

PART 1

**WORLD REVIEW OF FISHERIES
AND AQUACULTURE**

WORLD REVIEW OF FISHERIES AND AQUACULTURE

Status and trends

OVERVIEW

Capture fisheries and aquaculture supplied the world with about 148 million tonnes of fish in 2010 (with a total value of US\$217.5 billion), of which about 128 million tonnes was utilized as food for people, and preliminary data for 2011 indicate increased production of 154 million tonnes, of which 131 million tonnes was destined as food (Table 1 and Figure 1, all data presented are subject to rounding). With sustained growth in fish production and improved distribution channels, world fish food supply has grown dramatically in the last five decades, with an average growth rate of 3.2 percent per year in the period 1961–2009, outpacing the increase of 1.7 percent per year in the world's population. World per capita food fish supply increased from an average of 9.9 kg (live weight equivalent) in the 1960s to 18.4 kg in 2009, and preliminary estimates for 2010 point to a further increase in fish consumption to 18.6 kg¹ (Table 1 and Figure 2). Of the 126 million tonnes available for human consumption in 2009, fish consumption was lowest in Africa (9.1 million tonnes, with 9.1 kg per capita), while Asia accounted for two-thirds of total consumption, with 85.4 million tonnes (20.7 kg per capita), of which 42.8 million tonnes was consumed outside China (15.4 kg per capita). The corresponding per capita fish consumption figures

Notes: Excluding aquatic plants. Totals may not match due to rounding. Data for 2011 are provisional estimates.

for Oceania, North America, Europe, and Latin America and the Caribbean were 24.6 kg, 24.1 kg, 22.0 kg and 9.9 kg, respectively. Although annual per capita consumption of fishery products has grown steadily in developing regions (from 5.2 kg in 1961 to 17.0 kg in 2009) and in low-income food-deficit countries (LIFDCs, from 4.9 kg in 1961 to 10.1 kg in 2009), it is still considerably lower than in more developed regions, although the gap is narrowing. A sizeable share of fish consumed in developed countries consists of imports, and, owing to steady demand and declining domestic fishery production (down 10 percent in the period 2000–2010), their dependence on imports, in particular from developing countries, is projected to grow in coming years.

China has been responsible for most of the increase in world per capita fish consumption, owing to the substantial increase in its fish production, particularly from aquaculture, despite a downward revision of China's production statistics for recent years (Box 1). China's share in world fish production grew from 7 percent in 1961 to 35 percent in 2010. Driven by growing domestic income and an increase in the diversity of fish available, per capita fish consumption in China has also increased dramatically, reaching about

Figure 1

World capture fisheries and aquaculture production

Figure 2

World fish utilization and supply

31.9 kg in 2009, with an average annual rate of 6.0 percent in the period 1990–2009. If China is excluded, annual fish supply to the rest of the world in 2009 was about 15.4 kg per person, higher than the average values of the 1960s (11.5 kg), 1970s (13.5 kg), 1980s (14.1 kg) and 1990s (13.5 kg).

Fish and fishery products represent a very valuable source of protein and essential micronutrients for balanced nutrition and good health. In 2009, fish accounted for 16.6 percent of the world population's intake of animal protein and 6.5 percent of all protein consumed. Globally, fish provides about 3.0 billion people with almost 20 percent of their intake of animal protein, and 4.3 billion people with about 15 percent of such protein. Differences among developed and developing countries are apparent in the contribution of fish to animal protein intake. Despite the relatively lower levels of fish consumption in developing countries, the share contributed by fish was significant at about 19.2 percent, and for LIFDCs it was 24.0 percent. However, in both developing and developed countries, this share has declined slightly in recent years as consumption of other animal proteins has grown more rapidly.

Figure 3

World capture fisheries production

Box 1

Improvements in China's fishery and aquaculture statistics

As stated in previous issues of *The State of World Fisheries and Aquaculture*, China revised its production statistics for capture fisheries and aquaculture for 2006 onwards using a revised statistical methodology based on the outcome of China's 2006 National Agricultural Census, which contained questions on fish production for the first time, as well as on results from various pilot sample surveys. FAO subsequently estimated revisions for its historical statistics for China for 1997–2005.

Sample surveys have been increasingly adopted in China as an efficient means of collecting data, with the possibility of tailoring them to collect more detailed information required specifically for the local situation in which they are conducted. Prior to the implementation of more systematic sample surveys, pilot surveys were undertaken to test their utility in a variety of very different situations. In addition to some undertaken independently by Chinese authorities, the following pilot sample surveys were conducted jointly by China and FAO:

- marine capture fisheries in Xiangshan County, Zhejiang Province (2002–03);
- marine capture fisheries in Putuo District, Zhoushan (China's largest fishing port), Zhejiang Province, and in Haimen City, Jiangsu Province (2004–05);
- marine capture fisheries in Laizhou City, Shandong Province (2008–09);
- inland capture fisheries at Lake Liangzi, Hubei Province (2008–09);
- inland capture fisheries at Lake Taihu, Jiangsu Province (2009–2010).

Recognizing the importance of its statistics on fisheries and aquaculture as a basis for its sectoral policy-making and management, as well as their major implications for global statistics, it is notable that China has continued to implement improvements to many aspects of its statistical systems, including the further use of sample-based surveys. Further improvements are in progress, including the disaggregation of primary-sector employment statistics between fisheries and aquaculture. Since 2009, improvement of statistics has been a priority for national fisheries and aquaculture development

Overall global capture fisheries production continues to remain stable at about 90 million tonnes (Table 1) although there have been some marked changes in catch trends by country, fishing area and species. In the last seven years (2004–2010), landings of all marine species except anchoveta only ranged between 72.1 million and 73.3 million tonnes. In contrast, the most dramatic changes, as usual, have been for anchoveta catches in the Southeast Pacific, which decreased from 10.7 million tonnes in 2004 to 4.2 million tonnes in 2010. A marked decrease in anchoveta catches by Peru in 2010 was largely a result of management measures (e.g. fishing closures) applied to protect the high number of juveniles present as a consequence of the La Niña event (cold water). This action paid dividends in 2011

and management, and additional funds have been allocated annually to strengthen the national and local capacity in collecting data and improving data quality through the following activities:

- training of enumerators and statistical officers from county to provincial levels;
- establishment of a qualification system for enumerators and a national database and communication network for enumerators and statistical officers overseen by an advisory expert panel;
- establishment of an Internet-based data reporting and validation system;
- development of field manuals for enumerators.

In addition to annual data collection and reporting, China has established monthly and mid-year data collection and reporting systems for important statistical indicators. Specialized institutes have been commissioned to use geographic information system (GIS) technologies to verify inland fishery and aquaculture areas. Parallel to the national data collection system, networks involving research institutions and fisheries authorities of key producing areas in the country have been established under the Chinese Academy of Fisheries Sciences to monitor aquaculture production of “staple species”.

The current data collection system in China covers capture production (by species, fishing area and fishing gear), fishing vessels, aquaculture production (by species, farming system and method), aquaculture areas, aquaculture seed production, fishery products processing, damage and losses in capture and aquaculture, employment and the fishery-dependent population, and fishery household-level economic indicators. China also collects and reports weekly wholesale fish prices for major marketing centres in all the provinces.

In recent years, communication between the Chinese reporting office and FAO has improved, resulting in more information becoming available on fish utilization, more detailed and accurate fishing fleet statistics, and disaggregation of primary-sector employment statistics between fisheries and aquaculture.

when anchoveta catches exceeded their 2009 level. Inland water capture production continued to grow continuously, with an overall increase of 2.6 million tonnes in the period 2004–2010 (Figure 3).

The Northwest Pacific is still by far the most productive fishing area. Catch peaks in the Northwest Atlantic, Northeast Atlantic and Northeast Pacific temperate fishing areas were reached many years ago, and total production had declined continuously from the early and mid-2000s, but in 2010 this trend was reversed in all three areas. As for mainly tropical areas, total catches grew in the Western and Eastern Indian Ocean and in the Western Central Pacific. In contrast, the 2010 production in the Western Central Atlantic decreased, with a reduction in United States catches by about

100 000 tonnes, probably mostly attributable to the oil spill in the Gulf of Mexico. Since 1978, the Eastern Central Pacific has shown a series of fluctuations in capture production with a cycle of about 5–9 years. The latest peak was in 2009, and a declining phase may have started in 2010. Both the Mediterranean–Black Sea and the Southwest Atlantic have seen declining catches, with decreases of 15 and 30 percent, respectively, since 2007. In the Southeast Pacific (excluding anchoveta) and the Southeast Atlantic, both areas where upwelling phenomena occur with strongly varied intensity each year, historical catch trends have been downward in both areas. In the Eastern Central Atlantic, production has increased in the last three years, but there are some reporting inconsistencies for this area.

Chilean jack mackerel catches have declined for this transboundary resource with a very wide distribution in the South Pacific, ranging from the national exclusive economic zones (EEZs) to the high seas. After having peaked at about 5 million tonnes in the mid-1990s, catches were about 2 million tonnes in the mid-2000s but have since declined abruptly, and the 2010 catches were 0.7 million tonnes, the lowest level since 1976. In contrast, Atlantic cod catches have increased by almost 200 000 tonnes in the last two years. In fact, in 2010, the whole group of gadiform species (cods, hakes, haddocks, etc.) reversed the negative trend of the previous three years in which it had declined by 2 million tonnes. Preliminary data for this group also report growing catches for 2011. Capture production of other important commercial species groups such as tunas and shrimps remained stable in 2010. The highly variable catches of cephalopods resumed growth after a decrease in 2009 of about 0.8 million tonnes. In the Antarctic areas, interest in fishing for krill resumed, and a catch increase of more than 70 percent was registered in 2010.

Total global capture production in inland waters has increased dramatically since the mid-2000s with reported and estimated total production at 11.2 million tonnes in 2010, an increase of 30 percent since 2004. Despite this growth, it may be that capture production in inland waters is seriously underestimated in some regions. Nevertheless, inland waters are considered as being overfished in many parts of the world, and human pressure and changes in the environmental conditions have seriously degraded important bodies of freshwater (e.g. the Aral Sea and Lake Chad). Moreover, in several countries that are important in terms of inland waters fishing (e.g. China), a good portion of inland catches comes from waterbodies that are artificially restocked. It is not clear to what extent improvements in the statistical coverage and stock enhancement activities may be contributing to the apparent increase in inland fishery production. Growth in the global inland water catch is wholly attributable to Asian countries. With the remarkable increases reported for 2010 production by India, China and Myanmar, Asia's share is approaching 70 percent of global production. Inland water capture production in the other continents shows different trends. Uganda and the United Republic of Tanzania, fishing mostly in the African Great Lakes, and Nigeria and Egypt, with river fisheries, remain the main producers in Africa. Catches in several South and North American countries have been reported as shrinking. Increased European production between 2004 and 2010 is all attributable to a rise of almost 50 percent in catches of the Russian Federation. Inland fishery production is marginal in countries in Oceania.

In the last three decades (1980–2010), world food fish production of aquaculture has expanded by almost 12 times, at an average annual rate of 8.8 percent. Global aquaculture production has continued to grow, albeit more slowly than in the 1980s and 1990s. World aquaculture production attained another all-time high in 2010, at 60 million tonnes (excluding aquatic plants and non-food products), with an estimated total value of US\$119 billion. When farmed aquatic plants and non-food products are included, world aquaculture production in 2010 was 79 million tonnes, worth US\$125 billion. About 600 aquatic species are raised in captivity in about 190 countries for production in farming systems of varying input intensities and technological sophistication. These include hatcheries producing seeds for stocking to the wild, particularly in inland waters.

In 2010, global production of farmed food fish was 59.9 million tonnes, up by 7.5 percent from 55.7 million tonnes in 2009 (32.4 million tonnes in 2000). Farmed food fish include finfishes, crustaceans, molluscs, amphibians (frogs), aquatic reptiles (except crocodiles) and other aquatic animals (such as sea cucumbers, sea urchins, sea squirts and jellyfishes), which are indicated as fish throughout this document. The reported grow-out production from aquaculture is almost entirely destined for human consumption. The total farmgate value of food fish production from aquaculture is estimated at US\$119.4 billion for 2010.

Aquaculture production is vulnerable to adverse impacts of disease and environmental conditions. Disease outbreaks in recent years have affected farmed Atlantic salmon in Chile, oysters in Europe, and marine shrimp farming in several countries in Asia, South America and Africa, resulting in partial or sometimes total loss of production. In 2010, aquaculture in China suffered production losses of 1.7 million tonnes caused by natural disasters, diseases and pollution. Disease outbreaks virtually wiped out marine shrimp farming production in Mozambique in 2011.

The global distribution of aquaculture production across the regions and countries of different economic development levels remains imbalanced. In 2010, the top ten producing countries accounted for 87.6 percent by quantity and 81.9 percent by value of the world's farmed food fish. Asia accounted for 89 percent of world aquaculture production by volume in 2010, and this was dominated by the contribution of China, which accounted for more than 60 percent of global aquaculture production volume in 2010. Other major producers in Asia are India, Viet Nam, Indonesia, Bangladesh, Thailand, Myanmar, the Philippines and Japan. In Asia, the share of freshwater aquaculture has been gradually increasing, up to 65.6 percent in 2010 from around 60 percent in the 1990s. In terms of volume, Asian aquaculture is dominated by finfishes (64.6 percent), followed by molluscs (24.2 percent), crustaceans (9.7 percent) and miscellaneous species (1.5 percent). The share of non-fed species farmed in Asia was 35 percent (18.6 million tonnes) in 2010 compared with 50 percent in 1980.

In North America, aquaculture has ceased expanding in recent years, but in South America it has shown strong and continuous growth, particularly in Brazil and Peru. In terms of volume, aquaculture in North and South America is dominated by finfishes (57.9 percent), crustaceans (21.7 percent) and molluscs (20.4 percent). In Europe, the share of production from brackish and marine waters increased from 55.6 percent in 1990 to 81.5 percent in 2010, driven by marine cage culture of Atlantic salmon and other species. Several important producers in Europe have recently ceased expanding or have even contracted, particularly in the marine bivalve sector. In 2010, finfishes accounted for three-quarters of all European aquaculture production, and molluscs one-quarter. Africa has increased its contribution to global production from 1.2 percent to 2.2 percent in the past ten years, mainly as a result of rapid development in freshwater fish farming in sub-Saharan Africa. African aquaculture production is overwhelmingly dominated by finfishes, with only a small fraction from marine shrimps and marine molluscs. Oceania accounts for a minor share of global aquaculture production and this consists mainly of marine molluscs and finfishes, with the latter increasing owing mainly to the development of farming of Atlantic salmon in Australia and chinook salmon in New Zealand.

The least-developed countries (LDCs), mostly in sub-Saharan Africa and in Asia, remain minor in terms of their share of world aquaculture production (4.1 percent by quantity and 3.6 percent by value) with the main producers including Bangladesh, Myanmar, Uganda, the Lao People's Democratic Republic and Cambodia. However, some developing countries in Asia and the Pacific (Myanmar and Papua New Guinea), sub-Saharan Africa (Nigeria, Uganda, Kenya, Zambia and Ghana) and South America (Ecuador, Peru and Brazil) have made rapid progress to become significant or major aquaculture producers in their regions. In contrast, in 2010, developed industrialized countries produced collectively 6.9 percent (4.1 million tonnes) by quantity and 14 percent (US\$16.6 billion) by value of the world's farmed food fish production, compared with 21.9 percent and 32.4 percent, respectively, in 1990. Aquaculture

production has contracted or stagnated in Japan, the United States of America and several European countries. An exception is Norway, where, thanks to the farming of Atlantic salmon in marine cages, aquaculture production grew from 151 000 tonnes in 1990 to more than one million tonnes in 2010.

Freshwater fishes dominate global aquaculture production (56.4 percent, 33.7 million tonnes), followed by molluscs (23.6 percent, 14.2 million tonnes), crustaceans (9.6 percent, 5.7 million tonnes), diadromous fishes (6.0 percent, 3.6 million tonnes), marine fishes (3.1 percent, 1.8 million tonnes) and other aquatic animals (1.4 percent, 814 300 tonnes). While feed is generally perceived to be a major constraint to aquaculture development, one-third of all farmed food fish production (20 million tonnes) is currently achieved without artificial feeding, as is the case for bivalves and filter-feeding carps. However, the percentage of non-fed species in world production has declined gradually from more than 50 percent in 1980 to the present level of 33.3 percent, reflecting the relatively faster body-growth rates achieved in the culture of fed species and increasing consumer demand for higher trophic-level species of fishes and crustaceans.

Fisheries and aquaculture provided livelihoods and income for an estimated 54.8 million people engaged in the primary sector of fish production in 2010, of whom an estimated 7 million were occasional fishers and fish farmers. Asia accounts for more than 87 percent of the world total with China alone having almost 14 million people (26 percent of the world total) engaged as fishers and fish farmers. Asia is followed by Africa (more than 7 percent), and Latin America and the Caribbean (3.6 percent). About 16.6 million people (about 30 percent of the world total) were engaged in fish farming, and they were even more concentrated in Asia (97 percent), followed by Latin America and the Caribbean (1.5 percent), and Africa (about 1 percent). Employment in the fisheries and aquaculture primary sector has continued to grow faster than employment in agriculture, so that by 2010 it represented 4.2 percent of the 1.3 billion people economically active in the broad agriculture sector worldwide, compared with 2.7 percent in 1990. In the last five years, the number of people engaged in fish farming has increased by 5.5 percent per year compared with only 0.8 percent per year for those in capture fisheries, although capture fisheries still accounted for 70 percent of the combined total in 2010. It is apparent that, in the most important fishing nations, the share of employment in capture fisheries is stagnating or decreasing while aquaculture is providing increased opportunities. Europe experienced the largest decrease in the number of people engaged in capture fishing, with a 2 percent average annual decline between 2000 and 2010, and almost no increase in people employed in fish farming. In contrast, Africa showed the highest annual increase (5.9 percent) in the number of people engaged in fish farming in the same period, followed by Asia (4.8 percent), and Latin America and the Caribbean (2.6 percent). Overall, production per person is lower in capture fisheries than in aquaculture, with global outputs of 2.3 and 3.6 tonnes per person per year respectively, reflecting the huge numbers of fishers engaged in small-scale fisheries.

Apart from the primary production sector, fisheries and aquaculture provide numerous jobs in ancillary activities such as processing, packaging, marketing and distribution, manufacturing of fish-processing equipment, net and gear making, ice production and supply, boat construction and maintenance, research and administration. All of this employment, together with dependants, is estimated to support the livelihoods of 660–820 million people, or about 10–12 percent of the world's population.

The total number of fishing vessels in the world in 2010 is estimated at about 4.36 million, which is similar to previous estimates. Of these, 3.23 million vessels (74 percent) are considered to operate in marine waters, with the remaining 1.13 million vessels operating in inland waters. Overall, Asia has the largest fleet, comprising 3.18 million vessels and accounting for 73 percent of the world total, followed by Africa (11 percent), Latin America and the Caribbean (8 percent), North America (3 percent) and Europe (3 percent). Globally, 60 percent of fishing vessels

were engine-powered in 2010, but although 69 percent of vessels operating in marine waters were motorized, the figure was only 36 percent for inland waters. For the fleet operating in marine waters, there were also large variations among regions, with non-motorized vessels accounting for less than 7 percent of the total in Europe and the Near East, but up to 61 percent in Africa.

Over 85 percent of the motorized fishing vessels in the world are less than 12 m in length overall (LOA). Such vessels dominate in all regions, but markedly so in the Near East, and Latin America and the Caribbean. About 2 percent of all motorized fishing vessels corresponded to industrialized fishing vessels of 24 m and larger (with a gross tonnage [GT] of roughly more than 100 GT) and that fraction was larger in the Pacific and Oceania region, Europe, and North America.

Data from some countries indicate a recent expansion in their fleets. For example, the motorized fishing fleets in Malaysia, Cambodia and Indonesia increased by 26, 19 and 11 percent, respectively, between 2007 and 2009, and Viet Nam reported a 10 percent increase in offshore fishing vessels (those with engines of more than 90 hp) between 2008 and 2010. The case of Sri Lanka illustrates potential overshoot in efforts to re-establish a fishing fleet, of which 44 percent of the motorized vessels were destroyed by the tsunami that swept the region at the end of 2004, with the result that by 2010 there were 11 percent more motorized vessels than before the tsunami.

Many countries have policies to reduce overcapacity in their fishing fleets. China's marine fishing vessel reduction plan for 2003–2010 did achieve a reduction by 2008 close to the target, but since then both the number of vessels and total combined power have started to increase again. Japan implemented various schemes that resulted in a net reduction of 9 percent in the number of vessels, but a net increase of 5 percent in combined power between 2005 and 2009. The evolution in the combined number, tonnage, and power of European Union fishing vessels indicates a downward tendency in the last decade and the combined EU-15 motorized fishing fleet achieved a net reduction of 8 percent in the number of vessels and of 11 percent in power between 2005 and 2010. Other important fishing nations that achieved a net reduction in fleet size in the period 2005–2010 include Iceland, Norway and the Republic of Korea.

The world's marine fisheries increased markedly from 16.8 million tonnes in 1950 to a peak of 86.4 million tonnes in 1996, and then declined before stabilizing at about 80 million tonnes. Global recorded production was 77.4 million tonnes in 2010. The Northwest Pacific had the highest production with 20.9 million tonnes (27 percent of the global marine catch) in 2010, followed by the Western Central Pacific with 11.7 million tonnes (15 percent), the Northeast Atlantic with 8.7 million tonnes (11 percent), and the Southeast Pacific, with a total catch of 7.8 million tonnes (10 percent). The proportion of non-fully exploited stocks has decreased gradually since 1974 when the first FAO assessment was completed. In contrast, the percentage of overexploited stocks has increased, especially in the late 1970s and 1980s, from 10 percent in 1974 to 26 percent in 1989. After 1990, the number of overexploited stocks continued to increase, albeit at a slower rate. Increases in production from these overexploited stocks may be possible if effective rebuilding plans are put in place. The fraction of fully exploited stocks, which produce catches that are very close to their maximum sustainable production and have no room for further expansion and require effective management to avoid decline, has shown the smallest change over time, with its percentage stable at about 50 percent from 1974 to 1985, then falling to 43 percent in 1989 before gradually increasing to 57 percent in 2009. About 29.9 percent of stocks are overexploited, producing lower yields than their biological and ecological potential and in need of strict management plans to restore their full and sustainable productivity in accordance with the Johannesburg Plan of Implementation that resulted from the World Summit on Sustainable Development (Johannesburg, 2002), which demands that all overexploited stocks be restored to the level that can produce maximum sustainable yield by 2015, a target that seems unlikely to be met. The remaining 12.7 percent of stocks were non-fully exploited in 2009, and these are under

relatively low fishing pressure and have some potential to increase their production although they often do not have a high production potential and require proper management plans to ensure that any increase in the exploitation rate does not result in further overfishing.

Most of the stocks of the top ten species, which account in total for about 30 percent of world marine capture fisheries production, are fully exploited and, therefore, have no potential for increases in production, while some stocks are overexploited and increases in their production may be possible if effective rebuilding plans are put in place. The two main stocks of anchoveta in the Southeast Pacific, Alaska pollock in the North Pacific and blue whiting in the Atlantic are fully exploited. Atlantic herring stocks are fully exploited in both the Northeast and Northwest Atlantic. Japanese anchovy in the Northwest Pacific and Chilean jack mackerel in the Southeast Pacific are considered to be overexploited. Chub mackerel stocks are fully exploited in the Eastern Pacific and the Northwest Pacific. The largehead hairtail was estimated in 2009 to be overexploited in the main fishing area in the Northwest Pacific.

Among the seven principal tuna species, one-third were estimated to be overexploited, 37.5 percent were fully exploited, and 29 percent non-fully exploited in 2009. Although skipjack tuna continued its increasing trend up to 2009, further expansion should be closely monitored, as it may negatively affect bigeye and yellowfin tunas (multispecies fisheries). In the long term, the status of tuna stocks (and consequently catches) may further deteriorate unless there are significant improvements in their management. This is because of the substantial demand for tuna and the significant overcapacity of tuna fishing fleets. Concern about the poor status of some bluefin stocks and the inability of some tuna management organizations to manage these stocks effectively led to a proposal in 2010 to ban the international trade in Atlantic bluefin tuna under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) and, although the proposal was ultimately rejected, the concern remains.

The overall situation when summarized by FAO statistical areas shows three main patterns in catch trends. Areas that have demonstrated oscillations in total catch are the Eastern Central Atlantic (Area 34), Northeast Pacific (Area 67), Eastern Central Pacific (Area 77), Southwest Atlantic (Area 41), Southeast Pacific (Area 87), and Northwest Pacific (Area 61). These areas have provided about 52 percent of the world's total marine catch on average in the last five years. Several of these areas include upwelling regions that are characterized by high natural variability. The second group consists of areas that have demonstrated a decreasing trend in catch since reaching a peak at some time in the past. This group has contributed 20 percent of global marine catch on average in the last five years, and includes the Northeast Atlantic (Area 27), Northwest Atlantic (Area 21), Western Central Atlantic (Area 31), Mediterranean and Black Sea (Area 37), Southwest Pacific (Area 81), and Southeast Atlantic (Area 47). It should be noted that lower catches in some cases reflect fisheries management measures that are precautionary or aim at rebuilding stocks, and this situation should, therefore, not necessarily be interpreted as negative. The third group comprises the FAO areas that have shown continuously increasing trends in catch since 1950 and includes the Western Central Pacific (Area 71), Eastern (Area 57) and Western (Area 51) Indian Ocean. They have together contributed 28 percent of the total marine catch on average over the last five years. However, in some regions, there is still high uncertainty about the actual catches owing to the poor quality of statistical reporting systems in coastal countries.

The declining global marine catch over the last few years together with the increased percentage of overexploited fish stocks and the decreased proportion of non-fully exploited species around the world convey the strong message that the state of world marine fisheries is worsening and has had a negative impact on fishery production. Overexploitation not only causes negative ecological consequences, but it also reduces fish production, which further leads to negative social and economic consequences. To increase the contribution of marine fisheries to the food security,

economies and well-being of the coastal communities, effective management plans must be put in place to rebuild overexploited stocks. The situation seems more critical for some highly migratory, straddling and other fishery resources that are exploited solely or partially in the high seas. The United Nations Fish Stocks Agreement that entered into force in 2001 should be used as a legal basis for management measures of the high seas fisheries.

In spite of the worrisome global situation of marine capture fisheries, good progress is being made in reducing exploitation rates and restoring overexploited fish stocks and marine ecosystems through effective management actions in some areas. In the United States of America, 67 percent of all stocks are now being sustainably harvested, while only 17 percent are still overexploited. In New Zealand, 69 percent of stocks are above management targets, reflecting mandatory rebuilding plans for all fisheries that are still below target thresholds. Similarly, Australia reports overfishing for only 12 percent of stocks in 2009. Since the 1990s, the Newfoundland–Labrador Shelf, the Northeast United States Shelf, the Southern Australian Shelf, and California Current ecosystems have shown substantial declines in fishing pressure such that they are now at or below the modelled exploitation rate that gives the multispecies maximum sustainable yield of the ecosystem. These and other successes can serve as examples to assist in more effective management of other fisheries.

The information summarizing the state of the major marine fish stocks is impossible to duplicate for the state of most of the world's inland fisheries, for which the exploitation rate is often not the main driver affecting the state of the stocks. Other drivers such as habitat quantity and quality, aquaculture in the form of stocking and competition for freshwater, influence the state of the majority of inland fishery resources much more than exploitation rates do. Water abstraction and diversion, hydroelectric development, draining wetlands, and siltation and erosion from land-use patterns can negatively affect inland fishery resources regardless of the rate of exploitation. Conversely, stock enhancement from aquaculture facilities, which is widely practised in inland waters, can keep catch rates high in the face of increased fishing and in spite of an ecosystem that is not capable of producing that level of catch through natural processes. Overexploitation also affects inland fishery resources, but the result is generally a change in species composition and not necessarily a reduced overall catch. Catches are often higher where smaller and shorter-lived species become the main component of the catch; however, the smaller fish may be much less valuable. Another issue complicating the assessment of inland fishery resources is the definition of a "stock". Very few inland fisheries have stocks that are defined precisely or are defined at the level of species. There are notable exceptions such as the Lake Victoria Nile perch and Tonle Sap dai fisheries, but many inland fishery resources are defined by watershed or river and comprise numerous species. Taking all of these considerations into account, FAO is leading efforts to improve data collection and develop new assessment methodologies for inland fishery resources that are so important but often underestimated in terms of their economic, social and nutritional benefits and contribution to livelihoods and food security. The intention is to utilize the new methodology to provide a more robust and informative summary of the state of the world's inland capture fishery resources in the future.

Concerning utilization of the world's fish production, 40.5 percent (60.2 million tonnes) was marketed in live, fresh or chilled forms, 45.9 percent (68.1 million tonnes) was processed in frozen, cured or otherwise prepared forms for direct human consumption, and 13.6 percent destined for non-food uses in 2010. Since the early 1990s, there has been an increasing trend in the proportion of fisheries production used for direct human consumption rather than for other purposes. Whereas in the 1980s about 68 percent of the fish produced was destined for human consumption, this share increased to more than 86 percent in 2010, equalling 128.3 million tonnes. In 2010, 20.2 million tonnes was destined to non-food purposes, of which 75 percent (15 million tonnes) was reduced to fishmeal and fish oil; the remaining 5.1 million tonnes was largely utilized as fish for ornamental purposes, for culture (fingerlings,

fry, etc.), for bait, for pharmaceutical uses as well as for direct feeding in aquaculture, for livestock and for fur animals. Of the fish destined for direct human consumption, the most important product form was live, fresh or chilled fish, with a share of 46.9 percent in 2010, followed by frozen fish (29.3 percent), prepared or preserved fish (14.0 percent) and cured fish (9.8 percent). Freezing represents the main method of processing fish for human consumption, and it accounted for 55.2 percent of total processed fish for human consumption and 25.3 percent of total fish production in 2010.

The proportion of frozen fish grew from 33.2 percent of total production for human consumption in 1970 to reach a record high of 52.1 percent in 2010. The share of prepared and preserved forms remained rather stable during the same period, and it was 26.9 percent in 2010. Developing countries have experienced a growth in the share of frozen products (24.1 percent of the total fish for human consumption in 2010, up from 18.9 percent in 2000) and of prepared or preserved forms (11.0 percent in 2010, compared with 7.8 percent in 2000). Owing to deficiencies in infrastructure and processing facilities, together with well-established consumer habits, fish in developing countries is commercialized mainly in live or fresh form (representing 56.0 percent of fish destined for human consumption in 2010) soon after landing or harvesting. Cured forms (dried, smoked or fermented) still remain a traditional method to retail and consume fish in developing countries, although their share in total fish for human consumption is declining (10.9 percent in 2000 compared with 8.9 percent in 2010). In developed countries, the bulk of production destined for human consumption is commercialized frozen or in prepared or preserved forms.

Fishmeal is produced from whole fish or fish remains resulting from processing. Small pelagic species, in particular anchoveta, are the main contributors for reduction, and the volume of fishmeal and fish oil produced worldwide fluctuates annually according to the fluctuations in the catches of these species, which are strongly influenced by the El Niño phenomenon. Fishmeal production peaked in 1994 at 30.2 million tonnes (live weight equivalent) and has followed a fluctuating trend since then. In 2010, it dropped to 15.0 million tonnes owing to reduced catches of anchoveta, representing a decrease of 12.9 percent compared with 2009, of 18.2 percent compared with 2008, and of 42.8 percent with respect to 2000. Waste from commercial fish species used for human consumption is increasingly used in feed markets, and a growing percentage of fishmeal is being obtained from trimmings and other residues from the preparation of fish fillets. About 36 percent of world fishmeal production was obtained from offal in 2010.

Technological development in food processing and packaging is progressing rapidly. Processors of traditional products have been losing market share as a result of long-term shifts in consumer preferences as well as in processing and in the general fisheries industry. Processing is becoming more intensive, geographically concentrated, vertically integrated and linked with global supply chains. These changes reflect the increasing globalization of the fisheries value chain, with large retailers controlling the growth of international distribution channels. The increasing practice of outsourcing processing at the regional and world levels is very significant, but further outsourcing of production to developing countries might be restricted by sanitary and hygiene requirements that are difficult to meet as well as by growing labour costs. At the same time, processors are frequently becoming more integrated with producers, especially for groundfish, where large processors in Asia, in part, rely on their own fleet of fishing vessels. In aquaculture, large producers of farmed salmon, catfish and shrimp have established advanced centralized processing plants. Processors that operate without the purchasing or sourcing power of strong brands are also experiencing increasing problems linked to the scarcity of domestic raw material, and they are being forced to import fish for their business.

Fish and fishery products continue to be among the most traded food commodities worldwide, accounting for about 10 percent of total agricultural exports and 1 percent of world merchandise trade in value terms. The share of total fishery production exported in the form of various food and feed items increased from 25 percent in 1976

to about 38 percent (57 million tonnes) in 2010. In the same period, world trade in fish and fishery products grew significantly also in value terms, rising from US\$8 billion to US\$102 billion. Sustained demand, trade liberalization policies, globalization of food systems and technological innovations have furthered the overall increase in international fish trade. In 2009, reflecting the general economic contraction affecting consumer confidence in major markets, trade dropped by 6 percent compared with 2008 in value terms as a consequence of falling prices and margins, whereas traded volumes, expressed in live weight equivalent, increased by 1 percent to 55.7 million tonnes. In 2010, trade rebounded strongly, reaching about US\$109 billion, with an increase of 13 percent in value terms and 2 percent in volume compared with 2009. The difference between the growth in value and volume reflects the higher fish prices experienced in 2010 as well as a decrease in the production of and trade in fishmeal. In 2011, despite the economic instability experienced in many of the world's leading economies, increasing prices and strong demand in developing countries pushed trade volumes and values to the highest level ever reported and, despite some softening in the second half of the year, preliminary estimates indicate that exports exceeded US\$125 billion.

Since late 2011 and early 2012, the world economy has entered a difficult phase characterized by significant downside risks and fragility, and key markets for fisheries trade have slowed sharply. Among the factors that might influence the sustainability and growth of fishery trade are the evolution of production and transportation costs and the prices of fishery products and alternative commodities, including meat and feeds. In the last few decades, the growth in aquaculture production has contributed significantly to increased consumption and commercialization of species that were once primarily wild-caught, with a consequent price decrease, particularly in the 1990s and early 2000, with average unit values of aquaculture production and trade declining in real terms. Subsequently, owing to increased costs and continuous high demand, prices have started to rise again. In the next decade, with aquaculture accounting for a much larger share of total fish supply, the price swings of aquaculture products could have a significant impact on price formation in the sector overall, possibly leading to more volatility.

As for trade, fish prices also contracted in 2009 but have since rebounded. The FAO Fish Price Index (base year 2002–04 = 100) indicates that average prices in 2009 declined by 7 percent compared with 2008, then increased by 9 percent in 2010 and by more than 12 percent in 2011. Prices for species from capture fisheries increased by more than those for farmed species because of the larger impact from higher energy prices on fishing vessel operations than on farmed species.

Since 2002, China has been by far the leading fish exporter, contributing almost 12 percent of 2010 world exports of fish and fishery products, or about US\$13.3 billion, and increasing further to US\$17.1 billion in 2011. A growing share of fishery exports consists of reprocessed imported raw material. Thailand has established itself as a processing centre of excellence largely dependent on imported raw material, while Viet Nam has a growing domestic resource base and imports only limited, albeit growing, volumes of raw material. Viet Nam has experienced significant growth in its exports of fish and fish products, up from US\$1.5 billion in 2000 to US\$5.1 billion in 2010, when it became the fourth-largest exporter in the world. In 2011, its exports rose further to US\$6.2 billion, linked mainly to its flourishing aquaculture industry. In 2010, developing countries confirmed their fundamental importance as suppliers to world markets with more than 50 percent of all fishery exports in value terms and more than 60 percent in quantity (live weight). For many developing nations, fish trade represents a significant source of foreign currency earnings in addition to the sector's important role as a generator of income, source of employment, and provider of food security and nutrition. The fishery industries of developing countries rely heavily on developed countries, not only as outlets for their exports, but also as suppliers of their imports for local consumption or for their processing industries. In 2010, in value terms, 67 percent of the fishery exports of developing countries were directed to developed countries. A

growing share of these exports consisted of processed fishery products prepared from imports of raw fish to be used for further processing and re-export. In 2010, in value terms, 39 percent of the imports of fish and fishery products by developing countries originated from developed countries. For LIFDCs, net export revenues amounted to US\$4.7 billion in 2010, compared with US\$2.0 billion in 1990.

World imports² of fish and fish products set a new record at US\$111.8 billion in 2010, up 12 percent on the previous year and up 86 percent with respect to 2000. Preliminary data for 2011 point to further growth, with a 15 percent increase. The United States of America and Japan are the major importers of fish and fishery products and are highly dependent on imports for about 60 percent and 54 percent, respectively, of their fishery consumption. China, the world's largest fish producer and exporter, has significantly increased its fishery imports, partly a result of outsourcing, as Chinese processors import raw material from all major regions, including South and North America and Europe, for re-processing and export. Imports are also being fuelled by robust domestic demand for species not available from local sources, and, in 2011, China became the third-largest importer in the world. The European Union is by far the largest single market for imported fish and fishery products owing to its growing domestic consumption. However, it is extremely heterogeneous, with markedly different conditions from country to country. European Union fishery imports reached US\$44.6 billion in 2010, up 10 percent from 2009, and representing 40 percent of total world imports. However, if intraregional trade is excluded, the European Union imported fish and fishery products worth US\$23.7 billion from suppliers outside the European Union, an increase of 11 percent from 2009. In addition to the major importing countries, a number of emerging markets have become of growing importance to the world's exporters. Prominent among these there are Brazil, Mexico, the Russian Federation, Egypt, Asia and the Near East in general. In 2010, developed countries were responsible for 76 percent of the total import value of fish and fishery products, a decline compared with the 86 percent of 1990 and 83 percent of 2000. In terms of volume (live weight equivalent), the share of developed countries is significantly less, 58 percent, reflecting the higher unit value of products imported by developed countries.

Owing to the high perishability of fish and fishery products, 90 percent of trade in fish and fishery products in quantity terms (live weight equivalent) consists of processed products. Fish are increasingly traded as frozen food (39 percent of the total quantity in 2010, compared with 25 percent in 1980). In the last four decades, prepared and preserved fish have nearly doubled their share in total quantity, going from 9 percent in 1980 to 16 percent in 2010. However, trade in live, fresh and chilled fish represented 10 percent of world fish trade in 2010, up from 7 percent in 1980, reflecting improved logistics and increased demand for unprocessed fish. Trade in live fish also includes ornamental fish, which is high in value terms but almost negligible in terms of quantity traded. In 2010, 71 percent of the quantity of fish and fishery products exported consisted of products destined for human consumption. The US\$109 billion exports of fish and fishery products in 2010 do not include an additional US\$1.3 billion for aquatic plants (62 percent), inedible fish waste (31 percent) and sponges and corals (7 percent). In the last two decades, trade in aquatic plants has increased significantly, rising from US\$0.2 billion in 1990 to US\$0.5 billion in 2000 and to US\$0.8 billion in 2010, with China as the major exporter and Japan as the leading importer.

A recent major event related to governance of fisheries and aquaculture has been the UN Conference on Sustainable Development, known as Rio+20, to renew political commitment for sustainable development, assess progress and gaps in the implementation of existing commitments, and address new challenges. The two themes of the conference were the institutional framework for sustainable development and the support of a green economy. As a concept, the green economy aims to ensure that resource exploitation contributes to sustainability, inclusive social development and economic growth, while seeking to counter the notion that sustainability and growth are mutually exclusive.

At Rio+20, FAO promoted the message that there will be no green economy without sustainable growth in agriculture (including fisheries) and that improved management and efficiencies throughout the food value chain can increase food security while using fewer natural resources. The message calls for policies that create incentives to adopt sustainable practices and behaviour and promotes the wide application of ecosystem approaches. FAO also contributed to interagency submissions to Rio+20 concerning the sustainable management of the world's oceans with a focus on the green economy as it relates to marine and coastal resources, sustainable use and poverty eradication, small-scale fisheries and aquaculture operations, and the potential contribution of small island developing States.

The dependence of the fisheries and aquaculture sectors on ecosystem services means that supporting sustainable fishing and fish farming can provide incentives for wider ecosystem stewardship. The greening of fisheries and aquaculture requires recognition of their wider societal roles within a comprehensive governance framework. There are several mechanisms to facilitate this transition, including adopting an ecosystem approach to fisheries and aquaculture with fair and responsible tenure systems to turn resource users into resource stewards.

Small-scale fisheries employ more than 90 percent of the world's capture fishers, and their importance to food security, poverty alleviation and poverty prevention is becoming increasingly appreciated. However, the lack of institutional capacity and the failure to include the sector in national and regional development policies hamper their potential contribution. Since 2003, the FAO Committee on Fisheries (COFI) has promoted efforts to improve the profile of, and understand the challenges and opportunities facing, small-scale fishing communities in inland and marine waters. It has also recommended the development of international voluntary guidelines to complement the Code of Conduct for Responsible Fisheries (the Code) as well as other international instruments with similar purposes. The preparation of the guidelines is expected to contribute to policy development and have considerable impact on securing small-scale fisheries and creating benefits, especially in terms of food security and poverty reduction. The guidelines promote good governance, including transparency and accountability, participation and inclusiveness, social responsibility and solidarity, a human rights approach to development, gender equality, and respect and involvement of all stakeholders.

Regional fishery bodies (RFBs) are the primary organizational mechanism through which States work together to ensure the long-term sustainability of shared fishery resources. The term RFB also embraces regional fisheries management organizations (RFMOs), which have the competence to establish binding conservation and management measures. As intergovernmental organizations, RFBs depend on the political will of their member Governments to implement agreed measures and undertake reform. Most RFBs are experiencing difficulties in fulfilling their mandates (many of which are outdated). However, important progress in extending the global coverage of RFBs is being made through new, strengthened and emerging bodies. In addition, numerous RFBs have been undergoing independent reviews of their performance. The 2010 United Nations Review Conference described the modernizing of RFMOs as a priority and noted that progress had been made in developing best practices for RFMOs and in reviewing their performance against emerging standards. Ten RFBs have so far undergone performance reviews. The Review Conference observed that performance reviews were generally recognized as being useful, particularly when they led to the adoption of new management measures.

