Needham, S. & Funge-Smith, S. J. (2014) *"The consumption of fish and fish products in the Asia-Pacific region based on household surveys"*. FAO Regional Office for Asia and the Pacific, Bangkok, Thailand . RAP Publication 2015/12. 87pp

Foreword

Fish and fish products play a highly important role in the food and nutritional security of rural, urban and coastal populations throughout Asia and the Pacific.

In many countries, catching or farming aquatic resources forms a vital part of rural people's livelihoods and contributes a major source of protein, especially for vulnerable populations. While the importance of fish in both cultural and nutritional terms is clear, far harder to pin down are the actual amounts of fish that people throughout the region are consuming.

For example, the practice of cultivating fish in rice fields or irrigation canals is common and provides a nutritional lifeline for the poor in parts of Asia during certain times of the year. For statistical purposes however, these fish are all but invisible; absent from the official production figures or the FAO Food Balance Sheets (FBS) which represent the only global source of standardized consumption data.

Consumption of fish from rice fields or artisanal fisheries is however picked up by household surveys. Carried out on a regular basis and to a high level of statistical accuracy, such surveys provide a wealth of information about consumption patterns and habits. This data can play a vital role in the development of fisheries and natural resource policies that may have considerable impact on the most vulnerable segments of the population.

This study, carried out by the Asia Pacific Fishery Commission, examines household survey data pertaining to fish and fish product consumption in 30 countries across the region. The information is also compared and contrasted with consumption estimates obtained through Food Balance Sheets.

It is hoped that this publication can help shine the light on consumption patterns of fish and fisheries products at household level as well as some of the reasons for the differences between household survey and FBS derived figures. It is also hoped that the presentation of this data demonstrates the contribution it can make to more informed policy and decision making.

FAO plays a key role in the global compilation, processing and dissemination of food and agriculture statistics. It commits considerable resources towards gathering accurate data and also provides essential statistical capacity development to member countries. Considerable support has been provided to governments throughout the region to assist them to carry out more effective household surveys and this should increasingly pay dividends in years to come.

Fish and fisheries products make an appreciable contribution to human well-being, food security and poverty alleviation in Asia-Pacific. The more detailed our understanding of consumption patterns, the more effective our management actions will be, potentially to the benefit of millions.

Kundhavi Kadiresan

Assistant Director-General and Regional Representative for Asia and the Pacific

Fish consumption in the Asia-Pacific region

Fish and other aquatic animals are known to play an important role in the diet throughout the Asia-Pacific region. The wide range of fishery resources, both marine and freshwater have given rise to a strong tradition of fish eating in most countries of the region and this is also reflected in strong cultural traditions associated with fish. Whilst this may be obvious for small island states with their strong dependence upon fisheries, it is also found in continental countries. This affinity is also not only confined to coastal areas, but may extend far inland. This is partly due to the nature of tropical rivers and floodplain fisheries, but is also a direct consequence of the rice production systems and the associated (often traditional) water storage and management infrastructure of the region. These managed wetlands can extend the range of freshwater fish species by providing habitat and refuge beyond floodplains into upland mountainous areas.

Despite the apparent importance of fish in the diet, it is often overlooked in discussions on nutrition and food security. Gaining an accurate picture of fish consumption and its contribution in the diet in the region is a challenge, partly because it is often important to a subset of the population, but also due to the tendency to miss fish when conducting surveys and censuses. This may be because it is often a crop of opportunity, rather than an agricultural staple. It may also be that fishing takes place away from home, off the holding, and thus is “invisible” to routine surveys on household production. Fishing activity is only a relatively recent addition to agricultural censuses, a clear sign that it has been overlooked in the past. In a similar manner, livestock surveys, typically exclude fish culture as fish is not considered as livestock.

Some countries have dedicated surveys of aquaculture production and attempt to monitor catches at landing sites. This allows some insight to the level of production, but much of the small-scale artisanal production may be missed. In developing countries especially, a large amount of inland water catch as well as that brought to shore by small-scale marine artisanal fishers goes unrecorded. The contribution of small-scale aquaculture ponds can also be mis-estimated, resulting in under reporting more in some cases, overly optimistic estimates. Much of this fish production is also marketed and consumed locally and is therefore not formally recorded at the landing site, farm, or as sales the marketplace. The numbers of fishers and small scale-fish ponds can be underestimated, as many fishers are missed by censuses because they are active on a part-time or occasional basis and many small fishponds are not recorded in land-use inventories.

There are a number of approaches to gaining an insight to how much fish is consumed within a country:

- Direct measurement using long term food consumption/nutrition studies (the most rigorous, but typically using small sample sizes)
- Indirect measurement using short term (often as little as three days) household consumption surveys larger sample sizes, but constrained by short time frame)
- Indirect estimation using household economic surveys of production, expenditure, consumption and sale (can be undertaken at large sample size, but consumption is based on estimates and may require a high degree of recall by respondents)
- Indirect estimation of fish availability by use of national food balance sheets (this is typically a national figure and indicates the apparent amount of fish available within a country for consumption)

At the 32nd session of the Asia-Pacific Fishery Commission (APFIC), the importance of fish in the diet and nutrition of the APFIC member countries was noted and that effort should be made to communicate this into policy decision-making.

In order to respond to this request the Asia Pacific Fishery Commission (APFIC) has attempted here to collate and examine two principle sources of information on fish and fish product consumption from 30 Asia-Pacific countries. The objective of this is to provide an insight into both national figures as well as differences within countries. This downscaled information covers contributions by types of seafood, differences between rural and urban areas and in some cases regional differences within countries. It must be noted that due to the differences in how data is collected and also the sample sizes and quality of data, no attempt has been made to undertake rigorous statistical comparisons between countries, or even within them. This document attempts to draw attention to the value of comparison of different sources of information related to consumption of aquatic products and at the same time, highlight the contribution and importance of fish in diets across the Asia-Pacific region.

Sources of consumption and apparent consumption data

A primary source of information for this study was derived from national household consumption surveys.

- 28 surveys were carried out by government statistical departments
- 1 country (China) was based on national statistical surveys and the household nutrition survey
- 2 surveys (Cambodia and Timor-Leste) were carried out by government fisheries agencies with donor support

Comparative information on apparent fish consumption (or “fish availability”) was extracted from the FAOSTAT food balance sheets (FAOSTAT FBS). Additional information was drawn from research papers and other documents, which are duly referenced.

Understanding fish consumption through household surveys

Household consumption surveys are undertaken on a regular basis in many countries throughout the Asia region. These may estimate weights of foods consumed, or be based on economic expenditures and incomes, from which consumption figures may be derived. These household level surveys present a wealth of useful data concerning fish consumption, nutrition supply, species consumed, urban, rural or other geographical trends and preferences. These national household surveys are usually undertaken by specialist agencies across all regions of a country and within a rigorously devised sampling framework helping to derive large-scale, statistically valid data.

Whilst they may provide valuable insight into differences between parts of a population, household consumption surveys do have limitations that can result in under- or over-estimation. Reasons for this include:

- the surveys require a high degree of recall
- the respondent may have to estimate consumption by other household members

- respondents may deliberately misreport for income and expenditure surveys;
- the survey may not account of consumption outside of the home;
- surveys which only cover expenditure on food items and which do not record consumption, require estimates of cost;
- the degree of detail on individual food item may vary (e.g. data recorded as 'fish' versus detailed information on individual species);
- distinction made between fresh and various preserved or processed products forms (this has an effect on the fresh weight equivalents);
- different calculation methods may be used to adjust for participant recall (e.g. protein conversion factors and live weight equivalents of the fish products consumed);
- small-scale surveys carried out in smaller areas or specific communities may produce very different results than national averages, often reflecting the availability of fish and local eating habits.

Comparing household consumption survey results between countries can also be problematic because there may be substantial differences in the methodologies used.

Despite limitations due to differing assumptions and methodologies, household surveys can provide very useful comparisons for checking purposes and yield additional information, particularly in relation to sub-national variations in diets.

Strengths and limitations of Food Balance Sheets

Another primary source of information that indicates fish consumption in countries is the Food Balance Sheet (FBS) data provided by FAO. Food Balance Sheets describe the apparent consumption of fish per capita of the population for a country. This figure is calculated based on the national availability, derived from fish production and imports, subtracting fish exports. The FBS figure is a national figure and can be used to compare fish availability between countries. This is one of its strongest features, since it allows comparison between countries. The FAO Food Balance Sheets (FBS) are therefore important, because they represent the only global source of standardized consumption data, which allows time series comparison to be made.

This means that FBS data cannot provide information on the variability within areas of a country or between different socio-demographic subgroups in the population. Those data are provided by individual cross-sectional dietary surveys at the national level. To determine the influences of socio-demographics, geography and the environment, it is necessary to examine the data from such national surveys.

Household consumption survey results will typically differ from apparent consumption estimates in the FAO Food Balance Sheets¹. The apparent consumption figure in the FBS does not represent the actual amount of fish consumed and almost invariably results in an overestimation in food consumption compared with figures found in dietary surveys at the household or individual level².

The apparent consumption figure in the FBS is particular prone to error in those developing countries where there are high levels of informal cross border trades as well as local small-scale fishery and aquaculture production. This activity often escapes formal monitoring and data collection processes and can lead to substantial errors in the national statistics.

