kg for triazophos, which replaces the previous recommendations.

Coriander seed

Altogether 223 samples were analysed (positive results in brackets) for acetamiprid (0.02 mg/kg), profenofos (0), phorate (0) and triazophos (0). The reported LOQ was 0.1 mg/kg.

The residue data was not sufficient to estimate a maximum residue level for acetamiprid.

The Meeting estimated maximum and median residue levels of 0.1 mg/kg for profenofos, phorate and triazophos in coriander seed.

Cumin seed

The results of analyses of 447 samples were reported for acetamiprid, phorate and profenofos.

Out of 447 samples acetamiprid (33) and phorate (7) residues were detected above the LOQ of 0.1 mg/kg.

As the number of detected residues is lower than the minimum required (58), no recommendations could be made for maximum residue levels for acetamiprid and phorate.

Out of 447 samples 76 contained profenofos residues which were in rank order: 0.10 (2), 0.11 (2), 0.12, 0.13 (4), 0.14 (2), 0.15 (2), 0.16 (2), 0.17, 0.18, 0.19(2), 0.20, 0.22 (2), 0.24 (2), 0.25, 0.27, 0.31 (2), 0.32, 0.34, 0.38, 0.39, 0.41, 0.42, 0.44, 0.47, 0.56, 0.63, 0.64, 0.65 (2), 0.66, 0.68 (2), 0.73, 0.77, 0.80, 0.82, 0.85, 0.86, 0.94, 0.95, 0.99, 1.03, 1.05, 1.07, 1.10, 1.21, 1.22 (2), 1.26(2), 1.30, 1.38, 1.51, 1.52, 1.61, 1.85, 1.98, 2.11, 2.32, 2.47, 2.69, 2.90, 3.83, and 4.12 mg/kg.

The 95th percentile of the residues is 2.52 mg/kg. The database is insufficient for calculation of the upper confidence limit. Taking into account the limited database, the Meeting estimated a maximum residue level of 5 mg/kg and median residue of 0.635 mg/kg for profenofos.

Fennel, seed

Altogether 255 samples were analysed (positive results in brackets) for acetamiprid (0.023, 0.03 mg/kg), profenofos (0), phorate (0) and triazophos (0).

The Meeting estimated maximum and median residue levels 0.1 mg/kg for profenofos, phorate and triazophos.

Maximum residue level recommendations for Spices

Pesticide	CCN	Commodity	MRL mg/kg		Median mg/kg
			New	Previous	
Acetamiprid (246)	HS 0790	Pepper, Black; White	0.1		0.1
	HS 0775	Cardamom	0.1		0.1
Cypermethrin (118)	HS 0775	Cardamom	3		0.43
Lambda-cyhalothrin (146)	HS 0775	Cardamom	2	0.03	0.28
	HS 0191	Spices, Fruits and Berries (except Cardamom)	0.03		
Phorate (112)	HS 0779	Coriander, seed	0.1	0.5	0.1
	HS 0731	Fennel, seed	0.1	0.5	0.1
	HS 0190	Spices, Seeds (except Coriander seed and Fennel seed)	0.5		
Profenofos (171)	HS 0775	Cardamom	3	0.07	0.3
	HS 0779	Coriander, seed	0.1		0.1
	HS 0780	Cumin seed	5		0.635
	HS 0731	Fennel, seed	0.1		0.1
	HS 0191	Spices, Fruits and Berries (except Cardamom)	0.07		
Triazophos (143)	HS 0775	Cardamom	4	0.07	0.45
	HS 0779	Coriander, seed	0.1		0.1
	HS 0731	Fennel, seed	0.1		0.1
	HS 0191	Spices, Fruits and Berries (except Cardamom)	0.07		

DIETARY RISK ASSESSMENT

Long-term intake

The contribution of residues present in the pepper, black white to the long-term-intake of acetamiprid and lambda-cyhalothrin was addressed in the evaluation of these compounds. No consumption data is available for cardamom, coriander, cumin and fennel seeds in the 17 GEMS/Food Cluster diets to estimate the contribution of the residues present in these spices to the long-term-intake of acetamiprid, cypermethrin, lambda-cyhalothrin, profenofos, phorate and triazophos.

Short-term intake

The International Estimated Short-Term Intake (IESTI) of acetamiprid and lambda-cyhalothrin from the consumption of pepper, black white and cardamom seed was addressed in the evaluation of these compounds.

The IESTIs for profenofos, phorate and triazophos from the consumption of the spices considered by the current Meeting were estimated. The results are shown in Annex 4 to the 2015 Report. The IESTI represented 0% of the ARfD of cypermethrin and profenofos, a maximum of 10% of the ARfD of phorate and a maximum of 7% of the ARfD of triazophos. The Meeting concluded that the short-term intake of cypermethrin, profenofos, phorate and triazophos residues from the uses considered by the current Meeting was unlikely to present a public health concern.