Illegal, unreported and unregulated (IUU) fishing and related activities (often encouraged by corrupt practices) threaten efforts to secure long-term sustainable fisheries and promote healthier and more robust ecosystems. The international community continues to express its grave concern at the extent and effects of IUU fishing. Developing countries, often with limited technical capacity, bear the brunt of this IUU fishing, which undermines their limited efforts to manage fisheries, denies them revenue and adversely affects their attempts to promote food security, eradicate

poverty and achieve sustainable livelihoods. However, there are indications that IUU fishing is moderating in some areas (e.g. the Northeast Atlantic Ocean) as policies and measures take effect.

Nonetheless, the international community is deeply frustrated by the failure of many flag States to meet their primary responsibilities under international law, which are to exercise effective control over their fishing vessels and ensure compliance with conservation and management measures. Of particular concern are those vessels flying flags of "non-compliance", which are flags belonging to States that are either unable or unwilling to exercise effective control over their vessels. As a result, the burden of controlling these rogue vessels is gradually falling on coastal States, port States, RFBs and others. This has led FAO Members to request that a Technical Consultation on Flag State Performance be convened. It is anticipated that the outcome will be a set of voluntary criteria for assessing the performance of flag States together with a list of possible actions to be taken against vessels flying the flags of States not meeting such criteria and possibly an agreed procedure for assessing compliance.

Although their achievements in terms of limiting IUU fishing vary widely, most RFBs promote and implement measures to combat IUU fishing. The measures range from more passive activities such as awareness building and dissemination of information (mainly RFBs without fisheries management functions) to aggressive port, air and surface surveillance programmes (RFMOs).

Beyond national boundaries, there is increasing need for international cooperation to improve global fisheries management of shared marine resources and to preserve the associated employment and other economic benefits of sustainable fisheries. Recognizing this, the European Union and the United States of America, as leaders in the global fish trade, undertook (in 2011) to cooperate bilaterally to combat IUU fishing by keeping illegally caught fish out of the world market. Strengthening fisheries management capacity is fundamental in developing countries in order to facilitate sustainable fisheries and to reduce the impacts of IUU fishing. Capacity development is especially important to support the full and effective implementation of existing and new global instruments such as the 2009 Port State Measures Agreement to combat IUU fishing.

Governance of aquaculture has become increasingly important and has made remarkable progress. To improve planning and policy development in aquaculture, many Governments utilize the Code as well as FAO guidelines and manuals on farming techniques promoted by industry organizations and development agencies. Several countries have adequate national aquaculture development policies, strategies, plans and laws, and use "best management practices". The insert: 2011 FAO Technical Guidelines on Aquaculture Certification constitute an additional important tool for good governance of the sector. By setting minimum substantive criteria for developing aquaculture certification standards, these guidelines provide direction for the development, organization and implementation of credible aquaculture certification schemes towards orderly and sustainable development of the sector. Long-term prosperity requires technological soundness, economic viability, environmental integrity and social licence, which, in combination, also ensure that ecological well-being is compatible with human well-being.

An important component of human well-being is employment, which in aquaculture has grown rapidly in the last three decades. More than 100 million people now depend on the sector for a living, either as employees in the producing and support sectors or as their dependants. In many places, these employment opportunities have enabled young people to stay in their communities and have strengthened the economic viability of isolated areas, often enhancing the status of women in developing countries, where more than 80 percent of aquaculture output occurs. Aquaculture has been heavily promoted in several countries with fiscal and monetary incentives and this has improved accessibility to food for many households and increased aquaculture's contribution towards the Millennium Development Goals (MDGs). However, the sector has developed at a time of growing scrutiny from

the public, improved communications and vociferous opposition groups. Although opposition groups can act as environmental and social watchdogs, putting pressure on businesses to increase transparency and improve working conditions, it is also important to consider the benefits accruing from the sector, including those related to employment.

Unfair employment practices in aquaculture, including exploitation of local labour, gender discrimination and child employment, can undermine trust in the sector, threaten the credibility of policy-makers and jeopardize markets for farmed seafood. Most countries have legislation to protect workers but compliance therewith can deter enterprises, with some opting to operate in countries with lower labour and social standards where they can gain a competitive advantage. A possible result is that Governments will be under pressure from companies to reduce labour and social standards.

Employment in aquaculture must be equitable and non-exploitative, with principled values guiding activities to induce beyond-compliance behaviour. With an ethos of corporate social responsibility, aquaculture companies would assist local communities, employ fair labour practices and demonstrate transparency. Increasingly, with rising consumer awareness, it makes good business sense for aquaculture enterprises to demonstrate that they meet the best standards. Legislation should protect labour and reflect concepts of social justice and human rights, but it needs to strike a balance as overly cumbersome regulations can make an otherwise viable business unprofitable.

CAPTURE FISHERIES PRODUCTION

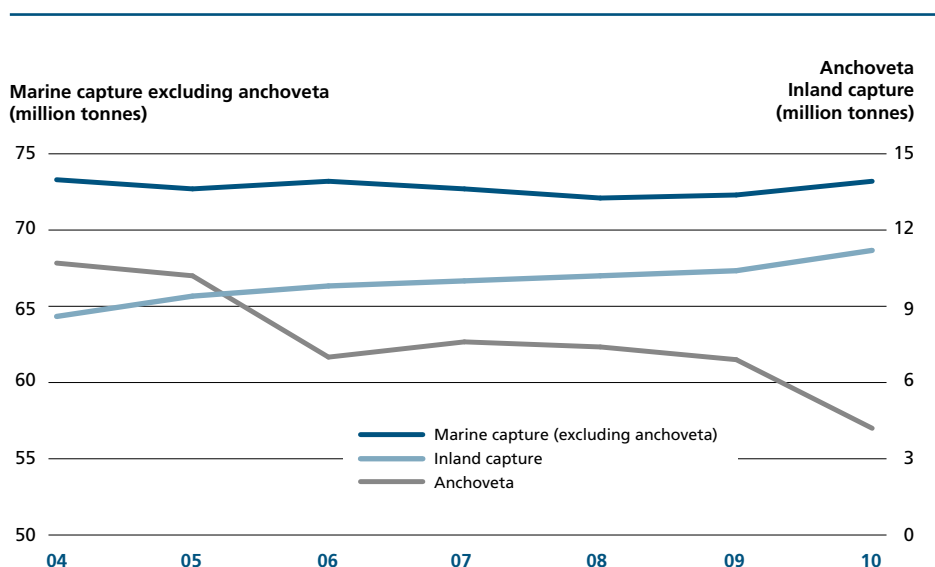

Total capture fisheries production

Overall global capture fisheries production, as derived from the FAO capture database, continues to remain stable (Table 1). This does not mean that there are no changes in catch trends by country, fishing area or species, which indeed do vary significantly throughout the years, but rather that the summation of all the annual fluctuations has been close to zero in recent years.

To analyse trends, global production can be separated into three major components: marine catches excluding anchoveta (*Engraulis ringens*); anchoveta catches; and inland water catches (Figure 4). In the last seven years (2004–2010) for

Figure 4

Recent capture fisheries production by three major components

which detailed catch statistics are available, absolute variations in comparison with the previous year of total marine catches excluding anchoveta never exceeded 1.2 percent, ranging between 72.1 and 73.3 million tonnes. However, anchoveta catches decreased from 10.7 million tonnes in 2004 to 4.2 million tonnes in 2010, and the variation on the previous year exceeded 30 percent in two cases. In the same period, inland water capture production grew continuously, with an overall increase of 2.6 million tonnes (see below).

A marked decrease in anchoveta catches by Peru in 2010 was mostly due to management measures (e.g. fishing closures) that were applied in the final quarter to protect the high number of juveniles present in the anchoveta stock as a consequence of the La Niña event (cold water), which had favoured spawning and generated a good recruitment. Thanks to this precautionary management decision, the 2011 anchoveta catches exceeded their 2009 level. Other preliminary reports from important fishing countries (e.g. the Russian Federation) show that 2011 should have been a year of increased catches. However, Japanese fishery production will probably have dropped significantly as the five prefectures hit by the earthquake and tsunami of 11 March 2011 accounted for about 21 percent of Japan's total marine fisheries and aquaculture production. Overall, preliminary information suggests that the total 2011 global catch should exceed 90 million tonnes, marking a return to 2006–07 levels (Table 1).

Notwithstanding the protracted global economic downturn, which has reduced the funds available to national administrations, the submission rates of 2009 and 2010 catch data to FAO have remained reasonably stable. However, it is well known that the quality of fishery data is very uneven among countries. An evaluation³ of data quality in capture statistics submitted to FAO found that more than half of the countries reported inadequately. This percentage was greater for developing countries, but also about one-fourth of reports by developed countries were not satisfactory. Countries that should improve their data collection and reporting systems are mainly found in Africa, Asia and among the island States in Oceania and the Caribbean (Table 2).

World marine capture fisheries production

With the great decrease in anchoveta catches, Peru is no longer second after China in the ranking of the major marine producer countries in terms of quantity as it has been surpassed by Indonesia and the United States of America. Some major Asian fishing countries (i.e. China, India, Indonesia, Myanmar and Viet Nam) reported significant increases in 2010, but also other countries (i.e. Norway, the Russian Federation and

Table 2
Countries or territories with no adequate 2009 catch data submission

	Countries	Countries with no adequate submission	Percentage
	(Number)	(Number)	(%)
Developed	54	13	24.1
Developing	164	100	61.0
Africa	54	33	61.1
North America	37	18	48.6
South America	14	5	35.7
Asia	51	31	60.8
Europe	39	8	20.5
Oceania	23	18	78.3
Total	218	113	51.8

Source: Garibaldi, L. 2012. The FAO global capture production database: a six-decade effort to catch the trend. *Marine Policy*, 36(3): 760–768.

Spain) fishing in other areas and with more robust data collection systems showed growing catches after some years of sluggish production.

In particular, catches reported by the Russian Federation have grown by more than one million tonnes since the low point of 2004. According to the authorities of the Russian Federation, the recent increase is also a consequence of the management decision to remove excessive formalities on documentation of landing operations, as up until early 2010 landings by vessels of the Russian Federation in national ports were treated as imports. Moreover, an official forecast of the Russian Federation indicates further catch increases to a level of 6 million tonnes in 2020, representing an increase of more than 40 percent above present levels.

Besides decreased production by Peru and Chile as a consequence of the drop in anchoveta catches, other major fishing countries with downward trends in total marine catches in 2009 and 2010 were: Japan, the Republic of Korea, and Thailand in Asia; Argentina, Canada and Mexico in the Americas; Iceland in Europe; and to a lesser extent New Zealand. Despite variable trends, Morocco, South Africa and Senegal maintained their positions as the three major marine producers in Africa.

The Northwest Pacific is still by far the most productive fishing area. Catch peaks in the Northwest Atlantic, Northeast Atlantic and Northeast Pacific temperate fishing areas were reached many years ago (in 1968, 1976 and 1987, respectively) and total production had declined continuously from the early and mid-2000s, but in 2010 this trend was reversed in all three areas.

As for mainly tropical areas, total catches grew in the Western and Eastern Indian Ocean and in the Western Central Pacific, and, in the last two, 2010 marked a new maximum. In contrast, the 2010 production in the Western Central Atlantic decreased, driven by the reduction in United States catches by about 100 000 tonnes, probably mostly attributable to the oil spill in the Gulf of Mexico. Since 1978, the Eastern Central Pacific has shown a series of fluctuations in capture production with a cycle of about 5–9 years. The latest peak was in 2009, and a declining phase may have started in 2010.

Both the Mediterranean–Black Sea and the Southwest Atlantic seem to be areas where fisheries are in trouble as, since 2007, total catches have decreased by 15 and 30 percent, respectively. In the two areas along the southwest sides of America and Africa, upwelling phenomena occur, although their intensity varies strongly each year. In 2010, catches in the Southeast Pacific (excluding anchoveta) decreased whereas in the Southeast Atlantic they grew, but examination of historical trends from an earlier period reveals clear downward trajectories in both areas.

Finally, in the Eastern Central Atlantic, production has increased in the last three years. However, in this area, total capture production is significantly influenced by the activities of distant-water fleets and whether their catches are reported only by the flag States or also complemented with information by some coastal countries that register foreign fleet catches in their EEZ but only make these data available to FAO intermittently.

As noted above, annual catches by fishing area, country and in particular by species very often fluctuate considerably, but all these variations combined seem to have a counterbalancing effect on the global total. A demonstration of this is that catches of more than 60 percent of the species varied by more than 10 percent in comparison with 2009 but the global total (excluding anchoveta) changed by only 1.2 percent.

It is well documented⁴ that fish populations show large fluctuations in abundance, also in the absence of fishing. Although the causes are well known for some species (e.g. anchoveta – driven by changing environmental regimes), they remain unknown for many others. Besides fishes, such variations also occur in other commercial groups of species. For example, Argentina started industrial-level exploitation of *Pleoticus muelleri*, a high-value shrimp, in the 1980s. However, this species showed a major drop in 2005. Facing much reduced catches, the national authorities implemented management plans to help the species to recover. After six years, catches had rebounded tenfold reaching a new maximum recorded level in 2011 (Figure 5).

Figure 5

Catch trend for Argentine red shrimp

Despite the decreased 2010 catches, anchoveta is again the most-caught species. However, also in the presence of future favourable environmental regimes, yearly catches of this species should not attain the past peaks as the Government of Peru has introduced an annual quota for the whole country, subdivided by vessel, with the purpose of stabilizing the capacity of both the fleet and processing plants.

In the list of top ten species, the most evident change is the disappearance from the list of the Chilean jack mackerel (*Trachurus murphyi*), which had been sixth in 2008. This species is a transboundary resource with a very wide distribution in the South Pacific, ranging from the national EEZs to the high seas. After having peaked at about 5 million tonnes in the mid-1990s, catches were about 2 million tonnes in the mid-2000s but have since declined abruptly, and the 2010 catches were 0.7 million tonnes, the lowest level since 1976. Atlantic cod (*Gadus morhua*) has returned to the list, with a total increase of almost 200 000 tonnes in the last two years to rank tenth in 2010, a position not reached since 1998. In fact, in 2010, the whole group of gadiform species (cods, hakes, haddocks, etc.) reversed the negative trend of the previous three years in

Figure 6

Catch trends for marine bivalve species groups

which it had declined by 2 million tonnes. Preliminary data for this group also report growing catches for 2011.

Capture production of other important commercial species groups such as tunas and shrimps remained stable in 2010. The highly variable catches of cephalopods resumed growth after a decrease in 2009 of about 0.8 million tonnes. In the Antarctic areas, interest in fishing for krill resumed and a catch increase of more than 70 percent was registered in 2010.

Of the four marine bivalve groups (Figure 6), clams and cockles, which in the early 1990s contributed more than half of the overall bivalve catches, have recently accelerated their rate of decline. In 2009–2010, they were largely surpassed by scallops, which in contrast have shown a rising trend since the late 1990s. Capture production of mussels and oysters, for which reporting countries often have difficulty in separating harvest of natural populations from aquaculture production, has not varied much over the years, but an overall downward trend can be noted.

World inland capture fisheries production

Total global capture production in inland waters has increased dramatically since the mid-2000s (Figure 3). Total production, as submitted by countries and as estimated by FAO in cases of non-reporting, amounted to 11.2 million tonnes in 2010, an increase of 30 percent since 2004. Despite this growth, there are still claims that global production is much greater as some studies⁵ have pointed out that capture production in inland waters is seriously underestimated in some regions. However, the little well-documented evidence available concerns a limited number of countries. On the other hand, inland waters are considered as being overfished⁶ in many parts of the world, and human pressure and changes in the environmental conditions have seriously degraded important bodies of freshwater (e.g. the Aral Sea, and Lake Chad). Moreover, in several countries that are important in terms of inland waters fishing (e.g. China), a good portion of inland catches comes from waterbodies that are artificially restocked and closely monitored and, hence, it is probable that production is recorded quite carefully. Therefore, both improvements in the statistical coverage and stock enhancement activities may be contributing to the apparent increase in inland fishery production.

A closer look at the statistics shows that the growth in the global inland water catch is wholly attributable to Asian countries (Table 3). With the remarkable increases reported for 2010 production by India (up 0.54 million tonnes on 2009) and by China and Myanmar (up 0.1 million tonnes each), Asia's share is approaching 70 percent of global production. Considerable increases by some major Asian countries have seriously influenced the global total in recent years but, in some cases, they seem to be

Table 3
Inland capture fisheries production by continent and major producer

Continent/country	2004	2010	Variation 2004–2010	
	(Tonnes)	(Tonnes)	(Tonnes)	(Percentage)
Asia	5 376 670	7 696 520	2 319 850	43.1
China	2 097 167	2 289 343	192 176	9.2
India	527 290	1 468 757	941 467	178.5
Bangladesh	732 067	1 119 094	387 027	52.9

World total	8 642 262	11 211 200	2 568 938	29.7

consequences of a tendency to report continuously increasing catches or of changes in the national data collection system.

For example, until 2009, the calculation of inland catches by Bangladesh was linked to the population increase and, as a consequence, total production grew by 67 percent between 2004 and 2009. Production reported by Myanmar has quadrupled in the last decade, increasing at an average growth rate of almost 18 percent per year, gaining 11 positions in the global ranking of major producer countries, and exceeding one million tonnes in 2010. The gathering of India's catch statistics is complex as the Ministry of Agriculture has to receive and assemble data from 28 states, which often have different systems of collecting and reporting data. It is very difficult to discern whether the dramatic growth (179 percent) in inland catches between 2004 and 2010 is ascribable to a real increase, to overestimation or to improvement in the data collection system of some of these states.

Inland water capture production in the other continents shows different trends. Uganda and the United Republic of Tanzania, fishing mostly in the African Great Lakes, and Nigeria and Egypt, with river fisheries, remain the main producers in Africa. Catches in several South American countries (e.g. Argentina, Colombia, Paraguay and Venezuela [Bolivarian Republic of]) as well as in North American ones have been reported as shrinking. Increased European production between 2004 and 2010 is all attributable to a rise of almost 50 percent in catches of the Russian Federation. Inland fishery production is marginal in countries in Oceania.

More than half of the global inland water capture production is still reported as "catches unidentified by species". However, in recent years, several countries have made efforts to improve the quality of their inland catch statistics and collect data at a finer species breakdown. In the last ten years, the increase in inland water species with statistics in the FAO database has been five times that for marine species (Table 4). Moreover, the percentage of inland water species in total species has improved, reaching 12.3 percent in 2010 – a value very close to the share (12.7 percent) of inland water catches in global catches in that year.

AQUACULTURE

Global aquaculture production has continued to grow in the new millennium, albeit more slowly than in the 1980s and 1990s. In the course of half a century or so, aquaculture has expanded from being almost negligible to fully comparable with capture production in terms of feeding people in the world (see below). Aquaculture has also evolved in terms of technological innovation and adaptation to meet changing requirements.

World aquaculture production attained another all-time high in 2010, at 60 million tonnes (excluding aquatic plants and non-food products), with an estimated

Table 4
Number of species items with statistics in the FAO capture database

	2001	2010	Variation 2001–2010
	(Number)	(Number)	(Percentage)
Inland water fish, crustaceans and molluscs	113	190	68.1
Marine and diadromous fish, crustaceans and molluscs	1 194	1 356	13.6
Total species items	1 307	1 546	18.3
Share of inland water species on total species	8.6%	12.3%	

total value of US\$119 billion. One-third of the world's farmed food fish harvested in 2010 was achieved without the use of feed, through the production of bivalves and filter-feeding carps. When farmed aquatic plants and non-food products are included, world aquaculture production in 2010 was 79 million tonnes, worth US\$125 billion.

About 600 aquatic species are raised in captivity worldwide for production in a variety of farming systems and facilities of varying input intensities and technological sophistication, using freshwater, brackish water and marine water. Aquaculture also contributes substantially, with hatchery-produced seeds for stocking, to culture-based capture fishery production, particularly in inland waters.

However, the stage of development and the distribution of aquaculture production remain imbalanced in all regions. A few developing countries in Asia and the Pacific, sub-Saharan Africa and South America have made considerable progress in aquaculture development in recent years and they are becoming significant or major producers in their respective regions. However, the disparity remains huge across the continents and georegions, as well as among countries of comparable natural conditions in the same region, with aquaculture in many of the LDCs yet to make a significant contribution to national food and nutrition security.

In 2010, FAO recorded 181 countries and territories with aquaculture production, and 9 countries and territories not reporting production in 2010 but with production recorded previously. Of these 190 countries and territories, about 30 percent of them, including a few major producers in Asia and Europe, had failed to report any statistics on national aquaculture production even a year after the 2010 reference year. Less than 30 percent of them were able to report national data covering grow-out production broken down by culture environment and farming method or in terms of seed production and culture areas and facilities. More than 40 percent of them reported national data in varying degrees of completeness, data quality and timeliness of reporting. To compensate for such gaps, FAO made estimates using information available from additional sources where possible.

Global statistics are still lacking on: (i) non-food aquaculture production, including live bait for fishing, live ornamental species (animals and plants) and ornamental products (pearls and shells); (ii) fishes cultured as feed for certain carnivorous farmed species; (iii) culture of biomass of many species (such as plankton, *Artemia* and marine worms) for use as feed in aquaculture hatcheries and grow-out operations; (iv) aquaculture hatchery and nursery outputs for on-growing in captivity or stocking to the wild; and (v) inputs in terms of captured wild fish on-grown in captivity. These practices are often specialized and segmented standalone operations of local importance in many countries. There is an urgent need to improve and expand national and international aquaculture statistics collection and reporting schemes in order to have a full understanding of aquaculture in accordance with the commitments made by States in 2003 in adopting the FAO Strategy and Outline Plan for Improving Information on Status and Trends of Aquaculture.

Food fish production

In 2010, global production of farmed food fish was 59.9 million tonnes, up by 7.5 percent from 55.7 million tonnes in 2009 (32.4 million tonnes in 2000). Farmed food fish include finfishes, crustaceans, molluscs, amphibians (frogs), aquatic reptiles (except crocodiles) and other aquatic animals (such as sea cucumbers, sea urchins, sea squirts and jellyfishes) that are indicated as fish throughout this document. The reported grow-out production from aquaculture is almost entirely destined for human consumption.

In the last three decades (1980–2010), world food fish production of aquaculture has expanded by almost 12 times, at an average annual rate of 8.8 percent. Aquaculture enjoyed high average annual growth rates of 10.8 percent and 9.5 percent in the 1980s and 1990s, respectively, but has since slowed to an annual average of 6.3 percent.

Since the mid-1990s, aquaculture has been the engine driving growth in total fish production as global capture production has levelled off. Its contribution to world total fish production climbed steadily from 20.9 percent in 1995 to 32.4 percent in 2005 and 40.3 percent in 2010. Its contribution to world food fish production for human consumption was 47 percent in 2010 compared with only 9 percent in 1980.

The growth rate in farmed food fish production from 1980 to 2010 far outpaced that for the world population (1.5 percent), resulting in average annual per capita consumption of farmed fish rising by almost seven times, from 1.1 kg in 1980 to 8.7 kg in 2010, at an average rate of 7.1 percent per year.

The total farmgate value of food fish production from aquaculture is estimated at US\$119.4 billion for 2010. This might be overstated considering that some countries reported values other than first-sale prices (e.g. using retail, export or processed product prices).

World aquaculture production is vulnerable to adverse impacts of natural, socio-economic, environmental and technological conditions. For example, marine cage culture of Atlantic salmon in Chile, oyster farming in Europe (notably France), and marine shrimp farming in several countries in Asia, South America and Africa have experienced high mortality caused by disease outbreaks in recent years, resulting in partial or sometimes total loss of production. Countries prone to natural disasters suffer seriously from production damage or losses caused by floods, droughts, tropical storms and, less frequently, earthquakes. Water pollution has increasingly threatened production in some newly industrialized and rapidly urbanizing areas. In 2010, aquaculture in China suffered production losses of 1.7 million tonnes (worth US\$3.3 billion) caused by diseases (295 000 tonnes), natural disasters (1.2 million tonnes), pollution (123 000 tonnes), etc. Disease outbreaks virtually wiped out marine shrimp farming production in Mozambique in 2011.

Production among regions

Asia accounted for 89 percent of world aquaculture production by volume in 2010, up from 87.7 percent in 2000 (Table 5). The contribution of freshwater aquaculture has gradually increased, up to 65.6 percent in 2010 from around 60 percent during 1990s. In terms of volume, Asian aquaculture is dominated by finfishes (64.6 percent), followed by molluscs (24.2 percent), crustaceans (9.7 percent) and miscellaneous species (1.5 percent). The share of non-fed species farmed in Asia was 35 percent (18.6 million tonnes) in 2010 (compared with 50 percent in 1980). The contribution of China to world aquaculture production volume in 2010 declined to 61.4 percent from its highest level of about 66 percent in the period 1996–2000. Other major producers in Asia (India, Viet Nam, Indonesia, Bangladesh, Thailand, Myanmar, the Philippines and Japan) are among the world's top producers.

In the Americas, the share of freshwater aquaculture in total production declined from 54.8 percent in 1990 to 37.9 percent in 2010. In North America, aquaculture has ceased expanding in recent years, but in South America it has shown strong and continuous growth, particularly in Brazil and Peru. In terms of volume, aquaculture in North and South America is dominated by finfishes (57.9 percent), crustaceans (21.7 percent) and molluscs (20.4 percent). Bivalve production fluctuated between 14 and 21 percent of total aquaculture production in the 1990s and 2000s, after dropping rapidly in the 1980s from 48.5 percent.

In Europe, the share of production from brackish and marine waters increased from 55.6 percent in 1990 to 81.5 percent in 2010, driven by marine cage culture of Atlantic salmon and other species. Several important producers in Europe have recently ceased expanding or have even contracted, particularly in the marine bivalve sector. In 2010, finfishes accounted for three-quarters of all European aquaculture production, and molluscs one-quarter. The share of bivalves in total production decreased continuously from 61 percent in 1980 to 26.2 percent in 2010.

Africa has increased its contribution to global production from 1.2 percent to 2.2 percent in the past ten years, albeit from a very low base. The share of freshwater

aquaculture in the region fell from 55.2 percent to 21.8 percent in the 1990s, largely reflecting the strong growth in brackish-water culture in Egypt, but it recovered in the 2000s, reaching 39.5 percent in 2010 as a result of rapid development in freshwater fish farming in sub-Saharan Africa, most notably in Nigeria, Uganda, Zambia, Ghana and Kenya. African aquaculture production is overwhelmingly dominated by finfishes (99.3 percent by volume), with only a small fraction from marine shrimps (0.5 percent) and marine molluscs (0.2 percent). In spite of some limited successes, the potential for bivalve production in marine waters remains almost completely unexplored.

Oceania is of relatively marginal importance in global aquaculture production. Production from this region consists mainly of marine molluscs (63.5 percent) and finfishes (31.9 percent), while crustaceans (3.7 percent, mostly marine shrimps) and other species (0.9 percent) constitute less than 5 percent of its total production. Marine bivalves accounted for about 95 percent of the total produced in the first half of 1980s but, reflecting the development of the finfish culture sector (especially Atlantic salmon in Australia and chinook salmon in New Zealand), they currently account for less than 65 percent of the region's total production. Freshwater aquaculture accounts for less than 5 percent of the region's production.

Notes: Data exclude aquatic plants and non-food products. Data for 2010 for some countries are provisional and subject to revisions. Production values for 1980 for Europe include the former Soviet Union.

The global distribution of aquaculture production across the regions and countries of different economic development levels remains imbalanced. In 2010, the top ten producing countries accounted for 87.6 percent by quantity and 81.9 percent by value of the world's farmed food fish. At the regional level, production is also concentrated in a few major producers (Table 6).

The LDCs, mostly in sub-Saharan Africa and in Asia, and home to 20 percent of the world's population (1.4 billion people), remain very small in terms of their share of world aquaculture production (4.1 percent by quantity and 3.6 percent by value). The major producers in the LDCs in 2010 include Bangladesh, Myanmar, Uganda, the Lao

Note: Data exclude aquatic plants and non-food products. Data for 2010 for some countries are provisional and subject to revisions.

People's Democratic Republic (82 100 tonnes), Cambodia (60 000 tonnes) and Nepal (28 200 tonnes).

While aquaculture production has shown strong growth in developing countries, particularly in Asia, annual growth rates in developed industrialized countries averaged only 2.1 percent and 1.5 percent in the 1990s and 2000s, respectively. In 2010, they produced collectively 6.9 percent (4.1 million tonnes) by quantity and 14 percent (US\$16.6 billion) by value of world farmed food fish production, compared with 21.9 percent and 32.4 percent in 1990. Aquaculture production has contracted or stagnated in Japan, the United States of America, Spain, France, the United Kingdom of Great Britain and Northern Ireland, Canada and Italy. An exception is Norway, where, thanks to the farming of Atlantic salmon in marine cages, aquaculture production grew from 151 000 tonnes in 1990 to more than one million tonnes in 2010, at an average growth rate of 12.6 percent in the 1990s and 7.5 percent in the 2000s.

In the recent past, some developing countries in Asia and the Pacific (Myanmar and Papua New Guinea), sub-Saharan Africa (Nigeria, Uganda, Kenya, Zambia and Ghana) and South America (Ecuador, Peru and Brazil) have made rapid progress to become significant or major aquaculture producers in their regions.

Immediately after their independence more than two decades ago, countries in the former Soviet Union were producing an annual total of almost 350 000 tonnes of food fish from aquaculture. However, production capacity in all these countries deteriorated rapidly in the 1990s to about one-third of its original level. In spite of starting to recover in the 2000s, their combined total production in 2010 amounted to only 59 percent of that in 1988. The lost capacity, especially in hatchery and nursery output, has also had a negative impact on inland culture-based capture fisheries. While Armenia, Belarus, Estonia and Republic of Moldova have exceeded their 1988 production levels, and output in Lithuania and the Russian Federation is at more than 80 percent of its original 1988 level, other countries remain at one-third or less of their 1988 production levels. In 2010, farmed fish production in Kazakhstan and Turkmenistan was less than 5 percent of that before independence.

Production with and without feed

While feed is generally perceived to be a major constraint to aquaculture development, one-third of all farmed food fish production, 20 million tonnes, is currently achieved without artificial feeding (Figure 7). Oysters, mussels, clams, scallops and other bivalve species are grown with food materials that occur naturally in their culture environment in the sea and lagoons. Silver carp and bighead carp feed on planktons proliferated through intentional fertilization and the wastes and leftover feed materials of fed species grown in the same multispecies polyculture systems. Rice–fish farming has long been a common practice, particularly in Asia (Box 2).

However, the percentage of non-fed species in world production has declined gradually from more than 50 percent in 1980 to the present level of 33.3 percent, strongly dominated by changing practices in Asia. This reflects the relatively faster growth in the fed-species culture subsector supported by, among others, the development and improved availability of formulated aquaculture feeds for finfishes and crustaceans.

Some fed species grow on a mixture of natural food proliferated from fertilization and supplementary feeds. If the non-fed portion in their total production were considered, the non-fed portion of world production of all farmed food fish would be higher than the aforesaid 33.3 percent. Owing to the unavailability of information and data needed for the calculation, the said percentage does not include: (i) the non-fed portion of production of some fed species (such as milkfish that grow partially on algal aggregates known as “lab-lab” proliferated through fertilization in culture ponds); and (ii) the non-fed filter feeding carps reported by some producers in aggregation with other species and treated wholly as fed species.

Box 2

Fish culture in rice fields

History and tradition

The capture and culture of aquatic organisms from rice fields has a long history and tradition especially in Asia, where the availability of rice and fish has been associated with prosperity and food security. Designs of rice fields with fish on ancient Chinese pottery from tombs of the Han Dynasty (206 BC–225 AD), inscriptions from a thirteenth century king of Thailand, and traditional sayings, such as one from Viet Nam – “rice and fish are like mother and children”, are all testament that the combination of rice and fish has traditionally been regarded as an indicator of wealth and stability.

Status

The cultivation of almost 90 percent of the world's rice crops in irrigated, rainfed and deep-water systems equivalent to about 134 million hectares offers a suitable environment for fish and other aquatic organisms. Rice-based ecosystems provide habitats for a wide range of aquatic organisms extensively used by local people. They also offer opportunities for the enhancement and culture of aquatic organisms. The different integrations of rice and fish farming – either on the same plot, on adjacent plots where by-products of one system are used as inputs on the other, or consecutively – are all variations of production systems that aim to increase the productivity of water, land and associated resources while contributing to increased fish production. The integration can be more or less complete depending on the general layout of the irrigated rice plots and fishponds. There are many options for enhancing food production from fish in managed aquatic systems, which are ingeniously realized by farmers all over the world.¹

As regards the general scale of rice–fish culture, China is the main producer with an area of about 1.3 million hectares of rice fields with different forms of fish culture, which produced 1.2 million tonnes of fish and other aquatic animals in 2010.² Other countries reporting their rice–fish production to FAO include Indonesia (92 000 tonnes in 2010), Egypt (29 000 tonnes in 2010), Thailand (21 000 tonnes in 2008), the Philippines (150 tonnes in 2010) and Nepal (45 tonnes in 2010). Trends observed in China show that fish production from rice fields has increased thirteenfold in the last two decades, and rice–fish culture is now one of the most important aquaculture systems in China, making a significant contribution to rural livelihoods and food security. A broad range of aquatic species including different carps, tilapias, catfish and breams are being farmed in rice fields. Market prices and preferences may provide important opportunities to farmers for a more diversified use of species, especially targeting eels, loaches and various crustaceans, and the sale and marketing of higher-valued organic products.³ Also in India the practice cuts across different ecosystems from terraced rice fields in the hilly terrain to coastal lands and

deep-water rice fields, and reportedly covered an area of two million hectares in the 1990s. Rice–fish farming is being tried and practised in other countries and continents although to a lesser extent. Apart from Asia, activities have been reported from, among others, Brazil, Egypt, Guyana, Haiti, Hungary, Iran (Islamic Republic of), Italy, Madagascar, Malawi, Nigeria, Panama, Peru, Senegal, Suriname, the United States of America, Zambia, and several countries in the Central Asia and Caucasus region.¹

Benefits, issues and challenges

Rice–fish farming provides additional food and income by diversifying farm activities and increasing yields of both the rice and fish crops. Evidence shows that although rice yields are similar, the integrated rice–fish system uses 68 percent less pesticide than rice monoculture.⁴ Fish feed on rice pests, thus reducing pest pressure. Together with the fact that most broad-spectrum insecticides are a direct threat to aquatic organisms and healthy fish culture, knowledgeable farmers are much less motivated to spray pesticides. Therefore, it has been suggested that fish farming in rice and the integrated management of pests in rice production are complementary activities.⁵ Similarly, complementary use of nitrogen between rice and fish resulted in 24 percent less chemical fertilizer application and low nitrogen release into the environment, suggesting positive interactions in the use of resources.⁴ Fertilizers and feeds used in the integrated system are more efficiently utilized and converted into food production, and nutrient discharge to the natural environment is minimized. Rice–fish farming reduces the emission of methane by almost 30 percent compared with traditional rice farming.⁶

The challenges related to rice–fish farming are not different from those related to general aquaculture development. They include availability of and access to seed, feed and capital as well as natural risks associated with water control, disease and predation. Freshwater is rapidly becoming one of the scarcest natural resources, and competition for freshwater is among the most critical challenges facing developing countries. Sufficient and good-quality water is a key resource in rice–fish farming, which increases the productivity per unit of water used. Rice–fish farming and other forms of aquaculture in rice-based farming are one component of integrated water management approaches that produce food of high nutritional quality and, often, high economic value. Profits vary depending on production characteristics but income increases of up to 400 percent compared with rice monoculture have been reported and these may be even greater where high-value aquatic species are farmed.³

The use of aquatic genetic resources in rice is part of the work of the FAO Fisheries and Aquaculture Department with the Commission on Genetic Resources for Food and Agriculture as part of the preparation for *The State of the World on Aquatic Genetic Resources*. In addition, the rice–fish system has been included as one of the Globally Important Agricultural Heritage Systems under an FAO initiative supported by the Global Environment Facility.

It is the combination of efficient production and use of resources coupled with environmental benefits that has prompted recent international

Box 2 (cont.)

gatherings of the International Rice Commission, the Convention of Biological Diversity, and the Ramsar Convention to recommend that rice-producing countries promote the further development of integrated rice and fish systems as a means of enhancing food security and sustainable rural development. In addition, some countries with a long tradition in integrated rice–fish systems are giving renewed attention to the complex rice ecosystem with a focus on its role in biodiversity conservation, as in the Japanese *satoyama* landscape initiative.

The way forward

An increase in integrated farming of rice and fish is possible and would benefit farmers, consumers and the environment worldwide. Several organizations, active in global policies for food production and/or environmental sustainability, have become aware of this, and key policy-makers have formulated and disseminated relevant recommendations to governments, institutions and stakeholders. This is encouraging and, given the benefits of rice–fish farming, it is important to give priority to its continued promotion.

Taking China, the main producer, as an example, with currently 15 percent of the suitable rice area under integrated rice–fish cultivation, there is considerable scope for expansion.³ The same is true for many rice-producing countries around the globe. Similarly, there is much room for intensification of existing systems. Capacity building with increased knowledge and improved management techniques will be critically important, in particular focusing on all farming household members, both men and women, as well as extension agents. In recent decades, excellent progress has been achieved by applying a “farmer field school” (FFS) approach. This is a discovery-based learning approach where small groups of farmers meet regularly, facilitated by a specially trained technician, to explore new methods, through simple experimentation and group discussion and analysis, over the course of a growing season. This approach allows farmers to modify and adapt newly introduced methods to local contexts and knowledge, ultimately providing a higher likelihood of appropriate adaptation and adoption of improved technologies. It is only relatively recently that aquaculture has been integrated into an FFS-style curriculum in Guyana and Suriname.⁷

In terms of food security, producers in Asia, especially China, Viet Nam, India, Indonesia and Bangladesh, have benefited from the development of culture of low-trophic-level species, such as carps and barbs, tilapias and *Pangasius* catfish, in easing dependence on high-protein feeds, and thus reduced the vulnerability of their sectors to externalities. Grass carp, the world’s most-produced finfish species from aquaculture, is grown partially with cultivated and wild-collected “pastures”, instead of using formulated feeds only.

The production of 253 000 tonnes of highly carnivorous Mandarin fish (*Siniperca chuatsi*), which feeds on live prey only, was achieved by feeding them with low-trophic-level carp fingerlings grown with low-protein feeds plus pond fertilization.

The approach to validate and disseminate integrated rice–fish farming systems through FFS has been pioneered in Latin America. It is currently being tested in field activities in Mali, with testing also scheduled for Burkina Faso, where considerable potential for the integration of irrigated rice and aquaculture exists.⁸ Strong interest has been noted from several other sub-Saharan countries such as the Democratic Republic of the Congo, Senegal, the United Republic of Tanzania, and Zambia.⁹

⁹ Yamamoto, K., Halwart, M. and Hishamunda, N. 2011. Supporting African rice farmers in their diversification efforts through aquaculture. *FAO Aquaculture Newsletter*, 48: 42–43.

Comparable in quantity with the total production of farmed rainbow trout in Europe (257 200 tonnes), or the combined world production of gilthead seabream and European seabass (265 100 tonnes), Mandarin fish production has been assumed to be dependent on fishmeal and fish oil for feed, and this now needs reconsideration. As discussed above, part of its production could be treated as the non-fed portion of fed species production.

In sub-Saharan Africa, the carnivorous North African catfish (*Clarias gariepinus*) has replaced tilapia as the most-produced fish in aquaculture since 2004. The progressive dominance of catfish species in aquaculture is particularly pronounced in Nigeria and Uganda. Being the largest producer of catfish in Africa, Nigeria even imports catfish feeds from as far away as Northern Europe.