¹John Kearney (2010). Food consumption trends and drivers. *Phil. Trans. R. Soc. B* 365, 3083–3097

²L Serra-Majem, D MacLean, L Ribas, D Brulé, W Sekula, R Prattala, R Garcia-Closas, A Yngve, M Lalonde, A Petrasovits (2003). Comparative analysis of nutrition data from national, household, and individual levels: results from a WHO-CINDI collaborative project in Canada, Finland, Poland, and Spain. *J. Epidemiol. Community Health* 57, 74–80.

The FAO FBS data are based on live weight equivalents of available fish for human consumption while household survey data are based on recollections of edible quantities consumed (i.e. product weight). This means at typically, values for household consumption from survey data should be lower than the estimate from the FBS.

In some cases (e.g. Bhutan, Cambodia, Timor-Leste, Philippines, Lao PDR and Thailand as well as six Pacific islands) the household survey consumption figure is higher than the FAO apparent consumption figure. The reasons for these differences could not be investigated in this study, but for at least some of these countries, the differences point to underestimates of national fish production.

Many countries underestimate their total production figures because their statistical systems are unable to adequately record dispersed artisanal fisheries production in both marine and freshwaters. In some cases, there is no catch statistics system in place and national production figures are a best “guess”. In other cases, fisheries production is only recorded for industrial production or high value or large scale operations, again missing out the contribution of small-scale producers. Small-scale catch/production of fish and fish products which are consumed locally and are consequently unlikely to register in official fish production statistics, but can be identified by household surveys, thus giving higher consumption estimates.

In some cases, particularly for small, landlocked countries, the import of fish may be underestimated. This is because there may be many cross border channels bring fresh, dried and canned fish into the country. Due to the dispersed nature of this importation, the amounts of fish may be quite underestimated. This may partly explain the fact that household consumption in Bhutan appears much higher than the apparent consumption figure.

Household consumption surveys may also provide lower figures due to the survey design or the conversion factors used. FBS use per capita availability of whole fresh fish, whereas consumption surveys focus on the amount consumed. This may be only part of a fish or a preserved or processed product. In all these cases, the amount consumed is less than the original fresh fish equivalent from which the food was derived.

Consumption of fish and fish products

The countries of the Asia-Pacific region have a range of environments, spanning landlocked mountainous areas, large tropical floodplains, arid grasslands and oceanic tropical islands. This affects accessibility to fish in its different forms and unsurprisingly, fish consumption figures vary considerably; from 110.7 kg per capita per year in the Pacific island of Tuvalu to 0.18 kg per capita per year in Mongolia and parts of western China.

Fish consumption figures can be broken down across geographical regions as follows:

Pacific: Of the 16 countries and territories reviewed, Tuvalu had the highest consumption at 110.7 kg per capita per year while Papua New Guinea was lowest at 13 kg per capita per year.

Southeast Asia: Data was obtained for eight countries in Southeast Asia. Of these consumption in Cambodia was highest at 63.5 kg per capita per year while Timor-Leste was lowest at 6.1 kg per capita per year.

South Asia: Data was obtained for four countries in South Asia. Sri Lanka recorded the highest consumption of 15.3 kg per capita per year while Pakistan recorded the lowest at 0.6 kg per capita per year.

North Asia: Data was obtained for two North Asian countries. Consumption in Bhutan was recorded as 5.6 kg per capita per year while Mongolia stood at 0.2 kg per capita per year.

Fish and fish products as a share of total protein consumption

Not all surveys examined converted fish consumed into levels of protein consumption. Of the 10 which did it can be seen that fish provided the highest levels of protein in the diet in Cambodia, accounting for 37 percent of total protein consumed followed by Myanmar at 22 percent. The lowest levels were recorded in India where fish represented just 2 percent of protein intake (this is unsurprising in a country where 31 percent of the population are vegetarians and lacto-vegetarians and hides) and Mongolia where a figure of 0.1 percent reflects the negligible levels of fish consumed.

Consumption of marine and inland fish and other aquatic animals

Only six surveys identified the type of fish species consumed and their origin. In Cambodia, Myanmar and Bangladesh more inland water fish and aquatic animals were consumed than marine counterparts. For example in Cambodia the breakdown by weight was 71 percent inland to 27 percent marine. Meanwhile in Thailand, Indonesia and Sri Lanka more marine fish were eaten than inland fish. In Indonesia, for example, close to 80 percent by weight of all fish consumed were marine species.

Common species consumed

Major inland species consumed included tilapia, catfish, carp, perch and snakehead. Marine species commonly eaten include tuna, anchovy, sardines, mackerel, scad, shad and milkfish.

Bangladesh

Consumption of fish and fish products in Bangladesh based on the household consumption survey was **11.9 kg per capita per year** (2010) which accounted for 11.1 percent of total protein consumption. This is remarkably close to the figure of 11.3 kg per capita per year recorded in 1964³.

Consumption in the Chittagong area was highest at 17.2 kg per capita per year while that in Rangpur was lowest at 7.5 kg per capita per year.

Overall, 76 percent of the fish consumed were inland species and 18 percent were of marine origin.

Urban consumption stood at 14.5 kg per capita per year and rural at 11 kg per capita per year with rural communities eating more inland fish (70 percent) than urban communities (61 percent).

Contribution to protein from fish consumption varied greatly between income groups ranging from 1.31 kg per capita per year in the lowest income group (bottom 20 percent income group) to 3.39 kg per capita per year in the highest (top 20 percent income group).

The species most commonly consumed were all freshwater including tilapia, catfish and mrigal carp. Hilsa shad and other shads were the most commonly consumed marine/estuarine species.

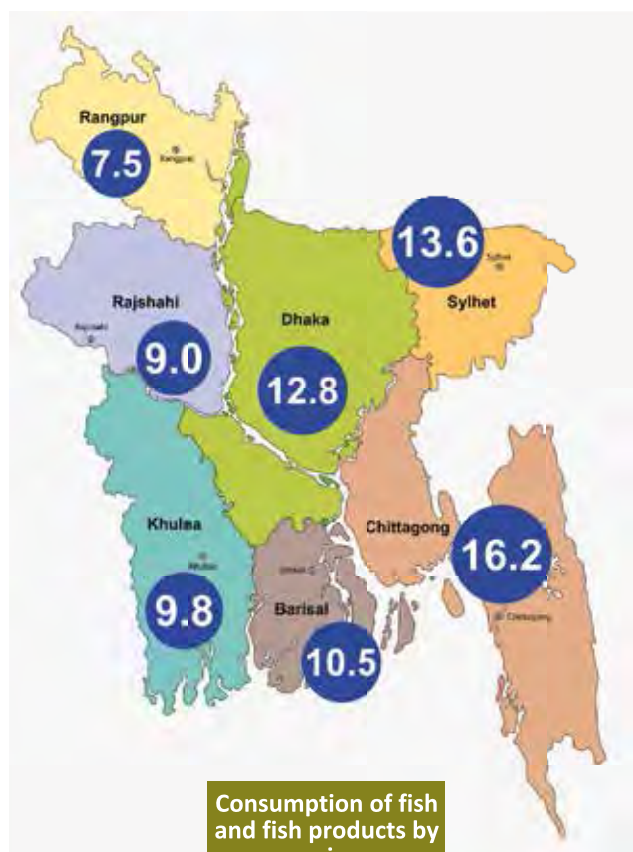

Apart from the estuarine species, the majority of freshwater species are most probably derived from stocked inland water bodies and rice fields. Aquaculture production certainly provides a significant proportion of carps, barbs and tilapia.

It is not possible to clearly disaggregate the relative contributions to consumption from wild capture fishery and aquaculture, but based on the FAO reported aquaculture and fishery statistics, aquaculture production accounts for 52.9 percent, freshwater and estuarine fisheries (includes hilsa) 38.4 percent and marine fisheries 8.7 percent of total production, respectively.

The per capita annual consumption figure is 32 percent less than the FAO apparent consumption figure.

³Khan, M. I. (1969). Aggregative Analysis of Food Consumption in Pakistan. The Pakistan Development Review, 426-441. [Note that at this time Bangladesh was referred to as East Pakistan].

Notes

1. Based on actual consumption. 2010 population of Bangladesh 151 125 475. Ref: <http://countryeconomy.com/demography/population/bangladesh>
2. Household Income and Expenditure Survey 2010 carried out by the Bangladesh Bureau of Statistics (BBS). A two-stage stratified random sampling technique was followed. The survey has completed in one complete year (1 February 2010 - 31 January 2011) in order to capture the seasonal variations. In all, 12 240 households were selected with 7 840 from rural areas and 4 400 from urban areas. Data has been revised with the support of FAO using harmonized methodologies.

Bhutan

Based on household surveys (published in 2009)⁴, national consumption is in the order of 3 931 tonnes per year. Fish and fish product consumption in Bhutan based on the household consumption survey was 5.58 kg per capita per year (2009) while fish accounts for 3.18 percent of all protein consumed.

Urban households also eat over twice as much fresh fish as their rural counterparts. This is mainly imported frozen fish (~61 percent), but a significant proportion (24 percent) is recorded “fresh fish” which is assumed to be a mixture of fish caught from the wild and imported “chilled” fish (from India).

The “fresh fish” category may also include as salted or dried fish (equivalent to about 943 tonnes per year) . There is no way to verify this from the survey data, but the following points lead us to assume that this is correct:

- Chilled fish (fish on ice) is imported in trucks from India and finds its way into urban markets in particular. Quality and “freshness” are variable.
- This Indian chilled fish probably does not get marketed into rural areas.
- Salted and dried marine fish, imported from India is found in all urban markets and also makes its way into most districts. Based on examples seen in markets, the quality seems rather poor.
- Fresh caught wild fish in Bhutan is not widely marketed into towns or beyond the area where it is captured.

