The metabolism and degradation kinetics of fluensulfone in aerobic soils was investigated by Moser (2011, Report R-27436). In that study, [Bu-¹⁴C] or [Th-¹⁴C] labelled fluensulfone was applied at a rate of 4 kg/ha to six different soils (Table 35). The soils were incubated under dark, aerobic conditions at 20 °C for 120 days. Samples were collected at various time points throughout the study, extracted first with CaCl₂ and then with ACN:H₂O and analysed for residues by LSC, HPLC, and/or TLC. In addition, the Fislis soil underwent Soxhlet extraction and analysis by LSC and TLC.

Table 35 Characteristics of the soils used in the aerobic metabolism study for fluensulfone

Parameter	Value					
Name	Fislis	Hagenthal	Horn	Montesquieu	Senozan	Sevelen
pH (CaCl ₂)	6.75	7.13	7.23	7.36	7.54	7.36
Organic carbon %	2.13	1.65	2.36	1.5	0.61	1.61
CEC (meq/100 g soil)	22.99	18.79	21.72	21.09	13.63	9.09
Soil type	silt loam	silt loam	loam	clay loam	loam	sandy loam
Bulk density [kg/dm ³]	1.08	1.22	0.99	1.18	1.21	1.18
Particle size analyses (mm):						
0.002 (clay) [%]	26.42	24.42	25.11	38.70	20.58	9.51
0.002–0.05 (silt) [%]	65.57	53.51	36.22	31.84	35.25	36.96
0.05–2.0 (sand) [%]	8.01	22.07	38.67	29.46	44.17	53.53
Water holding capacity (g water/100 g soil):						
at pF 1.0	75.62	56.80	73.15	59.76	48.77	58.94
at pF 2.0	39.65	36.88	33.52	33.52	29.97	31.48
at pF 2.5	30.98	25.83	28.47	25.91	19.52	21.45
Biomass determination as mg C/100 g soil (%)						
pre-study	26.9 (1.3)	22.5 (1.4)	15.1 (0.6)	26.9 (1.8)	26.9 (4.4)	18.1 (1.1)
test initiation	28.0 (1.3)	22.5 (1.4)	39.1 (1.7)	22.5 (1.5)	17.0 (2.8)	22.5 (1.4)
mid-study	22.5 (1.1)	22.5 (1.4)	22.5 (1.0)	28.1 (1.9)	17.0 (2.8)	17.0 (1.1)
test end	18.1 (0.8)	28.0 (1.7)	33.6 (1.4)	17.0 (1.1)	17.0 (2.8)	22.5 (1.4)

Table 38 Summary of half-life estimates for fluensulfone and BSA in six soils

Soil	Fislis	Hagenthal	Horn	Montesquieu	Senozan	Sevelen
Type	Silt loam	Silt loam	Loam	Clay loam	Loam	Sandy loam
Model	SFO ^a	SFO	SFO	SFO	SFO	SFO
Residue	Half-life (days)					
Fluensulfone	10.5	7.6	7.2	11.1	16.5	7.1
BSA	19.7	22.6	21.9	17.8	^b	26.3

^a SFO = Single First-Order

^b Degradation rate of BSA could not be calculated due to insufficient data points

Aerobic soil degradation rate (TSA)

The degradation rate of TSA metabolite of fluensulfone in three aerobic soils was investigated by Brands (2011, R-28470). In that study, Fislis, Horn, and Sevelen soils (see fluensulfone aerobic soil metabolism section above) were treated with the test substance at a nominal concentration of 3.2 mg/kg dry soil and incubated, in the dark, for 150 days. Duplicate samples were collected at nine time points throughout the study, extracted with ACN:H₂O (50:50, v/v), and analysed by HPLC-MS/MS.

Overall procedural recoveries from freshly fortified soils ranged from 95–112% of the applied amount (Table 39) and levels of TSA showed a slow decline over the incubation period (Table 40). Single first-order half-life estimates for TSA were 560 days for Fislis soil, 450 days for Horn soil, and 230 days for Sevelen soil.