Figure 7

World aquaculture production of non-fed and fed species

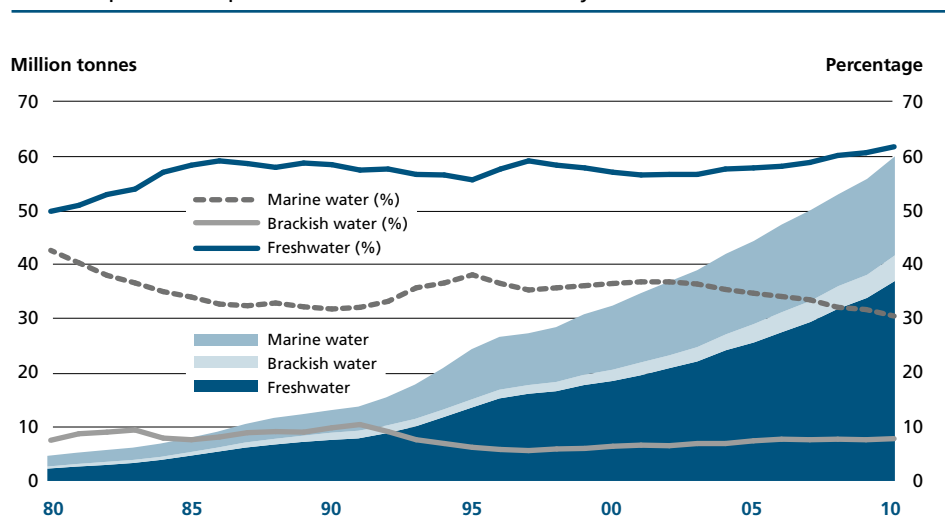

Figure 8

World aquaculture production and relative share by culture environment

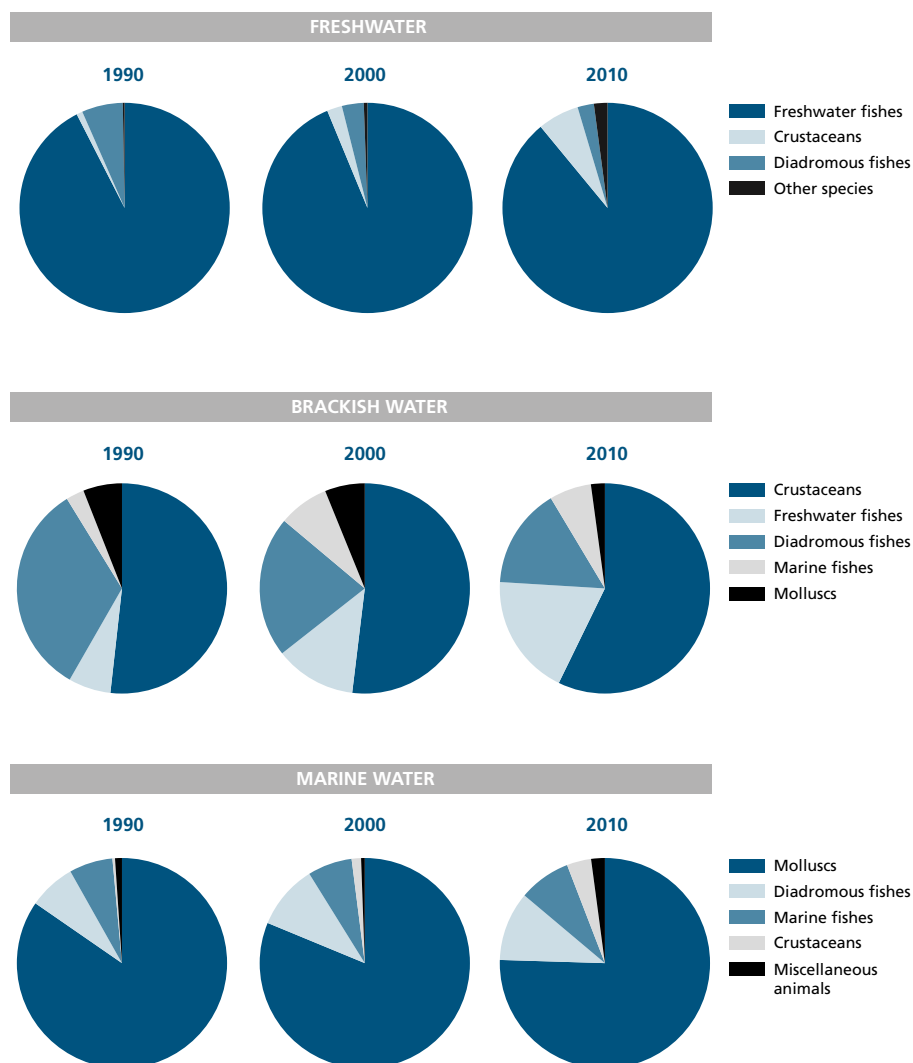

*Production by culture environment*

Aquaculture production uses freshwater, brackish water and full-strength marine water as culture media. Data available at FAO show that, in terms of quantity, the percentage of production from freshwater rose from less than 50 percent before the 1980s to almost 62 percent in 2010 (Figure 8), with the share of marine aquaculture production declining from more than 40 percent to just above 30 percent. In 2010, freshwater aquaculture was the source of 58.1 percent of global production by value. Brackish-water aquaculture yielded only 7.9 percent of world production in terms of quantity but accounted for 12.8 percent of total value because of the relatively high-valued marine shrimps cultured in brackish-water ponds. Marine water aquaculture accounted for about 29.2 percent of world aquaculture production by value.

The average annual growth rate for freshwater aquaculture production from 2000 to 2010 was 7.2 percent, compared with 4.4 percent for marine aquaculture production. Freshwater fish farming has been a relatively easy entry point for practising aquaculture in developing countries, particularly for small-scale producers.

Figure 9

World aquaculture production composition by culture environment

As such, freshwater aquaculture is expected to contribute further to total aquaculture production in the 2010s.

The share of brackish-water aquaculture production has been stable, ranging between 6 and 8 percent, for most of the time. An exception was in the 1980s and early 1990s when accelerated development of brackish-water culture of marine shrimp species, particularly in coastal regions of Asia and South America, led to brackish-water aquaculture reaching 8–10 percent of total production. However, in the period 1994–2000, world marine shrimp farming was hit by disease outbreaks in Asia and South America, and the share of brackish-water production fell to 6 percent.

At the global level, the composition and types of farmed species differ greatly among the three culture environments, and they have also undergone changes within environments over the years (Figure 9).

Freshwater aquaculture production (36.9 million tonnes) was overwhelmingly dominated by finfishes (91.7 percent, 33.9 million tonnes) in 2010, as in the past. Crustaceans accounted for 6.4 percent, and all other types of species contributed only

1.9 percent. The development of freshwater farming of crustaceans and other species (such as soft-shell turtles and frogs) in the past two decades has slightly eroded the dominance of finfish in production. The share of diadromous fishes, including rainbow trout and other salmonids, eels and sturgeons, shrank from 6.3 percent in 1990 to 2.5 percent in 2010.

Brackish-water aquaculture production (4.7 million tonnes) consisted of crustaceans (57.2 percent, 2.7 million tonnes), freshwater fishes (18.7 percent), diadromous fishes (15.4 percent), marine fishes (6.5 percent) and marine molluscs (2.1 percent) in 2010. More than 99 percent of the crustaceans were marine shrimps. The share of freshwater fishes has increased dramatically in the past two decades, driven largely by rapid development in Nile tilapia and other species in Egypt. Milkfish and barramundi remain important but their combined share has dropped significantly. Salmonids and eels are also cultured in brackish-water in small quantities.

Marine-water aquaculture production (18.3 million tonnes) consists of marine molluscs (75.5 percent, 13.9 million tonnes), finfishes (18.7 percent, 3.4 million tonnes), marine crustaceans (3.8 percent) and other aquatic animals (2.1 percent), e.g. sea cucumbers, and sea urchins. The share of molluscs (mostly bivalves, e.g. oysters, mussels, clams, cockles, arkshells and scallops) declined from 84.6 percent in 1990 to 75.5 percent in 2010, reflecting the rapid growth in finfish culture in marine water, which grew at an average annual rate of 9.3 percent from 1990 to 2010 (seven times faster than the rate for molluscs). Salmonid production, particularly Atlantic salmon, increased dramatically from 299 000 tonnes in 1990 to 1.9 million tonnes in 2010, at an average annual rate exceeding 9.5 percent. Other finfish species also increased rapidly, from 278 000 tonnes in 1990 to 1.5 million tonnes in 2010, at an average annual rate exceeding 8.6 percent. Other finfish species cultured in marine water include amberjacks, seabreams, seabasses, croakers, grouper, drums, mullets, turbot and other flatfishes, snappers, cobia, pompano, cods, puffers and tunas.

Species produced in aquaculture

In 2010, the composition of world aquaculture production was: freshwater fishes (56.4 percent, 33.7 million tonnes), molluscs (23.6 percent, 14.2 million tonnes), crustaceans (9.6 percent, 5.7 million tonnes), diadromous fishes (6.0 percent, 3.6 million tonnes), marine fishes (3.1 percent, 1.8 million tonnes) and other aquatic animals (1.4 percent, 814 300 tonnes). Figure 10 summarizes the production volumes of the major categories. Aquaculture production exceeds capture production for many of the staple species for aquaculture. For example, the wild catch accounts for less than 1 percent of Atlantic salmon production, and farmed marine shrimps contribute 55 percent to the total global production.

Production of freshwater fishes has always been dominated by carps (71.9 percent, 24.2 million tonnes, in 2010). Among carps, 27.7 percent are non-fed filter-feeders and the rest are fed with low-protein feeds. Production of tilapias has a wide distribution, and 72 percent are raised in Asia (particularly in China and Southeast Asia), 19 percent in Africa, and 9 percent in America. Viet Nam dominates production of omnivorous *Pangasius* catfishes although there are other producers, such as Indonesia and Bangladesh. World production of *Pangasius* catfish may be understated because booming production in India has yet to be reflected in statistics. In 2010, Asia accounted for 73.7 percent of the production of other catfish species, America took its share to 13.5 percent (with channel catfish production), leaving 12.3 percent of production in Africa (dominated by North African catfish). Carnivorous species such as perches, basses and snakeheads accounted for only 2.6 percent of all freshwater fish produced in 2010.

Since the beginning of 1990s, more than half of the world production of diadromous fishes has come from salmonids, and the share peaked at 70.4 percent in 2001 before declining slightly in the face of increased milkfish production in Asia. The production of Japanese and European eels, mostly raised in East Asia and to a much lesser extent in Europe, has remained at about 270 000 tonnes in recent years. Limited

by the supply of seeds, the chances of a significant increase in coming years appear remote. Other eel species have been tested with wild-collected seeds with only limited success. Culture of sturgeons, for meat and for caviar, has risen steadily in Asia, Europe and America although production is still small. An increased number of farming systems with sophisticated equipment requiring high investment have been set up to target caviar production in some countries.

World production of marine fishes is more evenly distributed across the cultured species. However, almost half a million tonnes, or one-quarter of global production, are reported without identifying the species, particularly by a few top producers from Asia. There is evidence that production of European seabass and gilthead seabream has been significantly under-reported in some areas in the Mediterranean.

World aquaculture production of crustaceans in 2010 consisted of freshwater species (29.4 percent) and marine species (70.6 percent). The production of marine species is dominated by white leg shrimp (*Penaeus vannamei*), including substantial production in freshwater. In sharp contrast, the giant tiger prawn has lost importance in the last decade. Major freshwater species include red swamp crayfish, Chinese mitten crab, oriental shrimp and giant river prawn.

Regarding molluscs, aquaculture production of clams and cockles has increased much faster than that of other species groups. In 1990, clam and cockle production was half that of oysters, but by 2008 it exceeded oysters and became the most-produced species group of molluscs. Among other aquatic animals, production of sea cucumbers and soft-shell turtles has increased rapidly.

Use of aquatic species in aquaculture production

The number of species recorded in FAO aquaculture production statistics increased to 541 species and species groups in 2010, including 327 finfishes (5 hybrids), 102 molluscs, 62 crustaceans, 6 amphibians and reptiles, 9 aquatic invertebrates and 35 algae. The increase reflects improvements in data collection and reporting at the international and national levels, as well as the farming of new species, including hybrids. In view of the high degree of species aggregation reported by many countries, it is estimated that aquaculture production worldwide uses about 600 aquatic food fish and algae species.

Exotic aquatic species have been widely introduced and used for mass production in aquaculture, and their use is particularly common and important in Asian countries. Successful internationally introduced species for finfishes include tilapias from Africa (especially Nile tilapia), Chinese carps (silver carp, bighead carp and grass carp), Atlantic salmon (*Salmo salar*), *Pangasius* catfishes (*Pangasius* spp.), largemouth black bass (*Micropterus salmoides*), turbot (*Scophthalmus maximus*), piarapatinga (*Piaractus brachypomus*), pacu (*Piaractus mesopotamicus*), and rainbow trout (*Oncorhynchus mykiss*).

Measured by production, white leg shrimp is the most successful internationally introduced marine crustacean species for aquaculture. In 2010, it accounted for 71.8 percent of world production of all farmed marine shrimp species, of which 77.9 percent was produced in Asia (with the rest in its native home in America). Some shrimp-farming countries maintain bans on the farming of this exotic species, and Bangladeshi shrimp growers and seafood exporters have recently requested a lifting of the ban. Red swamp crayfish (*Procambarus clarkii*) from North America and giant river prawn (*Macrobrachium rosenbergii*) from South and Southeast Asia have also become important for freshwater culture in countries foreign to these species.

A significant part of the global production of marine molluscs, particularly in Europe and America, relies on the widely introduced Japanese carpet shell (*Ruditapes philippinarum*, also known as Manila clam) and Pacific cupped oyster (*Crassostrea gigas*). China now produces large quantities of Atlantic bay scallop (*Argopecten irradians*) and Yesso scallop (*Patinopecten yessoensis*).

A considerable number of hybrids, most notably of finfish, are used in aquaculture, especially in countries with a relatively high level of development in aquaculture technologies. Commercially farmed hybrids include: sturgeons (such as beluga *Huso huso* x starlet sturgeon *Acipenser ruthenus* known as "bester") in Asia and Europe;

Figure 10

Production of major species or species group from aquaculture in 2010

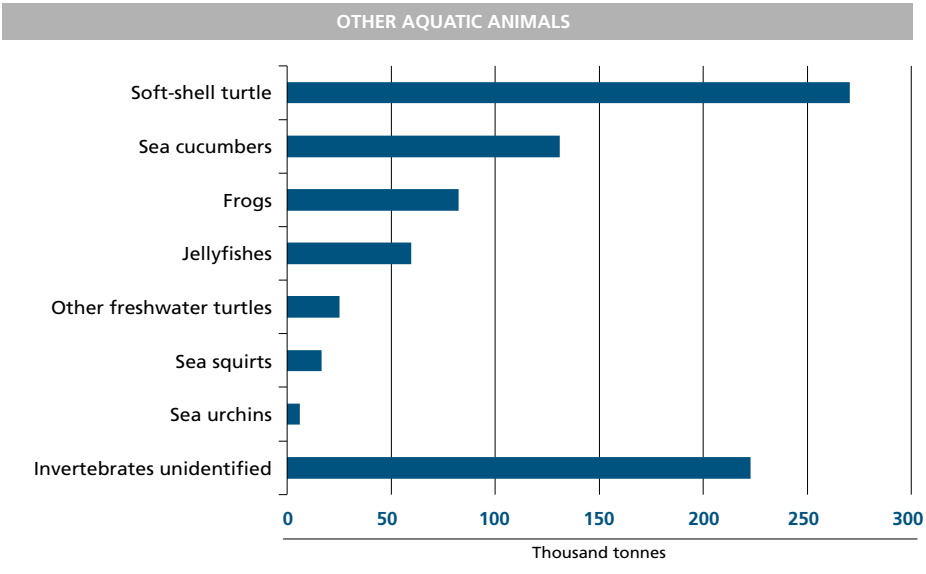

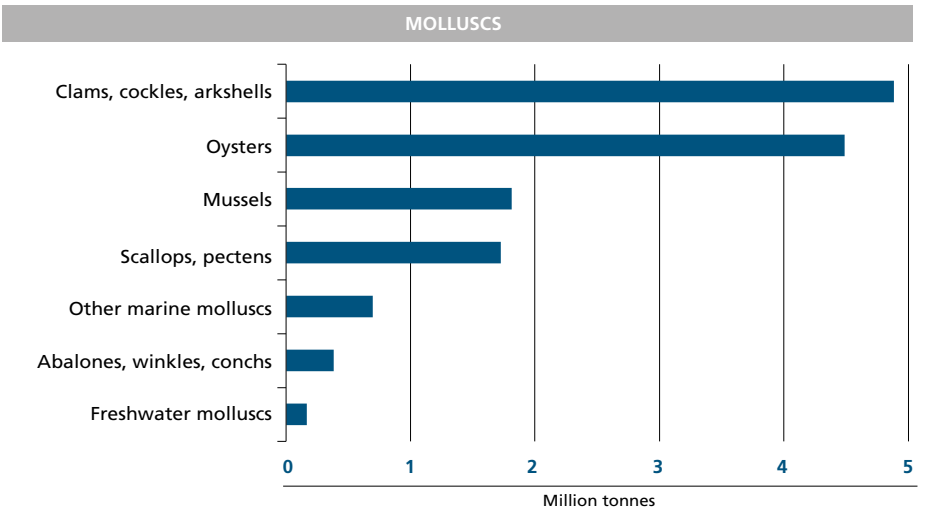

Figure 10 (cont.)

Production of major species or species group from aquaculture in 2010

Carassius spp., snakeheads and groupers in China; characins in South America; and freshwater catfishes (*Clarias gariepinus* x *Heterobranchus longifilis*) in Africa and Europe. The culture of hybrid tilapias is particularly common around the world. The hybrid of *Oreochromis aureus* x *O. niloticus* (with a high percentage of male offspring) is farmed in China, and the saline-resistant hybrid of *O. niloticus* x *O. mossambicus* in the Philippines.

Five finfish hybrids have been recorded with national production statistics and FAO estimates, indicating world production levels in 2010 of 333 300 tonnes of blue and Nile tilapia hybrid (*Oreochromis aureus* x *O. niloticus*, in China and in Panama), 116 900 tonnes of *Clarias* catfish hybrid (*Clarias gariepinus* x *C. macrocephalus*, in Thailand), 21 600 tonnes of "tambacu" hybrid (*Piaractus mesopotamicus* x *Colossoma macropomum*, in Brazil), 4 900 tonnes of "tambatinga" hybrid (*Colossoma macropomum* x *Piaractus brachipomus*, in Brazil) and 4 200 tonnes of striped bass hybrid (*Morone chrysops* x *M. saxatilis*, in the United States of America, Italy and Israel).

Aquatic plant (algae) production

To date, only aquatic algae have been recorded globally in farmed aquatic plant production statistics. Global production has been dominated by marine macroalgae, or seaweeds, grown in both marine and brackish waters.

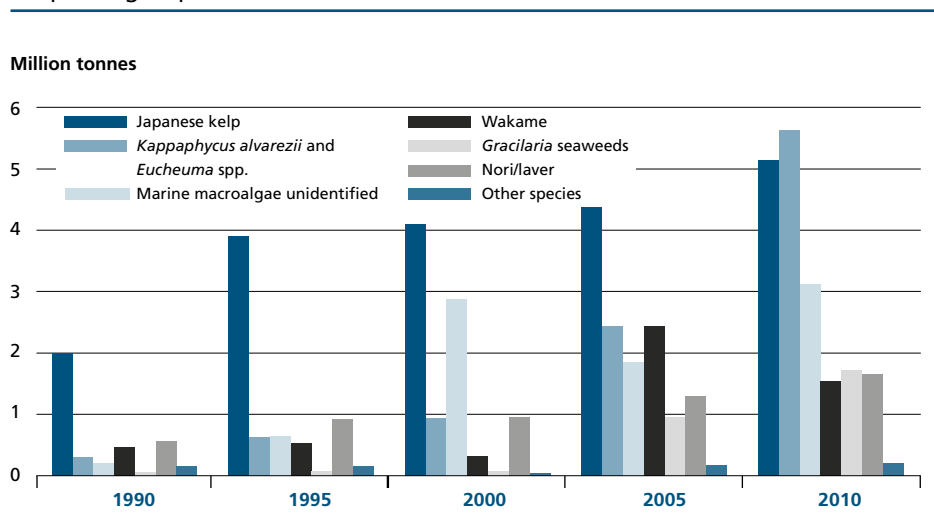

Aquatic algae production by volume increased at average annual rates of 9.5 percent in the 1990s and 7.4 percent in the 2000s – comparable with rates for farmed aquatic animals – with production increasing from 3.8 million tonnes in 1990 to 19 million tonnes in 2010. Cultivation has overshadowed production of algae collected from the wild, which accounted for only 4.5 percent of total algae production in 2010.

Following downward adjustments by FAO of the estimated value of several major species from a few major producers with incomplete reported data, the estimated total value of farmed algae worldwide has been reduced for a number of years in the time series. The total value of farmed aquatic algae in 2010 is estimated at US\$5.7 billion, while that for 2008 is now re-estimated at US\$4.4 billion.

As shown in Figure 11, a few species dominate algae culture, with 98.9 percent of world production in 2010 coming from Japanese kelp (*Saccharina/Laminaria japonica*) (mainly in the coastal waters of China), *Euclima* seaweeds (a mixture of *Kappaphycus alvarezii*, formerly known as *Euclima cottonii*, and *Euclima* spp.), *Gracilaria* spp., nori/laver (*Porphyra* spp.), wakame (*Undaria pinnatifida*) and unidentified marine macroalgae species (3.1 million tonnes, mostly from China). The remainder consists of

Figure 11

World production of farmed aquatic plant (algae) by major species or species group

marine macroalgae species farmed in small quantities (such as *Fusiform sargassum* and *Caulerpa* spp.) and microalgae cultivated in freshwater (mostly *Spirulina* spp., plus a small fraction of *Haematococcus pluvialis*). The production increase is most obvious in the farming of *Eucheuma* seaweeds. The 2000 production value for unidentified marine macroalgae shown in Figure 11 contains a significant portion of wakame, which was not separately reported by the main producer.

In sharp contrast to fish aquaculture, the cultivation of aquatic algae is practised in far fewer countries. Only 31 countries and territories are recorded with algae farming production in 2010, and 99.6 percent of global cultivated algae production comes from just eight countries: China (58.4 percent, 11.1 million tonnes), Indonesia (20.6 percent, 3.9 million tonnes), the Philippines (9.5 percent, 1.8 million tonnes), the Republic of Korea (4.7 percent, 901 700 tonnes), Democratic People's Republic of Korea (2.3 percent, 444 300 tonnes), Japan (2.3 percent, 432 800 tonnes), Malaysia (1.1 percent, 207 900 tonnes) and the United Republic of Tanzania (0.7 percent, 132 000 tonnes).

FISHERS AND FISH FARMERS

Millions of people around the world find a source of income and livelihood in the fisheries sector. The most recent estimates (Table 7) indicate that in 2010 there were 54.8 million people engaged in the primary sector of capture fisheries and aquaculture. Of these, an estimated 7 million people were occasional fishers and fish farmers (of whom 2.5 million in India, 1.4 million in China, 0.9 million in Myanmar, and 0.4 million each in Bangladesh and Indonesia).

More than 87 percent of all people employed in the fisheries sector in 2010 were in Asia, followed by Africa (more than 7 percent), and Latin America and the Caribbean (3.6 percent). Approximately 16.6 million (about 30 percent of all people employed in the fisheries sector) were engaged in fish farming, and they were even more concentrated in Asia (97 percent), followed by Latin America and the Caribbean (1.5 percent), and Africa (about 1 percent).

In the period 2005–2010, employment in the fisheries sector continued to grow faster (at 2.1 percent per year) than the world's population (at 1.2 percent per year)

Note: ... = data not available.

¹ Estimates for 1990 and, partly, for 1995 were based on data available for a smaller number of countries and, therefore, may not be fully comparable with those for later years.

and than employment in the traditional agriculture sector (at 0.5 percent per year). The 54.8 million fishers and fish farmers in 2010 represented 4.2 percent of the 1.3 billion people economically active in the broad agriculture sector worldwide, compared with 2.7 percent in 1990.

However, the relative proportion of those engaged in capture fisheries within the sector actually decreased from 87 percent in 1990 to 70 percent in 2010, while the proportion of those engaged in fish farming increased from 13 to 30 percent (Figure 12). In fact, in the last five years for which data are available, the number of people engaged in fish farming has increased at 5.5 percent per year compared with a mere 0.8 percent per year for those engaged in capture fisheries. It is apparent that, in the most important fishing nations, the share of employment in capture fisheries is stagnating or decreasing while aquaculture is providing increased opportunities. Moreover, as many countries still do not report employment data separately for the capture and farming sectors, the relative importance of employment in aquaculture may be underestimated.

The trends in employment vary according to the regions. Europe experienced the largest decrease in the number of people engaged in capture fishing with a 2 percent average annual decline between 2000 and 2010, and almost no increase in people employed in fish farming in the same period. In contrast, Africa showed the highest annual increase (5.9 percent) in the number of people engaged in fish farming in the last decade, followed by Asia (4.8 percent), and Latin America and the Caribbean (2.6 percent).

Table 8 presents the employment statistics for selected countries, including China, where almost 14 million people (26 percent of the world total) are engaged as fishers and fish farmers. In general, employment in fishing has been decreasing in capital-intensive economies, in particular in most European countries, North America, and Japan. For example, in the period 1990–2010, the number of people employed in marine fishing decreased by 53 percent in the United Kingdom of Great Britain and Northern Ireland, by 45 percent in Japan, by 40 percent in Norway, and by 28 percent in Iceland. Several factors may account for this, including the application of policies to reduce overcapacity and less reliance on human power owing to technological developments.

Table 9 compares per capita annual productivity in the capture fisheries and aquaculture primary sector for each region. Overall, average annual production per person is consistently lower in capture fisheries than in aquaculture, with global outputs of 2.3 and 3.6 tonnes per person per year, respectively.

Figure 12

Employment in the fisheries sector for the period 1990–2010

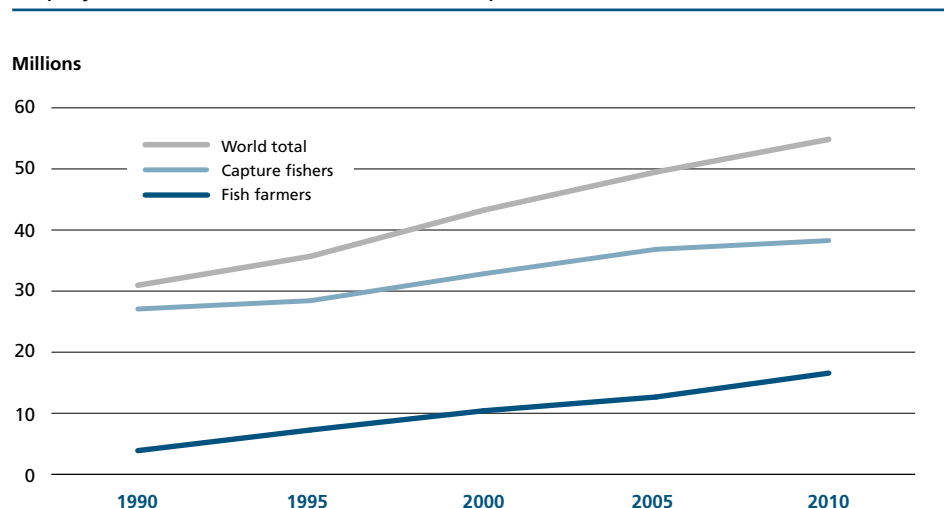

Table 8

Box 3

Child labour – an important issue also in fisheries and aquaculture

Child labour is a great concern in many parts of the world. In 2008, some 60 percent of the 215 million boys and girls estimated to be child labourers worldwide were engaged in the agriculture sector, including in fisheries, aquaculture, livestock and forestry.¹ In addition to work interfering with schooling and harming personal development in other ways, many of these children work in hazardous occupations or activities that threaten their health and sometimes their lives. They do work that they should not do according to international conventions and/or national legislation, and this situation endangers not only the children themselves but also efforts at poverty alleviation and sustainable development in a larger sense for their families and communities.

However, tackling child labour is no easy task. The occurrence of child labour is entwined in poverty and social injustices and cannot be addressed in isolation. Moreover, some types of work are not harmful but can even be beneficial for children. While it may be relatively easy to identify and agree to eliminate the “worst forms of child labour”, the distinction between “acceptable work” and “harmful labour” is not always clear and assessments can be muddled by local and traditional practices and beliefs. There is a need to exercise due care in analysing existing situations, in applying existing conventions, legislation and guidelines, and in raising the awareness and understanding of child labour issues in order to ensure that they are directly addressed as well as integrated into broader policies and programmes. Improvements have proved possible and the overall number of child labourers in the world has declined since 2000.

Information on child labour in fisheries and aquaculture is limited, and data on agriculture child labour are not generally disaggregated by subsector. Nevertheless, case studies and specific surveys indicate that the numbers are important. Child labour is particularly common in the small-scale informal sector, and children work in a large variety of activities, as part of family enterprises, as unpaid family workers or employed by others. They are found, for example, working on board fishing vessels, preparing nets and baits, feeding and harvesting fish in aquaculture ponds, and sorting, processing and selling fish.

A number of factors influence whether a task should be considered acceptable work, child labour or “worst form of child labour”. With the support of initiatives such as the global International Partnership for Cooperation on Child Labour in Agriculture, launched by key international agricultural organizations in 2007,² the knowledge base and guidance on how to classify and tackle child labour in agriculture have improved in the last decade. However, there is still an urgent need to learn more about child labour also in fisheries and aquaculture and to address the specific situations.

In April 2010, FAO, in cooperation with the International Labour Organization (ILO), organized a workshop³ to generate inputs and guidance to the contents and process of developing guidance materials on policy and practice in tackling child labour in fisheries and aquaculture. In order to promote awareness on and effective implementation of the

relevant UN and ILO conventions on child labour and the rights of the child, the workshop participants:

- reviewed the nature, incidence and causes of child labour in fisheries, fish processing and aquaculture;
- examined the different forms and types of child labour in large-scale, small-scale and artisanal fishing operations, shellfish gathering, aquaculture, seafood processing, and work onboard fishing vessels and fishing platforms;
- examined the health and safety hazards of fishing and aquaculture, including the use of hazardous technologies and relevant alternatives;
- shared examples of good practice in the progressive elimination of child labour drawn from various sectors and regions.

The workshop participants agreed on a series of recommendations relating to legal and enforcement measures, policy interventions and practical actions, including risk assessments, to address child labour issues in fisheries and aquaculture. FAO and ILO were called upon for priority actions to assist governments in withdrawing trafficked children and to effectively prohibit slavery and forced labour. The workshop participants also prioritized awareness raising among all stakeholders and the preparation of guidance materials. In addition, they stressed the need to consider gender issues in all actions and to address adequately issues relating to discrimination and exclusion of fishing communities, castes, tribal and indigenous peoples, and ethnic minorities in fisheries and aquaculture.

FAO and ILO are collaborating in helping to assess and address child labour issues in countries such as Cambodia and Malawi. They have also produced a preliminary version of a good practice guide for addressing child labour in fisheries and aquaculture.⁴

Table 9
Fishery production per fisher or fish farmer by region in 2010

Region	Production ¹ per person		
	Capture	Aquaculture (Tonnes/year)	Capture + aquaculture
Africa	2.0	8.6	2.3
Asia	1.5	3.3	2.1
Europe	25.1	29.6	25.7
Latin America and the Caribbean	6.8	7.8	6.9
North America	16.3	183.2	18.0
Oceania	17.0	33.3	18.2
World	2.3	3.6	2.7

¹ Production excludes aquatic plants.

Although 87.3 percent of the world's fishers and fish farmers were in Asia, the region accounted for only 68.7 percent of global production with an average of 2.1 tonnes per person per year in 2010, compared with 25.7 tonnes in Europe, 18.0 tonnes in North America, and 6.9 tonnes in Latin America and the Caribbean. The high productivity of Oceania reflects the contributions mainly of New Zealand and Australia and could be caused by the incomplete statistics provided by many other countries in the region. Production per person is considered to reflect a certain degree of industrialization of fishing activities as well as the relative importance of small-scale operators, especially in Africa and Asia.

The contrast is even more evident for aquaculture production. In 2010, fish farmers in Norway had an average annual production of 187 tonnes per person, while in Chile the corresponding figure was 35 tonnes, in China about 7 tonnes, in India about 4 tonnes, and in Indonesia only about 1 tonne.

As a general global trend, while productivity has dropped slightly from 2.8 to 2.3 tonnes per person in capture production, aquaculture has increased its productivity from 3.1 to 3.6 tonnes per person in the last decade.

Although the information available to FAO does not allow detailed analyses by gender, it is estimated that, overall, women accounted for at least 15 percent of all people directly engaged in the fisheries primary sector in 2010. The proportion of women is considered to be somewhat higher, at least 19 percent, in inland water fishing, and far more important, as high as 90 percent, in secondary activities, such as processing.

As in other sectors, child labour is a cause for concern in the fisheries and aquaculture sector. Therefore, together with other organizations, FAO is working to address this issue (Box 3).

The fisheries and aquaculture sector provides numerous jobs in ancillary activities in addition to fishers and fish farmers, such as processing, packaging, marketing and distribution, manufacturing of fish processing equipment, net and gear making, ice production and supply, boat construction and maintenance. Other people are involved in research, development and administration linked with the fisheries sector. Assuming that for each person directly engaged in fisheries production in 2010 about three to four related jobs were generated in secondary activities, and further assuming that, on average, each jobholder provided for three dependants or family members, then fishers, fish farmers and those supplying services and goods to them would have assured the livelihoods of about 660–820 million people, or about 10–12 percent of the world's population.

THE STATUS OF THE FISHING FLEET

Coverage and quality of data

In 2011, FAO obtained data on national fishing fleets from 138 countries, accounting for 67 percent of the countries involved in capture fisheries. When considering the catch amount together with corresponding fleet size, it is estimated that the reported information accounts for 96 percent of the global fishing fleet. While FAO has estimated the fleet size for another 49 countries for the analysis in this section, no estimation has been made for the remaining 18 countries for which data have never been reported or estimated and whose contribution to the global fishing fleet is considered to be negligible.

Depending on countries, national reports on fleet status may be based on national fishing vessel registers and administrative records that reflect the physical existence of vessels and often include vessels not actually engaged in fishing operations in a certain year. Even for the countries whose statistics correspond to active fishing vessels, there is no information about the extent of their engagement in fishing activities, e.g. full-time, part-time, or occasional. This means that the “fleet size” referred to in this section is only a rough estimate and should not be considered as an indicator for either global fishing capacity or global fishing effort, which in principle should be substantially smaller than those indicated here.

At the same time, data quality varies widely by country from well-maintained, long time series of consistent data to very fragmented records. In general, the data available for marine fishing fleets are of better quality and detail than that available for vessels deployed in inland waters. Moreover, small boats are often not well covered as frequently they are not subject to compulsory registration, especially those used in inland waters.

This year, for the first time, an attempt has been made to separate, to the extent possible, the marine fishing fleet from the fleet operating in inland waters.

Estimate of global fleet and its regional distribution

The total number of fishing vessels in the world was estimated to be about 4.36 million vessels in 2010, a value similar to the previous estimates. The fleet in Asia was the largest, consisting of 3.18 million vessels accounting for 73 percent of the global fleet, followed by Africa (11 percent), Latin America and the Caribbean (8 percent), North America (3 percent) and Europe (3 percent).

Among the global fleet, 3.23 million vessels (74 percent) were considered to operate in marine waters, with the remaining 1.13 million vessels operating in inland waters. The separation between inland and marine fishing fleets was made based on: (i) national reported statistics with sufficient details (e.g. China, Indonesia, and Japan); and (ii) allocation of whole fleets of landlocked countries to inland waters (e.g. Burkina Faso, Burundi, Chad, Kazakhstan, Malawi, Mali, Niger, Uganda, Uzbekistan and Zambia).

This preliminary analysis indicated that the inland fleet represents about 26 percent of the global fleet, but the proportion of vessels operating in inland waters varies substantially depending on the regions (Figure 13), the highest being in Africa (42 percent), followed by Asia (26 percent) and Latin America and the Caribbean (21 percent). Although preliminary, this resolves past confusion as to whether the inland-water operating component was included or excluded in the overall fleet analysis. Further work would be needed to disaggregate components operating specifically in the African Great Lakes.

Globally, 60 percent of fishing vessels were engine-powered in 2010. While 69 percent of vessels operating in marine waters were motorized, the corresponding value for those operating in inland waters was only 36 percent. For the fleet operating in marine waters, there were also large variations among regions, with non-motorized vessels accounting for less than 7 percent of the total in Europe and the Near East, but up to 61 percent in Africa (Figure 14). Although North America has

Figure 13

Proportion of fishing vessels in marine and inland waters by region in 2010

Figure 14

Proportion of marine fishing vessels with and without engine by region in 2010

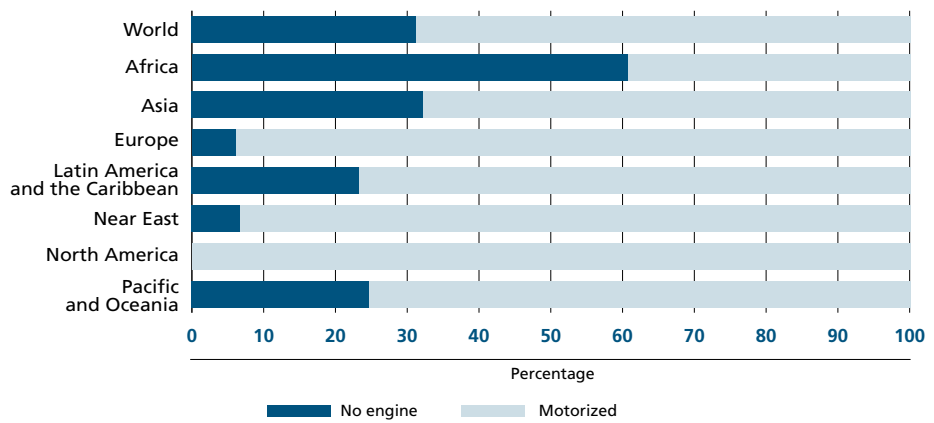

Figure 15

Distribution of motorized fishing vessels by region in 2010

no report of non-motorized vessels, this could be a reflection of the data collection systems in use there.

Globally, the motorized fishing fleet is distributed unevenly among regions. The vast majority of motorized vessels (72 percent) were reported from Asia (Figure 15), with the rest from Latin America and the Caribbean (9 percent), Africa (7 percent), North America (4 percent), and Europe (4 percent).

Size distribution and the importance of small boats

In 2010, more than 85 percent of the motorized fishing vessels in the world were less than 12 m LOA. Such vessels dominated in all regions, particularly the Near East, and Latin America and the Caribbean (Figure 16). About 2 percent of all motorized fishing vessels corresponded to industrialized fishing vessels of 24 m and larger (with a GT of roughly more than 100 GT) and that fraction was larger in the Pacific and Oceania region, Europe, and North America. A segment of the industrialized fishing fleet mentioned above is registered with unique identification numbers provided by the International Maritime Organization (IMO), whose list included more than 22 000 active fishing vessels by the end of 2010.

While the bulk of the global fishing fleet is composed of small-sized vessels (less than 12 m LOA), this is the component for which reliable information is least available. Such is particularly the case in Africa, parts of Asia and the Americas. In many cases, vessels smaller than a certain size are not subject to national registration or are only subject to local registries that might not be reflected in national statistics. In addition, fishing fleets operating in inland waters usually consist mostly of vessels of less than 12 m LOA, which are commonly not subject to either national or local registries and are often omitted from most analyses, particularly in developing countries. Therefore, estimations of the relative importance of the small-scale and industrial components of fisheries for social, economic, and food security purposes are then likely to be skewed owing to inadequate appraisal of the small-scale segment. In Africa, and in Latin America and the Caribbean, small vessels constitute a vast sector of artisanal and subsistence fisheries on which the livelihoods of a great number of fisher households depend.

Table 10 illustrates some examples of the relevance of small motorized vessels for selected countries in different regions. The proportion of vessels of less than 12 m LOA exceeds 90 percent in most cases. In addition, an estimated 98 percent of non-motorized fishing vessels would be less than 12 m LOA.

Continuous efforts are being made in Africa (in collaboration with regional and subregional fisheries organizations such as the Fishery Committee for the Eastern Central Atlantic [CECAF], Regional Fisheries Committee for the Gulf of Guinea, Fishery Committee for the West Central Gulf of Guinea, and Southwest Indian Ocean Fisheries Commission [SWIOFC]) as well as in Central America (in collaboration with the Organization of Fishing and Aquaculture in Central America) to establish vessel registers as part of fishery resources management plans and policies. Frame surveys and fisheries censuses have already yielded invaluable information, but it may require some time before the results of these efforts are reflected in the official statistics.

Effect of efforts to reduce overcapacity in fishing fleets

In response to the International Plan of Action for the Management of Fishing Capacity, several countries have tried establishing targets for the reduction of national overcapacity of fishing fleets. While the numbers of fishing vessels have been decreasing in some parts of the world in recent years, they have been increasing elsewhere.

Republic of Korea: Response to FAO questionnaires, national authorities.

When considering measures to limit fleet capacity, decisions will have to evaluate relative contributions and, therefore, the priority in capacity reduction of the industrial component and the small-scale component. When deciding on such policies, many nations are faced with difficult dilemmas, as not only fishery resources but also social and economic issues are at stake.

Data from some countries indicate a continuous expansion of their fleets. For example, the motorized fishing fleet in Cambodia increased by 19 percent from 38 960 vessels in 2007 to 46 427 in 2009. Indonesia's motorized marine fleet increased by 11 percent from 348 425 fishing vessels in 2007 to 390 770 in 2009. Viet Nam reported a 10 percent increase in offshore fishing vessels (those with engines of more than 90 hp) from a total of 22 729 in 2008 to 25 346 in 2010, and Malaysia reported a 26 percent increase from 24 048 licensed motorized fishing vessels in 2007 to 30 389 in 2009. The case of Sri Lanka illustrates the potential overshoot in efforts to re-establish a fishing fleet partly destroyed by the tsunami that swept the region at the end of 2004. The pre-tsunami fishing fleet numbered 15 307 motorized vessels, which according to official reports was reduced to about 6 700 vessels (a 44 percent reduction) by the tsunami. By 2007, the fishing fleet numbered 23 400 and by 2010 had increased even further to 25 973 motorized fishing vessels; a net increase of 11 percent for the whole period.

Table 11 provides summary details of motorized fleets for several major fishing nations. In 2008–2010, the combined total captures of these countries represented about 33 percent of the world total capture.

China's 2003–2010 marine fishing vessel reduction plan was aimed at achieving a marine fishing fleet of 192 390 vessels with a total combined power of 11.4 million kW. The statistics available indicate that, up to 2008, China did achieve a reduction with 199 949 vessels and 12.95 million kW, still short of the target by about 4 percent for the number of vessels and 13 percent for combined power. However, after 2008, both the number of vessels and total combined power started to increase again.

Japan implemented various schemes in order to reduce its fishing fleet, which resulted in a net reduction of 9 percent in the number of vessels, but a net increase of 5 percent in combined power between 2005 and 2009. In fact, while the number of vessels declined, the mean engine power conversely increased, from 40 kW to 46 kW in the same period.

The restructuring of the European fishing fleet to achieve a sustainable balance between the fleet and the available fishery resources has been a major goal of European Union policies. The evolution in the combined number, tonnage, and power of European Union fishing vessels indicates a downward tendency in the last decade. The combined EU-15 motorized fishing fleet achieved a net reduction of 8 percent in number of vessels, and of 11 percent in power between 2005 and 2010. For this same period, mean engine power also decreased slightly from 88 kW to 85 kW.