The highest consumption figures are recorded in the Transhi-yangtse district at 11.5 kg per capita per year while Samtse in the far southwest of the country sees the lowest at 2.5 kg per capita per year. Urban dwellers consume more fish (6.4 kg per capita per year) than those in rural areas (5.3 kg per capita per year).

These consumption figures are much higher than those which are calculated based on nationally reported statistics. The FAO apparent consumption figure, which is based on reported national production, exports and imports, gives a much lower figure (0.3 kg per capita per year) for Bhutan. The difference between the two estimates is almost certainly due to the “unreported levels of imports together with and underestimation of the national production.

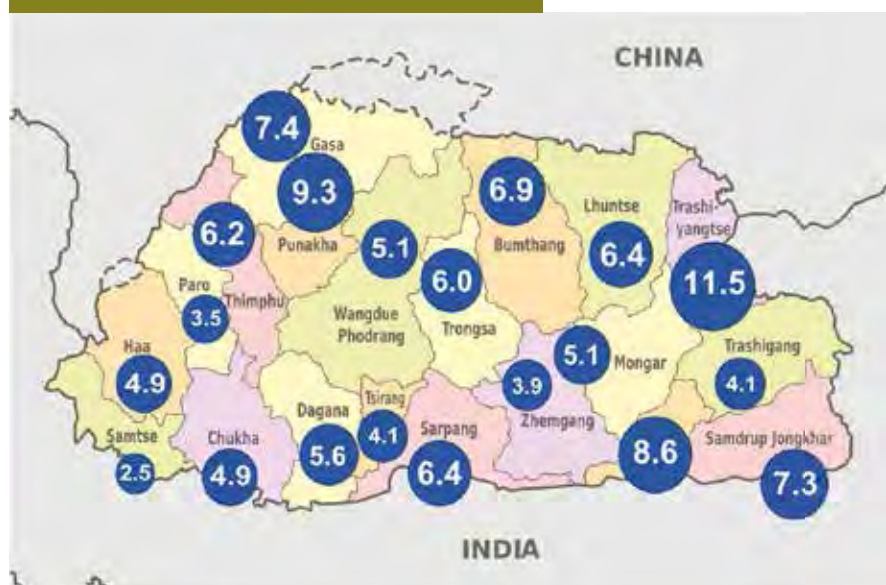

The consumption and expenditure surveys have their own weaknesses, with under- or over- estimations arising from errors during surveying due to seasonality, recall and the way questions are phrased (e.g. it seems that dried and salted fish were either not recorded, in which case the consumption figure is under-estimated, or were included in the fresh category, in which case the fresh fish figure is a mixture of products). Despite possible shortcoming, the sample size of 10 000 households of the household survey gives the data statistical credibility.

⁴Based on actual consumption, using 2008 population of Bhutan. Survey data from Bhutan Standard Survey (BLS) 2007 (Sample size 10,000 households)

Notes

1. Based on actual consumption. 2008 population of Bhutan 704 542. Ref <http://countryeconomy.com/demography/population/bhutan>
2. The Bhutan Standard Survey (BLSS) 2007 was the second round of a nation-wide survey of households. The BLSS 2007 was designed to generate statistical indicators for all the twenty Dzongkhags (Districts) in the country. The survey collected information from ten thousand (10 000) households selected by circular systematic sampling. Information was collected through an integrated household questionnaire covering consumption, expenditure, assets, housing, education, health, fertility, and prices of varying commodities.

Cambodia

The edible quantity of fish and fish products consumed in Cambodia based on the household consumption survey was **63.15 kg per capita per year** (2011). This appears to be amongst the highest in the Asia-Pacific region.

With most of the country forming part of the Lower Mekong Basin and with highly productive Tonle Sap being the largest freshwater lake in Southeast Asia, fish consumption figures are relatively high across all regions of the country ranging from 90.2 kg per capita per year in coastal areas to 52.2 kg per capita per year in mountain and plateau regions.

The inland regions of the country consume more inland fish than marine fish, ranging between 62.2 – 83.3 percent of total fish consumed. In the coastal areas marine fish is the principal source providing 57.5 percent of total fish.

Nationally, inland capture fisheries resources account for 71 percent of fish and fish products consumed and marine fisheries resources 27 percent.

There is relatively little difference between urban and rural consumption of inland and marine fish, although there are some differences in the types of inland fish consumed. In particular the air-breathing, “blackfish” are more predominant in the diet of the Phnom Penh and the mountain and plateau areas.

Fish and fish products represent some 37 percent of total animal protein consumed.

Aquaculture accounts for a relatively low percentage of the consumption (2 percent).

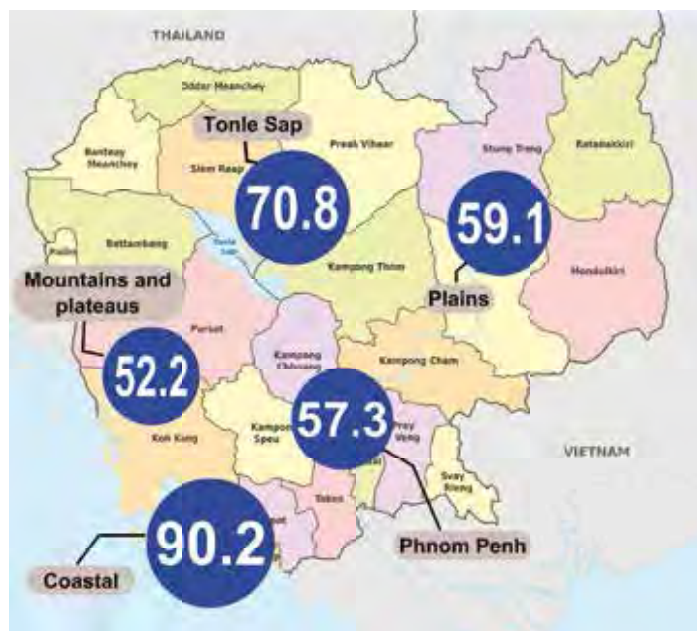

Amongst the most commonly consumed species are snakehead, catfish, climbing perch and mud carp. Other aquatic animals contribute 6.4 percent of the total consumed.

There are several estimates of total fish consumption available for Cambodia. These are based on different methods of estimation. The figure derived from the consumption survey is highest (63.2 kg per capita per year) and differs by 18 percent from the adjusted consumption figure (52.4 kg per capita per year) in the MRC study conducted by Hortle⁵.

The FAO apparent consumption figure is much lower (34.2 kg per capita per year) and is almost certainly a result of underestimated fishery production officially reported to FAO. This is an example where consumption survey data can provide supporting evidence for actual production, in cases where national production estimates are not based on statistical data collection systems.

Notes

1. The Inland Fisheries Research and Development Institute (IFReDI) of the Fisheries Administration carried out a survey of fish consumption as part of the 'Food and Nutrition Security Vulnerability to Mainstream Hydropower Dam Development in Cambodia' project which was co-funded by the Fisheries Administration, World Wildlife Fund for Nature (WWF), Oxfam Australia and DANIDA. As part of this initiative a Household Food Consumption Survey was carried out from 2011-2012 with 1 200 households nationwide, in five of Cambodia's major ecological zones namely: Phnom Penh, Coastal, Plains, Plateau/Mountain and Tonle Sap. This survey took into consideration the stratification framework of the National Institute of Statistics for the National Census. 2. Actual consumption. According to the Cambodian National Institute of Statistics, the estimated population of Cambodia was 12 014 343 in 2000 and is expected to grow to 15 104 768 by 2015. This gives a figure of 14 095 147 people in 2011 (rounded up to 14 100 000). 3. The Hortle study for the Mekong River Commission (2007) saw the analysis of 20 consumption studies spanning the Lower Mekong Basin countries (Lao PDR, Thailand, Cambodia and Vietnam).

China

There are very distinct patterns in the consumption of aquatic products between the different regions in China. Major consumers are in China's coastal south and southeast provinces. Aquatic products are consumed less in China's western provinces, especially in the northwest. This trend is generally reflected in both urban and rural consumption patterns.

Aquatic product consumption is typically concentrated in China's coastal south-east provinces, which is also the base of most aquacultural production⁶. The consumption of aquatic products has increased significantly in the past ten years. The rapid increase in demand for aquatic products has been mainly met by domestic supplies from freshwater aquaculture. Fish production from inland freshwaters provides the majority of fish, and this can be broadly interpreted as coming from aquaculture (mostly carp species).

For 2009, significant gaps also exist between rural and urban consumers in the consumption of aquatic products. Rural per capita consumption (5.3 kg per capita per year) is just over one third of that by urban residents (14.3 kg per capita per year). This level is lower than the consumption level of urban residents in the early 1980s indicating a lag of 30 years⁶.

Bottom income consumers (10 kg per capita per year) consumed 42.5 percent less aquatic products than the top income consumers (17.4 kg per capita per year). Meanwhile, fish is the second most important source of animal protein (meat/flesh products) in the Chinese diet after pork for both rural and urban dwellers.

The per capita consumption calculated from the 2009 FAO balance sheet (39.60 kg per capita per year) is much higher than the Chinese State Statistical Bureau (SSB) survey figure (9.66 kg per capita per year) for the same year. This gives an annual total consumption figure of 12.9 million tonnes, considerably lower than the national total production figure reported to FAO of over 70 million tonnes.