CORRIGENDA

Pesticide Residues in Food 2014. Evaluations Part 1 - Residues. FAO Plant Production and Protection Paper 222, 2015

Changes are shown in bold

Fenpropathrin (185)

Page 700, paragraph 11 should read:

The Meeting estimated a maximum residue value of 2mg/kg and, based on the processing factor of 0.065, HR of **0.078 mg/kg** and STMR values 0.02 mg/kg for citrus fruit group.

Page 701, paragraph 11 should read:

The meeting estimated maximum residue, HR and STMR values for subgroups of: peaches 3 mg/kg, 1.1 mg/kg and 0.71 mg/kg; plums 1 mg/kg, **0.67 mg/kg** and 0.25 mg/kg; and cherries 7 mg/kg, 3.53, and 1.85 mg/kg, respectively

Page 702, paragraph 11 should read:

The Meeting noted that the trials were not conducted at maximum GAP. For multiple treatments proportionality could **not** be applied. As a result no recommendations could be made.

Page 706, the table should read:

RAC/processed fraction	Processing factors					PF estimated	STMR-P (mg/kg)
RAC: Whole orange	-						
Juice	<0.02	<0.22				<0.02	0.007
Oil	78.7	21.56				50.1	16.5

201 Promoting the Growth and Development of Smallholder Seed Enterprises for Food Security Crops
Case Studies from Brazil, Côte d'Ivoire and India (E) 2010

202 Seeds in Emergencies: a technical handbook (E) 2011

203 Sustainable wheat rust resistance – Learning from history

204 State of knowledge on breeding for durable resistance to soybean rust disease in the developing world

205 The FAO/IAEA Spreadsheet for Designing and Operation of Insect Mass Rearing Facilities

206 Pesticide Residues in food 2010 – Evaluations – Part 1

207 Plant breeding and seed systems for rice, vegetables, maize and pulses in Bangladesh

208 The dynamic tension between public and private plant breeding in Thailand

209 The strategic role of plant breeding in Uruguay: analysis through an agricultural innovation system framework

210 Evolving a plant breeding and seed system in sub-Saharan Africa in an era of donor dependence

211 Pesticide residues in food 2011 − Report, 2011 (E)

212 Pesticide Residues in food 2011 – Evaluations – Part 1

213 Evaluation of pesticide residues - Training Manual

214 Agricultural handtools; Guidelines for Field Officers and Procurement

215 Pesticide residues in food 2012 − Report, 2011 (E)

216 Pesticide residues in Food 2011 – Evaluations – Part 1 (E)

217 Good Agricultural Practices for greenhouse vegetable crops: Principles for Mediterranean climate areas (E)

218 Cassava Farmer Field Schools – Resource material for facilitators in sub-Saharan Africa

219 Pesticide residues in food 2013 − Report, 2011 (E)

220 Pesticide Residues in food 2013 – Evaluations – Part 1

221 Pesticide residues in food 2014 − Report, 2011 (E)

222 Pesticide Residues in food 2014 – Evaluations

223 Pesticide residues in food 2015 Joint FAO/WHO Meeting - Report 2015

224 FAO Training Manual on Evaluation of Pesticide Residues for Estimation of Maximum Residue Levels and Calculation of Dietary Intake

225 FAO Manual on the submission and evaluation of pesticide residues data for the estimation of maximum residue levels in food and feed (3rd edition)

226 Pesticide residues in food 2015 Joint FAO/WHO Meeting - Evaluation 2015

The annual Joint Meeting of the FAO Panel of Experts on Pesticide Residues in Food and the Environment and the WHO Core Assessment Group on Pesticide Residues was held in Geneva, Switzerland, from 15 to 24 September 2015. The FAO Panel of Experts had met in preparatory sessions from 10 to 14 September 2015. The Meeting was held in pursuance of recommendations made by previous Meetings and accepted by the governing bodies of FAO and WHO that studies should be undertaken jointly by experts to evaluate possible hazards to humans arising from the occurrence of pesticide residues in foods. During the meeting the FAO Panel of Experts was responsible for reviewing pesticide use patterns (use of good agricultural practices), data on the chemistry and composition of the pesticides and methods of analysis for pesticide residues and for estimating the maximum residue levels that might occur as a result of the use of the pesticides according to good agricultural use practices. The WHO Core Assessment Group was responsible for reviewing toxicological and related data and for estimating, where possible and appropriate, acceptable daily intakes (ADIs) and acute reference doses (ARfDs) of the pesticides for humans. This report contains information on ADIs, ARfDs, maximum residue levels, and general principles for the evaluation of pesticides. The recommendations of the Joint Meeting, including further research and information, are proposed for use by Member governments of the respective agencies and other interested parties.