Other examples of net reduction in fleet for important fishing nations in the period 2005–2010 include Iceland (with a net reduction of 7 percent in the number of vessels and 10 percent in total combined power) and Norway (with a net reduction of 18 percent in the number of vessels but a mere 1.5 percent decrease in total combined power, and increased mean engine power from 165 kW to 199 kW). In a different region, the Republic of Korea achieved a net reduction of 15 percent in the number of vessels but a 3 percent increase in combined power, resulting in the mean engine power increasing from 110 kW to 133 kW for the same period.

THE STATUS OF FISHERY RESOURCES

Marine fisheries

The world's marine fisheries have experienced different stages, increasing from 16.8 million tonnes in 1950 to a peak of 86.4 million tonnes in 1996, and then declining to stabilize at about 80 million tonnes, with interannual fluctuations. Global recorded production was 77.4 million tonnes in 2010. Of the marine areas (Figure 17), the Northwest Pacific had the highest production with 20.9 million tonnes

(27 percent of the global marine catch) in 2010, followed by the Western Central Pacific with 11.7 million tonnes (15 percent), the Northeast Atlantic with 8.7 million tonnes (11 percent), and the Southeast Pacific, with a total catch of 7.8 million tonnes (10 percent).

The proportion of non-fully exploited⁷ stocks has decreased gradually since 1974 when the first FAO assessment was completed (Figure 18). In contrast, the percentage of overexploited stocks increased, especially in the late 1970s and 1980s, from 10 percent in 1974 to 26 percent in 1989. After 1990, the number of overexploited stocks continued to increase, albeit at a slower rate. The fraction of fully exploited stocks demonstrates the smallest change over time. Its percentage was stable at about 50 percent from 1974 to 1985, then dropped to 43 percent in 1989 before gradually increasing to 57.4 percent in 2009.

By definition, the fully exploited stocks produce catches that are at or very close to their maximum sustainable production. Therefore, they have no room for further expansion in catch, and may even be at some risk of decline unless properly managed. Among the remaining stocks, 29.9 percent were overexploited, and 12.7 percent non-fully exploited in 2009. Overexploited stocks produce lower yields than their biological and ecological potential. They require strict management plans to rebuild stock abundance and restore full and sustainable productivity. The Johannesburg Plan of Implementation that resulted from the World Summit on Sustainable Development (Johannesburg, 2002) demands that all these stocks be restored to the level that can produce maximum sustainable yield by 2015.⁸ The non-fully exploited stocks are under relatively low fishing pressure and have some potential to increase their production. However, these stocks often do not have a high production potential. The potential for increase in catch may be generally limited. Nevertheless, proper management plans should be established before increasing the exploitation rate of these non-fully exploited stocks in order to avoid following the same track of overfishing as many currently overexploited stocks.

Most of the stocks of the top ten species, which account in total for about 30 percent of the world marine capture fisheries production, are fully exploited and, therefore, have no potential for increases in production, while some stocks are overexploited and increases in their production may be possible if effective rebuilding plans are put in place. The two main stocks of anchoveta in the Southeast Pacific, Alaska pollock (*Theragra chalcogramma*) in the North Pacific and blue whiting (*Micromesistius poutassou*) in the Atlantic are fully exploited. Atlantic herring (*Clupea harengus*) stocks are fully exploited in both the Northeast and Northwest Atlantic. Japanese anchovy (*Engraulis japonicus*) in the Northwest Pacific and Chilean jack mackerel (*Trachurus murphyi*) in the Southeast Pacific are considered to be overexploited. Chub mackerel (*Scomber japonicus*) stocks are fully exploited in the Eastern Pacific and the Northwest Pacific. The largehead hairtail (*Trichiurus lepturus*) was estimated in 2009 to be overexploited in the main fishing area in the Northwest Pacific.

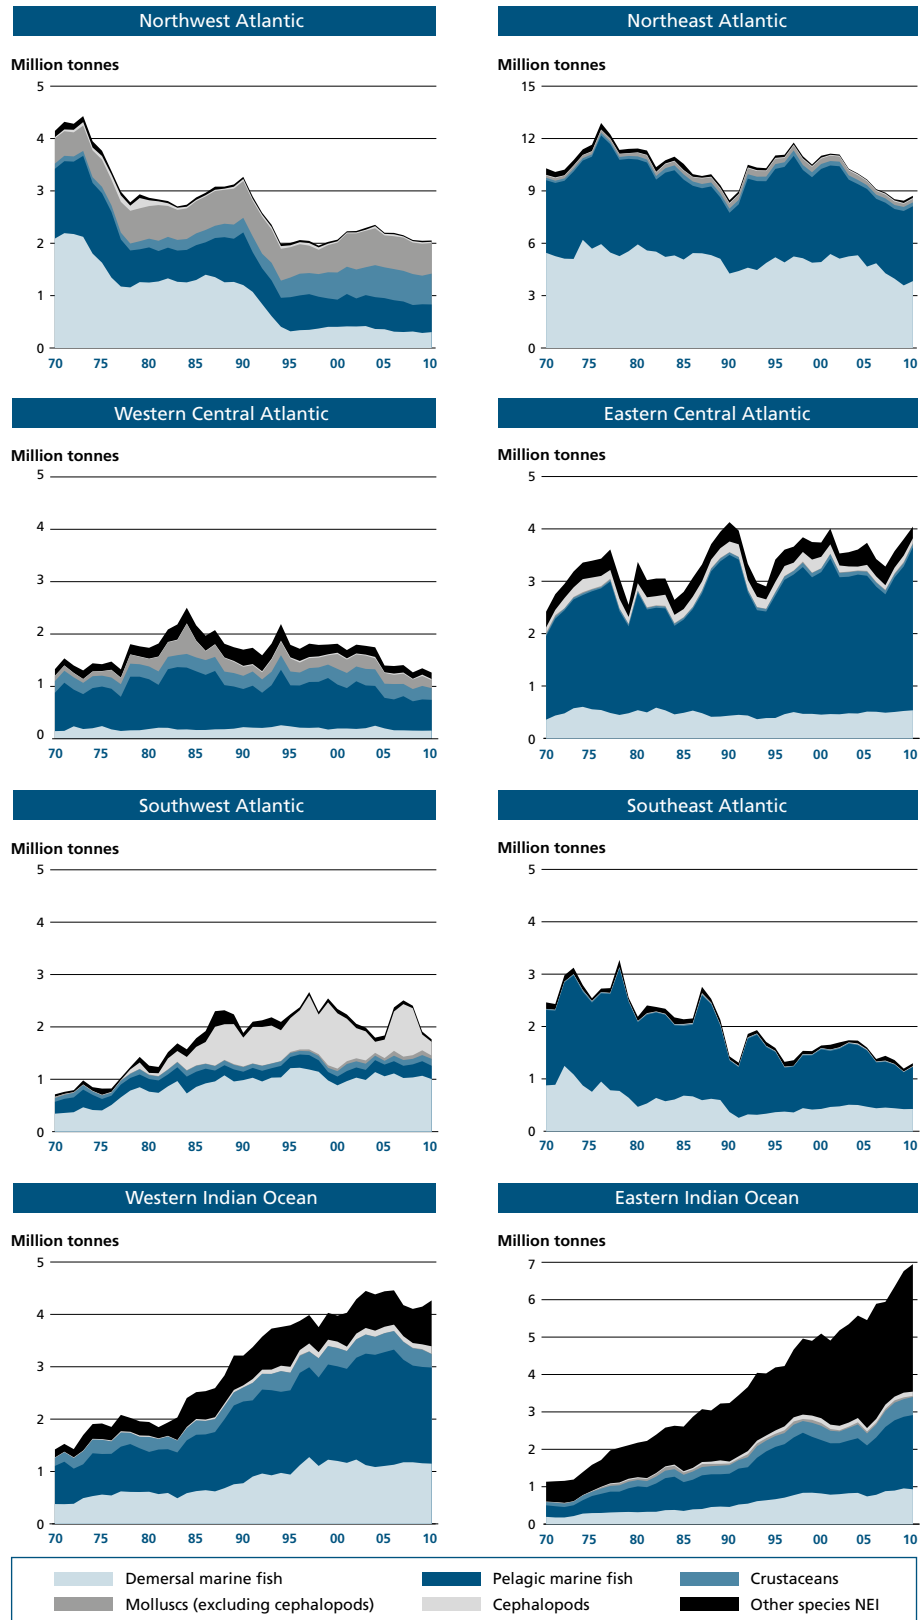

The total catch of tuna and tuna-like species was about 6.6 million tonnes in 2010. The principal market tuna species – albacore, bigeye, bluefin (three species), skipjack and yellowfin – contributed 4.3 million tonnes, maintaining approximately the same level since 2002. About 70 percent of these catches were from the Pacific. The skipjack was the most productive principal market tuna, contributing about 58 percent, and the yellowfin and bigeye were the other two productive species, contributing about 27 and 8 percent, respectively, to the 2010 catch of principal tunas. Bigeye, Atlantic bluefin, Pacific bluefin, southern bluefin and yellowfin tunas have all shown a gradual decline in catch after reaching historical peaks.

Among the seven principal tuna species, one-third were estimated to be overexploited, 37.5 percent were fully exploited, and 29 percent non-fully exploited in 2009. Although skipjack tuna continued its increasing trend up to 2009, further expansion should be closely monitored, as it may negatively affect bigeye and yellowfin tunas (multispecies fisheries). Only for very few stocks of the principal tuna species is their status unknown or very poorly known. In the long term, the status of tuna

Figure 17

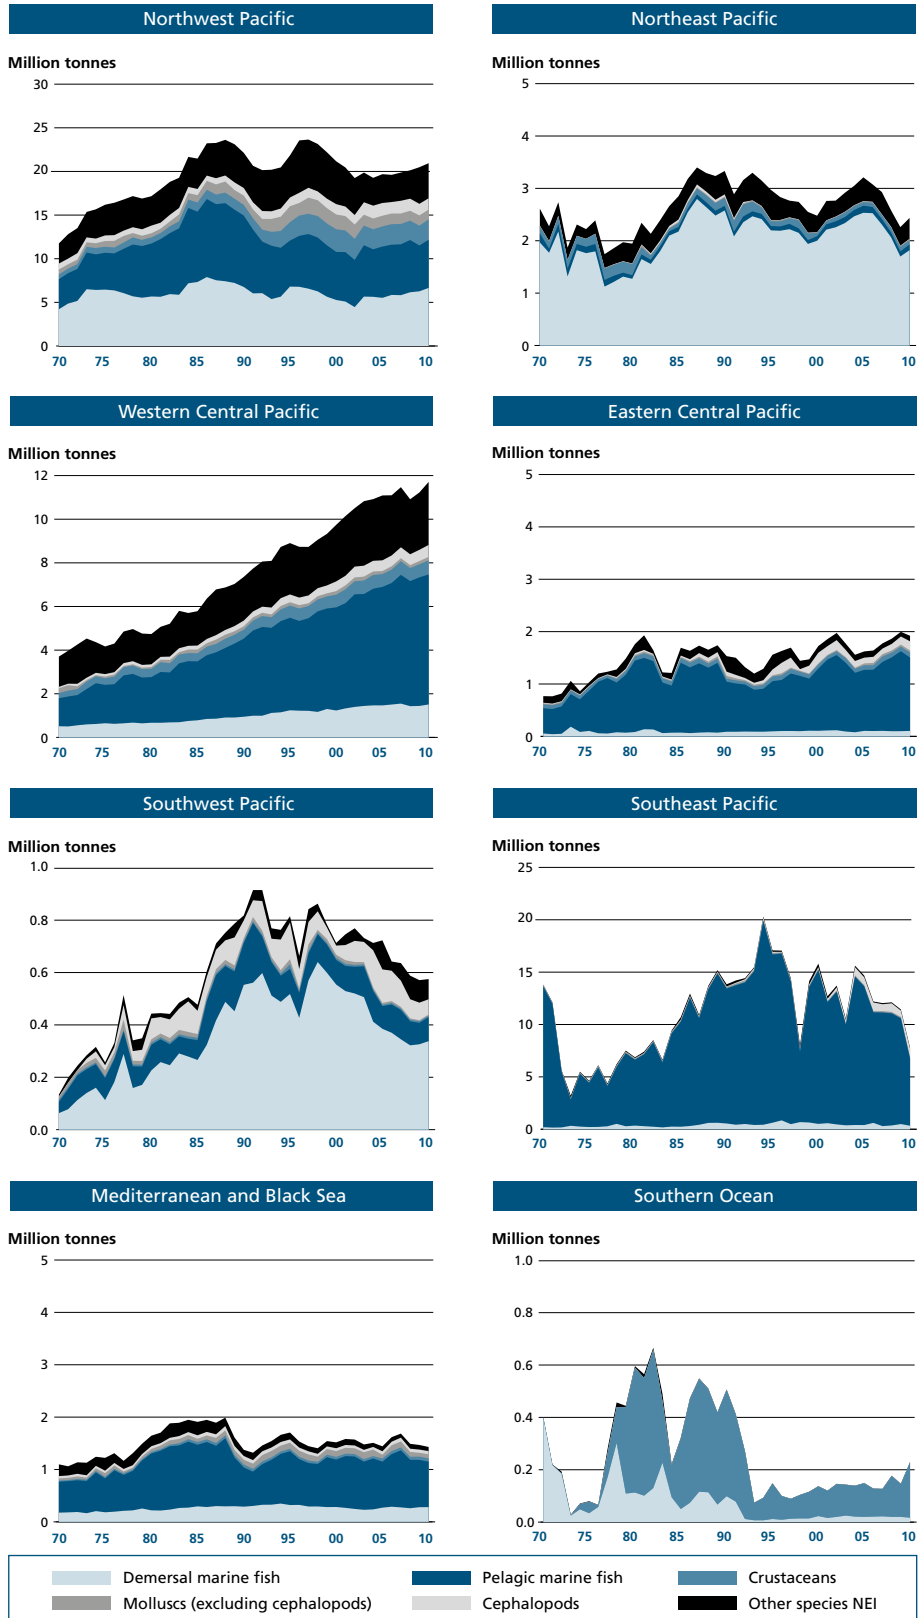

Capture fisheries production in marine areas

(Continued)

Figure 17 (cont.)

Capture fisheries production in marine areas

Note: NEI = not elsewhere included.

stocks (and consequently catches) may further deteriorate unless there are significant improvements in their management. This is because of the substantial demand for tuna and the significant overcapacity of tuna fishing fleets.

The concern about the poor status of some bluefin stocks and the inability of some tuna management organizations to manage these stocks effectively led to a proposal by Monaco in 2010 to ban the international trade in Atlantic bluefin tuna under CITES. Although it was hardly disputed that the stock status of this high-value food fish met the biological criteria for listing on CITES Appendix I, the proposal was ultimately rejected. Many parties that opposed the listing stated that in their view the International Commission for the Conservation of Atlantic Tunas (ICCAT) was the appropriate body for management of such an important commercially exploited aquatic species.

World marine fisheries have gone through significant changes since the 1950s. Accordingly, the exploitation level of fish resources and their landings have also varied over time. The temporal pattern of landings differs from area to area depending on the level of urban development and changes that countries surrounding that area have experienced. In general, they can be divided into three groups, i.e. one characterized by oscillations in the catches, another by an overall declining trend following historical peaks, and a third with increasing catch trends.

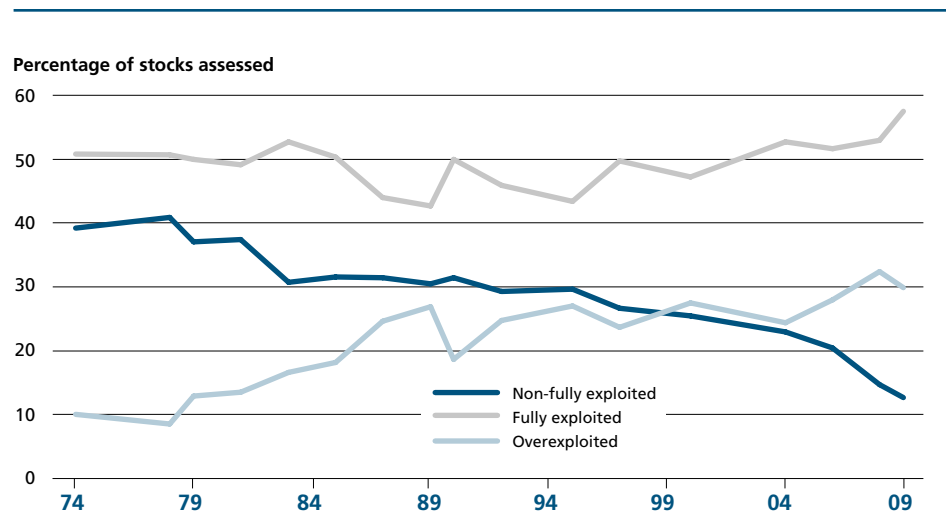

The first group includes those FAO areas that have demonstrated oscillations in total catch (Figure 17), i.e. the Eastern Central Atlantic (Area 34), Northeast Pacific (Area 67), Eastern Central Pacific (Area 77), Southwest Atlantic (Area 41), Southeast Pacific (Area 87), and Northwest Pacific (Area 61). These areas have provided about 52 percent of the world's total marine catch on average in the last five years. Several of these areas include upwelling regions that are characterized by high natural variability.

The second group consists of areas that have demonstrated a decreasing trend in catch since reaching a peak at some time in the past. This group has contributed 20 percent of global marine catch on average in the last five years, and includes the Northeast Atlantic (Area 27), Northwest Atlantic (Area 21), Western Central Atlantic (Area 31), Mediterranean and Black Sea (Area 37), Southwest Pacific (Area 81), and Southeast Atlantic (Area 47). It should be noted that lower catches in some cases reflect fisheries management measures that are precautionary or aim at rebuilding stocks, and this situation should, therefore, not necessarily be interpreted as negative.

The third group comprises the FAO areas that have shown continuously increasing trends in catch since 1950. There are only three areas in this group: Western Central

Figure 18

Global trends in the state of world marine fish stocks since 1974

Pacific (Area 71), Eastern (Area 57) and Western Indian Ocean (Area 51). They have contributed 28 percent of the total marine catch on average over the last five years. However, in some regions, there is still high uncertainty about the actual catches owing to the poor quality of statistical reporting systems in coastal countries.

The Northwest Pacific has the highest production among the FAO statistical areas. Its total catch fluctuated between about 17 and 24 million tonnes in the 1980s and 1990s, and was about 21 million tonnes in 2010. Small pelagics are the most abundant category in this area, with the Japanese anchovy providing 1.9 million tonnes in 2003 but having since declined to about 1.1 million tonnes in 2009 and 2010. Other important contributors to the total catch in the area are the largehead hairtail, considered overexploited, and the Alaska pollock and chub mackerel, both considered fully exploited. Squids, cuttlefish and octopuses are important species, yielding 1.3 million tonnes in 2010.

The Eastern Central Pacific has shown a typical oscillating pattern in its total catch since 1980 and produced about 2 million tonnes in 2010. The Southeast Pacific has had a large interannual variation with a generally declining trend since 1993. There have been no major changes in the state of exploitation of stocks in these two areas, which are characterized by a large proportion of small pelagic species and great fluctuations in catches. The most abundant species in the Southeast Pacific are the anchoveta, the Chilean jack mackerel and the South American pilchard or sardine (*Sardinops sagax*), accounting for more than 80 percent of the current and historical catches, while in the Eastern Central Pacific the most abundant species are California pilchard and Pacific anchoveta. A moderate El Niño developed in 2009 and continued throughout the equatorial Pacific in the first few months of 2010. Deep tropical convection remained enhanced across central and eastern parts of the tropical Pacific with relatively mild impacts reported on the state of stocks and fisheries in the eastern Pacific.

For the Eastern Central Atlantic, total catches, which have fluctuated since the 1970s, were about 4 million tonnes in 2010, about the same as the 2001 peak. The small pelagic species constitute almost 50 percent of the landings, followed by "miscellaneous coastal fishes". The single most important species in terms of landings is sardine (*Sardina pilchardus*) with landings in the range of 600 000–900 000 tonnes in the last ten years. The sardine in Zone C (Cape Bojador and southwards to Senegal) is still considered non-fully exploited; otherwise, most of the pelagic stocks are considered fully exploited or overexploited, such as the sardinella stocks in Northwest Africa and in the Gulf of Guinea. The demersal fish resources are to a large extent fully exploited to overexploited in most of the area, and the white grouper stock (*Epinephelus aeneus*) in Senegal and Mauritania remains in a severe condition. The status of some of the deepwater shrimp stocks seems to have improved and they are now considered fully exploited, whereas the other shrimp stocks in the region range between fully exploited and overexploited. The commercially important octopus (*Octopus vulgaris*) and cuttlefish (*Sepia* spp.) stocks remain overexploited. Overall, the Eastern Central Atlantic has 43 percent of its assessed stocks fully exploited, 53 percent overexploited and 4 percent non-fully exploited, a situation warranting attention for improvement in management.

In the Southwest Atlantic, total catches have fluctuated around 2 million tonnes after a period of increasing catches ended in the mid-1980s. Major species such as Argentina hake and Brazilian sardinella are still estimated to be overexploited, although there seem to be some signs of recovery for the latter. The catch of Argentina shortfin squid was only one-fourth of its peak level in 2009 and considered fully exploited to overexploited. In this area, 50 percent of the monitored fish stocks were overexploited, 41 percent fully exploited and the remaining 9 percent considered non-fully exploited.

The Northeast Pacific produced 2.4 million tonnes of fish in 2010, similar to the production level in the early 1970s, although more than 3 million tonnes was seen in the late 1980s. Cods, hakes and haddocks are the largest contributors to its catch.

In this area, only 10 percent of fish stocks were estimated to be overexploited, with 80 percent fully exploited, and another 10 percent non-fully exploited.

In the Northeast Atlantic, total catch appeared to have a decreasing trend after 1975, with a recovery in the 1990s, and was 8.7 million tonnes in 2010. The blue whiting stock decreased rapidly from the peak of 2.4 million tonnes in 2004 to only 0.6 million tonnes in 2009. Fishing mortality has been reduced in cod, sole and plaice, with recovery plans in place for the major stocks of these species. The Arctic cod spawning stock was particularly large in 2008, having recovered from the low levels observed in the 1960s–1980s. Similarly, the Arctic saithe and haddock stocks have increased to high levels, although stocks elsewhere remain fully exploited or overexploited. The largest sand eel and capelin stocks remain overexploited. Concern remains for redfishes and deep-water species for which data are limited and which are likely to be vulnerable to overfishing. Northern shrimp and Norway lobster are generally in good condition, but there are indications that some stocks are being overexploited. Recently, maximum sustainable yield has been adopted as the standard basis for reference points. Overall, 62 percent of assessed stocks are fully exploited, 31 percent overexploited, and 7 percent non-fully exploited.

Although fishery resources in the Northwest Atlantic continue to be under stress from previous and/or current exploitation, some stocks have recently shown signs of renewal in response to an improved management regime in the last decade (e.g. Greenland halibut, yellowtail flounder, Atlantic halibut, haddock, spiny dogfish). However, some historical fisheries such as cod, witch flounder and redfish still evidence lack of recovery, or limited recovery, which may be the result of unfavourable oceanographic conditions and the high natural mortality caused by increasing numbers of seals, mackerel and herring. These factors appear to have affected fish growth, reproduction and survival. Conversely, invertebrates remain at near record levels of abundance. The Northwest Atlantic has 77 percent of stocks fully exploited, 17 percent overexploited and 6 percent non-fully exploited.

The Southeast Atlantic is a typical example of the group of areas that has demonstrated a generally decreasing trend in catches since the early 1970s. This area produced 3.3 million tonnes in the late 1970s, but only 1.2 million tonnes were recorded in 2009. The important hake resources remain fully exploited to overexploited although there are signs of some recovery in the deepwater hake stock (*Merluccius paradoxus*) off South Africa and of the shallow-water Cape hake (*Merluccius capensis*) off Namibia, as a consequence of good recruitment years and of the strict management measures introduced since 2006. A significant change concerns the Southern African pilchard, which was at a very high biomass and estimated to be fully exploited in 2004, but which now, under unfavourable environmental conditions, has declined considerably in abundance and is now fully exploited or overexploited. In contrast, Southern African anchovy has continued to improve and its status was estimated to be fully exploited in 2009. Whitehead's round herring has not been fully exploited. The condition of Cunene horse mackerel has deteriorated, particularly off Namibia and Angola, and it was overexploited in 2009. The condition of the perlemoen abalone stock continues to be worrying, exploited heavily by illegal fishing, and it is currently overexploited and probably depleted.

The Mediterranean has maintained an overall stable catch in a difficult situation in recent years. All hake (*Merluccius merluccius*) and red mullet (*Mullus barbatus*) stocks are considered overexploited, as are probably also the main stocks of sole and most seabreams. The main stocks of small pelagic fish (sardine and anchovy) are assessed as either fully exploited or overexploited. A newly identified threat is the increasing penetration of exotic Red Sea species, which in some cases seem to be replacing native species, especially in the Eastern Mediterranean. In the Black Sea, the situation of small pelagic fish (mainly sprat and anchovy) has recovered somewhat from the drastic decline suffered in the 1990s, probably as a consequence of unfavourable oceanographic conditions, but they are still considered fully exploited to overexploited, an assessment shared with turbot, while most other stocks are probably fully exploited

to overexploited. In general, the Mediterranean and Black Sea had 33 percent of assessed stocks fully exploited, 50 percent overexploited, and the remaining 17 percent non-fully exploited in 2009.

Total production in the Western Central Pacific grew continuously to a maximum of 11.7 million tonnes in 2010. This area contributes about 14 percent of the global marine production. Despite this catch trend, there are reasons for concern as regards the state of the resources, with most stocks being either fully exploited or overexploited, particularly in the western part of the South China Sea. The high catches have probably been maintained through expansion of the fisheries to new areas and possible double counting in the transshipment of catches between fishing areas, which leads to bias in estimates of production, potentially masking negative trends in stock status.

The Eastern Indian Ocean (Fishing Area 57) is still experiencing a high growth rate in catches, with a 17 percent increase from 2007 to 2010, and now totalling 7 million tonnes. The Bay of Bengal and Andaman Sea regions have seen total catches increase steadily and there are no signs of the catch levelling off. However, a very high percentage (about 42 percent) of the catches in this area are attributed to the category "marine fishes not identified", which is a cause of concern as regards the need for monitoring stock status and trends. Increased catches may in fact be due to the expansion of fishing to new areas or species. Declining catches in the fisheries within Australia's EEZ can be partly explained by a reduction in effort and in catches following a structural adjustment and a ministerial direction in 2005 aimed at ceasing overfishing and allowing overfished stocks to rebuild. The economics of fishing in this area are expected to improve in the medium and long term, but higher profits can also be expected for individual fishers in the short term because fewer vessels are operating.

In the Western Indian Ocean, total landings reached a peak of 4.5 million tonnes in 2006, but have declined slightly since, and 4.3 million tonnes were reported in 2010. A recent assessment has shown that narrow-barred Spanish mackerel (*Scomberomerus commerson*), a migratory species found in the Red Sea, Arabian Sea, Gulf of Oman, Persian Gulf, and off the coast along Pakistan and India, is overexploited. Catch data in this area are often not detailed enough for stock assessment purposes. However, the Southwest Indian Ocean Fisheries Commission conducted stock assessments for 140 species in its mandatory area in 2010 based on best-available data and information. Overall, 65 percent of fish stocks were estimated to be fully exploited, 29 percent overexploited, and 6 percent non-fully exploited in 2009.

The declining global catch over the last few years together with the increased percentage of overexploited fish stocks and the decreased proportion of non-fully exploited species around the world convey a strong message – the state of world marine fisheries is worsening and has had a negative impact on fishery production. Overexploitation not only causes negative ecological consequences, but it also reduces fish production, which further leads to negative social and economic consequences. To increase the contribution of marine fisheries to the food security, economies and well-being of the coastal communities, effective management plans must be put in place to rebuild overexploited stocks. The situation seems more critical for some highly migratory, straddling and other fishery resources that are exploited solely or partially in the high seas. The United Nations Fish Stocks Agreement that entered into force in 2001 should be used as a legal basis for management measures of the high seas fisheries.

In spite of the worrisome global situation of marine capture fisheries, good progress is being made in reducing exploitation rates and restoring overexploited fish stocks and marine ecosystems through effective management actions in some areas. In the United States of America, the Magnuson–Stevens Act and subsequent amendments have created a mandate to put overfished stocks into restoration; 67 percent of all stocks are now being sustainably harvested, while only 17 percent are still being overexploited. In New Zealand, 69 percent of stocks are above management targets, reflecting mandatory rebuilding plans for all fisheries that are still below target thresholds. Similarly, Australia reports overfishing for only 12 percent of stocks in 2009.⁹ Since the 1990s, the Newfoundland–Labrador Shelf, the Northeast United

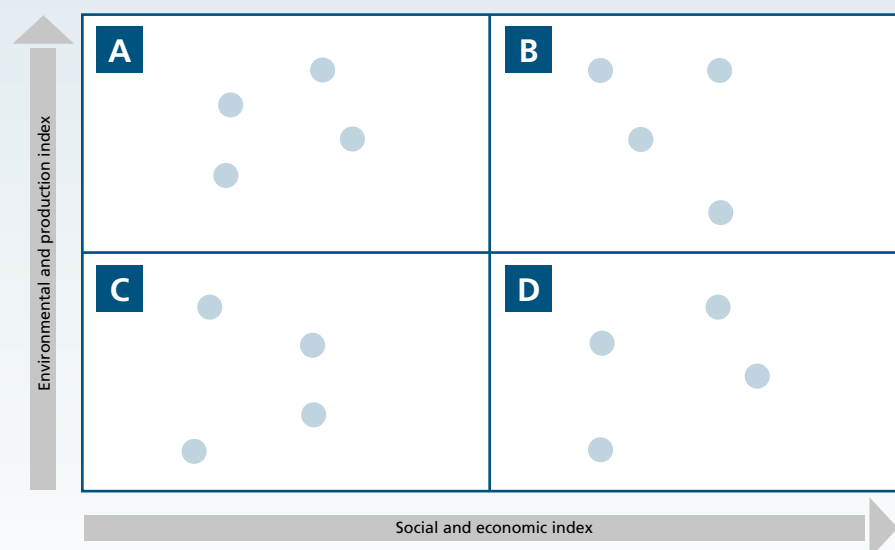

Box 4

Developing an assessment strategy for inland fishery resources

An accurate assessment of inland fishery resources must take into account the numerous aspects and drivers that influence the health of inland aquatic ecosystems and the status of inland fishery resources. Given the multiple uses of freshwater, it is recognized that an assessment of inland fishery resources should be based on more than just the amount of catch and the effort applied. The assessment should determine whether or not the management goals for the fishery or waterbody are being met. In general, the goals of responsible inland fisheries include an environmental component, e.g. production and protection of biodiversity, and a social and economic component, e.g. poverty reduction, income generation, and cultural heritage. Thus, rather than a single dimensional plot of status of exploitation rate, inland fisheries could be plotted on multidimensional axes that examine environmental and production parameters in the light of social and economic parameters. In the accompanying figure, specific inland capture fisheries (●) are assigned to a given quadrant (A, B, C or D) depending on how they perform according to environmental and production parameters (y-axis) and social and economic parameters (x-axis). Fisheries in quadrant B would be performing well on both environmental/production and social/economic criteria, whereas fisheries in quadrant C would be performing poorly. Individual fisheries could be tracked over time to determine how the state of the fishery was changing and whether changes to management are indicated. For example, a highly productive fishery that provided very little economic value would be placed in quadrant A; a very lucrative recreational fishery that focused on a few high-value species that were stocked from aquaculture facilities would be placed in D.

Conceptual diagram of assessment of the status of inland capture fisheries

For such an assessment, it will be necessary to develop appropriate indicators (i.e. data requirements) in order to create indices that can be expressed in a simple and effective graph. The objective would be to examine the services provided by inland fisheries over time to assess whether or not the fishery was performing as desired. The services provided by inland fisheries are similar to the ecosystem services provided by inland water ecosystems (see accompanying table). Specific services provided by inland capture fisheries could also be seen as management objectives. It is not expected that indices would be developed to encompass the complete range of services provided by inland capture fisheries. Additional work will be needed to prioritize data requirements and develop indicators that are informative, practical and cost-effective.

Ecosystem services provided by inland capture fisheries

Ecosystem service type	Specific service provided by inland capture fisheries
Provisioning	Food provision – extraction of aquatic organisms for human consumption and nutrition Livelihood provision – contribution to employment and income, including recreational and ornamental fisheries Aquaculture seed provision – inputs to aquaculture for grow-out
Cultural and scientific	Cultural heritage and identity – value associated with freshwater fisheries themselves Recreational fisheries – the non-commercial perspective Cognitive values – education and research resulting from the fisheries Catch composition and species as bio-indicators of health of ecosystem
Regulation	Regulation of food web dynamics Nutrient transport and cycling Control of pest organisms
Support	Maintenance of genetic, species and ecosystem biodiversity Resilience and resistance – life support by the freshwater environment and its response to pressures, including maintenance of ecosystem balance

The specific data requirements, indicators and indices for this assessment have not yet been established. However, together with partners and resource managers, FAO will work on refining the model and test its applicability in selected inland fisheries around the world.

States Shelf, the Southern Australian Shelf, and California Current ecosystems have shown substantial declines in fishing pressure such that they are now at or below the modelled exploitation rate that gives the multispecies maximum sustainable yield of the ecosystem.¹⁰ It is critically important to understand the key elements of these and other successes and apply them well to other fisheries.

Inland fisheries

The difficulty in assessing the state of inland capture fisheries has been noted in past editions of *The State of World Fisheries and Aquaculture* as well as by those working on the active management and development of inland fishery resources.¹¹ Reasons for the lack of adequate assessments include:

- the diffuse nature of the sector, with numerous landing sites and methods of fishing;
- the large number of people involved and the seasonality of fishing effort;
- the subsistence nature of many small-scale inland fisheries;
- the fact that catch is often consumed or traded locally without entering the formal market chain;
- a lack of capacity and resources to collect adequate data;
- activities not associated with inland fishing can greatly influence the abundance of inland fishery resources, e.g. stocking from aquaculture, water diversion for agriculture and hydroelectric development.

The informative and widely cited data summarizing the state of the major marine fish stocks are virtually impossible to duplicate for the state of the world's inland fisheries. The primary reason for this is that whereas exploitation rate is the main driver affecting the state of the major marine stocks that comprise the figure, other drivers affect the status of inland fishery resources to a much greater extent.¹² Drivers associated with habitat quantity and quality, including aquaculture in the form of stocking and competition for freshwater, influence the state of the majority of inland fishery resources much more than exploitation rates do. Water abstraction and diversion, hydroelectric development, draining wetlands, and siltation and erosion from land-use patterns can negatively affect inland fishery resources regardless of the rate of exploitation. Conversely, stock enhancement from aquaculture facilities, which is widely practised in inland waters, can keep catch rates high in the face of increased fishing and in spite of an ecosystem that is not capable of producing that level of catch through natural processes. Overexploitation can also affect inland fishery resources, but the result is generally a change in species composition and not necessarily a reduced overall catch. Catches are often higher where smaller and shorter-lived species become the main component of the catch; however, the smaller fish may be much less valuable.

Another issue complicating the assessment of inland fishery resources is the definition of a "stock". The major marine fish stocks are well defined biologically and geographically, and comprise management units. Very few inland fisheries have stocks that are defined as precisely or are defined at the level of species. There are notable exceptions, e.g. Lake Victoria Nile perch and Tonle Sap dai fisheries, but many inland fishery stocks are defined by watershed or river and comprise numerous species.

Nonetheless, it is vitally important that an accurate assessment be made of those inland fishery resources that are of major importance. The Twenty-eighth Session of COFI observed that data and statistics on small-scale fisheries, especially in inland waters, were not always comprehensive, resulting in underestimating their economic, social and nutritional benefits and contribution to livelihoods and food security.¹³ FAO convened a workshop in late 2011 to develop a strategy to undertake such an assessment¹⁴ (Box 4). The intention is to utilize the new methodology to provide a more robust and informative summary of the state of the world's inland capture fishery resources for future editions of *The State of World Fisheries and Aquaculture*.

FISH UTILIZATION AND PROCESSING

Fishery production is very heterogeneous in terms of its range of species and product forms. Being highly perishable, fish needs timely harvesting and procurement, efficient transportation, and advanced storage, processing and packaging facilities for its marketing. In particular, specific requirements and preservation techniques (Box 5) are needed in order to preserve its nutritional quality, extend its shelf-life, minimize the activity of spoilage bacteria and avoid losses caused by poor handling. Fish is also very versatile as it can be processed into a wide array of products to increase its economic value. It is generally distributed as live, fresh, chilled, frozen, heat-treated, fermented, dried, smoked, salted, pickled, boiled, fried, freeze-dried, minced, powdered or canned, or as a combination of two or more of these forms. Fish can also be preserved by many other methods destined for food or non-edible uses.

In 2010, 40.5 percent (60.2 million tonnes) of world fish production was marketed in live, fresh or chilled forms, 45.9 percent (68.1 million tonnes) was processed in frozen, cured or otherwise prepared forms for direct human consumption, and 13.6 percent destined to non-food uses (Figure 19). Since the early 1990s, there has been an increasing trend in the proportion of fisheries production used for direct human consumption rather than for other purposes. In the 1980s, about 68 percent of the fish produced was destined for human consumption, this share increased to 73 percent in the 1990s, and in 2010 it was more than 86 percent, equalling 128.3 million tonnes. In 2010, 20.2 million tonnes was destined to non-food purposes, of which 75 percent (15 million tonnes) was reduced to fishmeal and fish oil; the remaining 5.1 million tonnes was largely utilized as fish for ornamental purposes, for culture (fingerlings, fry, etc.), for bait, for pharmaceutical uses as well as raw material for direct feeding in aquaculture, for livestock and for fur animals.

In 2010, of the fish destined for direct human consumption, the most important product form was live, fresh or chilled fish, with a share of 46.9 percent, followed by frozen fish (29.3 percent), prepared or preserved fish (14.0 percent) and cured fish (9.8 percent). Freezing represents the main method of processing fish for human consumption, and it accounted for 55.2 percent of total processed fish for human consumption and 25.3 percent of total fish production in 2010. These general data mask significant differences. The utilization of fish and, more significantly, the processing methods vary according to the continent, region, country and even within countries. The highest percentage of fishmeal is produced by Latin American countries (44 percent of the total in 2010). In Europe and North America, fish in frozen and

Utilization of world fisheries production (breakdown by quantity), 1962–2010

Box 5

The work of the Codex Alimentarius Commission

The Codex Alimentarius Commission (CAC) develops Standards, Codes of Practice, and Guidelines in the area of food safety and fair practices in trade. The Standards specify the characteristics of food products, while the Codes of Practice identify the procedures that national competent authorities and operators in the food chain need to follow in order to reach those Standards. The Guidelines identify steps that need to be taken to protect consumers' health from certain specific food hazards. Standards, Codes of Practice and Guidelines are continuously updated, and new sections are added as required.

Recent work by the CAC has led to: (i) adoption of Standards for live and raw bivalve molluscs and fish sauce; (ii) updating of the Code of Practice for Fish and Fishery Products with sections on live and raw bivalve molluscs and smoked fish; and (iii) adoption of Guidelines on the Application of General Principles of Food Hygiene to the Control of Pathogenic *Vibrio* Species in Seafood.

canned forms represents more than two-thirds of fish used for human consumption. Africa has a higher proportion of cured fish (14 percent of total production) than the world average. In Africa, but also significantly in Asia, a large amount of production is commercialized in live or fresh forms. Live fish is particularly appreciated in Asia (especially by the Chinese population) and in niche markets in other countries, mainly among immigrant Asian communities. Commercialization of live fish has grown in recent years as a result of technological developments, improved logistics and increased demand. An elaborate network of handling, transport, distribution, display and holding facilities has been developed to support the marketing of live fish. New technological systems include specially designed or modified tanks and containers, as well as trucks and other transport vehicles equipped with aeration or oxygenation facilities to keep fish alive during transportation or holding and display. Nevertheless, marketing and transportation of live fish can be challenging as they are often subject to stringent health regulations and quality standards. In some parts of Southeast Asia, their commercialization and trade are not formally regulated but based on tradition. However, in markets such as the European Union, live fish have to comply with requirements, *inter alia*, concerning animal welfare during transportation.

Not only live fish, but, as mentioned above, fish and fishery products must be handled and transported by highly efficient distribution channels that can ensure that the integrity of the produce is maintained. Improvements in packaging help in preserving the quality of products. In the last few decades, major innovations in refrigeration, ice-making and transportation have also allowed the distribution of fish in fresh and other forms. As a result, developing countries have experienced a growth in the share of frozen products (24.1 percent of the total fish for human consumption in 2010, up from 18.9 percent in 2000) and of prepared or preserved forms (11.0 percent in 2010, compared with 7.8 percent in 2000). However, notwithstanding the technical advances and innovations, many countries, especially less-developed economies, still lack adequate infrastructure and services including hygienic landing centres, electric power supply, potable water, roads, ice, ice plants, cold rooms and refrigerated transport. These factors, associated with tropical temperatures, result in a high proportion of post-harvest losses and quality deterioration, with subsequent

risk to the health of consumers. In addition, marketing of fish is also more difficult owing to often limited and congested market infrastructure and facilities. Owing to these deficiencies, together with well-established consumer habits, fish in developing countries is commercialized mainly in live or fresh form (representing 56.0 percent of fish destined for human consumption in 2010) soon after landing or harvesting. Cured forms (dried, smoked or fermented) still remain a traditional method to retail and consume fish in developing countries, even if their share in total fish for human consumption is declining (10.9 percent in 2000 compared with 8.9 percent in 2010). In developed countries, the bulk of production destined to human consumption is commercialized frozen or in prepared or preserved forms. The proportion of frozen fish has been growing in the last four decades: it represented 33.2 percent of total production for human consumption in 1970, increased to 44.8 percent in 1990, to 49.8 percent in 2000, and reached a record high at 52.1 percent in 2010. The share of prepared and preserved forms remained rather stable during the same period and it was 26.9 percent in 2010 (Figure 20).