The considerable difference can be attributed to a number of reasons. The FAO balance sheet takes total reported production into account. This includes a large proportion of aquatic plants and molluscs (each comprised about 19 percent of total aquatic products in 2012). Aquatic plants are largely used for industrial purposes or processed food while mollusks contribute very little to household fish consumption in the SSB survey. Significant volumes of domestically produced fish and crustaceans are processed for export.

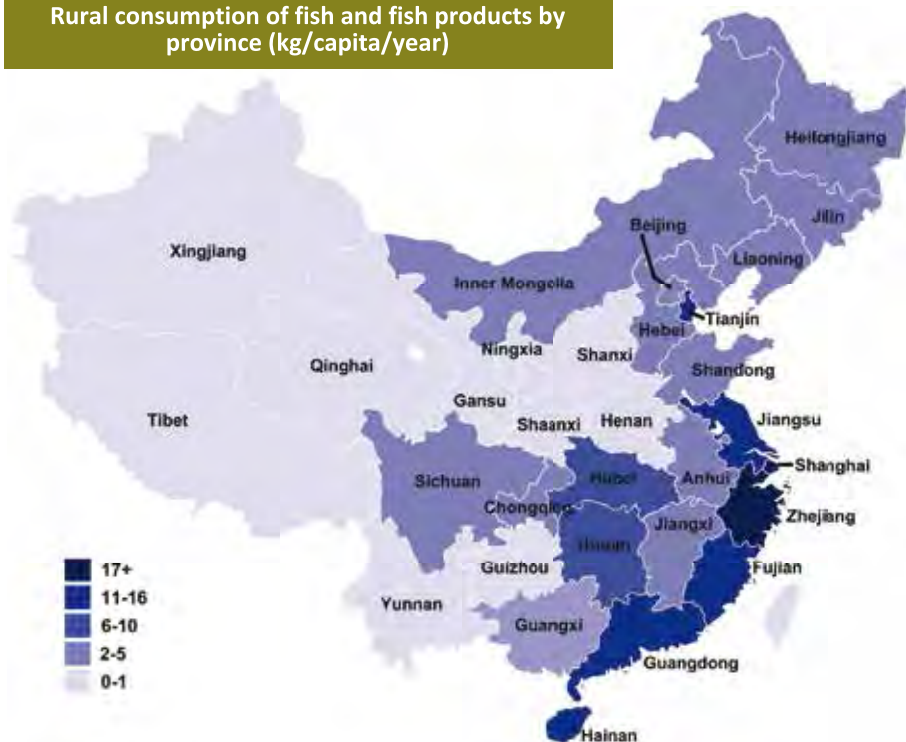

Even discounting these potential sources of error, the freshwater finfish aquaculture production alone is over 23 million tonnes (double the figure obtained from the consumption survey). There are good reasons to believe that the SSB fish consumption data is very probably underestimated. A significant reason is that the SSB surveys do not include consumption outside the home (i.e. consumption in schools, company canteens or restaurants). As a major producer and consumer of fish, it is important to try to obtain better resolution on these estimates of fish consumption.

⁶Food Consumption Trends in China , April 2012 Prepared by Zhangyue Zhou, Weiming Tian, Jimin Wang, Hongbo Liu and Lijuan Cao. Report submitted to the Australian Government Department of Agriculture, Fisheries and Forestry. http://www.daff.gov.au/__data/assets/pdf_file/0006/2259123/food-consumption-trends-in-china-v2.pdf

India

In India national average consumption of fish and fish products, based on the household consumption survey, was **2.85 kg per capita per year** (2010).

This accounted for 2.2 percent of total protein consumption, however it must be noted that 31 percent of the Indian population are vegans or lacto-vegetarians.

Considerable differences in consumption levels were recorded ranging from 22.7 kg per capita per year in the coastal province of Kerala to just 0.03 kg per capita per year in mountainous northern province of Himachal Pradesh.

Access to fish in the floodplains of western India and the coastal regions can explain some of the highest figures. However in areas where there is considerable fish culture (e.g. Andhra Pradesh), or marine fishery production (e.g. Gujarat), consumption figures are rather low. Wealth appears to be another factor influencing fish consumption.

In urban areas average fish consumption was 3.1 kg per capita per year in comparison to rural dwellers, who ate 2.7 kg per capita per year. It is unknown if this reflects higher purchasing power of urban citizens or greater fish availability in urban markets.

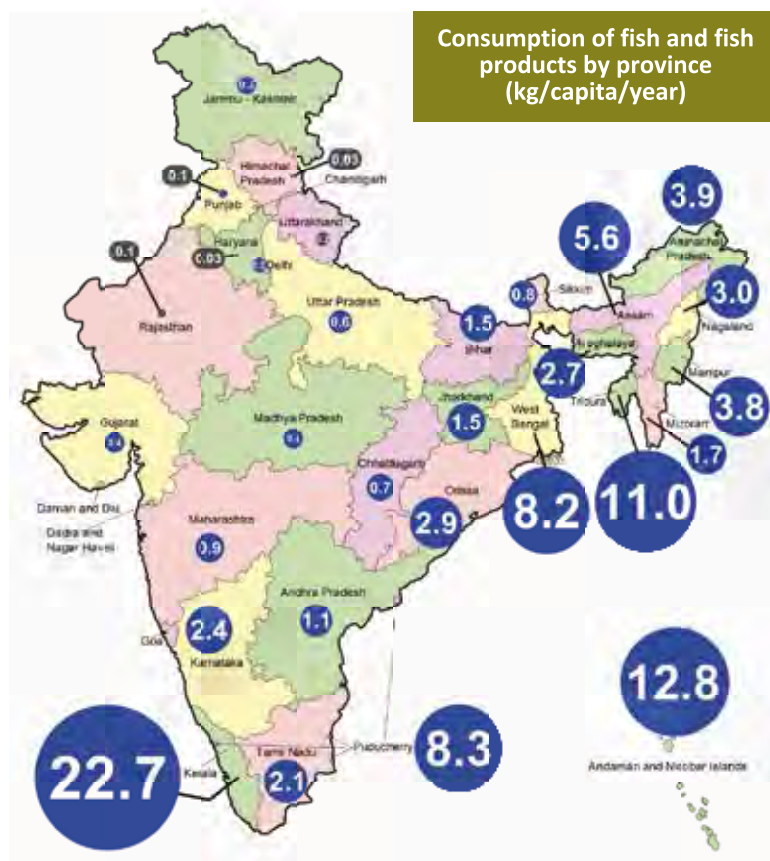

There are indicators of the influence of income on consumption. People in the lowest income group (the bottom 20 percent of income) consumed approximately one quarter of the protein from fish and fish products as those in the top 20 percent income group.

It would seem that wealth and food customs may play a more important role than fish availability, in determining fish consumption.

No data is available in the household survey on the types or sources of fish consumed, and this prevents further analysis.

The national consumption survey figure is derived from the consumption figure and population number by State. The 2010 Household survey consumption national figure is calculated as 2.85 kg per capita per year and is 48 percent less than the FAO Apparent Consumption figure of 5.50 kg per capita per year. As in the case of China, the large discrepancy between these figures is worth exploring, as the population numbers involved are considerable. This may indicate that either national statistics are over-estimated or the household surveys are greatly under-estimating consumption.

Notes

- Figure reflects actual consumption. Population of Indonesia in 2011: 243 801 639. Ref: <http://countryeconomy.com/demography/population/indonesia>
- The National Socio-economic Survey (SUSENAS) for 2011 was carried out by the Central Bureau of Statistics (BPS) of Indonesia and covered a nationwide sample of 300 000 households. Sampling follows the structured three phase methodology. Data has been revised with the support of FAO using harmonized methodologies.

Indonesia

Fish and fish product consumption in Indonesia was **12.8 kg per capita per year** (2011) representing 16.4 percent of total protein consumed.

Consumption levels ranged from 26.4 kg per capita per year in Maluku in the eastern part of the country to 4 kg per capita per year in Yogyakarta.

The high population density and relatively low fish consumption level in central Java brings the national average figure for consumption down, but it is clear that in most other parts of the country consumption levels are much higher.

Marine fish accounted for over 70 percent of consumption and inland species for some 25 percent. Although Indonesia is an archipelagic country with a massive coastline, it also has enormous freshwater resources and inland fisheries production in Indonesia is very substantial, particularly in the interior of the island and especially in Kalimantan. Inland fish were a much higher percentage of the fish consumed in Central and South Kalimantan and West Java (33-36 percent).

Skipjack tuna was reported to be the most commonly consumed marine fish followed by anchovy and Indian mackerel. For inland species tilapia ranked first followed by catfish and common carp, these are principally aquaculture species.

On a nationwide level the majority of fish products (70 percent by weight) are consumed fresh while 30 percent are eaten as preserved or processed products.