Fishmeal is the crude flour obtained after milling and drying fish or fish parts, and it is produced from whole fish, fish remains or other fish by-products resulting from processing. Many different species are used for fishmeal and fish-oil production. However, small pelagics, in particular anchoveta, are the main groups of species used for reduction, and the volume of fishmeal and fish oil produced worldwide annually fluctuates according to the fluctuations in the catches of these species. The El Niño phenomenon has considerable effects on catches of anchoveta, which has experienced a series of peaks and drastic drops in the last few decades, going from 12.5 million tonnes in 1994 to 4.2 million tonnes in 2010. Fishmeal production peaked in 1994 at 30.2 million tonnes (live weight equivalent) and has followed a fluctuating trend since then. In 2010, it dropped to 15.0 million tonnes owing to reduced catches of anchoveta, representing a 12.9 percent decrease compared with 2009, of 18.2 percent compared with 2008 and of 42.8 percent with respect to 2000. Another important source of raw material for the production of fishmeal is the processing waste from commercial fish species used for human consumption. Growing value addition in fishery products for human consumption leads to more residues, which in the past very often were simply discarded. Nowadays, more and more waste is used in feed markets, and a growing percentage of fishmeal is being obtained from trimmings and other residues from the preparation of fish fillets. According to recent estimates, about 36 percent of world fishmeal production was obtained from offal in 2010.

Figure 20

Utilization of world fisheries production (breakdown by quantity), 2010

In the past, fishery by-products, including waste, were considered to be of low value, or as a problem to be disposed of in the most convenient way or discarded. In the last two decades, there has been a global trend of growing awareness about the economic, social and environmental aspects of optimal use of fishery by-products, and of the importance of reducing discards and losses in post-harvesting phases (storage, processing and distribution). The utilization of fish by-products has become an important industry in various countries, with a growing focus on handling by-products in a controlled, safe and hygienic way. Improved processing technologies have also helped in their utilization. In addition to the fishmeal industry, fisheries by-products are also utilized for a wide range of other purposes, including the production of cosmetics and pharmaceuticals, other industrial processes, as direct feeding for aquaculture and livestock, incorporation into pet feed or feed for animals kept for fur production, ensiling, fertilizer and landfill. Technologies such as microencapsulation and nanoencapsulation are facilitating incorporation of important nutrients such as fish oils into various other foods. These technologies enable the extension of shelf-life, and provide a taste profile barrier eliminating fish-oil taste and odour while improving the nutritional availability. Chitin and chitosan obtained from shrimp and crab shells have a variety of uses, such as in water treatments, cosmetics and toiletries, food and beverages, agrochemicals and pharmaceuticals. From crustacean wastes, also the pigments carotenoids and astaxanthins can be extracted for use in the pharmaceutical industry, and collagen can be extracted from fish skin, fins and other processing discards. Fish silage and fish protein hydrolysates obtained from fish viscera are finding applications in the pet-feed and fish-feed industries. Calcium carbonate for industrial use can be obtained from mussel shells. In some countries, oyster shells are used as a raw material in the construction of buildings and for the production of quicklime (calcium oxide). Small fish bones, with a minimum amount of meat, are also consumed as snacks in some Asian countries. A number of anticancer agents have been discovered following research on marine sponges, bryozoans and cnidarians. However, following their discovery, for reasons of conservation, these agents are not extracted from marine organisms directly but are chemically synthesized. Another approach being researched is aquaculture of some sponge species. Fish skin, in particular of larger fish, is exploited to obtain gelatin as well as leather to be used in clothing, shoes, handbags, wallets, belts and other items. Species commonly used for leather include shark, salmon, ling, cod, hagfish, tilapia, Nile perch, carp and seabass. Shark cartilage is utilized in many pharmaceutical preparations and reduced in powder, creams and capsules, as are other parts of sharks, e.g. ovaries, brain, skin and stomach. In addition, shark teeth are used in handicrafts; similarly, the shells of scallops and mussels can be used in handicrafts and jewellery, and for making buttons. Procedures for the industrial preparation of biofuel from fish waste as well as from seaweeds are being developed.

Great technological development in food processing and packaging is in progress, with increases in efficient, effective and lucrative utilization of raw materials, and innovation in product differentiation for human consumption as well as for the production of fishmeal and fish oil. Processors of traditional products have been losing market share as a result of long-term shifts in consumer preferences as well as in processing and in the general fisheries industry. The fish industry is dynamic by nature and, in the last two decades, the utilization and processing of fish production have diversified significantly, fuelled by changing consumer tastes and advances in technology, packaging, logistics and transport. In developed countries, innovation in value addition is converging on convenience foods and a wider range of high-value-added products, mainly in fresh, frozen, breaded, smoked or canned forms to be marketed as ready and/or portion-controlled, uniform-quality meals. These require sophisticated production equipment and methods and, hence, access to capital. Supported by cheaper labour, in developing countries, processing is still done through less sophisticated methods of transformation, such as filleting, salting, canning, drying

and fermentation. These traditional labour-intensive, fish-processing methods provide livelihood support to large numbers of people in coastal areas in many developing countries, and they will probably remain important components in rural economies structured to promote rural development and poverty alleviation. However, in the last decade, fish processing has been evolving also in many developing countries, with increased fish processing. This may range from simple gutting, heading or slicing to more advanced value addition, such as breeding, cooking and individual quick-freezing, depending on the commodity and market value. Some of these developments are driven by demand in the domestic retail industry, by a shift in cultured species, by outsourcing of processing and by the fact that producers in developing countries are increasingly being linked with, and coordinated by, firms located abroad. Supermarket chains and large retailers are also emerging as important players in setting requirements for the products they buy. Processing is becoming more intensive, geographically concentrated, vertically integrated and linked with global supply chains. These changes reflect the increasing globalization of the fisheries value chain, with large retailers controlling the growth of international distribution channels. The increasing practice of outsourcing processing at the regional and world levels is very significant, its extent depending on the species, product form, and cost of labour and transportation. For example, in Europe, smoked and marinated products, for which shelf-life and transportation time are important, are being processed in Central and Eastern Europe, in particular in Poland and in the Baltic States. Whole frozen fish from European and North American markets are sent to Asia (China in particular, but also India and Viet Nam) for filleting and packaging, and then re-imported. The further outsourcing of production to developing countries might be restricted by sanitary and hygiene requirements that are difficult to meet as well as by growing labour costs.

At the same time, processors are frequently becoming more integrated with producers, especially for groundfish, where large processors in Asia, in part, rely on their own fleet of fishing vessels. In aquaculture, large producers of farmed salmon, catfish and shrimp have established advanced centralized processing plants to enhance the product mix, obtain better yields and respond to evolving quality and safety requirements in importing countries. Processors that operate without the purchasing or sourcing power of strong brands are also experiencing increasing problems linked to the scarcity of domestic raw material, and they are being forced to import fish for their business.

FISH TRADE AND COMMODITIES

Fish and fishery products are among the most traded food commodities worldwide. Trade plays a major role in the fishery industry as a creator of employment, food supplier, income generator, and contributor to economic growth and development. For many countries and for numerous coastal, riverine, insular and inland regions, fishery exports are essential to the economy. For example, in 2010 they accounted for more than half of the total value of traded commodities in Greenland, Seychelles, Faeroe Islands and Vanuatu. In the same year, fishery trade represented about 10 percent of total agricultural exports (excluding forest products) and 1 percent of world merchandise trade in value terms.

A significant share of total fishery production is exported in the form of various food and feed items. This share increased from 25 percent in 1976 to about 38 percent (57 million tonnes in 2010 (Figure 21), reflecting the sector's growing degree of openness to, and integration in, international trade. Sustained demand, trade liberalization policies, globalization of food systems and technological innovations have furthered the overall increase in international fish trade. Improvements in processing, packaging and transportation as well as changes in distribution and marketing have significantly changed the way fishery products are prepared, marketed and delivered to consumers. All these factors have facilitated and increased the movement of production in relative terms from local consumption to international markets. The fishery supply chain is complex as goods might cross national boundaries several times before final consumption, also owing to increasing outsourcing of processing to

countries where comparatively low wages and production costs provide a competitive advantage, as indicated above in the Fish Utilization and Processing section.

In the period 1976–2008, world trade in fish and fishery products grew significantly also in value terms, rising from US\$8 billion to US\$102 billion, with annual growth rates of 8.3 percent in nominal terms and of 3.9 percent in real terms. In 2009, as a consequence of the general economic contraction affecting consumer confidence in major markets, trade dropped by 6 percent compared with 2008. The decline was only in value terms as a consequence of falling prices and margins, whereas traded volumes, expressed in live weight equivalent, increased by 1 percent to 55.7 million tonnes. The decrease was not uniform and, in particular, many developing countries experienced rising demand and imports even during a difficult 2009. In 2010, trade rebounded strongly, reaching about US\$109 billion, with an increase of 13 percent in value terms and 2 percent in volume compared with 2009. The difference between the growth in value and volume reflects the higher fish prices experienced during 2010 as well as a decrease in the production of and trade in fishmeal.

In 2011, despite the economic instability experienced in many of the world's leading economies, increasing prices and strong demand in developing countries pushed trade volumes and values to the highest level ever reported and, despite some softening in the second half of the year, preliminary estimates indicate that exports exceeded US\$125 billion. It is worth noting that currency fluctuations influence not only sales and markets, but also trade statistics; for statistics stated in US dollars, a weakening dollar will inflate both import and export figures.

Fishery trade is closely tied to the overall economic situation. In the last few years, world trade has been hit by a series of economic, financial and food crises. After the 12 percent drop experienced in 2009, world trade recovered strongly in 2010 and, according to the World Trade Organization (WTO), merchandise exports increased by 14.5 percent, sustained by a 3.6 percent growth in global output as measured by gross domestic product.¹⁵ In 2010, economic conditions rebounded in both developed and developing economies, but the resurgence of both trade and output was slower in developed countries. The World Bank estimates that the volume of global trade (merchandise and services) increased by a further 6.6 percent in 2011.¹⁶ However, performance across the year was not uniform. Since late 2011 and early 2012, the world economy has entered a difficult phase characterized by significant downside risks and fragility, with great uncertainty on how markets will evolve in the medium

Figure 21

World fisheries production and quantities destined for export

term. The financial turmoil generated by the intensification of the fiscal crisis in Europe has expanded to both developing and high-income countries. As a result, and despite relatively strong activity in the United States of America and Japan, key markets for fisheries trade, global growth and world trade have slowed sharply. In addition, among other risks, there is the possibility that geopolitical and domestic political tensions could disrupt oil supplies, which could have an impact on increasing costs of capture fisheries as well. Therefore, according to the World Bank, the global economy is now expected to expand by 2.5 percent in 2012 and by 3.1 percent in 2013. The growth rate for high-income countries should be 1.4 percent in 2012 and 2.0 percent in 2013, while growth for developing countries is projected at 5.4 percent and 6.0 percent in 2012 and 2013, respectively. Reflecting this slowdown, world trade is expected to expand by 4.7 percent in 2012, before strengthening to 6.8 percent in 2013. Despite the renewed economic instability, fish trade has expanded in key markets in the first few months of 2012, and the long-term trend for fish trade remains positive, with a growing share of fish production entering international markets.

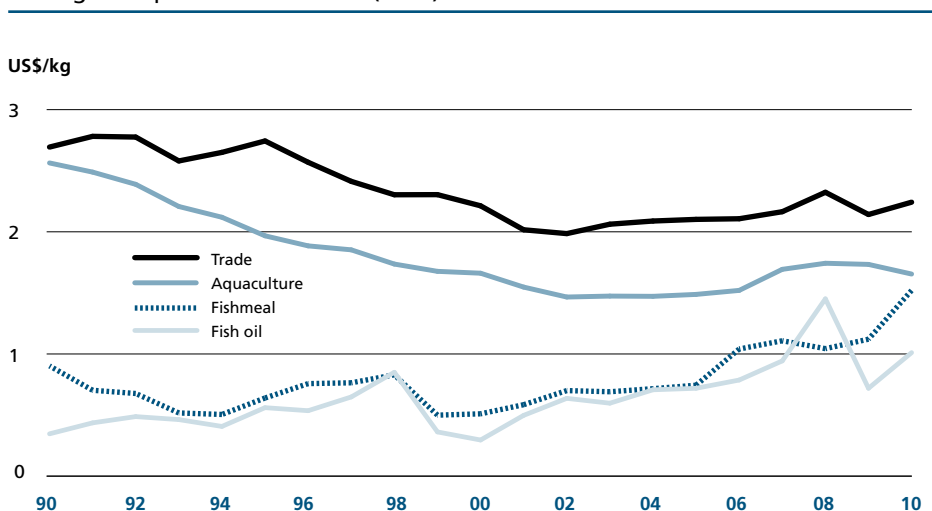

Among the factors that might influence the sustainability and growth of fishery trade are the evolution of production and transportation costs and the prices of fishery products and alternative commodities, including meat and feeds. As is the case for other products, fish prices are influenced by demand and supply factors. At the same time, the very heterogeneous nature of the sector, with hundreds of species and thousands of products entering international trade, makes it challenging to estimate price developments for the sector as a whole. In the last few decades, the growth in aquaculture production has contributed significantly to increased consumption and commercialization of species that were once primarily wild-caught, with a consequent price decrease. This was particularly evident in the 1990s and early 2000 (Figure 22), with average unit values of aquaculture production and trade in real terms regularly declining. Subsequently, owing to increased costs and continuous high demand, prices have started to rise again. In the next decade, with aquaculture accounting for a much larger share of total fish supply, the price swings of aquaculture products could have a significant impact on price formation in the sector overall, possibly leading to more volatility.

Similar to trade, also fish prices contracted in 2009 but have since rebounded. Fish prices rose strongly in the first part of 2011, declining slightly towards the end of the year and into early 2012, but remaining higher than levels of earlier years. Rising energy and feed costs will probably keep fish prices high in 2012, especially

Figure 22

Average fish prices in real terms (2005)

as alternative protein sources such as meat are influenced by the same factors. Since 2009, FAO has been working on the construction and enhancement of a fish price index to illustrate both relative and absolute price movements. The index is being developed in cooperation with the University of Stavanger and with data support from the Norwegian Seafood Council. The FAO Fish Price Index (base year 2002–04 = 100) indicates that average prices in 2009 declined by 7 percent compared with 2008, then increased by 9 percent in 2010 and by more than 12 percent in 2011. The absolute peak in the index was reached in August 2011 at 158.3 (14 percent more than in August 2010). Prices for species from capture fisheries increased by more than those for farmed species because of the larger impact from higher energy prices on fishing vessel operations than on farmed species.

Trade in fish and fishery products is characterized by a wide range of product types and participants. In 2010, 197 countries reported exports of fish and fishery products. The role of fishery trade varies among countries and is important for many economies, in particular for developing nations. Table 12 shows the top ten exporters and importers of fish and fishery products in 2000 and 2010. Since 2002, China has been by far the leading fish exporter, contributing almost 12 percent of 2010 world exports of fish and fishery products, or about US\$13.3 billion, and increasing further to US\$17.1 billion in 2011. China's fishery exports have grown considerably since the 1990s, although at present they represent only 1 percent of its total merchandise exports. A growing share of fishery exports consists of reprocessed imported raw material. Thailand has established itself as a processing centre of excellence largely dependent on imported raw material, while Viet Nam has a growing domestic resource base and imports only limited, albeit growing, volumes of raw material. Viet Nam has experienced significant growth in its exports of fish and fish products, up from US\$1.5 billion in 2000 to US\$5.1 billion in 2010, when it became the fourth-largest exporter in the world. In 2011, its exports rose further to US\$6.2 billion. Its rising exports are linked to its flourishing aquaculture industry, in particular to the production of *Pangasius* and of both marine and freshwater shrimps and prawns.

In addition to China, Thailand and Viet Nam, many other developing countries play a major role in global fisheries. In 2010, developing countries confirmed their fundamental importance as suppliers to world markets with more than 50 percent of all fishery exports in value terms and of more than 60 percent in quantity (live weight). For many developing nations, fish trade represents a significant source of foreign currency earnings in addition to the sector's important role as a generator of income, source of employment, and provider of food security and nutrition. The fishery industries of developing countries rely heavily on developed countries, not only as outlets for their exports, but also as suppliers of their imports for local consumption (mainly low-priced small pelagics as well as high-value fishery species for emerging economies) or for their processing industries. In 2010, in value terms, 67 percent of the fishery exports of developing countries were directed to developed countries. A growing share of these exports consisted of processed fishery products prepared from imports of raw fish to be used for further processing and re-export. In 2010, in value terms, 39 percent of the imports of fish and fishery products by developing countries originated from developed countries. Developing countries cover an important segment of world exports of non-food fish exports (74 percent in 2010 in terms of quantity). Fishmeal represents a significant share of their exports (35 percent by quantity, but only 5 percent by value in 2010). However, developing countries have also considerably increased their share of the quantity of world fish exports destined for human consumption, from 32 percent in 1980 to 47 percent in 2000 and to 56 percent in 2010. Net exports of fish and fish products (i.e. the total value of fish exports less the total value of fish imports) are particularly important for developing countries, being higher than those of several other agricultural commodities such as rice, meat, sugar, coffee and tobacco (Figure 23). They have grown significantly in recent decades, rising from US\$3.7 billion in 1980 to US\$10.2 billion in 1990, to US\$18.3 billion in 2000, and reaching US\$27.7 billion in 2010. For LIFDCs, net export revenues amounted to US\$4.7 billion in 2010, compared with

US\$2.0 billion in 1990.¹⁷ In 2010, their fishery exports (US\$8.2 billion) accounted for 8 percent of world exports in value terms.

World imports¹⁸ of fish and fish products set a new record at US\$111.8 billion in 2010, up 12 percent on the previous year and up 86 percent with respect to 2000. Preliminary data for 2011 point to further growth, with a 15 percent increase. The United States of America and Japan are the major importers of fish and fishery products and are highly dependent on imports for about 60 percent and 54 percent, respectively, of their fishery consumption. With a growing population and a positive long-term trend in seafood consumption, United States imports reached US\$15.5 billion in 2010, 12 percent more than in 2009, and further increased in 2011 to US\$17.5 billion. After the decline of 11 percent experienced in 2009 as compared with 2008, Japanese imports of fish and fishery products increased by 13 percent in 2010. In 2011, they grew by a further 16 percent, reaching US\$17.4 billion, also as a consequence of the tsunami that struck Japan in early 2011, which had an impact on the country's production capacity in the affected area, with damage to the fleet, aquaculture facilities, processing plants and port infrastructure. China, the world's largest fish producer and exporter, has significantly increased its fishery imports, partly a result of outsourcing, as Chinese processors import raw material from all major regions, including South and

Figure 23

Net exports of selected agricultural commodities by developing countries

North America and Europe for re-processing and export. Imports are also being fuelled by robust domestic demand for species not available from local sources, in particular marine species, as a consequence of economic growth and rising disposable incomes. Its imports increased from US\$1.8 billion in 2000 to US\$6.2 billion in 2010. Imports further grew by 23 percent in 2011 to US\$7.6 billion, when China became the third-largest importer in the world. This increase in imports also reflects the lowered import duties following China's accession to the WTO in late 2001.

The European Union is by far the largest single market for imported fish and fishery products owing to its growing domestic consumption. However, it is extremely heterogeneous, with markedly different conditions from country to country. European Union fishery imports reached US\$44.6 billion in 2010, up 10 percent from 2009, and representing 40 percent of total world imports. However, if intraregional trade is excluded, the European Union imported fish and fishery products worth US\$23.7 billion from suppliers outside the European Union, an increase of 11 percent from 2009. This makes the European Union the largest market in the world, with about 26 percent of world imports (excluding intra-European Union trade). In 2011, imports rose further to US\$50.0 billion including intra-European Union trade (US\$26.5 billion if excluded). The dependence of the European Union on imports for its fish consumption is growing. This is a result of the positive underlying trend in consumption, but also evidences the constraints within the European Union on further expansion of supply. In this respect, the current reform of its Common Fisheries Policy aims to rebuild its fish stocks, as well as boosting its aquaculture production. The results of the reform and the effects on supply and trade will only be felt in the medium-to-long term.

In addition to the major importing countries, a number of emerging markets have become of growing importance to the world's exporters. Prominent among these there are Brazil, Mexico, the Russian Federation, Egypt, Asia and the Near East in general. In Asia, Africa and South and Central America, regional trade continues to be of importance even though it is not always adequately reflected in official statistics. Improved domestic distribution systems for fish and fishery products have played a role in increased regional trade, as has growing aquaculture production. Domestic markets, in particular in Asia, but also in Central and South America, remained strong in 2010–11, providing welcome outlets for domestic and regional producers. Africa has also become a growing market for farmed freshwater species from Asia.

In 2010, developed countries were responsible for 76 percent of the total import value of fish and fishery products, a decline compared with the 86 percent of 1990 and 83 percent of 2000. In volume (live weight equivalent), the share of developed countries is significantly less, 58 percent, reflecting the higher unit value of products imported by developed countries. Owing to stagnating domestic fishery production, developed countries have to rely on imports and/or on domestic aquaculture to cover their increasing domestic consumption of fish and fishery products. This may be one reason for low import tariffs on fish in developed countries, albeit with a few exceptions, i.e. for some value-added products. As a consequence, in the last few decades, developing countries have increasingly been able to supply fishery products to markets of developed countries without facing prohibitive custom duties. In 2010, 48 percent of the import value of developed countries originated from developing countries.

In recent decades, there has been a tendency towards increased fishery trade within regions. Most developed countries trade more with other developed countries. In 2010, in value terms, 79 percent of fishery exports from developed countries were destined to other developed countries, and about 52 percent of fishery imports of developed countries originated from other developed countries. In the same year, fishery trade between developing countries represented only 33 percent of the value of their exports of fish and fishery products. Over time, fishery trade between developing countries will probably increase in the wake of rising disposable incomes in emerging economies, gradual trade liberalization and a reduction in the high import tariffs following the expanding membership of the WTO, and the entry into force of a number of bilateral trade agreements with strong relevance to the trade in fish. The maps in Figure 24 summarize the average trade flows of fish and fishery products by continent for the period 2008–2010. The overall picture presented by these maps is not exhaustive as trade data are not fully available for all countries, in particular for several African countries. However, the quantity of data at hand is sufficient to establish general trends, with no major changes taking in place compared with the past few years. The Latin America and the Caribbean region continues to maintain a solid positive net fishery exporter role, as is the case for the Oceania region and the developing countries of Asia. By value, Africa has been a net exporter since 1985, but it is a net importer in quantity terms, reflecting the lower unit value of imports (mainly for small pelagics). Europe and North America are characterized by a fishery trade deficit (Figure 25).

Some of the major issues in the past biennium that continue to affect fishery international trade are:

- the volatility of commodity prices in general and their influence on producers as well as on consumers;
- the impact on the domestic fisheries sector of the rising imports of farmed products;
- the role of the small-scale sector in future fish production and trade;
- the relationship between fisheries management design, allocation of rights and the economic sustainability of the sector;
- the introduction of private standards, including for environmental and social purposes, and their endorsement by major retailers;
- the multilateral trade negotiations within the WTO, including the focus on fisheries subsidies;
- climate change, carbon emissions and their impacts on the fisheries sector;
- the growing concern of the general public and the retail sector about overexploitation of certain fish stocks;
- the need to ensure that internationally traded fishery products from capture fisheries have been produced legally;
- the need for competitiveness versus other food products;
- the perceived and real risks and benefits of fish consumption.

Commodities

The fishery market is very dynamic and it is changing rapidly. It is becoming much more complex and stratified, with greater diversification among species and product forms. High-value species such as shrimp, prawns, salmon, tuna, groundfish, flatfish, seabass and seabream are highly traded, in particular towards more prosperous markets. Low-value species such as small pelagics are also traded in large quantities, mainly being exported to feed low-income consumers in developing countries. In the last two decades, aquaculture has contributed to a growing share of the international trade in fishery commodities, with species such as shrimp, prawns, salmon, molluscs, tilapia, catfish (including *Pangasius*), seabass and seabream. Aquaculture is expanding in all continents in terms of new areas and species, as well as intensifying and diversifying the product range in species and product forms to respond to consumer needs. Many of the species that have registered the highest export growth rates in the last few years are produced by aquaculture. However, it is difficult to determine the extent of this trade because the classification used internationally to record trade statistics for fish does not distinguish between products of wild and farmed origin. Hence, the exact breakdown between products of capture fisheries and aquaculture in international trade is open to interpretation.

Owing to the high perishability of fish and fishery products, 90 percent of trade in fish and fishery products in quantity terms (live weight equivalent) consists of processed products (i.e. excluding live and fresh whole fish). Fish are increasingly traded as frozen food (39 percent of the total quantity in 2010, compared with 25 percent in 1980). In the last four decades, prepared and preserved fish have nearly doubled their share in total quantity, going from 9 percent in 1980 to 16 percent in 2010. Notwithstanding their perishability, trade in live, fresh and chilled fish represented 10 percent of world fish trade in 2010, up from 7 percent in 1980, reflecting improved logistics and increased demand for unprocessed fish. Trade in live fish also includes ornamental fish, which is high in value terms but almost negligible in terms of quantity traded. In 2010, 71 percent of the quantity of fish and fishery products exported consisted of products destined for human consumption. The US\$109 billion exports of fish and fishery products in 2010 do not include an additional US\$1.3 billion for aquatic plants (62 percent), inedible fish waste (31 percent) and sponges and corals (7 percent). In the last two decades, trade in aquatic plants has increased significantly, going from US\$0.2 billion in 1990 to US\$0.5 billion in 2000 and to US\$0.8 billion in 2010, with China as the major exporter and Japan as the leading importer. Trade in inedible fish waste has also grown remarkably in this period, owing to the increasing production of fishmeal and other products deriving from fishery residues from processing (see the Fish Utilization and Processing section above). From just US\$61 million in 1990, exports of inedible fish rose to US\$0.2 billion in 2000 and reached US\$0.4 billion in 2010.

Shrimp

Shrimp continues to be the largest single commodity in value terms, accounting for about 15 percent of the total value of internationally traded fishery products in 2010. In 2010, the shrimp market recovered, after the decline of 2009, characterized by stable volumes, but by substantially decreases of prices. In 2011, notwithstanding a contraction in world production of farmed shrimp, the market performed well. Despite the scepticism and concern over the economic situation, both the United States of America and the European Union imported more shrimp than the year before. The Japanese market moved away from basic raw shrimp to value-added and processed shrimp, thus paying more for imports. Many domestic and regional markets in Asia and Latin America consumed more shrimp, which also kept their prices relatively high and stable throughout 2011 (Figure 26). In 2012, the shrimp market began with positive notes in demand and price trends in various markets. In value terms, the major exporting countries are Thailand, China and Viet Nam. The United States of America continues to be the main shrimp importer, followed by Japan.

Salmon

The share of salmon and trouts in world trade has increased considerably in recent decades, and in 2010 it was more than 14 percent. Overall, demand for farmed salmon has been growing steadily from year to year. However, supply has been more variable, mostly as a result of disease-related problems in the producing countries. In a situation with a positive long-term trend in demand, a temporary shortfall in supply is bound to lead to large price reactions, and this is what happened in 2010 and early 2011, with exceptionally high prices, in particular for farmed Atlantic salmon. Prices started to weaken in the following months also as a result of large additional volumes of farmed salmon reaching world markets. At the beginning of 2012, prices recovered from the low levels reached in late 2011. Demand growth continues to be consistent

in most markets and it is expanding geographically, in particular for farmed Atlantic salmon, also through new varieties of processed products. Norway remains the dominant producer and exporter of Atlantic salmon, but Chile is rapidly ramping up its production towards levels prior to the crisis experienced in 2010. Wild Pacific salmon also plays an important part in world salmon markets with wild salmon representing about 30 percent of the total market for salmonids.

Groundfish

Groundfish species represented about 10 percent of total fish exports by value in 2010. Their prices went down in 2010 and 2011 as a result of good supply from capture fisheries and strong competition from farmed species such as *Pangasius* and tilapia on the market (Figure 27). General demand for groundfish species is increasing, and increased supply will come from good management practices of the wild stocks. Emerging countries will provide new opportunities. For example, Brazil has become a growing destination for Norwegian cod, helping to ease somewhat the concerns of Norwegian exporters that their sales in southern Europe were being affected by the economic crisis, particularly in Portugal, which is the largest single importer of Norwegian cod.

Tuna

The share of tuna in total fish exports in 2010 was about 8 percent. In the last three years, tuna markets have been unstable owing to large fluctuations in catch levels. The major issues affecting the global tuna sector in 2011 were lower catches in major fishing areas, growing restrictions on longline and purse-seine fishing in the pursuit of more sustainable resource management, other moves towards sustainability and the introduction of ecolabels. These factors have had an impact on the tuna market for sashimi and as raw material for canning, with consequent increases in tuna prices (Figure 28). Japan continues to be the main market for sashimi-grade tuna, while the European Union and the United States of America represent the major importers and Thailand the main exporter of canned tuna.

Cephalopods

The share of cephalopods (squid, cuttlefish and octopus) in world fish trade was 4 percent in 2010. Spain, Italy and Japan are the largest consumers and importers of these species. Thailand is the largest exporter of squid and cuttlefish, followed by Spain, China and Argentina, while Morocco and Mauritania are the principal octopus exporters. Recently, Mexico has also emerged as an important supplier to Europe. Supplies of octopus have been a problem, and throughout 2011 this characterized the trade. Import volumes in the main markets, however, were relatively stable, with growing price levels (Figure 29). The diminishing catches of octopus have revived interest in octopus farming. Whether the new technologies being experimented will be able to produce significant amounts of octopus of the right market size in the future remains to be seen, although progress so far is encouraging. Squid supplies were also quite tight throughout 2011. This is reflected in the trade figures. Imports into all major markets, with the exception of Japan, declined. The cuttlefish market has been flat for the last few years. The main importers have seen little variation in imported volumes over the years, although there have been some changes among the suppliers to the various markets.

Pangasius

Pangasius is a freshwater fish, and it is a relatively recent arrival in terms of international trade. However, with production of about 1.3 million tonnes, mainly in Viet Nam and all going to the international markets, this species is an important source of low-priced fish. The European Union and the United States of America are the main importers of *Pangasius*. In 2011, imports declined in the European Union, while they increased in the United States market. Supply issues affected the *Pangasius* sector in Viet Nam, and overall output declined in 2011. Although Viet Nam is the largest supplier to the European Union markets, the product is also sourced from China and Thailand. Asian demand remains strong with new markets emerging, including those of India and the Near East, in particular for fillets. Local production facilitated by aggressive promotional activities is also increasing in many countries for domestic consumption.

Fishmeal

Fishmeal production and trade decreased significantly in 2010 owing to reduced catches of anchoveta, while production for 2011 increased by about 40 percent in the

Figure 29

Octopus prices in Japan

Note: kg/pc = kilograms per piece. Data refer to wholesale prices. Whole, 8 kg/block.

major producing countries. Demand for fishmeal was strong in 2010 and 2011, leading to sharply higher fishmeal prices (Figure 30). Despite some recent softening in late 2011 and early 2012, prices remain at fairly high levels. China remains the main market for fishmeal, importing more than 30 percent of the fishmeal quantity, while Peru and Chile are the major exporters.

Fish oil

Improved landings and access to raw material contributed to a rise in fish-oil production in 2011, after the decline in 2010. Notwithstanding some fluctuations, fish-

oil prices continued to be at high levels in 2011 and early 2012 (Figure 31). Demand from the aquaculture and health supplement sectors will continue to take most of the volumes offered. The share going to aquaculture is used as an ingredient in fish and shrimp feeds. In 2011, a large increase in salmonoid production in Chile boosted oil demand from Chile and Peru while producers in Europe were able to increase supply, despite high prices of mackerel and herring for direct human consumption.

FISH CONSUMPTION¹⁹

Fish and fishery products represent a valuable source of nutrients of fundamental importance for diversified and healthy diets. With a few exceptions for selected species, fish is usually low in saturated fats, carbohydrates and cholesterol. Fish provides not only high-value protein, but also a wide range of essential micronutrients, including various vitamins (D, A and B), minerals (including calcium, iodine, zinc, iron and selenium) and polyunsaturated omega-3 fatty acids (docosahexaenoic acid and eicosapentaenoic acid). While average per capita fish consumption may be low, even small quantities of fish can have a significant positive nutritional impact by providing essential amino acids, fats and micronutrients that are scarce in vegetable-based diets. There is evidence of beneficial effects of fish consumption²⁰ in relation to coronary heart disease,²¹ stroke, age-related macular degeneration and mental health.²² There is also convincing evidence of benefits in terms of growth and development, in particular for women and children during gestation and infancy for optimal brain development of children.²³

On average, fish provides only about 33 calories per capita per day. However, it can exceed 150 calories per capita per day in countries where there is a lack of alternative protein food and where a preference for fish has been developed and maintained (e.g. Iceland, Japan and several small island States). The dietary contribution of fish is more significant in terms of animal proteins, as a portion of 150 g of fish provides about 50–60 percent of the daily protein requirements for an adult. Fish proteins can represent a crucial component in some densely populated countries where total protein intake levels may be low. In fact, many populations, more those in developing countries than developed ones, depend on fish as part of their daily diet. For them, fish and fishery products often represent an affordable source of animal protein that may not only be cheaper than other animal protein sources, but preferred and part of local and traditional recipes. For example, fish contributes to, or exceeds, 50 percent of total animal protein intake in some small island developing States, as well as in Bangladesh,

Cambodia, Ghana, the Gambia, Indonesia, Sierra Leone and Sri Lanka. In 2009, fish²⁴ accounted for 16.6 percent of the global population's intake of animal protein and 6.5 percent of all protein consumed (Figure 32). Globally, fish provides about 3.0 billion people with almost 20 percent of their average per capita intake of animal protein, and 4.3 billion people with about 15 percent of such protein (Figure 33).

Linked to the strong expansion of fish production and of modern distribution channels, world fish food supply grew at an average rate of 3.2 percent per year in the period 1961–2009, outpacing the increase of 1.7 percent per year in the world's population; hence, average per capita availability has risen. World per capita fish consumption increased from an average of 9.9 kg in the 1960s to 11.5 kg in the 1970s, 12.6 kg in the 1980s, 14.4 kg in the 1990s, 17.0 kg in the 2000s and reached 18.4 kg in 2009. Preliminary estimates for 2010 point towards a further increase in per capita fish consumption to 18.6 kg. It should be noted that figures for 2000 are higher than those reported in previous editions of *The State of World Fisheries and Aquaculture*, as FAO has revised downwards the non-food estimates for China's apparent consumption, starting from 2000 data, to reflect improved national information on the sector. As a consequence, per capita fish consumption figures for China as well as for the world have increased in comparison with previous assessments.

Notwithstanding the strong increase in the availability of fish to most consumers, the growth in fish consumption differs considerably among countries and within countries and regions in terms of quantity and variety consumed per head. For example, per capita fish consumption has remained static or decreased in some countries in sub-Saharan Africa (e.g. the Congo, South Africa, Gabon, Malawi and Liberia) and in Japan in the last two decades, while the most substantial increases in annual per capita fish consumption have occurred in East Asia (from 10.6 kg in 1961 to 34.5 kg in 2009), Southeast Asia (from 12.8 kg in 1961 to 32.0 kg in 2009) and North Africa (from 2.8 kg in 1961 to 10.6 kg in 2009). China has been responsible for most of the increase in world per capita fish consumption, owing to the substantial increase in its fish production, in particular from aquaculture. China's share in world fish production grew from 7 percent in 1961 to 34 percent in 2009. Per capita fish consumption in China has also increased dramatically, reaching about 31.9 kg in 2009, with an average annual growth rate of 4.3 percent in the period 1961–2009 and of 6.0 percent in the period 1990–2009. In the last few years, fuelled by growing domestic income and wealth, consumers in China have experienced a diversification of the types

Table 13

¹ Preliminary data.

² Low-income food-deficit countries.

of fish available owing to a diversion of some fishery exports towards the domestic market as well as an increase in fishery imports. If China is excluded, annual per capita fish supply to the rest of the world was about 15.4 kg in 2009, higher than the average values of the 1960s (11.5 kg), 1970s (13.5 kg), 1980s (14.1 kg) and 1990s (13.5 kg). It should be noted that during the 1990s, world per capita fish supply, excluding China, was relatively stable at 13.1–13.5 kg and lower than in the 1980s as population grew more rapidly than food fish supply (at annual rates of 1.6 and 0.9 percent, respectively). Since the early 2000s, there has been an inversion of this trend, with food fish supply growth outpacing population growth (at annual rates of 2.6 percent and 1.6 percent, respectively).

Table 13 summarizes per capita fish consumption by continent and major economic group. The total amount of fish consumed and the species composition of the food fish supply vary according to regions and countries, reflecting the different levels of availability of fish and other foods, including the accessibility of fishery resources in adjacent waters as well as the interaction of several socio-economic and cultural factors. These factors include food traditions, tastes, demand, income levels, seasons, prices, health infrastructure and communication facilities. Annual per capita apparent fish consumption can vary from less than 1 kg in one country to more than 100 kg in another (Figure 34). Differences may also be significant within countries, with consumption usually higher in coastal, riverine and inland water areas. Of the 126 million tonnes available for human consumption in 2009, fish consumption was lowest in Africa (9.1 million tonnes, with 9.1 kg per capita), while Asia accounted for two-thirds of total consumption, with 85.4 million tonnes (20.7 kg per capita), of which 42.8 million tonnes was consumed outside China (15.4 kg per capita). The corresponding per capita fish consumption figures for Oceania, North America, Europe, and Latin America and the Caribbean were 24.6 kg, 24.1 kg, 22.0 kg and 9.9 kg, respectively.

Differences in fish consumption exist between the more-developed and the less-developed countries. Although annual per capita consumption of fishery products has grown steadily in developing regions (from 5.2 kg in 1961 to 17.0 kg in 2009) and in LIFDCs (from 4.9 kg in 1961 to 10.1 kg in 2009), it is still considerably lower than that of more developed regions, even though the gap is narrowing. The actual values may be higher than indicated by official statistics in view of the under-recorded contribution of subsistence fisheries and some small-scale fisheries. In 2009, apparent per capita fish consumption in industrialized countries was 28.7 kg, while for all developed countries it was estimated at 24.2 kg. A sizeable share of fish consumed in developed countries consists of imports, and owing to steady demand and declining domestic fishery production (down 10 percent in the period 2000–2010), their dependence on imports, in particular from developing countries, is projected to grow. In developing countries, fish consumption tends to be based on locally and seasonally available products, and the fish chain is driven by supply rather than demand. However, in emerging economies, imports of fishery products not available locally have recently been growing.

Disparities among developed and developing countries exist also with reference to the contribution of fish to animal protein intake. Despite their relatively low levels of fish consumption, this share was significant at about 19.2 percent for developing countries and 24.0 percent for LIFDCs. However, this share has declined slightly in recent years owing to the growing consumption of other animal proteins. In developed countries, the share of fish in animal protein intake, after consistent growth up to 1989, declined from 13.9 percent in 1984 to 12.4 percent in 2009, while consumption of other animal proteins continued to increase.

The seafood sector remains very fragmented, in particular for markets of fresh seafood, but it is in a phase of consolidation and globalization. Fish is very heterogeneous and differences may be based on species, production area, method of fishing or farming, handling practice and hygiene. Raw fish can be processed into

an even wider range of products to meet consumer demands that differ according to markets, flexibility in supply volumes, physical proximity, suppliers' trustworthiness, ability to adapt to different portion-size specifications, etc. In the last two decades, the consumption of fish and fishery products has also been influenced considerably by globalization in food systems and by innovations and improvements in processing, transportation, distribution, marketing and food science and technology. These factors have led to significant enhancements in efficiency, lower costs, wider choice and safer and improved products. Owing to the perishability of fish, developments in long-distance refrigerated transport and large-scale and faster shipments have facilitated the trade and consumption of an expanded variety of species and product forms, including live and fresh fish. Consumers can benefit from increased choice, with imports boosting the availability of fish and fishery products in the domestic markets.

Growing interest from local consumers has also underpinned aquaculture development in many regions in Asia and, increasingly, in Africa and in Latin America. Since the mid-1980s, and in particular in the last decade, the contribution of aquaculture to fish consumption has shown dramatic growth, as capture fisheries production has stagnated or even declined in some countries. In 2010, aquaculture contributed about 47 percent of the fishery output for human consumption – impressive growth compared with its 5 percent in 1960, 9 percent in 1980 and 34 percent in 2000 (Figure 35), with an average annual growth rate of 4.7 percent in the period 1990–2010. However, if China is excluded, the average contribution of aquaculture is significantly lower at 17 percent in 2000 and 29 percent in 2010, corresponding to an average annual growth rate of 5.4 percent. Aquaculture has pushed the demand for, and consumption of, species that have shifted from being primarily wild-caught to being primarily aquaculture-produced, with a decrease in their prices and a strong increase in their commercialization, such as for shrimps, salmon, bivalves, tilapia, catfish and *Pangasius*. Aquaculture also plays a role in food security through the significant production of some low-value freshwater species, which are mainly destined for domestic production, also through integrated farming.

The surging contribution of aquaculture can also be noted by observing fish consumption by major groups. Owing to the increasing production of shrimps, prawns and molluscs from aquaculture and the relative decline in their price, annual per capita availability of crustaceans grew substantially from 0.4 kg in 1961 to 1.7 kg in 2009, and that of molluscs (including cephalopods) rose from 0.8 kg to 2.8 kg in the

Figure 35

Relative contribution of aquaculture and capture fisheries to food fish consumption

same period. The increasing production of salmon, trouts and selected freshwater species has led to a significant growth in annual per capita consumption of freshwater and diadromous species, up from 1.5 kg in 1961 to 6.0 kg in 2009. In the last few years, no major changes have been experienced by the other broader groups. Annual consumption of demersal and pelagic fish species has stabilized at about 3.0 kg and 3.4 kg per capita, respectively. Demersal fish continue to be among the main species favoured by consumers in Northern Europe and in North America (8.6 kg and 7.0 kg per capita per year, respectively, in 2009), whereas cephalopods are mainly preferred by Mediterranean and East Asian countries. Of the 18.4 kg of fish per capita available for consumption in 2009, about 74 percent came from finfish. Shellfish supplied 26 percent (or about 4.5 kg per capita, subdivided into 1.7 kg of crustaceans, 0.5 kg of cephalopods and 2.3 kg of other molluscs).