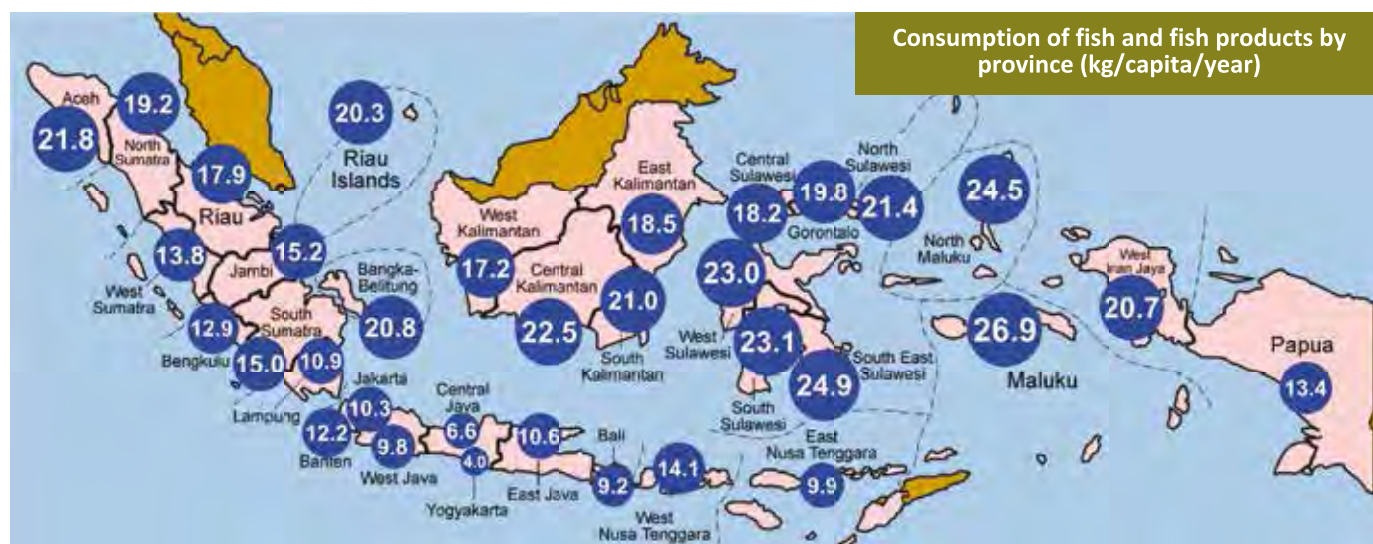

There were not large observable differences between the types of fish consumed in urban and rural areas, nor the quantity of fish consumed.

The FAO apparent consumption figure (24.7 kg per capita per year) is double the figure derived from the household surveys (12.8 kg per capita per year). The household survey figure will be underestimated in terms of fresh weight of fish because up to 30 percent of the fish consumed was processed in some way (processed fish typically has a lower weight than the fresh weight of fish from which it is produced).

Data source : National Socio-Economic Survey 2011²

Lao PDR

Consumption of fish and fish products in Lao PDR based on the household consumption survey was **19.1 kg per capita per year** (2008). This represented 10 percent of total protein consumption.

Based on the population of the country, this indicates a total fish consumption of 125 532 tonnes. The estimated production figure reported in FAO FishStatJ is 136 000 tonnes.

Fish consumption ranged from 7.5 kg per capita per year in Houaphan province in the northeast to 32.7 kg per capita per year in Champassak in the far south.

Generally the rise in consumption mirrors the southwards passage of the Mekong river from the mountainous north to the plains in the south until it passes into Cambodia.

Captured fresh fish made up the majority of consumption (approx. 80 percent, with a range of 74 – 98 percent).

Aquaculture fish consumed ranged from 1 – 26 percent, with a median value of 2.5 percent. The Province of Huaphanh was a significant outlier at 25 percent of aquaculture fish and this reflects the significant area of rice fish culture in the province.

Frozen or canned fish ranged between 1.5 - 8 percent of the total.

Fish which had been captured from waterways (as opposed to farmed) accounted for over 65 percent of rural consumption as opposed to around 25 percent for urban households.

Processed or preserved fish accounted for 12.5 percent.

Based on the consumption figures and populations of each province, the amount of inland fish consumed (and largely produced within the country) is approximately 100 000 tonnes. This difference between wild caught fish and cultured fish is not reflected in national production statistics, which overall indicate lower levels of capture fishery production (34 000 tonnes) and a greater contribution from aquaculture fish (100 000 tonnes). This contradiction reflects the absence of statistical data collection system, but also indicates how survey responses may not accurately report the source of production.

Despite the apparent contradiction regarding the source of fish consumed, the FAO apparent consumption figure (18.2 kg per capita per year) and that derived from the household survey (19.1 kg per capita per year) are reasonably close.

Comparison of provincial level fish and fish product consumption (actual consumption) obtained via LECS4 Household Survey and Hortle Study (kg/capita/year)

Mongolia

Consumption of fish and fish products in Mongolia based on the household consumption survey was **0.18 kg per capita per year** (2008) and accounts for just 0.13 percent of total protein consumption in the country.

The highest levels of consumption are recorded in the capital Ulan Bator (0.28 kg per capita per year). In both the eastern and western areas of the country the figure falls to 0.07 kg per capita per year.

Urban dwellers consume just over twice as much fish as rural dwellers; 0.23 kg per capita per year and 0.10 kg per capita per year respectively.

Fresh fish makes up the majority of that consumed (67 percent) followed by imported canned fish (28 percent). Dried, salted or smoked fish meanwhile accounts for 4 percent.

The overall low level of fish consumption and the relatively high levels of fish imports to the country means that errors in assessing imports will strongly influence the apparent consumption figure in the FAOSTAT Food Balance Sheet (FBS).

The FAO apparent consumption figure (0.4 kg per capita per year) is more than double that derived from the Household Consumption survey (0.18 kg per capita per year), but since both figures are less than half a kilo per capita per year, this difference is probably rather insignificant in terms of dietary contribution.

- The Household Socio-Economic Survey 2007/08 is a nationally representative survey and was carried out between July 2007 and June 2008. The sample of 11 232 households was allocated as follows: 3 600 in Ulaanbaatar, 2 640 in aimag centers and 4 992 in rural areas and small towns. Data has been revised with the support of FAO using harmonized methodologies.

Myanmar

In Myanmar national average consumption of fish and fish products based on the household consumption survey was **21.0 kg per capita per year** (2006).

This represented 22.6 percent of total dietary protein consumed and underlines the importance of fish and fishery products in the diet.

Of the fish consumed, inland species contributed to 31.5 percent of consumption and marine species to 23.5 percent. The accessibility to inland fish in Myanmar and its importance in the diet, compared with that of marine fish (available mainly in dried or salted forms in inland areas), is similar to that found in the Mekong Basin.

Four of the top six items consumed are processed fish (fish paste, fish sauce, shrimp paste and dried fish). Fermented fish paste (“ngapi”) is noted as one of the most important sources of calcium in the diet throughout Myanmar⁷. The species of fish used for ngapi are both freshwater, estuarine and to a lesser extent, marine.

Fermented fish paste was the most commonly consumed product while mrigal carp was the most regularly consumed species followed by striped snakehead and rohu carp.

Coastal Divisions tended to have the highest consumption of fish, although the strong contribution of freshwater species over marine species is worth noting. Kayin had an extraordinarily high consumption (67.7 kg per capita per year) and this may be largely attributable to fish paste consumption.

Of the marine species hilsa shad was the most commonly consumed.

There was relatively little difference in overall fish consumption between rural and urban populations. Urban dwellers consumed more fresh fish (53 percent) than rural dwellers (45 percent).

The conversion of processed fish forms (e.g. fish and shrimp pastes, sauces, dried fish etc.) into fresh weight equivalents, would considerably increase the national average fish consumption figure found in the household survey (21.0 kg per capita per year) and would move it somewhat closer to the FAO FBS figure of 46.5 kg per capita per year. This is a good example of how household consumption surveys can underestimate the fresh weight of fish consumed.

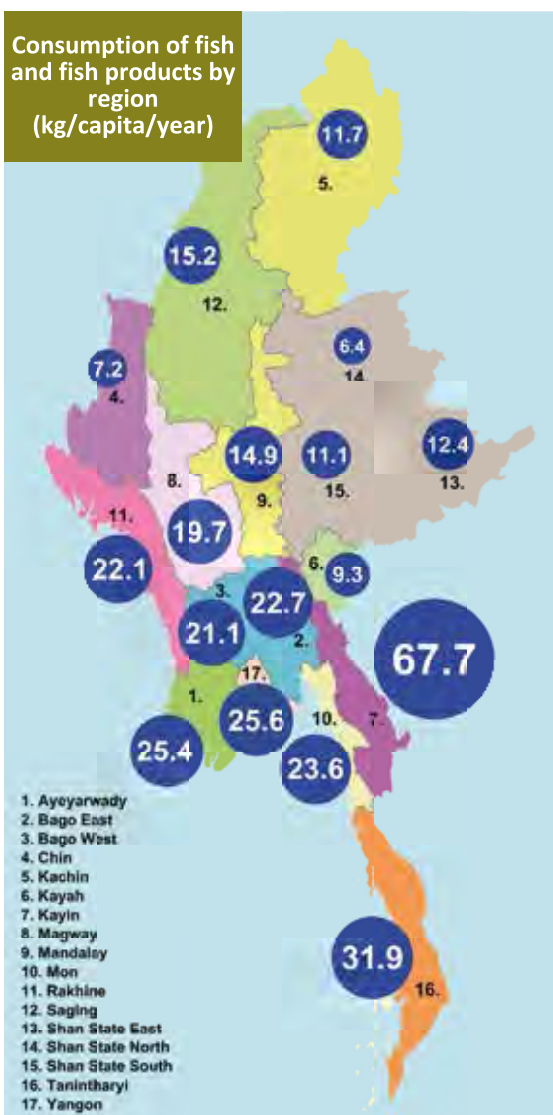

It must be pointed also that the national statistics of Myanmar from both freshwater and marine capture fisheries are not based on a comprehensive statistical data collection system and are best considered as estimates. There are indications from a recent survey of the marine fishery by the RV Fritjof Nansen, that marine capture production may be considerably lower than those reported to FAO. The large annual increases reported for inland freshwater capture production also appear to be rather more than that which a fishery can reasonably be expected to deliver. An effect of this over-reporting of fish production will be an inflated value for apparent consumption in the FBS.

2. In December 2006, the fourth nation-wide household income and expenditure survey was conducted by the Central Statistical Organization in 80 sample townships in all States and Divisions. A sample of 32 000 urban and rural households was selected using a three-stage stratified simple random sampling. Data has been revised with the support of FAO using harmonized methodologies.

Pacific Islands

The high levels of fish consumption throughout the Pacific islands reflects the strong tradition and dependence upon fish for food security.

Tuvalu recorded the highest consumption of fish and fish products in the Pacific at **110.7 kg per capita per year** followed by Samoa at 87.4 kg per capita per year.

Papua New Guinea, with its large interior population, had the lowest level of consumption at 13 kg per capita per year followed by Tonga and Vanuatu both at 20.3 kg per capita per year.

The Solomon Islands, Papua New Guinea and Kiribati all recorded higher urban than rural consumption while for all other Pacific nations covered rural consumption was higher.

With the exception of French Polynesia and Wallis and Futuna consumption in coastal communities was higher than in non-coastal communities.

In some countries there were considerable differences between “rural” and urban populations e.g. In Fiji where the national average was around 20.7 kg per capita per year while in coastal settlements the figure was nearer to 120 kg per capita per year.

Across the fifteen Pacific Island countries and territories, there was variable agreement between survey figures (surveys dated 2001-2006) and the FAOSTAT apparent consumption figures.

The differences are in two categories:

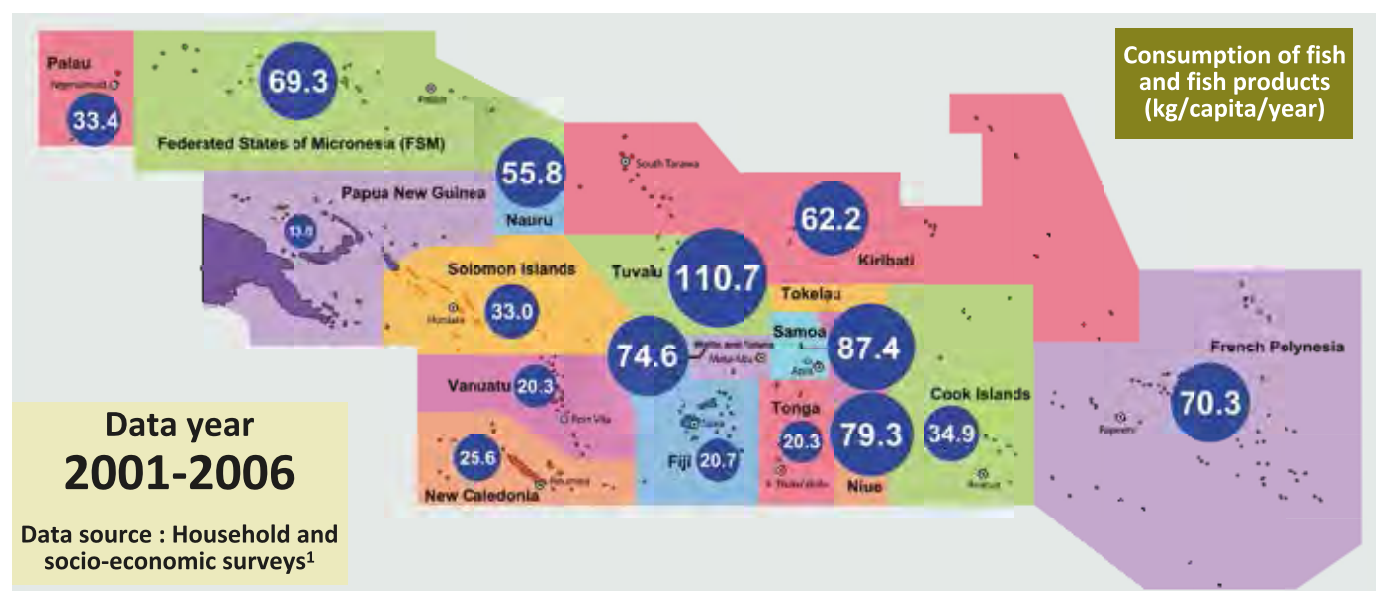

- FBS value substantially greater than household survey: Palau (51 percent), Fiji (42 percent), Tonga (41 percent), Vanuatu (40 percent)
- FBS value substantially less than the household survey: Tuvalu (168 percent), Nauru (133 percent), Samoa (86 percent), Niue (65 percent) and Wallis and Futuna,

In the cases where the FBS figure was greater than the household survey, this may reflect weaknesses in the design or conduct of the survey. It is equally possible that the quantity of fish landed and exported may be mis-recorded, since several of these countries all produce tuna for export. Another potential source of error is the estimation of production statistics.

Household consumption surveys tend to under-estimate fish consumption, so for those countries where the FBS figure was lower than the household consumption survey, this may indicate that households are accessing fish locally that are not being included in national production statistics.

Some effort to validate the actual consumption figures would be useful, considering the central role of fish in the diet of the Pacific island countries.

Pacific Islands

Pakistan

From household survey results it would appear that fish and fish products make only a very minor contribution to diets.

The national consumption figure based on the household consumption survey was just **0.6 kg per capita per year** (2011), whereas the FAOSTAT FBS apparent consumption figure is 300 percent greater at **1.9 kg per capita per year**.

The low figure is considered to be due to the tendency to export much of the fish production and low purchasing power inside the country.

This food survey figure of **0.6 kg per capita per year** is the same as the figure derived from surveys in 1964⁸. This indicates that there has been little change over time in the per capita fish consumption of the country.

Much of the fish accessed in the interior of the country is derived from inland fisheries and aquaculture.

Fish and fish products also account for 9.1 percent of all animal products eaten. Poultry is the most common animal product eaten at 3.4 kg per capita per year.

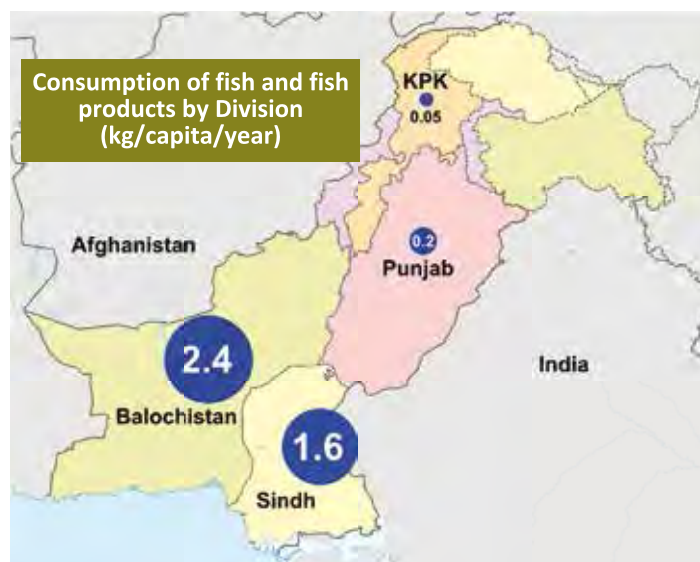

The highest fish consumption figures were recorded in the two coastal provinces of Balochistan (2.4 kg per capita per year) and Sindh (1.6 kg per capita per year).

Consumption tails off further north with households in the Punjab consuming just 0.2 kg per capita per year and those in the mountainous Khyber Pakhtunkhwa area negligible amounts (0.05 kg per capita per year).

In both rural and urban areas over 90 percent of fish products consumed were purchased with just 3-4 percent self-produced.

2. This Household Integrated Economic Survey (HIES) comprised all urban and rural areas of four provinces of Pakistan. However, military restricted areas were excluded. A sample size of 16 341 households from 1 180 sampled areas (enumeration blocks and villages) was considered appropriate to provide reliable estimates of key characteristics at the National/Provincial level. Data has been revised with the support of FAO using harmonized methodologies.

Philippines

Fish consumption based on the household consumption survey in the Philippines was **40.2 kg per capita per year** (2008).

Nationwide there is about 3-5 kg per capita per year variation from the national average.

The highest fish consumption levels were recorded in Western Visayas and Caraga which both stood at 46.7 kg per capita per year. The Cordillera Administrative Unit in the far north of the country recorded the lowest levels at 28.1 kg per capita per year.

Canned fish and sardines, mackerel scad and milkfish were the three most commonly consumed products/species followed by tilapia.