The global growth in fish consumption mirrors trends in food consumption in general. Per capita food consumption has also been growing in the last few decades. With the exception of the periods of the food and economic crises, the global food market, including the fish market, has experienced unprecedented expansion and a change in global dietary patterns, becoming more homogeneous and globalized. This change has been the result of several factors, including rising living standards, population growth, rapid urbanization and opportunities for trade and transformations in food distribution. A combination of these factors has led to growing demand for proteic food products, in particular meat, fish, milk, eggs as well as vegetables in the diet, with a reduction in the share of staples such as roots and tubers. Protein availability has increased in both the developed and developing world, but this growth has not been equally distributed. There has been a remarkable increase in the consumption of animal products in countries such as Brazil and China and in other less-developed countries. According to FAOSTAT, annual global per capita meat consumption grew from 26.3 kg in 1967 to 32.4 kg in 1987 to reach 40.1 kg in 2007. The growth was particularly marked in the most rapidly emerging economies of developing countries, and annual per capita meat consumption in developing countries more than doubled from 11.2 kg in 1967 to 29.1 kg in 2007. The supply of animal protein continues to remain significantly higher in industrialized and other developed countries than in developing countries. However, having attained a high level of consumption of animal protein, more developed economies have been increasingly reaching saturation levels and are less reactive than low-income countries to income growth and other changes. In developed countries, per capita meat consumption increased from 61.4 kg in 1967 to 80.7 kg in 1987, but then declined to 75.1 kg in 1997 before reaching 82.9 kg in 2007.

Notwithstanding the improvement in per capita availability of food and the positive long-term trends in nutritional standards, undernutrition (including inadequate levels of consumption of protein-rich food of animal origin) remains a huge and persistent problem. Malnutrition is a major problem worldwide, with one person in seven undernourished and more than one-third of infant mortality attributable to undernutrition. This is especially the case in many developing countries, with the bulk of undernourished people living in rural areas. According to the FAO report *The State of Food Insecurity in the World 2011*,²⁵ the number of undernourished people was 850 million in 2006–08, of whom 223.6 million were in Africa, 567.8 million in Asia and 47 million in Latin America and the Caribbean. About two-thirds of the undernourished originate in seven countries (Bangladesh, China, the Democratic Republic of the Congo, Ethiopia, India, Indonesia and Pakistan) and more than 40 percent of them live in China and India alone. According to preliminary estimates, the number of undernourished people could have reached about 925 million people in 2010–11. At the same time, many people in countries around the world, including developing countries, suffer from obesity and diet-related diseases. This problem is caused by excessive consumption of high-fat and processed products, as well as by inappropriate dietary and lifestyle choices.

The food sector in general is encountering a period of structural adjustment as a result of growing incomes, modifications in the population structure, new lifestyles, globalization, liberalization of trade and the emergence of new markets. A greater

focus is also being given to marketing, with producers and retailers becoming more attentive to consumer preferences and attempting to anticipate market expectations in terms of quality, safety standards, variety, value addition, etc. Consumer habits have changed significantly in the past few decades, and food issues such as indulgence, convenience, health, ethics, variety, value for money, and safety are becoming increasingly important, especially in more affluent economies. In these markets, consumers are requesting higher standards in terms of food freshness, diversity, convenience and safety, including quality assurances such as traceability, packing requirements and processing controls. Consumers now demand guarantees that their food has been produced, handled and sold in ways that safeguard their health, respect the environment and address various ethical and social concerns. Health and well-being are increasingly influencing consumption decisions, and fish has a particular prominence in this respect, following mounting evidence confirming the health benefits of eating fish (see above). This is partly related to an ageing society, but food safety issues as well as obesity and allergic reactions have also raised awareness about the relationship between food and health. In more-developed economies, rapid reductions in fertility combined with improvements in survival are leading to an ageing population, wherein an increasing proportion of the population is concentrated among older age groups. In many countries of the more developed regions, more than 20 percent of the population are aged 60 or over. This affects the demand for different types of food.

These ongoing changes in consumer preferences are having an increasing impact on technological innovations and on new procedures for organizing the supply chain. The majority of product innovations deal with incremental modifications, such as variations in taste and packages designed for different forms of consumption. World food markets have become more flexible, with new products entering the markets, including value-added products that are easier for consumers to prepare. Retail chains, transnational companies and supermarkets are also emerging as a major force, particularly in developing countries, offering consumers a wider choice, reduced seasonal fluctuation in availability and, often, safer food. Several developing countries, especially in Asia and Latin America, have experienced a rapid expansion in the number of supermarkets, which are increasingly targeting lower- and middle-income consumers as well as the higher-income groups.

Growing urbanization is one of the factors modifying food consumption patterns, with an impact also on the demand for fishery products. People living in urban areas tend to devote a higher proportion of their income to food purchased and, in addition, to eat out of the home more frequently, and to purchase larger quantities of fast and convenience foods. Moreover, increasing urbanization compounds the pressure on adjacent areas to meet the demand of large, concentrated populations. According to the United Nations Population Division,²⁶ in 2011 52.1 percent (3.6 billion people) of the world's population were living in urban areas. Disparities in the levels of urbanization persist among countries and regions of the world, with more-developed countries having an urban share of up to 78 percent, while others remain mostly rural, in particular, LDCs (with an urban share of about 29 percent) and Africa (40 percent) and Asia (45 percent). However, also in these latter areas, a vast movement of the population towards the cities is taking place. An additional 294 million and 657 million people are expected to become urbanized by 2015 and 2020, respectively, with the bulk of the increase in urban areas expected in Asia and Africa. By 2050, the shares of urban population will be 58 percent in Africa and 64 percent in Asia, although this will still be significantly less than most other continents. The rural population is expected to decline in every major area except in Africa.

The outlook for the global food sector remains uncertain. It is facing various challenges related to the economic turndowns in selected countries and demographic issues, including growing urbanization. The long-term forecast for food demand remains positive, also driven by population growth and urbanization. In particular,

demand for fish products is expected to continue to rise in the coming decades. However, future increases in per capita fish consumption will depend on the availability of fishery products. With capture fisheries production stagnating, major increases in fish food production are forecast to come from aquaculture (see p. 188). However, future demand will be determined by a complex interaction of several factors and elements. The global food sectors, including the fishery sector, will have to face several challenges stemming from demographic, dietary, climate and economic changes, including reduced reliance on fossil energy and increasing constraints on other natural resources. In particular, the future supply and demand of food commodities, including fisheries, will be affected by population dynamics and the location and rate of economic growth. World population growth is expected to slow in the next decade, in all regions and continents, with developing countries continuing to experience the most rapid population increases. The global population is set to increase from about 7 billion in 2011 to 7.3 billion in 2015 and to 7.7 billion in 2020 and 9.3 billion in 2050, with the bulk of the increase occurring in developing countries, according to the medium-variant projections prepared by the United Nations.²⁷ Much of this increase is projected to come from the high-fertility countries and it is expected to occur in urban areas (see above).

GOVERNANCE AND POLICY

Rio+20

The United Nations Conference on Sustainable Development was held in June 2012 to mark the twentieth anniversary of the 1992 United Nations Conference on Environment and Development, in Rio de Janeiro, and the tenth anniversary of the 2002 World Summit on Sustainable Development in Johannesburg. Known as Rio+20, the objective of the conference – envisioned as a gathering at the highest level possible – aimed to “secure renewed political commitment for sustainable development, assess the progress to date and the remaining gaps in the implementation of the outcomes of the major summits on sustainable development, and address new and emerging challenges”.²⁸ The two themes of the conference were the institutional framework for sustainable development and the support of a green economy in the context of sustainable development and poverty eradication.

While the green economy has no precise definition, it is viewed as a holistic, equitable and far-sighted approach to sustainability that seeks to eliminate the notion that sustainability and growth are mutually exclusive. The hope is that a transition to a green economy will result in resource exploitation that contributes to sustainability, inclusive social development and economic growth.

The conference prioritized seven thematic areas including green jobs and social inclusion, energy, sustainable cities, food security and sustainable agriculture, water, sustainable use of oceans and coasts, and disaster risk reduction and building resilience.

There are several ongoing international initiatives that seek to integrate fisheries and aquaculture into the Rio+20 agenda and framework and continue the processes established by Agenda 21 and the Rio Declaration.

FAO's corporate message to Rio+20 – and beyond – is that hunger eradication is essential for sustainable development, and sustainable consumption and production systems are essential to eradicate hunger and protect ecosystems. Underpinning this message is the need to increase food security – in terms of availability, access, stability and utilization – while using fewer natural resources, through improved management and efficiencies throughout the food value chain. This requires policies that create incentives for producers and consumers to adopt sustainable practices and behaviour. It is also necessary to promote the wide application of ecosystem approaches that encourage producers to participate in managing land, water, fisheries and water resources and help in internalizing environmental costs and benefits and rewarding environmental service provision.

FAO also contributed to specific interagency submissions that address the sustainable management of the world's oceans. The FAO Fisheries and Aquaculture Department co-authored, with the Intergovernmental Oceanographic Commission of the United Nations Educational, Scientific and Cultural Organization, the IMO and the United Nations Development Programme, a submission to Rio+20 titled "A Blueprint for Ocean and Coastal Sustainability",²⁹ which seeks to engage and focus leaders on oceans while attempting to define the green economy as it relates to marine and coastal resources. It also contributed to the "Monaco Message",³⁰ i.e. the outcome of a workshop convened by the Principality of Monaco on the sustainable use of oceans in the context of the green economy and poverty eradication. Key components include, *inter alia*: the protection and restoration of ocean biodiversity; a change in fisheries and aquaculture management regimes with an emphasis on non-subsidized and sustainable practices; climate change adaptation (CCA) and disaster risk management (DRM); integrated coastal management; and other cross-sectoral and comanagement approaches.

In addition, the FAO Fisheries and Aquaculture Department contributed to a paper co-ordinated by the United Nations Environment Programme on the "Green Economy in a Blue World",³¹ and it prepared with WorldFish Center and others a paper titled "Blending Green and Blue Economics: Sustainability Transitions in the Fisheries and Aquaculture Sector of Small Island Developing States".³²

The critical role of fisheries and aquaculture in food and nutrition security has been well-recognized at Rio+20. There is urgency to stem overfishing in marine and inland fisheries and curb the degradation of habitats caused by pollution and other forms of unsustainable use of aquatic ecosystems. Fisheries and aquaculture have considerable potential as vectors for the green economy. Their dependence on ecosystem services means that supporting sustainable fishing and fish farming can provide incentives for wider ecosystem stewardship. Therefore, in the context of the green economy, the greening of fisheries and aquaculture requires the overall recognition of their wider societal roles – in particular of small-scale operations for local economic growth, poverty reduction and food security – within a comprehensive governance framework, aiming *inter alia*: to manage externalities from or on the sector; to create alternative livelihood opportunities; and to improve access to social and financial services and education. The greening of marine fisheries and aquaculture also implicitly recognizes the urgency of reducing the carbon footprint of human activities to the goals of sustainable development and management and equitable benefit sharing of marine resources.

The main mechanisms for behavioural change and transition to green growth in fisheries and aquaculture include: (i) adopting an ecosystem approach to fisheries and aquaculture with fair and responsible tenure systems to turn resource users into resource stewards; (ii) integrating fisheries and aquaculture into watershed and coastal area management; (iii) supporting the development of and investment in "green" technology (e.g. low impact and fuel-efficient fishing methods; innovative aquaculture production systems, including greater use of environmentally friendly feeds, reduced energy use, greener refrigeration technologies and improved waste management in fish handling, processing and transportation); and (iv) building industry and consumer awareness to give preference to products from sustainable fisheries and aquaculture.

Furthermore, there is broad recognition of the need to improve ocean governance at all scales, i.e. local, national, regional and global. At the global level, there is the need for stronger coordination across the various UN agencies with mandates in ocean affairs and greater stakeholder participation, including by industry and civil-society organizations. There is also the need to strengthen the management framework for fisheries and other marine resources in areas beyond national jurisdictions. At the regional level, RFMOs need to coordinate more closely with other regional bodies and programmes including the regional seas and large marine ecosystem programmes. Capacity development and strengthening of legal and institutional arrangements are critical at the national and local levels where fisheries and aquaculture stakeholders

are often poorly represented and equipped to contribute to intersectoral planning and policy-making.³³

Small-scale fisheries

The importance of small-scale fisheries to food security, poverty alleviation and poverty prevention in the developing world is becoming increasingly understood and appreciated. However, a lack of institutional capacity and a failure to include the sector into national and regional development policies continue to hamper the potential contributions of small-scale fisheries to economic growth, poverty alleviation and rural development. According to the latest figures, the livelihoods of about 357 million people are directly affected by small-scale fisheries, and they employ more than 90 percent of the world's capture fishers.

Since 2003, COFI has promoted efforts to improve the profile of, and understand the challenges and opportunities facing, small-scale fishing communities in inland and marine waters. Prompted by COFI, in 2008, the FAO Fisheries and Aquaculture Department embarked on a broad-based consultative process that included a global conference³⁴ and a series of regional workshops for Asia and the Pacific, Africa, and Latin America and Caribbean³⁵ to examine the need and various options for an international instrument on small-scale fisheries and a global assistance programme for the sector.

Throughout this process, strong support was expressed for the creation of an international instrument as well as for the delivery of an assistance programme. Subsequently, COFI agreed to these suggestions and recommended that this instrument should take the form of international voluntary guidelines and complement the Code as well as other international instruments with similar purposes, in particular those related to human rights, sustainable development and responsible fisheries.

The preparation of the guidelines is expected to contribute to policy development at the national and regional levels. In addition, both the process and the final product are expected to have considerable impact on securing small-scale fisheries and creating benefits, especially in terms of food security and poverty reduction. The process itself has been designed to be highly participatory and collaborative, with the inclusion of cross-sectoral, national and international consultative workshops.³⁶ The guidelines should be a document that is agreed by governments, regional organizations and civil-society organizations. In addition, the document should be one that small-scale fishers, fishworkers and their communities across the world feel ownership of and can relate to, thus contributing to the process of turning resource users into resource stewards.

A set of basic principles underlie the development process of the guidelines. They promote good governance, including transparency and accountability as well as participation and inclusiveness. Social responsibility and solidarity are supported, as the guidelines take a human rights approach to development (which recognizes that everyone has legally mandated rights and that these rights carry with them responsibilities). These principles include equitable development based on gender equality, non-discrimination, and respect and involvement of all stakeholders, including indigenous people.

The consultative process also aims at identifying good practices, in particular with regard to governance and resource management through the implementation of an ecosystem approach to fisheries (EAF), and by reducing vulnerability and improving livelihoods' resilience through DRM and CCA.

The guidelines promote holistic and integrated approaches that combine natural-resource and ecosystem management with social and economic development. Equal consideration should be given to the environment, social and economic development needs, and community rights.³⁷ Sustainability is a key concept that is valid for both bioecological aspects and human dimensions. Actions should be guided by the precautionary approach and risk management to guard against undesirable outcomes, including not only overexploitation of fishery resources and negative environmental impacts but also unacceptable social and economic consequences.

The development of the guidelines serves as both process and objective, and intends to:

- provide a comprehensive framework that enhances the understanding of the actions needed to support the governance and sustainable development of small-scale fisheries;
- establish principles and criteria for the elaboration and implementation of national policies and strategies for the enhancement of small-scale fisheries governance and development, and provide practical guidance for implementation of these policies and strategies;
- serve as a reference tool for governments, their development partners and other stakeholders in the area of small-scale fisheries governance and development with a view to assisting in the formulation and implementation of relevant actions and the establishment or improvement of required institutional structures and processes;
- facilitate cooperation in support of small-scale fisheries governance and development;
- promote further research and the advancement of the knowledge on small-scale fisheries governance and development.

Ultimately, it is expected that policies and practices will be developed and adopted, and capacities strengthened for securing sustainable small-scale fisheries at the national and regional levels.

Regional fishery bodies

The RFBs are the primary organizational mechanism through which States work together to ensure the long-term sustainability of shared fishery resources. Throughout the twentieth and twenty-first centuries, the number and diversity of RFBs have expanded so that today the term "RFBs" can apply to fishery bodies with a mandate in a particular region, for a particular species, for marine or inland fisheries and/or for aquaculture bodies. The term RFB also embraces RFMOs, which are those RFBs that have the competence to establish binding conservation and management measures.

The 2010 United Nations Review Conference (the Review Conference) encouraged all States to become parties to RFBs, as these bodies rely upon State cooperation.³⁸ However, despite this significant endorsement of regional bodies, it is apparent that most RFBs are experiencing difficulties in fulfilling their mandates, and that many of these mandates are outdated as they do not provide appropriate frameworks within which RFBs can address current critical fisheries management issues. The situation is reflected in "alarming statistics" on global fish stocks "highlighting the need to strengthen the regulatory regime for regional fisheries management organizations and arrangements with a view to making them more accountable, transparent and open."³⁹ The RFBs are intergovernmental organizations and as such they depend on the political will of their member Governments to implement agreed measures or to undertake much needed reform.⁴⁰

New regional fishery bodies

Since publication of *The State of World Fisheries and Aquaculture 2010*, new RFBs have been established, existing RFBs have been modernized, and other RFBs are in the planning or development stage. These new, strengthened and emerging bodies represent an important step forwards in extending the global coverage of RFBs.

The Central Asian and Caucasus Regional Fisheries and Aquaculture Commission (CACFish) was approved by the Hundred and Thirty-seventh Session of the FAO Council in October 2009.⁴¹ It deals with fisheries management and aquaculture in inland waters within the territorial boundaries of the States of Central Asia (Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan and Uzbekistan) and of the Caucasus (Armenia, Azerbaijan, Georgia and Turkey). The agreement to establish CACFish came into effect on 3 December 2010.

The Southern Indian Ocean Fisheries Agreement (SIOFA)⁴² aims to ensure the long-term conservation and sustainable use of Southern Indian Ocean fishery resources

(other than tuna) outside national jurisdictions in the area (which is defined in Article 3 of the agreement).

In 2008, the Inter-American Tropical Tuna Commission (IATTC) comprehensively updated and replaced its 1950 convention with the new Antigua Convention.⁴³ The Antigua Convention deals with tuna and tuna-like species within the convention area, which is a broad zone of the Eastern Pacific Ocean delimited by boundaries prescribed in Article 3 of the convention. The Antigua Convention came into force on 27 August 2010. The current members are: Belize, Canada, China, Costa Rica, El Salvador, European Union, France, Guatemala, Japan, Kiribati, Republic of Korea, Mexico, Nicaragua and Panama. In accordance with the terms of the convention, Taiwan Province of China has lodged a written communication of commitment to abide by the terms of the Antigua Convention.

The South Pacific Regional Fisheries Management Organisation (SPRFMO) concluded its convention on 14 November 2009.⁴⁴ The convention aims to close the high seas gap that exists in the South Pacific for the conservation and management of non-highly migratory fish stocks, as well as the protection of marine biodiversity. The convention will enter into force 30 days after the date of receipt of the eighth instrument of ratification, accession, acceptance or approval, including three coastal States (one from each side of the Pacific) and three distant-water fishing States that have been or are fishing in the Convention Area. In 2011, there was a burst of activity by signatory States and the number of ratifications increased to five (Belize, Cook Islands, Cuba, Denmark and New Zealand). The SPRFMO anticipates that the convention will come into effect in the course of 2012.

Finally, preparatory discussions aiming to create an RFB for the Red Sea have been initiated with the Regional Organization for the Conservation of the Environment of the Red Sea and Gulf of Aden. Countries from this region have been calling for the establishment of such an RFB for many years.

Regional Fishery Body Secretariats Network

The third meeting of the Regional Fishery Body Secretariats Network was held on 7–8 February 2011 in Rome, Italy. Twenty-eight RFB secretariats, with varied responsibilities for inland, coastal and marine capture fisheries and aquaculture, were represented at the meeting. The meeting discussed a range of subjects of particular relevance or importance to RFBs. These subjects included, but were not limited to: combating IUU fishing; managing fishing capacity; ecolabelling and aquaculture certification; supporting small-scale fisheries; adopting an ecosystem approach to capture fisheries and aquaculture; identification of vulnerable marine ecosystems; rebuilding of stocks; low levels of financial and human resources; pollution control; climate change; bycatch; and, where a performance review had taken place, the ongoing need to address its recommendations. The meeting concluded that, to address these issues, RFBs need financial, administrative and scientific support, plus a strong regional (as distinct from a national) focus for achieving sustainable fish stocks.

Performance review of regional fishery bodies

The need for RFBs to modernize their mandates and ensure better compliance with fishery instruments has led to numerous RFBs undergoing independent reviews of their performance. The Review Conference noted that progress had been made in developing best practices for RFMOs and in reviewing their performance against emerging standards. In addition, the Review Conference described the modernizing of RFMOs as a priority. The criteria used to assess RFMO performance have been refined through the Kobe Process (itself developed through meetings by the five joint tuna RFMOs that commenced in Kobe, Japan, in 2007).

Seven RFMOs had undergone performance reviews by the end of 2009. They included: the North Atlantic Salmon Conservation Organization (NASCO, in 2004–05 (where performance was evaluated by stakeholders and non-governmental organizations [NGOs]);⁴⁵ the North East Atlantic Fisheries Commission (NEAFC,

in 2006);⁴⁶ the Commission for the Conservation of Southern Bluefin Tuna (CCSBT, in 2006); the Indian Ocean Tuna Commission (IOTC, in 2007);⁴⁷ the Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR, in 2008);⁴⁸ the International Commission for the Conservation of Atlantic Tunas (ICCAT, in 2009); and the South East Atlantic Fisheries Organisation (SEAFO, in 2009).⁴⁹

Since 2009, another three RFBs have completed a performance review: the North Pacific Anadromous Fish Commission (NPAFC, in 2010); the General Fisheries Commission for the Mediterranean (GFCM)⁵⁰ and the Northwest Atlantic Fisheries Organization (NAFO).⁵¹ Reports for these last two reviews were presented in 2011. The Western and Central Pacific Fisheries Commission (WCPFC) is currently undergoing a performance review.

To update its earlier stakeholder review, NASCO is planning a second performance review for 2012 using the Kobe Process. This is a significant initiative as the performance review exercise should not be seen as a singular event, and the United Nations General Assembly (UNGA) has noted the need for reviews to be regular.⁵²

When a performance review is conducted, the primary subject of evaluation is the management process. This is relevant to all RFMOs because they have a prescribed management mandate. However, the performance review process is also relevant for other RFBs, including those that mainly serve as advisory bodies. The critical issue for each body, whether an advisory RFB or an RFMO, is the nature of its mandate and how effectively it is addressing its mandate. The Review Conference has encouraged all RFMOs that have not yet done so to undertake a performance review.⁵³ It observed that performance reviews were generally recognized as being useful, particularly when they led to the adoption of new management measures.⁵⁴ In 2011, two FAO Article VI advisory RFBs (without a prescribed regulatory mandate) also underwent the process of independent review: the Fishery Committee for the Eastern Central Atlantic (CECAF) and the Southwest Indian Ocean Fisheries Commission (SWIOFC). The Committee for Inland Fisheries and Aquaculture of Africa (CIFA), another FAO Article VI body, is also investigating the possibility of conducting an independent review.

Regional fishery bodies can provide an example of strength through unity, with developed and developing States working cooperatively to produce sustainable fish stocks. This is more than a vision; it is a necessity for global food security.

Illegal, unreported and unregulated fishing

Illegal, unreported and unregulated (IUU) fishing and related activities threaten national, regional and international efforts to secure long-term sustainable fisheries and promote healthier and more robust ecosystems. Consequently, the international community continues to express its grave concern at the extent and effects of IUU fishing, referring to it as a "global scourge",⁵⁵ and calling for it to be addressed at all levels and on all fronts. Often, IUU fishing is encouraged through corrupt practices.

Some 90 percent of the world's fish harvest is estimated to be taken within the EEZs of coastal States. Given the limited technical capacity of developing coastal States to detect and eradicate IUU fishing and related activities, a very significant proportion of IUU fishing also occurs within their EEZs. Developing countries bear the brunt of this IUU fishing, which undermines their efforts to manage fisheries. It denies them revenue from the fish that is poached and stolen, and adversely affects their attempts to promote food security, eradicate poverty and achieve sustainable livelihoods.

There are indications that IUU fishing is moderating in some areas of the world (e.g. the northeast Atlantic Ocean) as successful policies and measures take hold. However, IUU fishing remains widespread both in the EEZs of coastal States and on the high seas, in contravention of conservation and management measures put in place by RFMOs that have mandates to take fisheries management decisions that are binding on their members. In many areas of the world, IUU fishing is of such magnitude and importance that it is considered routinely not only at RFB sessions but also at global meetings (e.g. at FAO and by the UNGA).

The issue of IUU fishing was covered in the 2010 Secretary General's report to the UNGA.⁵⁶ In UNGA Resolution 65/38,⁵⁷ IUU fishing was dealt with at length in Section IV. The emphasis given to IUU fishing in the resolution underscored the threat that this practice poses to fisheries and their ecosystem, and the need to intensify fisheries monitoring, control and surveillance, and to implement international instruments and catch documentation schemes (CDSs) and traceability schemes. In addition, the resolution encouraged international cooperation on IUU fishing among States, including through RFBs.

Shortly after the UNGA, the Twenty-ninth Session of the FAO Committee on Fisheries (COFI) addressed IUU fishing.⁵⁸ Discussion focused principally on FAO's work and activities to promote and enhance international action against IUU fishing. Subsequently, the 2011 meeting of the UN Open-ended Informal Consultative Process on Oceans and the Law of the Sea⁵⁹ also drew attention to IUU fishing, largely in the context of discussions relating to the implementation of global instruments and problems associated with unregulated fishing activities in EEZs.

The international community is deeply frustrated by the failure of many flag States to meet their primary responsibilities under international law, which are to exercise effective control over their fishing vessels and, at the same time, ensure compliance with conservation and management measures. Of particular concern are those vessels that fly flags of "non-compliance". These are flags belonging to States that sell them to raise revenue. Such States are either unable or unwilling to exercise effective control over their vessels. Many of the vessels carrying these flags engage in IUU fishing in areas beyond the national jurisdiction of the flag State (i.e. on the high seas or in areas under the sovereignty or jurisdiction of other States). As a result, the burden of controlling these rogue vessels is gradually falling on coastal States, port States, RFBs and others. Thus, these States and RFBs need to train staff, and to obtain and develop compliance tools and mechanisms required to combat IUU fishing. This shift in burden, which is costly, has important ramifications for developing countries.

The international community's irritation with IUU fishing by vessels carrying flags of "non-compliance" led FAO Members to request that a Technical Consultation on Flag State Performance be convened. Following extensive preparatory work, the first session of the Technical Consultation was held in May 2011 and a resumed session in March 2012. It is anticipated that the outcome of the Technical Consultation will be a set of voluntary criteria for assessing the performance of flag States. In addition, a list of possible actions to be taken against vessels flying the flags of States not meeting such criteria is likely to be developed.⁶⁰ An agreed procedure for assessing compliance would be an important part of the criteria.

The RFBs are grappling with IUU fishing and its effects on the resources they are attempting to manage. Many of them have difficulty in estimating the volume and value of IUU catches. Their achievements in terms of limiting IUU fishing vary widely, depending on factors that are either internal or external to their respective organizations and fisheries. Nonetheless, in one way or another, RFBs promote and implement measures to combat IUU fishing. Depending on the particular circumstances, the measures range from more passive activities such as awareness building and dissemination of information (mainly RFBs without fisheries management functions) to aggressive port, air and surface programmes (RFMOs).

Some recent examples of RFBs' activities in relation to their work on IUU fishing are:

- In 2010, the SEAFO underscored the importance of regional training. Measures to develop capacity were noted as critical tools to speed up the implementation of measures to combat IUU fishing.⁶¹
- In 2010, the CCAMLR expressed concern as estimates of IUU catches in the convention area had risen since 2009 and concluded that, despite progress in the control of nationals and the implementation of CDSs, IUU fishing did not appear to be declining significantly. Importantly, several Members expressed the view that the CCAMLR appeared to be unable to improve its control of IUU fishing and was,

therefore, neither fulfilling the objectives of Article II of its convention nor, as a consequence, the Antarctic Treaty.⁶²

- In 2010, the NEAFC informed the Conference of the Parties of the Convention on Biological Diversity of the importance of its two main tools in addressing IUU fishing: blacklisting of vessels flying the flags of non-contracting parties, and a port State control system that controls all landings of frozen fish into the ports of NEAFC contracting parties.⁶³ These tools have reduced considerably the level of IUU-caught product entering the European market.

The European Commission (EC) is moving forwards with the implementation of its CDS that took effect on 1 January 2010.⁶⁴ Its purpose is to stem the flow of IUU-caught fish into the European market. Cooperation between the EC and relevant RFBs has been established to assist them to develop schemes to ensure conformity with the European Union regulation. On the whole, CDSs should provide an effective tool to strengthen existing efforts to combat IUU fishing while also providing a mechanism for improved economic returns and social development for developing countries that trade fish internationally.

Beyond national boundaries, there is increasing need for international cooperation among fishing and seafood-importing countries to improve global fisheries

Box 6

An update on the 2009 Port State Measures Agreement

On 22 November 2009, the FAO Conference approved the FAO Agreement on Port State Measures to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing (the Agreement). It remained open for one year for signature. During that period, 23 FAO Members signed the Agreement. In addition, at the 2011 session of the FAO Committee on Fisheries (COFI), 13 Members indicated that they had domestic processes in train to ratify, accept or approve the Agreement. It will enter into force 30 days after the date of deposit with the Director-General of FAO of the twenty-fifth instrument of ratification, acceptance, approval or accession. As at 30 September 2011, four FAO Members (including the European Union) had become Parties to the Agreement.

In 2011, COFI reiterated that port State measures are a potent and cost-effective tool to combat illegal, unreported and unregulated (IUU) fishing.¹ It recognized the need to assist developing countries to combat IUU fishing by building their capacity to undertake port State measures.² Consequently, in April 2012, a global series of capacity-development workshops to support the implementation of the Agreement was launched. The initial workshop was convened in Thailand to cater for countries from Southeast Asia. To date, Australia, Canada, Norway, the Republic of Korea and the Indian Ocean Tuna Commission have contributed to the programme, which is planned to last three years.

¹ FAO. 2011. *Report of the twenty-ninth session of the Committee on Fisheries*. Rome, 31 January – 4 February 2011. Fisheries and Aquaculture Report No. 973. Rome. 59 pp.

² In this respect, Article 21 of the Agreement, which addresses the special requirement of developing States, is central.

management of shared marine resources and to preserve the associated employment and other economic benefits of sustainable fisheries. In September 2011, recognizing this and in line with their commitment to the fight against IUU fishing, the European Union and the United States of America undertook to cooperate bilaterally to combat IUU fishing effectively. As leaders in global fish trade, the United States of America and European Union Members recognize their obligation to keep illegal fish out of the world market. The agreement commits the two signatories to work together to adopt effective tools to combat IUU fishing.⁶⁵

Strengthening fisheries management capacity is fundamental in developing countries in order to facilitate sustainable fisheries and to reduce and mitigate the impacts of IUU fishing. Capacity development is especially important to support the full and effective implementation of existing and new global instruments (e.g. the 2009 Port State Measures Agreement [Box 6]) and other fisheries initiatives as tools to combat IUU fishing.

Aquaculture governance

With the recent dramatic growth in aquaculture, governance of this sector has become increasingly important and has made remarkable progress. Many governments worldwide utilize the Code, in particular its Article 9. They also use FAO published guidelines for reducing administrative burdens and for improving planning and policy development in aquaculture. In addition, several countries have adequate national aquaculture development policies, strategies, plans and laws, and use “best management practices” and manuals on farming techniques that have been promoted by industry organizations and development agencies. The FAO Technical Guidelines on Aquaculture Certification, which were approved by the Twenty-ninth Session of COFI held in Rome from 31 January to 4 February 2011, constitute an additional important tool for good governance of the sector. By setting minimum substantive criteria for developing aquaculture certification standards, including animal health and welfare, food safety, environmental integrity and socio-economic aspects, these guidelines provide direction for the development, organization and implementation of credible aquaculture certification schemes. The ultimate aim is to ensure orderly and sustainable development of the sector.

Many governments have now recognized sustainability as the principal goal of aquaculture governance because it enables aquaculture to prosper for a long period. Long-term prosperity is predicated on fulfilling the four prerequisites for sustainable aquaculture development: technological soundness, economic viability, environmental integrity and social licence. Meeting these prerequisites also ensures that ecological well-being is compatible with human well-being.

An important component of human well-being is employment. In the last three decades, employment in the primary fisheries and aquaculture sector has grown faster than the world's population and employment in traditional agriculture (see Employment section in Part 1, p. 41). Including employment in the primary aquaculture producing sector and in the secondary services and support sector together with household dependants, more than 100 million people depend on the aquaculture sector for a living; the industry has provided, and continues to create, a good number of jobs, particularly non-seasonal jobs.

In many places, these employment opportunities have enabled young people to stay in their communities and have strengthened the economic viability of isolated areas. By generating incomes for female workers, especially in fish processing and marketing, employment in aquaculture has enhanced the economic and social status of women in many places in developing countries, where more than 80 percent of aquaculture output occurs. Through incomes from these jobs and various multipliers, employment in aquaculture has also improved the accessibility to food for many households and has increased aquaculture's contribution to the Millennium Development Goals. For these reasons, aquaculture has been heavily promoted in several countries with fiscal and monetary incentives.

However, these benefits induced by employment in aquaculture are often overlooked. The sector has developed at a time of growing scrutiny from the public, improved communications and vociferous opposition groups. Although opposition groups can act as environmental and social watchdogs and as lobby groups, putting pressure on aquaculture businesses to increase transparency and improve working conditions, it is also important to consider the benefits accruing from the sector, including employment.⁶⁶

However, there are well-documented cases of unfair employment practices in aquaculture. For example, there are some research findings according to which aquaculture enterprises, especially large corporations, exploit local labour. One study argue that local labour is employed in lower-paid jobs, paid low salaries, and subjected to discriminatory practices such as willingly creating gender imbalances or paying female workers less than male workers doing the same jobs.⁶⁷ Child labour employment, for example, in factories, processing units, peeling sheds, and in the collection of shrimp seeds, is also sometimes highlighted.⁶⁸

Such claims can undermine trust in the sector, threaten the credibility of policy-makers and jeopardize markets for farmed seafood. Hence, there is a need for more research into this issue, as there are sufficient indications to suggest that these practices might occur on a large scale, especially in developing countries for economic reasons.

Most countries have labour legislation to protect workers. However, compliance with such legislation can result in high indirect costs and deter firms, especially when goods are intended for export. Where these costs are high for firms and differ amply across borders, they can give enterprises operating in countries with lower labour and social standards a competitive advantage compared with those in jurisdictions with higher standards.

A possible result is that governments will be under pressure from companies to reduce labour and social standards in order to ease the burden of high indirect labour costs, thereby enhancing their competitive edge. Otherwise, the companies, especially large transnationals, may threaten to make new investments, or even to relocate existing establishments, in jurisdictions where lower labour standards exist with more amenable regulations. The threat can be exacerbated when there are negative shocks, such as fish disease outbreaks, or price or currency fluctuations, that expose companies to the risk of further erosion of their competitive position.

This pattern of behaviour becomes possible because large companies farming some species (such as shrimp, salmon, tilapia, abalone and others that become global commodities) are generally located in isolated rural communities, which gives them power over the labour force as the sole or dominant employer. To remain attractive to these companies and safeguard employment in rural communities, governments may be prepared to sacrifice good working conditions or even accept the employment of minors. Workers in these communities may also accept reduced wages and salaries, work longer hours without compensation or forgo some benefits.

A thorough understanding of these and other aspects of governance of employment in aquaculture is necessary. It will assist policy-makers in implementing corrective measures where these claims are proved well founded or in taking preventive action otherwise.

For the purpose of improving human well-being, employment in aquaculture, as in any other sector of the economy, must be equitable and non-exploitative. Principled values should guide aquaculture activities so that farmers with strong corporate social responsibility induce beyond-compliance behaviour. This would obviate the need for restrictive regulations; the best regulation is self-regulation. With an ethos of corporate social responsibility, aquaculture companies would assist local communities, employ fair labour practices and demonstrate transparency. Increasingly, with rising consumer awareness of employment practices in general, it makes good business sense for aquaculture enterprises to demonstrate (through certification, or otherwise) that they conform to the best standards. For these reasons, legislation should protect labour, particularly in developing countries, reflecting concepts of social justice and human

rights. In reality, however, labour legislation will strike a balance between concern for social justice and control measures that discourage investment. Overly cumbersome regulations can make an otherwise viable business economically unprofitable.

At a minimum, research on the governance of aquaculture employment should lead to information on:

- existing labour legislation (monitoring, enforcement and compliance);
- types of labour contracts; employment characteristics such as the nature of employment (full time or part time);
- workers' educational background, age and gender;
- remuneration schemes including possible wage discrimination, salary levels and competitiveness and minimum wages;
- working conditions such as hours of work, occupational safety and job security;
- miscellaneous benefits including bonuses, training opportunities, maternity leave, health benefits (employer-provided insurance) and education grants.

Improved governance of aquaculture based on such improved knowledge will benefit the development of aquaculture in the long term.

NOTES

- 1 Figures for 2000 are higher than those reported in previous editions of *The State of World Fisheries and Aquaculture* as FAO has revised downwards the non-food use estimates for China from 2000 onwards to reflect improved national information on the sector. As a consequence, per capita fish consumption for China, as well as for the world, has increased in comparison with previous assessments.
- 2 Fish import figures differ from export figures because the former are usually reported in c.i.f. (cost, insurance and freight), whereas exports are reported at f.o.b. (free on board) values.

- 17 Compared with previous editions of *The State of World Fisheries and Aquaculture*, the share quoted for low-income food-deficit countries (LIFDCs) differs significantly as a consequence of the change in the composition of LIFDCs. The new list of the LIFDCs stands at 70 countries, seven fewer than in the 2009 LIFDC list. The seven countries no longer on the list are: Angola, Armenia, Azerbaijan, China, Equatorial Guinea, Morocco and Swaziland. All seven have graduated from the list having completed the “transitional phase”, exceeding the World Bank income threshold for three consecutive years.
- 18 See note 2.
- 19 Statistics reported in this section are based on data from the Food Balance Sheets published in *FAO yearbook. Fishery and Aquaculture Statistics. 2010* (FAO, 2012). Consumption data for 2009 should be considered as preliminary. Some discrepancies may occur with other sections that quote data made available to FAO more recently. Food Balance Sheet data calculated by FAO refer to “average food available for consumption”, which, for a number of reasons (for example, waste at the household level), is not equal to average food intake or average food consumption. It should be noted that the production from subsistence fisheries as well as border trade between some developing countries could be incompletely recorded and might therefore lead to an underestimation of consumption.

SELECTED ISSUES IN FISHERIES AND AQUACULTURE

Mainstreaming gender in fisheries and aquaculture: from recognition to reality

THE ISSUE

“Gender mainstreaming is not only a question of social justice but is necessary for ensuring equitable and sustainable human development. The long-term outcome of gender mainstreaming will be the achievement of greater and more sustainable human development for all.”¹

In 1997, the United Nations Economic and Social Council (ECOSOC) adopted gender mainstreaming as the methodology by which the entire UN system would work towards the advancement of women and gender equality goals, noting that: “Mainstreaming a gender perspective is the process of assessing the implications for women and men of any planned action, including legislation, policies or programmes, in all areas and at all levels. It is a strategy for making women’s as well as men’s concerns and experiences an integral dimension of the design, implementation, monitoring and evaluation of policies and programmes in all political, economic and societal spheres so that women and men benefit equally and inequality is not perpetuated. The ultimate goal of mainstreaming is to achieve gender equality”.²

In 2000, all 193 UN Member States and more than 23 international organizations agreed to the Millennium Development Goals (MDGs), and the issue of promoting gender equality and empowering women (MDG 3) was again highlighted on the international agenda. The objective was one of ensuring that, in whatever sector they may be working, men and women should have equal rights to participate in the development process, and their interests and needs should be protected.

Despite this, women tend to be marginalized in a variety of ways – and this is very much true for women in the fisheries and aquaculture sector. Thus, more than 30 years after the 1979 Convention on the Elimination of All Forms of Discrimination Against Women, some 15 years after the ECOSOC decision and more than a decade after the Millennium Declaration, and with only 3 years to go before the goal of achieving the MDGs by 2015, the issue at hand is how to ensure genuine and active mainstreaming of gender and the many facets of gender considerations in the fisheries and aquaculture sector.

Indeed, until recently, gender analysis in fishing communities focused mainly on the different occupational roles of men and women, i.e. that men usually do the actual fishing and women are to a large extent involved in post-harvest and marketing activities. While the role of women in the management and utilization of natural resources is generally acknowledged, their role does not carry the same weight as that of men. Given that production goals have tended to be the focus of research and policy, the predominantly male catching sector has remained the centre of attention.³

However, with the shift to a multidimensional and more holistic definition of poverty and the increased focus on reducing vulnerability, gender has become more central to fisheries policy and development practice. Fisheries resource management

is increasingly being linked to all levels of the so-called “deck to dish” fish value chain in which both men and women have important roles to play. With almost 45 million people worldwide directly engaged, full time or part time, in the fishery primary sector in 2008⁴ and an additional estimated 135 million people employed in the secondary sector, including post-harvest activities, this is no simple task. Many involved in these sectors are recognizing that it is vital to look beyond the simplified picture of men as fishers and women as processors and to examine the more complex picture of multifaceted relationships between men and women as boat owners, processors, sellers, family members, community members and co-workers (Box 7).

Information provided to FAO from 86 countries indicates that, in 2008, 5.4 million women worked as fishers and fish farmers in the primary sector and represented 12 percent of the total. In two major producing countries, China and India, women represented 21 percent and 24 percent, respectively, of all fishers and fish farmers. Women make up at least 50 percent of the workforce in inland fisheries, while as much as 60 percent of seafood is marketed by women in Asia and West Africa. Moreover, although comprehensive data are not available on a sex-disaggregated basis, case studies suggest that women may comprise up to 30 percent of all those employed in fisheries, including primary and secondary activities.

Revealing hidden contributions

While reliable estimates are not available, a recent expert panel review paper⁵ reported that women are probably more involved in aquaculture (Box 8) than in fisheries⁶ but that studies of women and gender issues are more numerous for the fisheries sector than for the aquaculture sector. As the review paper points out, this relative lack of attention to gender in aquaculture may reflect the more recent history of aquaculture

Box 7

A gender baseline in the fisheries and aquaculture sector

Men and women engage in distinct and often complementary activities that are strongly influenced by the social, cultural and economic contexts in which they live. Male–female relations in the fisheries sector vary greatly and are based on economic status, power relations and access to resources.

In most regions, women have rarely participated in commercial offshore and long-distance capture fishing. Ocean-going boats for offshore deep-sea fishing have male crews – not only because of the vigorous work involved, but also because of women’s domestic responsibilities and/or social norms.

More commonly, in coastal artisanal fishing communities, women manage the smaller boats and canoes that go out fishing. Women are also involved in gathering shells, sea cucumbers and aquatic plants in the intertidal zone. They also contribute as entrepreneurs and provide labour before, during and after the catch in both artisanal and commercial fisheries. In addition, they are often responsible for skilled and time-consuming onshore tasks, such as net making and mending, processing and marketing catches, and providing auxiliary services to the boats.

However, gender issues in the fisheries and aquaculture sector have seldom been examined, and the important role women that play has often been overlooked and, thus, not taken into account in decision-making processes and outcomes, thereby hindering development.

and academic interest in the complex sociology and anthropology of fishing communities and practices.

However, it is known that there are vital differences in the power positions of men and women (Box 9); as a result, women generally have less control over the value chain, their activities are less profitable, and they have access to fish of poorer quality. Women

Box 8

The contribution of women in the aquaculture sector

FAO's National Aquaculture Sector Overview¹ provides insights into the roles and contributions of women in the aquaculture sector in countries around the globe:

- In Bangladesh, women's non-governmental organizations and other entrepreneurs have encouraged women to participate in aquaculture activities.
- In Belize, most workers involved in processing are women from rural communities where unemployment levels are high and poverty is greatest.
- In Cuba, female workers constitute 27 percent of the aquaculture workforce (19 percent are intermediate and higher education technicians; 11 percent have attended higher education institutions).
- In Estonia, the gender ratio of the aquaculture workforce is 1:1.
- In Israel, the workforce is a skilled one because of the highly technical nature of aquaculture in the country. In a sector where women make up about 95 percent of the workforce, most workers have a high school diploma while a high percentage have a degree (Bachelor of Science or Master of Science).
- In Jamaica, about 8–11 percent of fish farmers are women who own and operate fish farms; and in processing plants, women dominate the workforce.
- In Malaysia, women account for about 10 percent of the total aquaculture workforce, and they are mostly involved in freshwater aquaculture and hatchery operations for marine fish, shrimp and freshwater fish.
- In Panama, 80 percent of the workforce in processing plants are women, but in the production sector only 7 percent of workers are women.
- In Sri Lanka, women constitute 5 percent of the workforce in shrimp aquaculture and 30 percent of those engaged in the production and breeding of ornamental fish.

Information such as this provides a starting point for learning about the differences between men and women in these situations and about whether there are similar opportunities, wages and benefits – or whether there are policy, governance and operational gaps that need to be addressed in order to really mainstream gender in the sector.

Box 9

Differences in power lead to different opportunities

Artisanal fisherwomen's relatively insecure access to fish resources and, hence, to fish leads to different opportunities for women and men. When fish business activities are being upscaled in response to increasing globalization, local women risk being forced out of the business and, therefore, not benefiting from development and market opportunities in the sector in which they were previously extensively involved. Examples are:

- In India in the early 1980s, shrimp marketing was initially largely in the hands of women. However, when shrimp became a higher-priced commodity, male traders arrived on bicycles and later in motorized transport, eventually forcing the fisherwomen out of this trade (Bay of Bengal Programme).
- In Cotonou, Benin, urban-based male and female traders entered the fish trade, forcing women from the fishing villages out of business and making their access to fish more difficult (Programme for the Integrated Development of Artisanal Fisheries in West Africa).
- In Senegal, as fishermen change gear and the focus of their effort in response to changing profit opportunities in their fishery (e.g. shifting from harvesting pelagic fish to cephalopods) and switch from selling into local to export markets, the local post-harvest sector can suffer (Network on Fishery Policies in West Africa).

tend to be excluded from the most profitable markets and enterprises, and from highly paid posts in fish-processing factories even though they make up the majority of workers in the post-harvest sector. Compared with men, they are often greater losers from increasing market globalization, and they are more vulnerable to poor services and catch declines.

The most significant role played by women in both artisanal and industrial fisheries is at the processing and marketing stages. Active in all regions of the world, in some countries, women have become significant entrepreneurs in fish processing. In fact, most fish processing is performed by women, either in their own household-level industries or as wage labourers in the large-scale processing industry. For example, in West Africa, women play a major role – they usually own capital and are directly and vigorously involved in the coordination of the fisheries chain, from production to the sale of fish.

Some of the factors that weaken women's capabilities in terms of participation in decision-making are:

- lower literacy and education levels;
- time burdens and constraints;
- mobility burdens and constraints;
- participation in less-formal organizations that are, as a result, weaker organizations;
- fewer or reduced organizational skills in the sense that women frequently associate in less-formal organizations and, where part of formal organizations, frequently do not hold leadership roles such as president and secretary because of poor literacy skills.

Very importantly, the absence of women from most post-harvest statistics means that it is extremely difficult to quantify the number of women and the extent of the value addition and contribution their work makes to economies. Nonetheless, inequalities are beginning to be quantified and publicized.

POSSIBLE SOLUTIONS

Women's participation as equal and productive partners in the fisheries and aquaculture sector has significant impacts on households' nutrition and living standards. If fisheries and aquaculture projects generate the data for and, potentially, include analyses of, all gender aspects (livelihood factors, relationships, actions and results), they can contribute to gender equality and promote women's participation as active agents for change in the sector (Box 10).

Data solutions

Comprehensive and accurate sex-disaggregated statistics are lacking, and this gap must be filled as one of the first steps in gender mainstreaming at the policy level. Quantitative and qualitative gender-sensitive indicators can be formulated with fishing communities to see how well policies and associated development projects satisfy the practical and strategic needs of men and women, and to help reduce existing gender gaps.

At the more macro level, statistical censuses should focus more attention on areas in which women are relatively more active. They should collect sex-disaggregated data on ownership of, access to and control over productive resources such as land, water, equipment, inputs, information and credit.

Macro-level policy solutions

As in other sectors, women's empowerment in fisheries requires examination of the means of production, gender relationships, and how to create equalities. New institutional arrangements are being created in response to climate change, resource depletion, aquaculture development and global trade. All these factors are increasingly affecting the sector, and it is vital that gender considerations are built into the new

Box 10

Quantifying inequalities

A study conducted for the United States Agency for International Development on the Bangladesh shrimp value chain¹ revealed differences in earnings between women and men (see table), a finding that created a starting point for addressing gender-related discrepancies.

Relative earnings of women compared with those of male counterparts

Activity	Percentage
Catching, sorting fry	64
Repairing ponds, undertaking casual agricultural labour	82
Processing plants – packing section	72
Processing plants – cooking/breading section	60

¹ Development & Training Services, Inc. 2006. *A pro-poor analysis of the shrimp sector in Bangladesh* [online]. USAID. [Cited 21 May 2012]. www.usaid.gov/our_work/cross-cutting_programs/wid/pubs/Bangladesh_Shrimp_Value_Chain_Feb_2006.pdf

arrangements. Increasingly, practical manuals for gender mainstreaming and gender analysis are being produced to facilitate just such changes.⁷

Responsible governance of tenure and tenure security, especially of access to natural resources, are issues where mainstreaming gender can have a marked effect. Providing policies that create the opportunities for ensuring equitable resource access rights, access to markets, benefits from aquaculture and codes of conduct for the industry – especially for the most marginalized and poorest categories of men and women – can empower people to become more equal stakeholders. However, where governance and policies are developed without a strategic assessment of the relative roles of the men and women involved, the effect can be to disempower stakeholders.

Resource control and access

In addition to the responsible governance of tenure, the broader issue of women's access to and control over resources is an important gender consideration. For women to have a real impact on their economic situation and their position in society, it is essential that they have access to and control over aquatic resources as well as appropriate information that enables them to use such resources wisely.⁸

Development arena solutions

Gendered value-chain approaches can be used to recognize and value women's roles and contributions to agriculture and fisheries. To mainstream gender equality in development cooperation programmes and related activities, a number of steps are essential:⁹

- Require that programmes and related activities generate or obtain sex-disaggregated statistics (not only at the level of project and/or programme beneficiary, but also at both middle and macro levels of policy and governance) and qualitative information on the situation of women and men for the population in question. This information is required.
- Conduct a gender analysis with regard to: the gendered division of labour; access to and control over material and non-material resources; the legal basis for gender equality/inequality; political commitments with respect to gender equality; and the culture, attitudes and stereotypes that affect all preceding issues. Gender analyses should be conducted at the micro, meso and macro levels.
- Conduct a gender analysis of a programme or project concept to reveal whether gender equality objectives are articulated in the initial idea, whether or not the planned activity will contribute to or challenge existing inequalities, and whether there are any gender issues that have not been addressed.
- During the identification and formulation phases, ensure that the gender analysis contributes to the identification of entry points for actions that will be needed in order to meet gender equality objectives.
- Strengthen the participatory and organizational capacity of stakeholders at various levels so that they are better able to translate gender concerns into actions. This includes strengthening female umbrella organizations that can participate in debates and in project and programme processes.
- Put in place a gender-sensitive monitoring and evaluation system from the design phase onwards, including the establishment of indicators to measure the extent to which gender equality objectives are met and changes in gender relations are achieved.

On the ground – closing the gap in social capital

Building women's social capital can be an effective way to improve information exchange and resource distribution, to pool risks and to ensure that women's voices are heard in decision-making at all levels. This includes strengthening women's organizational abilities and roles and developing the capacity of women to take on leadership positions and engage with decision-makers and other stakeholders.

Functioning as production cooperatives, savings associations and marketing groups, women's groups can promote production and help women maintain control over the additional income they earn, as has been demonstrated by a project based around polyculture fish production in Bangladesh. As the project proved successful in providing additional incomes, the position of women within the household and community was also strengthened.¹⁰ Indeed, in communities with a high level of gender segregation, single-sex groups may lead to more desirable outcomes for women.¹¹

However, excluding men can sometimes generate unnecessary obstacles. A project to introducing the new livelihood strategy of mud-crab production to supply hotels on Unguja Island, United Republic of Tanzania, excluded men. The resultant anger among the men added transaction and input costs as women had to rely on a small number of male fishers for seedstock and feedstuffs.¹²

The clear message here is that interventions within the local sociocultural dynamics should base their interventions on the specific context – including the gender segregation within a community – and the underlying problem.

RECENT ACTIONS

The issues of women, gender and fisheries have been highlighted in a series of international and now global symposiums and other related initiatives:¹³

- The Global Conference on Aquaculture 2010 delivered the Phuket Consensus and responded to the recommendations of Expert Panel VI.3 (Sustainable Aquaculture by Developing Human Capacity and Enhancing Opportunities for Women Development) by including a recommended action to: "Support gender sensitive policies and implement programmes in line with globally accepted principles of gender equality and women's empowerment."
- The 2011 Special Workshop on Future Directions for Gender in Aquaculture and Fisheries Action, Research and Development (Shanghai, China)¹⁴ prepared a working draft of a working vision statement for mainstreaming gender in the aquaculture and fisheries sectors: "To promote and achieve gender equity in the aquaculture and fisheries sector in support of responsible and sustainable use of resources and services for food and nutrition security, quality of life of all stakeholders, primarily women, children, vulnerable and marginalized groups/communities."

Other ongoing initiatives that have contributed to increasing attention on gender issues in fisheries and aquaculture include:

- the triennial symposia on women and gender in fisheries and aquaculture organized by the Asian Fisheries Society;
- the Women in Fisheries publications of the Secretariat of the Pacific Community, and *Yemaya* (published by the International Collective in Support of Fishworkers);
- the Asia–Europe Meeting Aquaculture Platform (AqASEM09) project work on Empowering Vulnerable Stakeholder Groups.

OUTLOOK

No single blueprint exists for closing the gender gap as yet, but some basic principles are universal,¹⁵ and it seems plausible that governments, the international community and civil society will work together to:

- eliminate discrimination under the law, improving women's endowments, opportunities and agency to help shape more positive outcomes for the next generation;
- promote equal access to resources and opportunities, reducing barriers to more efficient allocation of women's skills and talents and helping to generate large (and growing) productivity gains;
- ensure that policies and programmes are gender-aware, increasing women's individual and collective agency to produce better outcomes, institutions and policy choices;
- make women's voices heard as equal partners for sustainable development.¹⁶

In addition to helping to achieve the MDG of promoting gender equality and empowering women, mainstreaming gender is an essential component of alleviating poverty, achieving greater food and nutrition security, and enabling sustainable development of fisheries and aquaculture resources.

Gender considerations should be firmly placed on all fisheries and aquaculture policy agendas at all geographical and institutional scales. Attention to gender is needed in order to help improve women's productivity and enhance human justice. Increasing awareness on gender and being gender-sensitive are no longer sufficient. A coalition of gender champions, informed researchers, expert networks and policy advocates will be necessary.¹⁷

An opportunity to alleviate poverty and ensure greater food and nutrition security

Women who are offered and provided with the best circumstances to enhance their socio-economic empowerment will also be able to contribute meaningfully to food security, poverty alleviation and improved well-being for themselves, their families and their communities. In short, they will help to create a world in which responsible and sustainable use of fisheries and aquaculture resources can make an appreciable contribution to human well-being, food security and poverty alleviation.

An opportunity for economic empowerment

Economic empowerment should be the end goal of a road map on gender in fisheries and aquaculture. Economic empowerment is not narrowly focused on the financial component but rather on having the ability to recognize and exploit opportunities to make wealth and to make the right decisions, which means having the capacity for analytical thinking – and this boils down to having a good education (formal or informal) and appropriate human capacity development.

An opportunity to contribute fully

By mainstreaming gender in the fisheries and aquaculture sector, women will be given a chance to recognize and appropriately exploit opportunities to generate wealth and to make the right decisions in terms of more responsible fisheries and aquaculture practices and sustainable development.

Improved preparedness for and effective response to disasters in fisheries and aquaculture

THE ISSUE

Fishers, fish farmers and their communities around the world tend to be particularly vulnerable to disasters. This is because of their location, the characteristics of their livelihood activities, and their overall high levels of exposure to natural hazards, livelihood shocks and climate change impacts. Exposure and vulnerability to these hazards is increasing. For example, in the past century, there has been an increasing trend in the number of natural disasters reported around the world (Figure 36).

The social, economic and environmental impact of these disasters is significant, with disproportionate effects in developing countries and on vulnerable groups. Between 2000 and 2004, of the 262 million people affected annually by disasters related to weather and climate, more than 98 percent lived in developing countries and the vast majority were dependent mainly on agriculture and fisheries for their livelihoods.¹⁸ Loss of life from such events is more prevalent in developing countries – from 1970 to 2008, more than 95 percent of deaths from natural disasters were in developing countries.¹⁹ In 2010 alone, a total of 385 natural disasters killed more than 297 000 people worldwide, affected more than 217 million others and caused almost US\$124 billion of economic damages.²⁰ It is acknowledged that the poor will be most affected by such hazards in the future and that this is likely to undermine progress

toward poverty reduction.²¹ While total economic damage from disasters tends to be higher in developed countries, as a percentage of gross domestic product it is higher in developing countries.²²

The types of disasters that affect the fisheries and aquaculture sector include natural disasters such as storms, cyclones/hurricanes with associated flooding and tidal surges, tsunamis, earthquakes, droughts, floods and landslides. Disasters of human origin affecting the sector have included oil and chemical spills and nuclear/radiological material. Food and nutrition security, post-conflict and protracted crises, HIV/AIDS and sector-specific hazards (e.g. transboundary aquatic animal diseases and pest outbreaks) can also have significant impacts on aquaculture production and fisheries. In addition to the tragic loss of life, the effects of disasters on the sector can include the loss of livelihood assets such as boats, gear, cages, aquaculture ponds and broodstock, post-harvest and processing facilities, and landing sites. In the longer term, the impact of the effects of disasters can be considerably mitigated by the effectiveness of response activities. However, damage caused by disasters can have social and economic impacts throughout and well beyond the sector (such as in terms of reduced employment and food availability). Other longer-term disasters such as fish disease outbreaks can build up over time and significantly affect production.

The vulnerability of countries and communities to these hazards is determined, on the one hand, by their exposure to such hazards and, on the other, by their ability to withstand (sensitivity), respond to and recover from (adaptive capacity) the effects of such hazards. Thus, susceptibility is directly affected by underlying issues such as food and nutrition insecurity, weak institutions, conflict and poor access to markets. However, the way each of these issues affects people varies considerably. Men and women, the old and the young, the rich and the poor, and small-scale and large-scale undertakings are all affected differently and have different ways of responding to hazards that affect them. Different people can also have quite distinctly different needs in the face of an emergency, face different threats and have different skills and aspirations.²³

For coastal fishers, fish farmers and their communities, the relationship between them and the ecosystems that they depend on is complex.²⁴ This complexity is changing as the interface between fishers and fish farmers and the ecosystem is being affected by both slow- and rapid-onset hazards. The exposed nature of the livelihoods of fishers

Figure 36

Natural disasters reported worldwide, 1900–2010

Source: EM-DAT. 2012. *EM-DAT: The OFDA/ICRED International Disaster Database* [online]. Université Catholique de Louvain, Brussels. [Cited 22 March 2012]. www.emdat.be

and fish farmers, and the location of their communities, means that hazards often become disasters.

The extent of the impact of such disasters is also affected by people's social and economic conditions, which often include poverty and marginalization, especially in developing countries. Given the important role of the fisheries and aquaculture sector in food and nutrition security at both the local and national levels, disasters that affect these communities will also have multiplier effects on the wider economy. Fishers, fish farmers and their communities have been particularly affected by recent major events such as the Asian tsunami of 2004, Cyclone Nargis (which affected Myanmar in 2008), the recent floods in Bangladesh, Pakistan and Viet Nam, and the 2011 tsunami in Japan.

The effect of these hazards on fishing communities is increasing for a number of reasons. Extreme weather events are becoming more frequent, often associated with increasing climate variability and change. The impacts of disasters on coastal communities are particularly pronounced in the case of subsea events resulting in tsunamis (geological), storm surges and coastal flooding (hydrological), and coastal and lakeshore storms (meteorological). Droughts and floods can also affect river flows, wetland areas, and lacustrine and riparian communities. More indirectly, droughts and other catastrophic events can cause mass migration of people into areas normally occupied by fishing and fish-farming communities, so increasing competition for resources such as water.

Fishers, fish farmers and their communities are also often exposed to more prolonged hazards such as the spread of fish disease, the increase in invasive undesirable alien species, pollution from land and aquatic sources, and aquatic ecosystem degradation from farming, mining, industry and urbanization. Moreover, fishers, fish farmers and their communities often live in locations where tenure over land and other resources is contested, leading to disputes and more complex emergencies.

The land–water interface is being particularly affected by inward migration and the unsustainable use of resources. The result can be a depletion of the ecosystem services that these resources provide, particularly protection from coastal hazards such as storms and cyclones, and a reduction in support for productive livelihoods. Deforestation is leading to increased sedimentation and land erosion in coastal, lakeshore and delta regions, and this can adversely affect marine habitats (especially reefs). In addition, the effects of population increases in fishing and fish-farming communities are compounded by the lack of alternative livelihood options and weak market linkages.

The susceptibility of fishers, fish farmers and their communities to rapid-onset disasters is also being affected by climate change.²⁵ Seasonal weather patterns are likely to change, with some areas experiencing greater periods of drought and others more floods. Extreme weather events, such as storms, are likely to increase in frequency and affect fishing operations, and coastal and wetland flooding is likely to become more frequent. Increased precipitation in some areas will lead to the erosion of riparian lands and to greater sedimentation in coastal areas, affecting seagrass and reef production. Sea-level rise is likely to increase coastal flooding, and the incursion of saltwater into coastal areas will affect agricultural production and fish farming. Species distributions are also being changed, and increased temperatures are likely to affect coral reefs adversely, with higher incidences of coral bleaching occurring. Temperature changes will also affect fish physiology, with implications for both capture fisheries and fish farming. Increased ambient air temperatures could have very significant effects on the types of fish that can be cultured.

Changes in weather patterns will affect traditional fish processing methods, especially where fish is sun-dried. In some locations, this may be of benefit for processors. However, in other locations, poor weather in glut fish landing seasons will affect drying rates, with the potential for substantial losses. There are also likely to be changes in terms of road access to markets where unusual flooding or heavy rains occur.

Badly managed fisheries and aquaculture farms may cause increased stress in fish, reduce water quality, and make fisheries and aquaculture more exposed to climate change threats such as changes in water temperature and salinity.

Changing weather patterns will also affect non-fisheries livelihood strategies and will increase pressure on people to join a fishery where other opportunities have decreased. Efforts to redirect fishing to alternative livelihoods are also being affected by climate change effects on livelihood options and opportunities in the wider economy.

POSSIBLE SOLUTIONS

Reducing the effects of disasters on the fisheries and aquaculture sectors can be achieved through measures for prevention, mitigation,²⁶ and preparedness (disaster risk reduction [DRR]; Box 11). In the fisheries and aquaculture sector, this includes preparedness to respond rapidly and effectively if disasters occur, and early warning to provide information before potentially disastrous events occur. Managing the effects of hazards and disasters (disaster risk management [DRM]) goes beyond DRR to incorporate emergency response, recovery and rehabilitation within a management framework. Thus, as shown in Figure 37, DRM involves three distinct phases: (i) reducing vulnerability; (ii) responding to emergencies when they arise; and (iii) rehabilitating communities after the emergency has passed.

Box 11

Disaster management and climate change adaptation: key definitions

Disaster risk reduction (DRR) is the concept and practice of reducing disaster risks through systematic efforts to analyse and manage the causal factors of disasters, including through reduced exposure to hazards, lessened vulnerability of people and property, wise management of land and the environment, and improved preparedness for adverse events.¹

Disaster risk management (DRM) goes beyond preparedness, prevention and mitigation, which form the core of DRR, to incorporate emergency response, recovery and rehabilitation within a management framework.²

Climate change adaptation (CCA) refers to adjustments in ecological, social or economic systems in response to actual or expected climate stimuli and their effects or impacts. This term refers to changes in processes, practices and structures to moderate or offset potential damages or to take advantage of opportunities associated with changes in climate. It involves adjustments to reduce the vulnerability of communities, regions and activities to climate change and variability. Adaptation is important in the climate change issue in two ways: one relating to the assessment of impacts and vulnerabilities; and the other to the development and evaluation of response options.³

¹ United Nations International Strategy for Disaster Reduction. 2009. Terminology. In: *UNISDR* [online]. [Cited 20 April 2012].

² Baas, S., Ramasamy, S., Dey DePryck, J. and Battista, F. 2008. *Disaster risk management systems analysis: a guide book* [online]. Rome, FAO. [Cited 19 March 2012]. <ftp://ftp.fao.org/docrep/fao/010/ai504e/ai504e00.pdf>

³ Intergovernmental Panel on Climate Change. 2001. *Climate Change 2001: Impacts, Adaptation, and Vulnerability*. Contribution of Working Group II to the Third Assessment Report of the Intergovernmental Panel on Climate Change. Cambridge, UK, Cambridge University Press. 1042 pp.

Key actions in the DRM cycle may include:

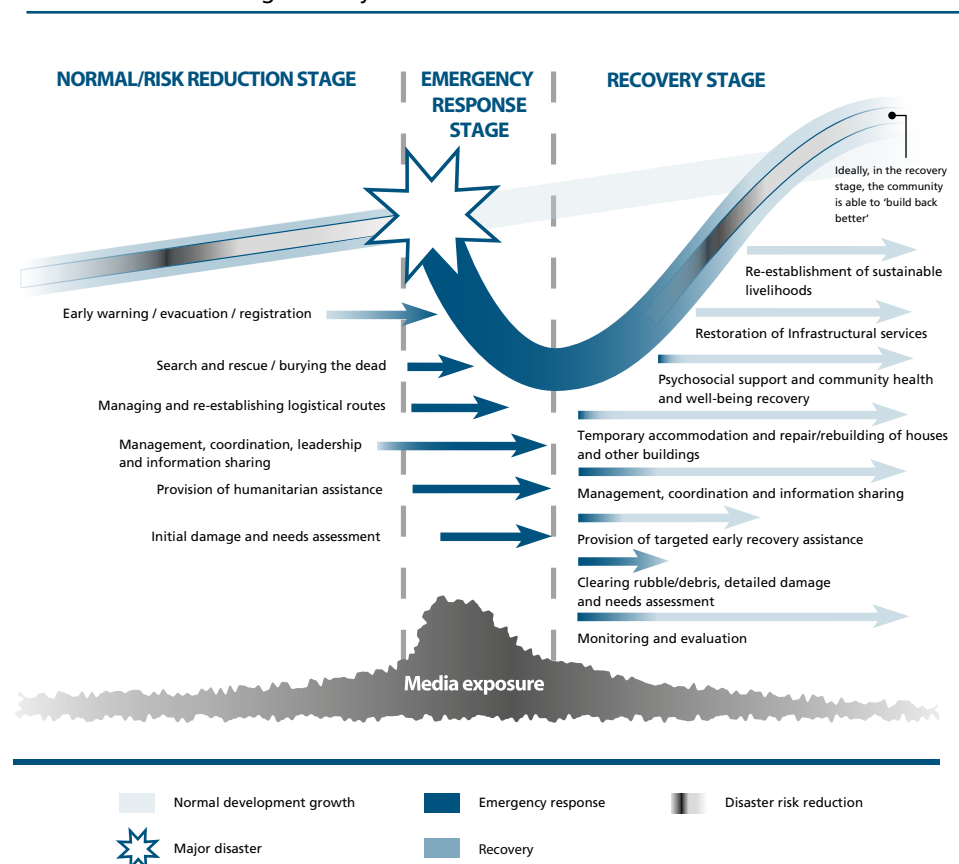

- assessment of damage and need (with respect to fisheries and aquaculture);
- rehabilitation of livelihoods (to reduce dependence on food aid);
- longer-term development and planning and preparedness;
- relief or emergency response to address immediate humanitarian needs and to protect livelihoods following a disaster;
- rehabilitation to initialize the restoration and rebuilding of livelihoods;
- reconstruction for replacing destroyed infrastructure;
- sustainable recovery for longer-term re-establishment and enhancement of livelihoods and livelihood support structures.

During emergency response, advocacy is required in order to ensure that recovery efforts comply with international instruments (including the Code of Conduct for Responsible Fisheries [the Code] and the MDGs) and are guided by international best practice, national policies and agreed recovery plans. This can include the promotion of:

- sustainable rehabilitation of fishing and fish farming;
- fish preservation and processing practices compatible with the state of fishery resources;
- rehabilitation and conservation of the environment and fisheries resources;
- strengthened governance and community-based planning;
- strengthening and diversification of sustainable livelihoods of traditional fishing and fish-farming communities.

Figure 37

The disaster risk management cycle¹

¹ This mainly applies to a relatively quick-onset disaster (e.g. cyclone, flood, earthquake, tsunami, bushfire), rather than a slow-onset one such as famine (due to drought/war).

Resilience to the effects of disasters can be achieved by working with communities and multilevel stakeholders to reduce their sensitivity to disasters (through preventive actions or by reducing levels of dependence) and/or by strengthening coping and adaptive strategies that respond to those hazards. In so doing, the differences between different stakeholder groups within a given community need to be carefully considered.

As the effects of climate change will be to alter the magnitude and frequency of extreme events, it is important to recognize that existing coping and response mechanisms to disasters – based on past vulnerabilities – may no longer be appropriate for what is to come. Indeed, in many countries, existing mechanisms are already insufficient for the current level of vulnerability.²⁷

Climate change and more rapid-onset hazards such as cyclones, floods and earthquakes are related in a number of ways:

- They both directly affect the livelihoods of fishers and fish farmers and invariably reduce the quality of those livelihoods.
- They interact to compound the adverse effects of both – most noticeable will be the increased frequency and impact of extreme events as a result of climate change.
- Climate change will interact with extreme events to change their location and, thus, the communities affected.
- Adaptation to both forms of hazard at the community level tends to have many aspects in common.

Effective DRM needs to consider changing climate risk patterns, and, given that an increase in extreme climate events is one of the major threats posed by climate change, DRM is a natural entry point for adaptation.²⁸ When considering adaptation to climate change risks, it should be recognized that adaptive capacity has developed as a response to existing vulnerability to extreme events. Improving the adaptive capacity of communities, civil society and governments to deal with current hazards is also likely to improve their capacity to adapt to climate change.²⁹

The extent of climate change effects on fishing and fish-farming communities has been extensively investigated.³⁰ The exposure and vulnerability of fishing communities to hazards is increasingly being seen as a convergence of climate change and more acute hazards. This compounds situations where natural resources are already overexploited or under other forms of pressure from human activities. The Intergovernmental Panel on Climate Change has recently drawn attention to the need to integrate expertise in climate science, DRM and adaptation in order to reduce and manage more effectively the risks of extreme events and disasters in a changing climate.³¹ However, climate change adaptation (CCA) is not simply an extension of DRM. Adaptation to climate change not only means addressing changes in the intensity and frequency of extreme events, but also more subtle changes in climate conditions as well as emerging risks that have not been experienced in a region before.³² Some effects of climate change, such as global changes in sea levels, are new within recent human history, and little experience is available to tackle such impacts.³³

This growing interconnectedness of climate change and more acute events suggests a need for a convergence of DRM and CCA preparedness and response approaches, particularly at the land–water interface where the effects are felt most strongly and particularly by fishers, fish farmers and their communities. This would suggest that DRM and CCA need to be fully incorporated into fisheries and fish-farming policies and plans, and that fisheries and fish farming should be fully considered in CCA and DRM approaches. In addition, the increasing vulnerability of the poor to both climate change and hazards would suggest that CCA and DRM need to link to livelihoods (taking account of the different assets and production, coping and adaptive strategies of different groups, such as the old and the young, men and women, and people from different cultures and religions) in a holistic and integrated way. Moreover, the implications of both extreme events and climate change for wider national and regional food security suggest that these elements also need to be integrated with each other.

RECENT ACTIONS

A World Conference on Disaster Reduction was convened by the United Nations General Assembly (UNGA) in Hyogo, Japan, in 2005 just a few weeks after the Indian Ocean tsunami. The conference, which was attended by representatives of 168 States, agreed on a strategic and systematic approach to reducing vulnerabilities and risks to hazards. The need for building resilience of nations and communities was stressed, and the conference adopted five priorities for action:

- Ensure that DRR is a national and a local priority with a strong institutional basis for implementation.
- Identify, assess and monitor disaster risks and enhance early warning.
- Use knowledge, innovation and education to build a culture of safety and resilience at all levels.
- Reduce the underlying risk factors.
- Strengthen disaster preparedness for effective response at all levels.

The Hyogo Framework for Action (HFA) 2005–2015: Building the Resilience of Nations and Communities to Disasters was endorsed by the UNGA in Resolution 60/195. The ten-year plan of the HFA reflects the intention to take a holistic approach in identifying and putting into action complex multidisciplinary DRR measures. The HFA supports a stronger recognition of climate change concerns in DRR strategies and seeks to establish a multidisciplinary, forward-looking approach. It also calls on the United Nations International Strategy for Disaster Reduction to facilitate the coordination of effective and integrated action among the organizations of the UN System and among other relevant international and regional entities, in accordance with their respective mandates, to support the implementation of the HFA.

In line with the HFA, FAO has developed a Framework Programme on Disaster Risk Reduction/Management. The Framework Programme strives to assist Members in implementing the HFA five priorities for action in the agriculture sector. The direction and content of the Framework Programme respond to recent recommendations by FAO governing bodies, including priority areas as identified by FAO Regional Conferences. These “pillars” are: (i) institutional strengthening and good governance for DRR in the agriculture sector; (ii) information and early warning systems on food and nutrition security and transboundary threats; (iii) preparedness for effective response and recovery in agriculture, livestock, fisheries and forestry; and (iv) good practices, processes and technologies for mitigation and prevention in farming, fisheries and forestry. Interventions under the Framework Programme are tailored to the specific strengths and needs of a country or region and delivered in a demand- and modular-responsive manner.

The fisheries and aquaculture sector must be considered in a different way to other sectors (such as agriculture) in emergencies in view of the many unique challenges related to management and the complex range of activities undertaken by fishers and fish farmers. Specifically, within the fisheries and fish-farming sector, FAO has initiated a programme of consultation with partners at the global level, where the synergies between managing climate change and DRR were explored.³⁴ At the regional level, in Bangkok, Maputo and San José, consultations with partners addressed regional issues,³⁵ where the integration of fisheries and aquaculture with DRM–CCA was discussed in detail and options for taking this integration forward were outlined. The need for this integration was further endorsed at the 29th Session of the FAO Committee on Fisheries (COFI) in 2011. The different initiatives at the regional and international level constitute important opportunities for ensuring that concerted efforts are made to tackle the issues relevant to DRM and CCA. However, challenges remain with regard to integrating CCA and DRM sufficiently in fisheries and aquaculture governance and development planning and implementation and, vice versa, integrating fisheries and aquaculture into CCA and DRM, and taking the characteristics and special needs of fishers, fish farmers and their communities into account in DRM and CCA policies and actions. To this extent, FAO is actively involved in identifying climate-related vulnerabilities and adaptation strategies, including DRR/DRM, specific to fisheries and

aquaculture in order to inform more fully fisheries and climate-change decision-makers. The work of the FAO Fisheries and Aquaculture Department is aligned to priorities expressed in international, regional and national policies and agreements, such as national adaptation programmes of action for least-developed countries and regional strategies/agreements for disaster reduction and related programme of action. It is also aligned with the FAO Framework Programme on Climate Change Adaptation (known as FAO-Adapt).

Furthermore, the FAO Fisheries and Aquaculture Department continues to provide support to FAO Members and partners in responding to emergencies affecting the fisheries and aquaculture sector. Since 2005, it has supported emergency responses through 135 projects in 25 countries. The overall objective of this support has been to strengthen food and nutrition security through the sustainable rehabilitation and long-term recovery of the fisheries and aquaculture sector and the livelihoods that depend on it. In particular, efforts have focused on targeting women and other marginalized groups. The technical advice provided aims to ensure that these efforts are aligned to national policies, regional strategies and international best practice and guidance for the sector, in particular the Code.

OUTLOOK

In view of the in-depth and ongoing consultation with partners and stakeholders from the DRM, CCA and fisheries and fish-farming sectors, it seems likely that the key areas for action in the coming years will include:

- strengthening policy coherence and institutional structures to ensure explicit and adequate consideration of fisheries and aquaculture activities in disaster preparedness and CCA strategies;
- integrating an understanding of the increasing vulnerability of fishers, fish farmers and their communities both to extreme events and to climate change, and developing and incorporating comprehensive preparedness and response strategies into fisheries and fish-farming sector plans and wider development frameworks;
- building an increased understanding of the vulnerability of fishers, fish farmers and their communities into wider social, economic and environmental development plans;
- working with communities, governments and civil society to help build their productive, coping and adaptive capacity and to ensure that the adaptive, coping and livelihood strategies of fishers, fish farmers and their communities are incorporated into wider disaster preparedness and response strategies;
- developing shared tools, guidance and approaches that combine DRM and CCA at a practical level and that link into fisheries and fish-farming development strategies to increase the resilience of communities and that of aquatic systems on which they depend;
- building partnerships at the global, regional, national and subnational levels among international agencies, national agencies, local government, civil society and communities to learn lessons about, prepare for and respond to slow- and rapid-onset hazards in an integrated and informed way.

Managing recreational fisheries and their development

THE ISSUE

Recreational fishing is well established in most developed countries and expanding fast elsewhere. It involves a large number of individuals, and there is growing awareness that recreational fishing is a considerable industry in terms of numbers of practitioners, catch and social and economic relevance. However, in many recreational fisheries, this awareness has not been accompanied by enhanced management practices, and

concerns are spreading about the influence of recreational fishing on the livelihood opportunities of full-time fishers, on the environment and on aquatic biodiversity.

Recreational fishing is fishing of aquatic animals that do not constitute the individual's primary resource to meet nutritional needs and are not generally sold or otherwise traded on export, domestic or black markets.³⁶ While angling is how most people perceive recreational fishing, the activity also includes gathering, trapping, spearing, bow fishing and netting aquatic organisms. Recreational fishing currently constitutes the dominant use of wild fish stocks in freshwater environments of industrialized countries. The increased affordability of high-efficiency fishing equipment (including navigational devices, fish finders and improved boats) and ongoing urbanization in coastal zones have resulted in a continuing expansion of recreational fisheries in coastal and marine environments.

Although estimates are difficult, the total annual catch by recreational fishers was estimated at 47 billion fish in 2004, or at about 12 percent of the total world catch.³⁷ Tentative estimates indicate that about 10 percent of the population in developed countries practise recreational fishing, and recreational fishers probably number more than 140 million worldwide.³⁸ One study,³⁹ summarizing ecosystem-based marine recreation valuation results, estimated the total number of marine recreational fishers for 2003 at 58 million. Several million jobs depend on recreational fisheries as associated spending may add up to billions of dollars annually. In the United States of America and in Europe, where angling is the best-documented form of recreational fishing, it has been estimated in recent years that there are at least 60 million and 25 million recreational anglers, respectively;⁴⁰ and it has been estimated that there are 8–10 million recreational saltwater fishers in Europe.⁴¹ Similarly, it was estimated in 2009 that some 10 percent of the population in Central Asia were involved in recreational fisheries in inland waters of that region.⁴²

The contribution that recreational fishing can make to local economies is considerable, including in less-developed countries. In some areas, the income and employment generated by the spending of recreational fishers is higher than that generated by commercial fisheries or aquaculture. Improved valuation of natural habitats and clean waters have been additional benefits of recreational fishing.⁴³

Recreational fishing has shown itself able to provide value as an educational activity, promoting the concept of responsibility for fish stocks and the environment they inhabit and upon which all people depend. Recreational fishers often have a strong sense of responsibility for the environment in which they fish, as is, for example, recognized by the Bern Convention of the Council for Europe in the European Charter on Recreational Fishing and Biodiversity (2010).⁴⁴

In some cases, aquaculture escapees have come under the control of sports fishers. In southern Chile, recreational fisheries that used to be based only on rainbow trout and brown trout now include escaped Atlantic salmon (*Salmo salar*) and chinook salmon (*Oncorhynchus tshawytscha*). In Chile and Argentina, where chinook salmon have migrated successfully in the ocean, self-sustained populations of chinook salmon have generated much enthusiasm among recreational fishers and concerns among conservationists.⁴⁵

However, at times, recreational fishers also interact negatively with professional small-scale and artisanal fishers in open-access areas and at common fishing grounds. There are records of controversial and anecdotal observations of the detrimental effects of recreational fisheries, such as spear fishing on individual species of groupers along the coasts of the Mediterranean and Australia⁴⁶ and in the eastern Red Sea.⁴⁷ Moreover, recreational diving for species such as Caribbean spiny lobster⁴⁸ in combination with commercial fisheries and other pressures (e.g. pollution) has caused significant declines in certain stocks.

Nevertheless, recreational fishers have the potential to enhance fish conservation and maintain or rehabilitate important habitat.⁴⁹ As stakeholders, they can be instrumental in successful fisheries conservation through participation in management and conservation endeavours.

Increasingly, recreational fishers are capable of reaching offshore fishing grounds and use technologies – including fish-locating devices – that can make them equivalent to commercial fishers in term of fishing capacity and capability. Recreational fisheries have developed for species historically only exploited by the commercial fishery, in some cases causing conflict between the sectors.⁵⁰ Fishing similar locations and using the same types of fishing gear and facilities, such as moorings, can also put recreational fishers in competition with coastal small-scale commercial fishers. Other specialized recreational fisheries target highly iconic species such as salmon, marlins, sailfish and swordfish, often in particular areas and seasons, contributing significantly to the total catch. However, it should be noted that most game fishing associations actively promote catch-and-release practices and that the fish caught in game fishing tournaments are generally released unless the fish caught is a record fish.

Many recreational fisheries tend to be highly selective. Often, recreational fisheries target larger individuals in the population. However, removal of larger individuals of long-lived species may have important effects on the reproductive potential of the population.⁵¹ Larger females are more fecund, spawn over prolonged periods (thus providing more resilience to changing environmental conditions), and can produce larvae with higher survival rates. Sequential hermaphroditic species may have large individuals of the same sex and their sustained removal can affect spawning success. Age- or size-truncated populations may suffer from changes in density or from behaviourally mediated indirect interactions, and cause significant effects in food webs, also altering the ecosystem structure and productivity.⁵² All this would assume even more relevance in the case of those stocks concurrently exploited by both commercial and recreational fisheries.