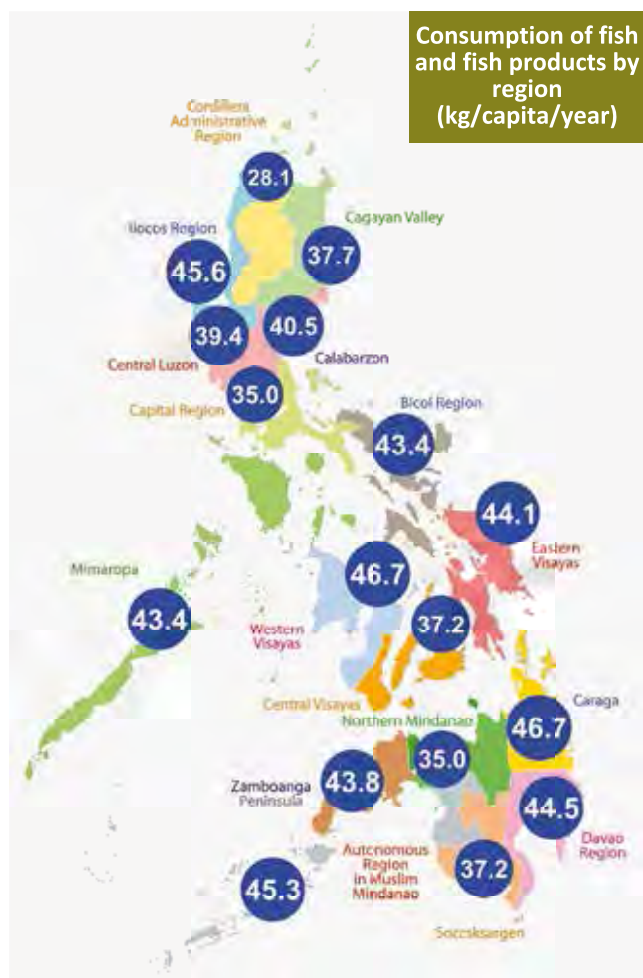

Amongst consumer age ranges those in the 60+ year old group ate the most fish (15.6 percent of total food consumption) followed by those aged 20-59 (14.7 percent).

Round scad and canned sardines were the most commonly consumed species/products for all age groups apart from the 60+ group which ate more round scad and milkfish.

This is the only household survey where age related consumption was presented.

There is reasonable agreement between the national average household consumption figure (40.2 kg per capita per year) and the FAOSTAT FBS figure of 35.9 kg per capita per year.

Comparison of fish and fish product consumption figures obtained via 'Apparent Consumption' and Household Survey methods (kg/capita/year)

Sri Lanka

Average national consumption of fish and fish products based on the household consumption survey in Sri Lanka was **15.3 kg per capita per year** (2010).

There is reasonable agreement between the national average household consumption figure and the FAOSTAT FBS figure of 21.1 kg per capita per year.

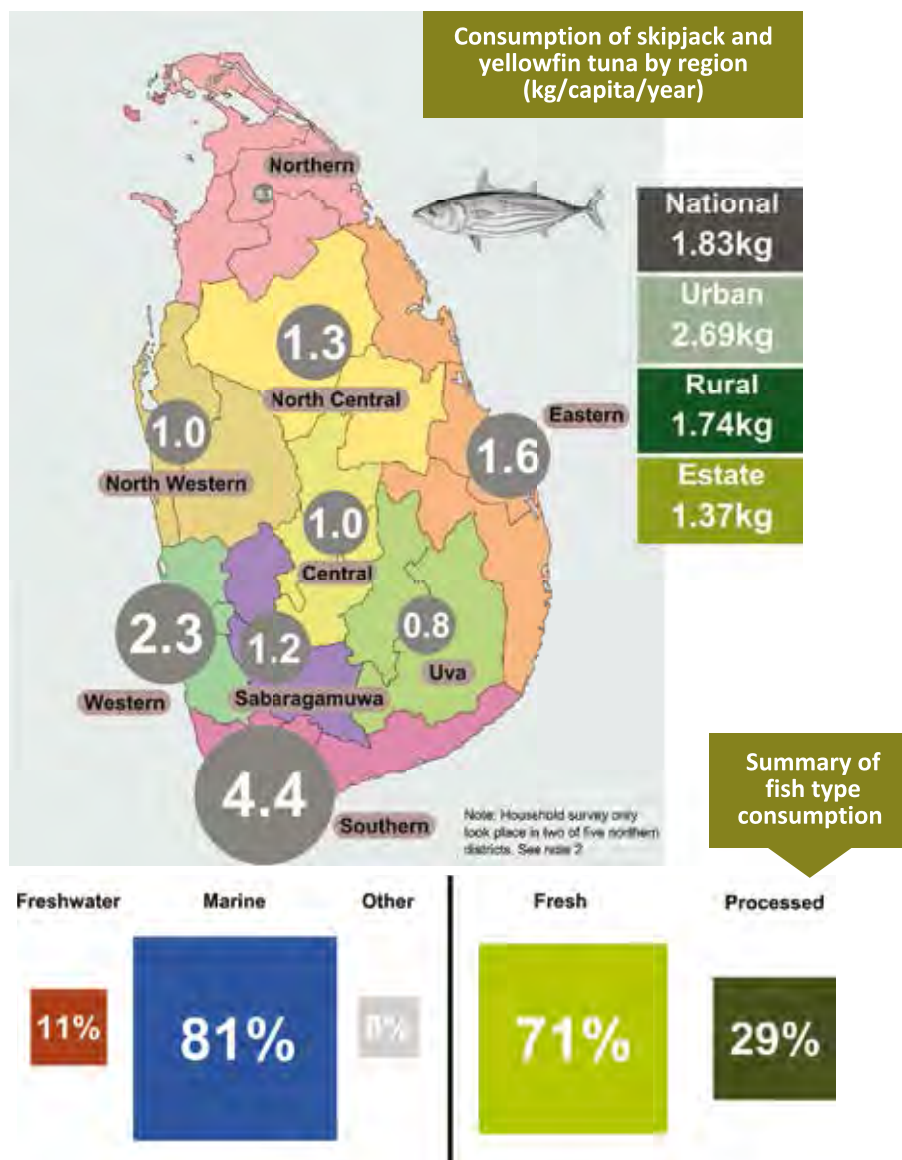

The difference can be attributed to processed or dry fish to fresh fish equivalents.

Overall 71 percent of fish was consumed fresh and the remaining 29 percent as dried or processed products.

Marine species accounted for 81 percent and inland species around 11 percent. Sprats were the most commonly consumed marine species followed by skipjack tuna and gold stripe sardinella.

Tilapia was by far the most commonly consumed freshwater species followed by catfish and snakehead.

2. The Sri Lanka Household Income and Expenditure Survey (HIES) is conducted by the Department of Census and Statistics (DCS) under the National Household Sample Survey Program. The field data collection took place in twelve monthly rounds starting from July 2009 to June 2010 and covered all districts excluding Mannar, Kilinochchi and Mullaithivu districts in the Northern province as post liberation resettlements of internally displaced persons were in progress in the three districts during the scheduled survey period.

Consumption of fish by species: Marine/ Freshwater and Dried fish/ Fresh fish (kg/capita/year)

Ranking of top three identified species consumed

Comparison of fish and fish product consumption figures obtained via 'Apparent Consumption' and Household Survey methods (kg/capita/year)

Thailand

Edible consumption of fish and fish products in Thailand was **31.4 kg per capita per year** (2011).

This represents 11.7 percent of total protein consumption.

The highest levels of consumption are in the southern provinces (41.4 kg per capita per year) followed by the northeast at 32.7 kg per capita per year.

Inland species and other aquatic animals represented 37 percent of fish consumed in comparison to 47 percent for marine equivalents. There is no disaggregation between capture fisheries and aquaculture production.

Miscellaneous processed products that could have been either marine or inland fish-based made up the remaining 16 percent that were consumed.

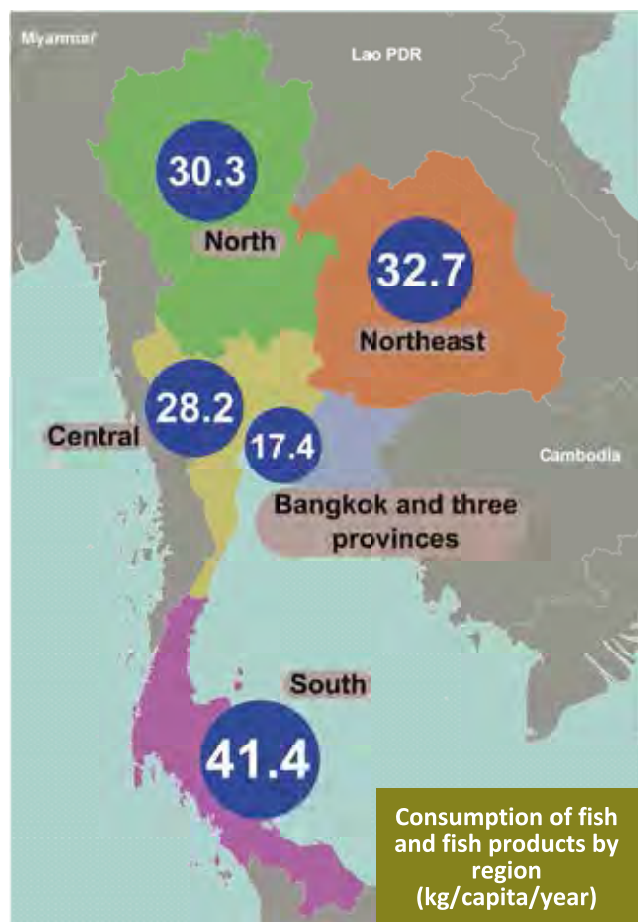

Rural dwellers ate more fish and fish products than their urban counterparts: 35.7 percent and 25.7 percent respectively. Nile tilapia was the most commonly eaten species in north, central and urban areas; snakehead in northeast and rural areas and chub mackerel in the South.