POSSIBLE SOLUTIONS

Development

Sustainable development of the recreational fisheries sector will depend on the acceptance of its multidisciplinary nature and whether recreational fishery stakeholders will be allowed to facilitate successful conservation and management. There is an urgent need to integrate biological and social sciences in order to provide insights into the dynamics of the entire social and ecological system of the recreational fishing industry.⁵³

The sustainability of recreational fisheries – including the conservation of aquatic animal biodiversity in areas fished – in combination with commercial fisheries requires recognition by those responsible for this sector. Policy-makers and managers responsible for recreational fisheries need to obtain information about the sector, as well as knowledge of possible factors that affect the sector negatively (including coastal development, fish habitat modification, pollution and extreme climate events). In addition, recreational fishing has a significant social component, and the benefits of the activity need to be weighed against investment in resource protection.⁵⁴

Appraisal of the performance of recreational fisheries and of their potentialities needs to be a multidimensional and multidisciplinary exercise in order to capture the societal, economic, environmental and educational components of the sector, and importantly, to ensure effective participation of stakeholders.⁵⁵ One recent study⁵⁶ has made an effort in this respect by recommending “methodologies assessing socio-economic benefits of European inland recreational fisheries”, which may be of use not only in Europe but also elsewhere.

Management

Management of recreational fisheries needs to reconcile conflicting demands for access to the wild fish while ensuring both sustained exploitation of the marine fauna and conservation of the marine ecosystem of which the fauna are a part.

To do this, management of recreational fisheries needs to follow a process that is similar to that used by most fisheries managers; it involves: (i) defining the resource to be managed, the state of the system and constraints; (ii) setting goals and objectives; (iii) evaluating management options; (iv) choosing appropriate

actions to achieve management objectives; (v) implementing such actions and monitoring outcomes; and (vi) evaluating the success of management, and adjusting management in the light of learning.⁵⁷ The choice of tools is wide in freshwater recreational fisheries. Management tools include: stocking, biomanipulation, prey enhancement, suppression of detrimental fishes, selective removal, renovation, and management of aquatic plants.

However, at the same time, fisheries managers need to recognize that freshwater recreational fisheries differ from commercial fisheries and aquaculture and that, therefore, they need to be dealt with in a way that reflects this difference. The main differences relate to species introduction, stocking of waterbodies, catch-and-release practices, the potential for selective overexploitation, and the role of recreational fishers in habitat and biodiversity conservation.

Managers also need to be aware that for many fisheries there exists a perception that the catch of the individual recreational fisher will have only a minimal and localized impact on resources, and that recreational fishing has had little influence on reported stock declines worldwide. However, this perspective often changes dramatically when the size and activity of the recreational fisher population is considered.

There is an open-access scenario characterizing many recreational fisheries, particularly marine ones, that has consequences for the sustainability of the resources and the fisheries. In contrast, many inland and coastal recreational fishing areas, especially in Europe, North America and Oceania, do not apply open-access regimes and sometimes have extremely restrictive access requirements instead.

However, traditional management objectives such as maximizing yield may not be the most appropriate goal for a recreational fishery – enjoyment of the fishing experience is the primary objective of recreational fishing, and this requires different management strategies and tools.⁵⁸

An integrated monitoring system in support of the management of recreational fisheries should entail all the relevant components of the recreational fishery. It could include, *inter alia*, representatives of: recreational fishers and their associations, equipment suppliers, commercial fishers and their organizations, public authorities, civil society, universities, research institutes, and the tourism industry.

The limited reliable data and scientific information available call for precautionary management. As in any other fishery, management of recreational fisheries requires clear identification of goals and measurable operational objectives. Simple and easy-to-obtain multidisciplinary indicators, and their reference points, should be used to measure the state of recreational fishery systems in terms of pressure exerted on the resources and generation of added value. Such indicators can be used to compare recreational fisheries with commercial fisheries.⁵⁹ Adequate funding and support should be available to manage recreational fishing within the wider context of fisheries and environmental management strategies. The recreational fishers may be requested to contribute to the cost of managing recreational fishing; “user-pay, user-benefit” systems could be used in some cases. The need to estimate total harvest, effort and impact has to be addressed in order to be able to manage a resource responsibly. Recreational fisheries registration and licensing can play a major role in this respect; registration being a means to quantify and identify participation, and licensing being a means to do the same and generate income. Issues to consider when establishing licensing schemes are the costs of their establishment and operation, and how to ensure that the licence revenues collected flow back into the sector.

Management that focuses on preserving larger specimens of a population may involve the creation of appropriate conservation areas (refugia, marine protected areas or areas closed to fishing) or guidance and/or regulations on catch and release.

Some recreational fisheries target individuals belonging to stocks of transboundary or migratory fish species that are exploited by recreational and commercial fisheries of more than one country. Moreover, some target species of marine recreational fisheries (e.g. tuna and marlin) migrate between high seas areas and areas under national

jurisdiction. This confers an additional international facet to the national management system. Regional fisheries management organizations (RFMOs) and regional fisheries advisory bodies can provide the regional frameworks required to include recreational fisheries into the regional dialogue and mechanisms for the conservation and management of recreational fisheries of common interest.

RECENT ACTIONS

The Code of Practice (COP) for Recreational Fisheries developed (2007–08) under the auspices of the then European Inland Fishery Advisory Commission (EIFAC, now the European Inland Fisheries and Aquaculture Advisory Commission [EIFAAC]) constituted a major step towards elaborating a suite of tools for the management and conservation of recreational inland fisheries.⁶⁰ The COP includes standards for responsible, environmentally friendly recreational fishing in consideration of changing societal values and conservation concerns. Its aim is to foster best practices in recreational fisheries that would promote their long-term viability in the face of expanding threats, such as habitat manipulation and destruction, resource overexploitation, and loss of biodiversity.

The relevance of the development and management of recreational fisheries beyond national jurisdictions is becoming evident in the agenda of regional fishery bodies (RFBs), particularly where recreational fishing occurs in international waterbodies or semi-closed seas.⁶¹ Regional bodies could develop long-term common monitoring frameworks and promote regional cooperation in order to: establish standard guidelines to describe the fishery and determine the impact upon the resources; and characterize the social and economical dimension of recreational fisheries that occur in the region of their competence.

At the global scale, the World Recreational Fishing Conference series is a major scientific forum for discussing progress and issues in the development and management of recreational fisheries. The conferences aim to increase dialogue and knowledge about the diversity, dynamics and future prospects of recreational fisheries.

FAO is developing technical guidelines on responsible recreational fisheries. In August 2011, an Expert Consultation met to develop the FAO Technical Guidelines for Responsible Fisheries: Recreational Fisheries. The technical guidelines cover all types of recreational fisheries (harvest-oriented angling, catch-and-release fishing, trapping, spearfishing, etc.) in all environments (marine, coastal and inland). They are global in scope, and will be congruent with the the Code.

OUTLOOK

Recreational fishing is developing and expanding in many countries, as are its impacts on fish stocks through exploitation or related practices such as stocking and introduction of non-native fishes. The social and economic importance to local and regional economies is also being recognized.⁶² The dimension of global fisheries is greater than previously assumed when recreational fisheries are considered, and local economies are a major beneficiary of good recreational fisheries management. The economic, educational, health and other social benefits of recreational fishing should be recognized and promoted. Ideally, both commercial and recreational fishing industries should share a common interest in ensuring the maintenance of fish stocks and their habitats.

It seems plausible that, over time, the development and management of recreational fisheries will build increasingly on the application of the precautionary and ecosystem approaches. This will include using a holistic approach to recreational fisheries management based on the concomitant consideration of fish biology, fishing activity, catches, and the economic and social values of recreational fishing.

Given the growing importance of recreational fisheries, national fisheries management will probably recognize and incorporate them in the overall fisheries management discourse, including in fisheries sector reviews, management plans and conservation strategies. Future fisheries management will probably aim for balanced

development of recreational and commercial fishing, including allocation of resource shares in order to optimize local community benefits and ecosystem health.

The potential role of recreational fisheries for livelihoods of rural communities will be assessed and promoted, given that, in many parts of the world, recreational fisheries and associated tourism activities could provide alternative livelihoods for small-scale fishers.

Barriers to achieving low-impact fuel-efficient fishing

THE ISSUE

Most fishing techniques in use today have their origin in an era when fisheries resources were abundant, energy costs were much lower than current levels, and less attention was paid to the negative impacts of fishing on aquatic and atmospheric ecosystems. Current high energy prices and greater awareness of ecosystem impacts are

Box 12

Fishing vessels and fuel consumption

With regard to consumption of fuel, recent overall estimates have shown that about 620 litres of fuel (530 kg) is used per tonne of landed fish.¹ The global fishing fleet is estimated to consume approximately 41 million tonnes of fuel per annum.² This amount of fuel generates about 130 million tonnes of CO₂. However, fuel consumption varies widely according to gear type, fishing practice, operational technique and the distance between the fishing ground and port. Moreover, there are substantial differences in fuel consumption between fisheries targeting groundfish or shellfish and those targeting pelagic fish or industrial fisheries.

Notwithstanding the above, studies of fuel consumption patterns by gear type indicate that passive fishing gear (e.g. pots, traps, longlines and gillnets) generally require lower amounts of fuel than active fishing gear (e.g. bottom trawls). Encircling gear types that are dragged a limited distance at slow speed, including gear such as bottom seines, rank between passive and towed gears in fuel consumption.

Active pelagic gear types like midwater trawls and purse seines target fish that form dense schools, and the catch can be hundreds of tonnes of fish in one short tow or haul; therefore, the fuel consumption is generally low in relation to the quantity of catch. In particular, purse seining is one of the most fuel-efficient techniques for catching fish although vessels using this gear often spend significantly more time and fuel searching for schools than actually catching fish. Fishing with the help of powerful artificial lights is common in purse seining, squid jigging and stick-held dip netting, particularly in Asia. While these fishing operations in themselves are fuel efficient, the use of the lights adds to the energy requirement.

¹ Tyedmers, P.H., Watson, R. and Pauly, D. 2005. Fueling global fishing fleets. *Ambio*, 34(8): 635–638.

² World Bank and FAO. 2009. *The sunken billions. The economic justification for fisheries reform*. Washington, DC, Agriculture and Rural Development Department, The World Bank. 100 pp.

now realities and present major challenges to the viability of fisheries, particularly in developing countries where access to and promotion of energy-efficient technologies have been limited. However, as illustrated in this article, which is largely based on a paper by Suuronen *et al.*,⁶³ each type of fishing gear and practice has advantages and disadvantages, and the suitability of each gear type depends considerably on the operational conditions and on the species to be targeted.

The impacts of fishing gear on ecosystems vary widely. Overall, these impacts largely depend on: the physical characteristics of the gear; the mechanics of its operation; where, when and how the gear is used; and the extent of its use. Moreover, gear types that rank high for one kind of impact may rank low for another. Physical damage to the environment may also result from the inappropriate use of an otherwise acceptable gear. Only a small number of fishing methods are recognized as inherently destructive no matter how they are used, prime examples being explosives and toxins. It should also be kept in mind that in spite of the fact that many fisheries are highly selective, fishers are often not capable of catching only the desired target species. When poorly selective fishing occurs, it leads to the incidental catch of fish and invertebrates, part of which may consist of juveniles of ecologically important and/or economically valuable species. In addition, fishing can also result in the incidental mortality of non-target species of seabirds, sea turtles and marine mammals, as well as causing damage to vulnerable ecosystems, such as coldwater corals, which can take many decades to recover.

With regard to greenhouse gas (GHG) emissions, insufficient attention has been paid to the fisheries sector as a whole and to fishing operations in particular. Consequently, it is difficult to rank fishing gear and practices in terms of GHG emissions. However, using the consumption of fuel as a proxy for total GHG emissions can provide a good estimate (Box 12). It is also a fact that, notwithstanding the provisions of existing international conventions, the quality of available fuel is not constant worldwide with regard to sulphur content.

It is noteworthy that life cycle assessments show that significant energy consumption and GHG emissions occur after the catch is taken on board and more so after landing, owing to fish processing, cooling, packaging and transport. Thus, minimizing the impacts and energy consumption throughout the whole product chain would be important to reducing the overall environmental costs of fishing.

POSSIBLE SOLUTIONS

The fishing sector should strive to further lower its fuel consumption and decrease ecosystem impacts. Despite a growing number of initiatives and experimentation with energy-reducing technologies, there is currently no viable alternative to fossil fuels for mechanically powered fishing vessels. However, it is well demonstrated that, through technological improvements, gear modifications and behavioural change, the fishing sector can substantially decrease the damage to aquatic ecosystems, reduce GHG emissions (which is a legal obligation for governments under existing international conventions) and lower operational costs for fuel without excessive negative impacts on fishing efficiency.

Solutions by fishing operation

Demersal trawling

Trawls are flexible gear and can be used on many types of areas and grounds, in shallow and deep waters, and by small and large vessels for a wide range of target species. These characteristics have made trawling the preferred method for many fishers, and it may be the only short-term economic solution for capturing, for example, certain shrimp species. However, bottom trawling has been identified as one of the most difficult to manage in terms of bycatch and habitat impacts.

There are many techniques and operational adaptations available to reduce the drag and weight of the bottom trawl gear and, thereby, to reduce significantly fuel consumption and sea-bed impacts without marked decrease in the catch of the target

species.⁶⁴ Fuel savings of 25–45 percent and gear-drag reductions of 20–35 percent have been reported.

However, in general, further work is needed to improve the construction of different components of trawl gear in order to minimize friction on the bottom and to reduce overall gear drag. In this regard, there is further potential to develop technologies in which the force of trawl doors and ground gear on the sea bed is automatically measured and adjusted by instrumentation (Figures 38 and 39). In the case of beam trawls, progress has been made in recent years by developing alternative

Figure 38

A new semi-pelagic low-impact and selective trawl gear (CRIPS-trawl) that is under development in Norway

Notes: The new trawl design (CRIPS-trawl) has a reduced bottom contact and less drag compared with a conventional bottom trawl. The trawl doors and the footrope of the trawl are lifted off the bottom. The front panels of the trawl are replaced by herding ropes, and the aft parts are made of square-mesh netting. This will reduce the drag of the trawl while still maintaining the stimulation for herding the fish into the codend. The extension piece and the codend are made of four panels and include a net camera and various selection devices to release unwanted fish from the trawl. The four-panel design improves the stability of the trawl and the selection devices. The net camera gives real-time information of the fish species and sizes entering the codend, and allows the skipper to make informed decisions regarding how to continue the fishing process. The trawl may also be fitted with an active mechanism to release unwanted catch (based on image analysis). The trawl concept also includes a cable connection from the vessel to the trawl headline. The cable will carry the video signal from the net camera and acoustic sensors, and it will also increase the vertical opening of the trawl. The concept will later also include an independent system to adjust the distance of the doors from the sea bed.

gear designs. In essence, the objectives are to reduce the amount of tickler chains, avoid excess weight in the beams, and use other stimuli (e.g. electric pulses) as an alternative to chains to scare the target fish off the bottom and into the net. The use of acoustics, light or any other additional stimuli to enhance encounters by target species within the catching zone of trawl nets is worth exploring.

The use of improved location and targeting of fish with the help of electronic seabed mapping tools and integrated global navigation satellite systems has resulted in avoidance of sensitive bottom habitats and helped to minimize fishing effort and fuel

Figure 39

Smart trawling: reduced seabed damage of bottom trawling

Note: In "smart trawling technology", the distance of trawl doors and ground gear from the sea bed is constantly and automatically measured and adjusted by special instrumentation. The use of ballast elements or dropper chains suspended from the footrope to hold the trawl near to, but not in contact with, the bottom offers potential in some fisheries to reduce sea bed contact while maintaining catching efficiency.

Source: Modified from Valdemarsen, J.W. and Suuronen, P. 2003. Modifying fishing gear to achieve ecosystem objectives. In M. Sinclair and G. Valdimarsson, eds. *Responsible fisheries in the marine ecosystem*, pp. 321–341. Rome, Italy, and Wallingford, UK, FAO and CABI International Publishing.

consumption. Multibeam acoustic technology, widely used in sea-bed exploration, has been successfully applied, for example, to mapping scallop beds off the east coast of Canada, thereby substantially reducing the time required to locate the grounds and the actual fishing time.

Bottom seining

Bottom seining (Danish, Scottish and pair seining) is generally considered to be a more environmentally friendly and fuel-efficient fishing method than bottom otter trawling. The gear is lighter in construction and the area swept is smaller than in bottom trawling. Moreover, because there are no trawl doors or heavy ground gear, there is less force on the sea bed. The light gear and low hauling speed mean that fuel usage can be significantly lower than for a comparable trawling operation. Bottom seine nets are generally also regarded as having low impact on benthic invertebrates. However, the high bycatch of both undersized individuals of the target species and individuals of non-target species can be a problem in some seine fisheries.

Trap-net

Trap-nets are passive fishing gear that are usually set on traditional sites in the path of migrating fish in relatively shallow coastal waters. Leader-netting herds and guides fish into a holding chamber or pound where they are entrapped. The pontoon trap is a more recent innovation and offers various advantages compared with traditional trap-nets such as being easy to transport, handle and haul, adjustable in terms of size, target species and capture depth, as well as being predator-safe. Future developments may include large-scale, ocean-based fish traps together with the technology to attract fish. Modern trap-net fisheries can be energy efficient, flexible, selective and habitat-friendly, providing catches of high quality as the catch is usually alive when brought aboard the vessel. Live capture provides the operator with a greater number of options to add value to the catch. However, designs and practices need to be developed to prevent the entangling of non-fish species in netting and mooring ropes of the trap.

Pots

A pot is a small transportable cage or basket with one or more entrances designed to allow the entry of fish, crustaceans or cephalopods, and prevent or retard their escape. Pots are usually set on the bottom, with or without bait. While pot fishing vessels in general have low fuel use, some pot fisheries have high fuel use owing to the need to tend fleets of many pots and lifting them more than once a day, necessitating travelling at high speed over long distances.

Pots are extensively used in the capture of crustaceans such as lobster and crab. Although the use of pots for capturing finfish has a long tradition in many parts of the world, it has progressively declined. Nevertheless, pots are still an efficient and economically viable fishing method for finfish. They are also successfully used in fisheries targeting coral-reef species inhabiting areas where the use of active gear is banned or not practical.

Recent tests with collapsible pots have shown promising results for Atlantic cod in Canada and for pink cusk-eel (*Genypterus blacodes*) in Argentina. A floating pot developed in Scandinavia provides another example of an innovative pot design that has shown significant potential (Figure 40).⁶⁵ Floating the pot off the bottom allows the pot to turn with the current so the entrance always faces down current, resulting in a higher catch rate of cod. It also avoids non-target catch of crabs and may also reduce the seabed impacts compared with a pot sitting on the bottom. The same type of floating pot has successfully been tested in the Baltic Sea as an alternative to the gillnet fishery for cod, where there are serious problems with depredation by seals.

Compared with many other types of fishing gear, pots, like trap-nets, possess several appealing characteristics such as low energy use, minimal habitat impact, high quality and live delivery. On the negative side, lost or abandoned pots may continue catching target and non-target species (ghost fishing) and contribute to marine debris with associated effects. Design features such as biodegradable materials may reduce ghost fishing, while delayed surface marker buoys and location aids may promote the recovery of lost gear. Understanding fish behaviour in relation to pots is essential in

Figure 40

A floating pot

Source: Adapted from Königson, S. 2011. *Seals and fisheries: a study of the conflict and some possible solutions*. Department of Marine Ecology, University of Gothenburg. (PhD thesis)

order to increase efficiency for those species that are currently not captured by pots in commercially viable quantities.⁶⁶

Hook and line

Hook and line refers to gear to which fish, squid or other species are attracted by natural or artificial bait or lures placed on a hook, on which they are caught. Wide variations in hook and line configuration and their mode of operation have made them an effective gear type for a wide variety of species. It is a versatile fishing method, employed by a wide range of vessels from artisanal boats to large mechanized longliners. Hook and line fishing is generally considered an environmentally friendly but labour-intensive fishing method that catches fish of high quality. Fuel consumption in these fisheries is comparatively low although it can increase significantly depending on the distances vessels have to travel to and from the fishing ground (e.g. coastal hook and line fisheries versus high seas tuna longlining). Longline fishing may cause the incidental mortality of seabirds, sea turtles and sharks, many of which are either protected or endangered. The lines can be set with a streamer⁶⁷ in order to deter seabirds from seizing the baited hooks – this system is reported to have led not only to a reduced mortality level of sea birds but also to higher catch rates of the target species. There are several other mitigation measures capable of reducing the likelihood of incidental bycatch of seabirds⁶⁸ and sea turtles,⁶⁹ such as the new “circle hook” and “weak hook”. While bottom-set longlines may snag and damage benthic epifauna and irregular objects on the bottom, longline fisheries do offer the potential to conduct fishing without severe habitat damage and to do so in a relatively energy-conscious manner.

Gillnetting

Bottom-set gillnets, entangling nets and trammelnets are widely used, and improved materials and techniques have allowed the expansion of such gear to rougher grounds (including wrecks and reefs) and deeper waters. Gillnetting is a very versatile and flexible fishing method but can also be labour-intensive. Except with trammelnets, the size selectivity for finfish is generally good, but species selectivity can be poor. In addition, fish are often injured and die during capture; accordingly, catch quality is typically not as good as with pots, traps and longlines, although gillnets may also give catch of good quality when the time the net is left in the water to fish is short.

Gillnet fishing operations in general can damage benthic epifauna during retrieval of the gear, at which time the nets and leadlines are more likely to snag bottom structures. Although the capture of seabirds, sea turtles and marine mammals by gillnets has received increased attention in recent years, more development work is required to develop mitigation measures further.

The impacts of ghost fishing by abandoned, lost or otherwise discarded gillnets are of concern as such nets may continue to fish for long periods depending on their construction, the depth, and prevailing environmental conditions. This problem can be addressed by increasing efforts to avoid losing gillnets and by facilitating the quick recovery of lost nets. Abandoned gillnets have been identified as a particular problem in deeper waters and where long lengths of gear are deployed.⁷⁰

Barriers to change

There are many barriers to the transition to low-impact and less fuel-intensive practices and gear.⁷¹ In summary, the most important seem to be:

- lack of familiarity with cost-effective and practical alternatives;
- limited availability of suitable technologies, especially in developing countries;
- incompatibility of vessels with alternative gear;
- risk of losing marketable catch;
- additional work at sea;
- concerns with safety at sea related to using unfamiliar gear or strategies;
- high investment costs;

- lack of capital or restricted access to capital;
- ineffective technology infrastructure support;
- inflexible fisheries management systems that include too rigid regulatory regimes.

With regard to inflexible management systems, regulatory regimes that are too rigid can create a new set of problems to be solved and deny fishers the flexibility required to innovate and adopt new technologies. In this regard, stakeholders should be an integral part of the management process, particularly as and when amendments to legislation are under consideration. Changes from high-energy high-impact fishing methods or practices to ones with lower energy consumption and lower ecosystem impacts offer opportunities for conserving fuel, preserving ecosystems and improving food security. However, the transition from one gear type to another is seldom easy or practical. First, the size and design of existing fishing vessels and their machinery and equipment often limit the possibilities of changing the fishing method. Second, fishing gear, fishing vessels, operations and practices have evolved around specific fishing grounds and the behaviour of target fish species over a considerable period. Accordingly, the evolved fishing gear and practices are “tailor-made” to catch specific target species or species groups in a manner that is often perceived to be optimized to the best technical and economic scenarios that will be encountered during fishing. Moreover, where fishing practices are rooted in tradition there is a strong resistance to change.

Nevertheless, fuel consumption and ecosystem impacts can often be reduced through simple modifications in operational techniques and gear design without drastic changes in the gear and operational practices. This approach has shown promising results in many cases and is often preferred by the fishing industry over transitioning to a completely new gear type and fishing practice, which is an alternative that has many more uncertainties and higher economic risks.

RECENT ACTIONS

Environment

International conventions include timetables for compliance regarding emissions of nitrogen oxides from diesel engines of over 130 kW and new fishing vessels are required to comply. Moreover, as a consequence of research and development (R&D) on energy-saving technologies carried out by designers of machinery and fishing vessels and gear, there are signs that the fishing industry has begun to improve its fuel efficiency. Nevertheless, fuel continues to be the major cost of operation in capture fisheries and further refinements to fuel quality, such as lowering the content of sulphur oxides and particulate matter, could well lead to even higher fuel and lubricating-oil costs. This may have an even greater impact on the fishing industry in developing countries where mechanization continues to increase, although it will also strengthen the drive for fuel efficiency.

Bycatch and discards

The seriousness of the impacts related to bycatch and discards has been recognized by the international community and in particular through the endorsement of the International Guidelines on Bycatch Management and Reduction of Discards at the Twenty-ninth Session of the FAO Committee on Fisheries in 2011. There is a range of tools to manage bycatch and reduce discards, including technological measures to improve the selectivity of fishing gear. The declines in the bycatches and discards in many fisheries have mainly been the result of introducing effective gear modifications and bycatch reduction devices.⁷² However, there remains concern about the impacts of unaccounted fishing mortalities such as ghost fishing by abandoned, lost or otherwise discarded fishing gear and the fact that such gear may also cause environmental damage.

Furthermore, at the sixty-second session of the Marine Environment Protection Committee of the International Maritime Organization (IMO) in July 2011, Annex V

of the International Convention for the Prevention of Pollution from Ships 1973/78 (MARPOL) was amended to provide a regulation for the loss of fishing gear that may be a substantial threat to the environment or the safety of navigation to be reported to the flag State, and, where the loss occurs in waters under the jurisdiction of another coastal State, to that State. This regulation is supported within guidelines for the application of Annex V currently under revision.

OUTLOOK

With continued exposure to rising fuel prices and little or no significant price increases at the point of first sale for catches, capture fisheries will probably continue to suffer declining profitability. Moreover, if resource abundance remains static, some bottom trawl and dredge fisheries may become uneconomic (although passive gear and seine net fisheries may be less affected). As demersal trawl fishing accounts for a significant part of the total catch destined for direct human use, there could be an adverse affect on global fish supply and food security, at least in the short term.

With medium-term forecasts indicating a high likelihood of further and steady increases in fuel prices, as indicated by the International Energy Agency, the future of the fishing industry is challenging. An increase in sulphur-oxide-emission control areas (the most recent being adopted by the IMO in 2011) would add to the cost of fuel for vessels operating in such zones.

The fishing sector will no doubt strive to lower its fuel consumption, reduce its carbon footprint, and decrease ecosystem impacts. Although the continuation or expansion of fuel subsidies would reduce immediate costs, this is less acceptable. To help the fisheries sector achieve significant and permanent reductions, governments will most probably strengthen their fisheries sector energy policy and create an enabling environment in which fishing industries can rapidly and comprehensively adopt low-impact fuel-efficient (LIFE) fishing technologies and practices. The development and adoption of such fishing techniques offer scope for maintaining the long-term profitability and sustainability of capture fisheries worldwide.

With fossil fuels remaining the dominant energy source, pursuing energy efficiency in capture fisheries may generate benefits by reducing operating costs, controlling GHG emissions and minimizing environmental impacts within the aquatic environment. However, the success of this transition will depend heavily on the response of governments to the implementation of international conventions together with a positive reaction from the engine manufacturing sector, fuel-oil and lubricating-oil producers and the fishing industry (including the manufacturers of fishing gear). This could lead to the development and application of suitable and acceptable measures to conventional fisheries and create an appropriate catalyst for change in the behaviour of fishers. Of equal importance are initiatives such as pursuing the modification of existing gear types and the development of low-resistance towed fishing gear with minimal impact within the aquatic environment. In some cases, it may be necessary to switch to completely new gear types or practices in order to enable LIFE fishing.

However, to be effective, this would require global R&D priorities to be established and work undertaken in support of the development and uptake of LIFE fishing.⁷³

These include:

- promoting and funding studies of cost-effective gear designs and fishing operations, including the establishment of technology incubators and other public-private sector initiatives to commercialize economically viable, practical and safe alternatives to conventional fishing methods;
- analysis and review of best practice operations across fisheries;
- improvement of technical ability among fishers;
- establishment of appropriate incentives;
- industry compliance with international conventions;
- execution of robust but flexible fishery policies that support the transition to alternative technologies.

Finally, close cooperation between the fishing industry, scientists, fisheries managers and other stakeholders will be fundamental to the development, introduction and acceptance of LIFE fishing technologies.

Putting into practice the ecosystem approach to fisheries and aquaculture

THE ISSUE

The ecosystem approach to fisheries (EAF) represents a move away from management systems that focus only on the sustainable harvest of target species to a system that also considers the major components in an ecosystem, and the social and economic benefits that can be derived from their utilization.

An ecosystem approach to aquaculture (EAA) follows similar considerations and it has been defined as: “a strategy for the integration of the activity within the wider ecosystem such that it promotes sustainable development, equity and resilience of interlinked social-ecological systems.”⁷⁴

While the term “ecosystem approach” often evokes the idea that the approach is mainly a natural-science undertaking, the approach adopted by FAO⁷⁵ explicitly states the importance of taking into account all the essential components of sustainability (ecological, social and economic), i.e. taking a genuinely systemic approach by considering fisheries and aquaculture as systems whose sustainability depends on all their parts.

In addition to sector-based approaches, the need for developing adequate institutional frameworks to address multisectoral management is also recognized (e.g. ecosystem-based management), and EAF/EAA will then be nested within these broader frameworks.

Despite general acceptance of the principles of EAF and EAA, a widespread perception has existed of their being too complex and impossible to implement in practice because they require human and financial resources that are usually not available, particularly in developing countries.

POSSIBLE SOLUTIONS

Despite the perceived complexity of implementing an ecosystem approach, there is good evidence that progress is being made at various levels, from formal adoption of the framework by regional and national institutions, to actually starting with implementation.

There are examples of concrete steps being taken towards an ecosystem approach, both in sectoral fisheries management (e.g. EAF and EAA) and at the multisectoral level (such as ecosystem-based management), the latter being necessary where more than one sector affects a given area or region. Management approaches that integrate across sectors become particularly relevant in inland waters (Box 13), where major impacts on fishery resources and ecosystems are often not caused by fishing activities but by water use and habitat modification. Moreover, as the once-separate sectors of “fisheries” and “aquaculture” increasingly overlap and integrate an ecosystem approach may well facilitate sustainable resource management (Box 14).

Practical implementation of EAF/EAA entails examining existing or developing fisheries or aquaculture activities so as to identify key priority issues to be dealt with by management in order to achieve sustainable outcomes within a risk-based management framework. An example of a framework for planning and implementation is presented in Figure 41. The framework facilitates the developing of the EAF/EAA management/development plans, which are the backbone of any ecosystem approach strategy.

The key features of the strategy proposed for implementing an ecosystem approach to fisheries and to aquaculture can be summarized as:

Box 13

The need for an ecosystem approach in inland waters

Inland waters are characterized by strong competition for freshwater resources from sectors outside the fisheries and aquaculture sector. Demands on freshwater are expected to double by 2050 as the world population reaches 9 billion people. Of the available 3 800 km³ of freshwater in the world, agriculture currently uses 70 percent, industry extracts another 20 percent, and 10 percent is for domestic use.¹ These sectors are extremely important in national economies, but they rarely consider fishery resources, although freshwater fisheries are a non-consumptive user of water. Implementing an ecosystem approach to managing freshwater resources for fisheries and aquaculture will necessitate involving these competing sectors and appreciating the value of multiple uses of freshwater resources.

In 2008, capture fishery production from inland waters was 10.2 million tonnes and was worth about US\$5.5 billion, while the corresponding figures for inland aquaculture were 33.8 million tonnes and US\$61.1 billion, respectively. However, these figures are much lower than the value derived from other uses of freshwater. On a global scale, the value of industrial and agricultural products produced with freshwater as a necessary factor of production is several magnitudes larger. However, at the regional or local level, there may be little industrial use for freshwater, and fish can be an essential contributor of animal protein and micronutrients in local diets. In such locations, using an ecosystem approach to the development and management of natural resource should ensure a place also for freshwater fisheries.

The continued use of freshwater as a locale for fish production, as industries and agriculture grow, can be promoted through technological change. There are encouraging signs of this, such as the development of improved fish passes that allow riverine fish to migrate past hydroelectric facilities and improvements in irrigation systems that increase their efficiency.² However, many countries still lack the institutional capacity to deal effectively with multisectoral issues.

² FAO. 2003. *Unlocking the water potential of agriculture*. Rome. 70 pp. (also available at www.fao.org/DOCREP/006/Y4525E/Y4525E00.HTM).

- adopting participatory approaches at all levels of the planning and implementation steps;
- ensuring that all the key components of the fishery/aquaculture system are considered, including those related to the ecological, social, economic and governance dimensions, while also taking into account external drivers (e.g. changes in the supply of and demand for inputs and outputs; climate change; and environmental disturbances);
- encouraging the use of the “best available knowledge” in decision-making, including both scientific and traditional knowledge, while promoting risk assessment and management and the notion that decision-making should take place also in cases where detailed scientific knowledge is lacking;

Figure 41

The EAF/EAA planning framework

Source: Modified from: FAO. 2003. *Fisheries management 2. The ecosystem approach to fisheries*. FAO Technical Guidelines for Responsible Fisheries No. 4, Suppl. 2. Rome. 112 pp.; and FAO. 2005. *Putting into practice the ecosystem approach to fisheries*. Rome. 76 pp.

- promoting the adoption of adaptive management systems, including monitoring performance and creating feedback mechanisms linked to performance, at different time scales, to permit the adjusting of the tactical and strategic aspects of the management/development plans;
- building on existing institutions and practices.

The methodology proposed has aspects that are common to any other sector utilizing renewable natural resources. The methodology is recommended by the ISO 14000 that deals specifically with the management of renewable resources.⁷⁶

The methodology builds on the accumulated experience of the management of fisheries and aquaculture but also embraces recent insights about what makes socio-ecological systems sustainable. These insights lead to an approach that:

Box 14

Interactions between fisheries and aquaculture

Increasingly – by design or by accident – fisheries and aquaculture occur in the same ecosystem. Aquaculture-based fisheries (stock enhancement programmes) and capture-based aquaculture are becoming more common and resulting in a growing interdependence of fisheries and aquaculture. Fish that escape from fish farms may affect not only local fisheries but have a wider interaction in the marine environment. Fisheries and aquaculture interact with increasing intensity as fishers shift from fishing to aquaculture and by competing in the same markets with similar products. The need to integrate planning and management of the two sectors seems vital to their future development and sustainability.

The implementation of the ecosystem approach to aquaculture and the ecosystem approach to fisheries should help to overcome the sectoral and intergovernmental fragmentation of resource management efforts and to develop institutional mechanisms and private-sector arrangements for effective coordination among the various sectors and subsectors active in ecosystems in which aquaculture and fisheries operate and between the various levels of government. Ecosystem-based management involves a transition from traditional sectoral planning and decision-making to the application of a more holistic approach to integrated natural resource management in an adaptive manner.

In the long run, all significant commercial seafood supplies and non-food fish will come from one of three sources: (i) fish farms/aquaculture; (ii) aquaculture-enhanced fisheries; and (iii) fisheries that adopt efficient management systems. The first two pose a challenge to aquaculture and require an emphasizing of the synergies and complementarities between fisheries and aquaculture including institutional, social, economic, environmental and biotechnological aspects. Acknowledgement of these interactions offers opportunities for sectoral development, for increasing food security, reducing poverty and improving rural livelihoods. The two subsectors need to form partnerships as both are strongly linked (see accompanying figure), both depend on healthy aquatic environments, and both are affected by other development activities. For example, in the coming decades, culture-based fisheries will probably play a much greater role in sustaining and increasing capture fisheries yields for an ultimate public good including conservation objectives. Therefore, it is important to analyse the present status of culture-based fisheries and stock enhancement, to assess comprehensively the impacts of the activities, and to identify constraints and ways to improve the ecological, economic and socio-economic benefits by implementing an ecosystem approach to overall fish production. It is also necessary to improve understanding on the potential and actual environmental impacts of stocking and escapees worldwide.

- is context-specific – it describes a process whose result depends on cultural context and needs;
- emphasizes stakeholder participation – the approach advocates participation of stakeholders in the planning and implementation processes, and encourages various forms of comanagement that will in turn be shaped by context and type of fisheries;
- is systemic – by taking a “systemic” approach, it tries to ensure that all “system” components move towards the same and agreed direction;

Biophysical linkages between capture fisheries and aquaculture

Addressing aquaculture-fisheries interactions through the implementation of the ecosystem approach to aquaculture (EAA). In R.P. Subasinghe, J.R. Arthur, D.M. Bartley, S.S. De Silva, M. Halwart, N. Hishamunda, C.V. Mohan and P. Sorgeloos, eds. *Farming the Waters for People and Food. Proceedings of the Global Conference on Aquaculture 2010, Phuket, Thailand, 22–25 September 2010*, pp. 385–436. Rome, FAO, and, Bangkok, NACA. 896 pp.

- is risk-based – being risk-based, it allows a more proactive approach to addressing information-poor situations, considered one of the main obstacles to the ecosystem approach in fisheries and aquaculture.

In summary, success in implementing the ecosystem approach to fisheries and aquaculture requires that management and development of the sectors are well-functioning components in a public-sector, multisectoral coordination effort supported by adequate governance. Consistent with the commitments reflected in the United Nations Convention on Biological Diversity (CBD), each economic sector (including,

mining, tourism, coastal development, fisheries and aquaculture) relying on the use of natural resources within a given region/ecosystem should adopt an ecosystem approach.

RECENT ACTIONS

The ecosystem approach was first defined by the CBD in 1993 as a strategy for the integrated management of land, water and living resources that promotes conservation and sustainable use in an equitable way.

Since 1993, countries have taken several steps to promote the use of the ecosystem approach, including specifically in fisheries. The Code of Conduct for Responsible Fisheries (the Code) was adopted in 1995 by FAO Members. The Reykjavik Declaration on Responsible Fisheries in the Marine Ecosystem (adopted in 2001) encouraged countries and fishing entities to achieve sustainable fisheries in the marine ecosystem. Guidelines for an EAF were produced by FAO in 2003. Aquaculture has also developed a framework for the adoption of the ecosystem approach.⁷⁷ At present, FAO is developing voluntary guidelines on securing small-scale fisheries. These guidelines will recognize the ecosystem approach as an important guiding principle.

Approaches are being developed to coordinate multiple uses of natural resources, such as marine spatial planning⁷⁸ and integrated watershed management. These are methodologies that complement the sectoral-based approaches to management that remain the basic pillars of sustainable development and its governance.

In some ways, the ecosystem approach has been practised in traditional management regimes for a long time. An example is the tenure system in marine fisheries as practised in Pacific island States.

More recently, many countries have made important strides towards the application of several of the principles contained in the EAF/EAA. Some are partly implementing the approach without necessarily recognizing this.⁷⁹ In some cases, progress has also been made in the development of multisectoral management.

In Australia, following the outcomes of the 1992 United Nations Convention on Environment and Development, a national strategy for ecologically sustainable development was endorsed in the same year.⁸⁰ Since then, significant progress has been made in implementing an ecosystem approach within the management of most individual fisheries and, and there has also been more recent progress in adopting more coordinated regional level management for this sector.⁸¹

In the European Union, substantial efforts are being made to integrate the objectives of its Marine Strategy Framework Directive within the new European Union Common Fisheries Policy, as part of an ecosystem-based management approach. As a result of the project Making the European Fisheries Ecosystem Plan Operational (funded by the European Union), fisheries ecosystem plans have been developed for three major European marine regions (North Sea, North Western Waters and South Western Waters).⁸² Efforts are also being made at the national level. For example, in Norway, an integrated management plan for the Barents Sea–Lofoten area has been developed to resolve conflicts between petroleum activities, fisheries activities and to address conservation concerns.⁸³ Implementation of the plan is ensured through multisectoral coordinating groups headed by a steering group that is in turn coordinated by the Ministry of Environment. Representatives from the Norwegian Petroleum Directorate and the Directorate of Fisheries have worked together to revise laws and regulations covering seismic activities in order to reduce conflicts. A central concept of the plan is that it is based on science and takes a precautionary approach. A similar plan has also been developed for the Norwegian Sea, and the idea is to cover all the Norwegian Exclusive Economic Zone (EEZ).⁸⁴

Ongoing efforts in the adoption of ecosystem-based approaches at both the sectoral and multisectoral level are being pursued in various large marine ecosystems including in the Caribbean,⁸⁵ the Canary Current,⁸⁶ the Benguela Current⁸⁷ and the Bay of Bengal.⁸⁸ However, in most of these large marine ecosystems, efforts are concentrated

on planning for an ecosystem-based approach – its full-scale implementation remains to be realized.

In addition, FAO has specifically addressed EAF by developing guidance⁸⁹ for its implementation and by providing extrabudgetary funding for regional and/or national case studies, dedicated workshops and training courses.

Collaborations with universities in Africa, i.e. University of Ghana (Ghana), Rhodes University (South Africa) and Ibn Zohr University (Morocco), have allowed a large number of fisheries professionals to be trained in the ecosystem approach, and it is hoped that the approach will be absorbed by universities in developing countries as part of existing curricula in fisheries science and management. These efforts have resulted in increased understanding of the approach and its “demystification”.

OUTLOOK

A dramatic shift in attitudes as regards the relevance and applicability of the ecosystem approach has taken place, including an increasing appreciation of how this approach can help in addressing the challenges linked to sustaining socio-ecological systems such as fisheries, both within the sector and across sectors affecting a given ecosystem. Pragmatic ways are being adopted to improve conventional fisheries and aquaculture management by incorporating ecosystem considerations and by dealing with the social dimension more properly.

However, important challenges still exist beyond the technical aspects of practical day-to-day implementation. The challenges are not only those related to controlling the direct drivers of marine ecosystem change such as fisheries and aquaculture. Probably the greatest challenges come from indirect drivers such as changes in human population coupled with a widespread aspiration for improved standards of living. At the national level, economic policies and social and economic conditions are often in conflict with sustainability objectives. Climate change will most probably emerge as a major driver of change in aquatic ecosystems and will in turn affect coastal communities. In this situation, modifying governance towards more holistic approaches (such as the ecosystem approach), both horizontally (across sectors and institutions) and vertically (from local to global), may take on increased urgency.