The FAOSTAT apparent consumption figure (26.5 kg per capita per year) is lower than, but close to, the figure from the household survey (31.4).

The household survey figure for the Northeast of Thailand (33.4 kg per capita per year) is also in close agreement to the MRC Hortle study⁹ (33.6 kg per capita per year), which covered only the northeast of Thailand.

2. The National Statistical Office carried out the 2011 Household Socio-Economic Survey from January to December 2011. The survey covered a total of approx 52 000 households in every province. Data has been revised with the support of FAO using harmonized methodologies.
3. The Hortle study for the Mekong River Commission (2007) saw the analysis of 20 consumption studies spanning the Lower Mekong Basin countries (Lao PDR, Thailand, Cambodia and Vietnam).

National consumption of fish by type (% of total/kg/capita/year)

Comparison of fish and fish product consumption figures obtained via 'Apparent Consumption' and Household survey with Hortle Study (kg/capita/year)

Timor - Leste

In Timor-Leste consumption of fish and fish products based on the household consumption survey was **6.1 kg per capita per year** (2011).

This represents 33.4 percent of all animal flesh products eaten.

Consumption patterns range greatly from 17.6 kg per capita per year in coastal communities to 4 kg per capita per year in non-coastal areas.

In urban areas the figure based on the household consumption survey was 6 kg per capita per year.

Consumption in coastal and urban areas is entirely of marine species while in non-coastal areas 1.8 percent of animal protein consumed is from inland species.

Sardines and mackerel are, by far, the most commonly consumed species followed by long tail tuna, snapper, prawns and long tom.

Nile tilapia and common carp are produced in small quantities (45 tonnes per year) by small-scale fish farmers.

There is a large difference between the FAOSTAT FBS figure of 6.1 kg per capita per year and the figure from the household survey (3.3 kg per capita per year). Resolving this should focus on the limited statistical information on production that is available in the country (all figures are estimates.) and the potential for under-estimation in the household survey.

Notes

1. Oecusse omitted from mean calculation due to sample not being representative. 2. Actual consumption. Population of Timor-Leste given as 1 066 582 (Population and Housing Census 2010) Ref: <http://timor-leste.gov.tl/> 3. The study of Fish and animal protein consumption and availability in Timor-Leste took place in 2010-2011 as part of the FAO/Spanish-funded Regional Fisheries Livelihoods Programme (RFLP). The study employed a mixed-method of quantitative and qualitative survey, with quantitative survey as the main focus. A random survey was conducted in five districts (namely Baucau, Dili, Bobonaro, Covalima, and Oecussi). The total number of respondents was 820. 4. This data is from an 'Analyses of the Current Situation and Potential for Aquaculture Development in Timor-Leste' which was carried out by the National Directorate of Fisheries and Aquaculture (NDFA) with assistance from the WorldFish Center, the FAO/Spain Regional Fisheries Livelihoods Programme (RFLP) and the Coral Triangle Support Partnership (CTSP).

Viet Nam

The average level of fish and fish product consumption in Viet Nam based on the household consumption survey was **14.6 kg per capita per year** (2011).

This represents 8.5 percent of total protein consumed.

Fresh fish and shrimp (9.7 kg per capita per year) were second behind pork (11.8 kg per capita per year) in animal product consumption. The difference between pork and fish consumption narrows if dried and processed fish and shrimp (0.8 kg per capita per year) are added, bringing consumption of all fish products to 10.6 kg per capita per year.

Consumption levels vary considerably throughout the country, ranging from 6.8 kg per capita per year in the midlands and northern mountainous areas to 24.4 kg per capita per year in the Mekong Delta.

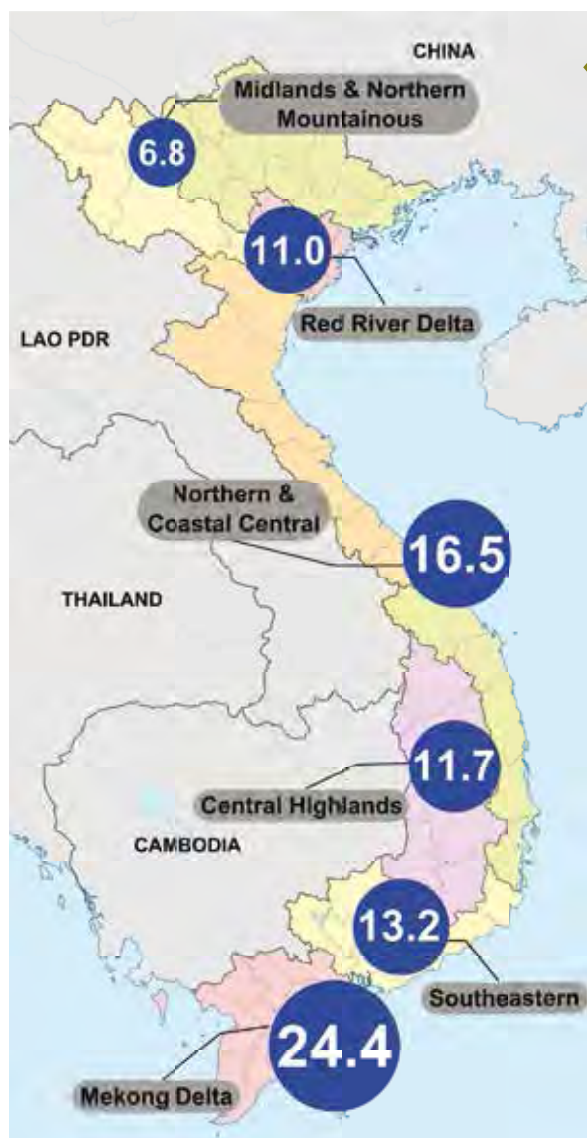

On a national level, fresh fish and shrimp make up 66.7 percent of consumption, fish and various dipping sauces 27.6 percent and dried/processed fish 5.7 percent.

Rural and urban consumption levels were fairly similar standing at 14.8 kg per capita per year and 14.2 kg per capita per year respectively.

The national average derived from the household consumption survey (14.6 kg per capita per year) is substantially lower than the FAOSTAT FBS (32.5 kg per capita per year). The household survey consumption figure for the Mekong Delta (24.4 kg per capita per year) is also much lower than the figure in the MRC Hortle¹⁰ study (which covered the Mekong Delta and returned a figure of 45 kg per capita per year). This suggests that the household survey is under-estimating fish consumption.

Notes

- Figure reflects actual consumption. Population of Viet Nam 2010 86 932 500. Ref: <http://countryeconomy.com/demography/population/vietnam>
- The VHLSS 2010 was conducted nationwide with a sample size of 69 360 households in 3 133 communes/wards which were representatives at national, regional, urban, rural and provincial levels. The survey collected information during four periods, each period in one quarter from the second quarter to the fourth quarter in 2010 and one period in the first quarter of 2011. Data has been revised with the support of FAO using harmonized methodologies.
- The Hortle study for the Mekong River Commission saw the analysis of 20 consumption studies spanning the Lower Mekong Basin countries (Lao PDR, Thailand, Cambodia and Viet Nam).

C Conclusions

From the data analyzed it is clear that per capita fish consumption in the Asia-Pacific region is highest in the Pacific followed by Southeast East Asia, South Asia and North Asia. However, although fish consumption in countries such as India and Pakistan is relatively low (2.85 and 0.6 kg per capita per year respectively) the large population size of these nations results in significant quantities of fish being consumed (e.g. for India this equates to more than 3.4 million tonnes/annum).

Within countries considerable geographical differences in fish consumption can be identified. Certain geographic reasons are clear such as those living along or in the proximity of large waterways or water bodies, such as the Mekong River or Cambodia's Tonle Sap lake. It is also unsurprising that available data points to higher consumption in coastal communities than those further inland.

There was no clear divide between rural and urban areas. In 13 countries where data was available consumption in rural areas was higher than urban while in nine others urban consumption was higher. This may point to higher or easier availability in certain rural areas as well as better purchasing power in some urban centres.

Where data is available, inland species would appear to play a major role in diets. Certain species such as tilapia and catfish featured prominently.

No single country survey will provide a wholly accurate figure for fish consumption on a national and subnational levels. Instead a combination of approaches using the food balance sheet (FBS) to give an idea of overall consumption and household surveys to provide better resolution of the range and types of consumption can help paint a picture of how much fish is available and who is accessing this.

Household surveys are uniquely positioned to gather detailed data on fish consumption on nationwide and local scales. Continued technical support should therefore be provided to national statistics offices to help them put into practice more effective data collection methods so as to enhance the accuracy, quality and value of fish consumption statistics both in quantity and nutrient values. Support should also continue to be provided with regards to technical areas such as the building national nutrient and product conversion factors including non-edible proportions of different types of fish.

Where possible, household surveys should seek to place added emphasis on gathering data related to the consumption of fish and other aquatic animals or products. This would, for example, help create better understanding of the contribution of small-size, freshwater fish from inland water to the diet, especially of the rural poor. Such information could help better inform policy relating to poverty, nutrition as well as resource management.

Survey data can furthermore play an important role in identifying apparent anomalies in statistics that can then be addressed at national level. Deeper analysis should be conducted to understand the mismatches between apparent live weight consumption from FBS and edible quantity figures from household surveys in certain countries. National authorities would for example then be better placed to address over or under reporting in their figures.

Finally, household survey data is available from most countries in Asia-Pacific region with a few notable exceptions. In order to gain a clearer picture of fish consumption across the region such data should ideally be made available from all countries.