Table 39 Procedural recovery of TSA from soils fortified at 3.2 mg/kg

	Fislis		Horn		Sevelen	
Sample time ID	TSA (mg/kg)	Recovery (% of nominal)	TSA (mg/kg)	Recovery (% of nominal)	TSA (mg/kg)	Recovery (% of nominal)
7	3.25	101	3.39	105	3.48	108
15	3.4	106	3.29	102	3.43	107
28	3.4	106	3.33	104	3.48	108

120	88, 86	88, 90	67, 74
150	83, 88	163 ^a , 0 ^a	57, 70

^a Unexpected results were not used for calculation of DT₅₀ and DT₉₀

Aerobic soil degradation rate (MeS)

The degradation rate of MeS metabolite of fluensulfone in three aerobic soils was investigated by Brands (2011, R-28472). In that study, Fislis, Horn, and Sevelen soils (see fluensulfone aerobic soil metabolism section above) were treated with the test substance at a nominal concentration of 0.4 or 0.04 mg/kg dry soil and incubated, in the dark, for 120 days. Duplicate samples were collected at eight time points throughout the study, extracted with ACN:H₂O (50:50, v/v), and analysed by HPLC-MS/MS.

Overall procedural recoveries from freshly fortified soils ranged from 95–112% of the applied amount (Table 41) and levels of MeS showed a slow decline over the incubation period (Table 42). Single first-order half-life estimates for MeS were 41 days for Fislis soil, 28 days for Horn soil, and 30 days for Sevelen soil.

Table 41 Procedural recovery of MeS from soils fortified at 0.4 or 0.04 mg/kg

	Fislis		Horn		Sevelen

Anaerobic soil metabolism

No anaerobic soil metabolism studies were provided.

Confined rotational crop studies

The fate of fluensulfone as relates to rotational crops was investigated by Quistad *et al.* (2011, Report OR-25457). In that study, radish, lettuce and wheat were planted into test boxes that had been treated with [Bu-¹⁴C] or [Th-¹⁴C] labelled fluensulfone at a rate of ca. 4 kg/ha. The crops were planted into the test boxes at 30, 120, and 360 days after treatment (390 days for lettuce due to crop failure at the 360-day plant-back interval). At each plant-back interval (PBI), samples consisted of radish roots and radish tops; lettuce leaves; and wheat forage, grain, hay, and straw.

After harvest, the samples were homogenized and an aliquot was taken for TRR determination by combustion and LSC. In addition, samples were extracted initially with ACN:H₂O (1:1, v/v) and ACN, followed by strong basic and, in some cases, acidic hydrolysis. Extracted residues were analysed by TLC and/or HPLC (UV and radio-chromatography via fraction collection and LSC) for residue determination. Multiple TLC systems and HPLC conditions were used to obtain adequate separation and analysis.

Total radioactive residues in the rotational crops are shown in Table 43. There was generally good agreement between TRR by combustion and TRR by sum of fractions. The TRR levels from the [Th-¹⁴C] treatments were higher from than those from the [Bu-¹⁴C] treatments and tended to show a plateau between the 120-day and 360/390-day PBIs that was not seen with the [Bu-¹⁴C] treatments.

The ACN:H₂O solution was able to extract the majority of the TRR from all of the rotational crop matrices (Tables 44–47). Analysis of the extracts showed levels of fluensulfone in radish (Tables 48–51), lettuce (Tables 52–55), and wheat (Table 56–63) samples from at least one PBI/radiolabel position/sample matrix combination. In all cases, the occurrence of fluensulfone was ≤ 5.1% TRR and

was higher in samples from the [Bu-¹⁴C] treatments. The major residues in all matrices were TSA and BSA from the [Bu-¹⁴C] and [Th-¹⁴C] treatments, respectively. Across PBIs, levels of BSA generally declined in terms of both absolute concentration and in terms of %TRR. Absolute levels of TSA generally declined with increasing PBI, especially between the 30-day and 120-day PBIs, but increased in terms of %TRR over the course of the study. Numerous minor metabolites and/or fractions were observed. Most of these were attributed to salts or chromatographic artifacts of TSA or BSA.

Table 43 Summary of TRRs in rotational crops at each plant-back interval

M1: This fraction consists of two compounds with the major part of this identified a salt of TSA.

M3: This polar radioactive fraction was always observed as a possible artifact due to the non-retention of TSA.

Alkaline and acid digestion released additional small amounts of radiolabelled compounds.

M1: This fraction consists of two compounds with the major part of this identified as a salt of TSA.

M3: This polar radioactive fraction was always observed as a possible artifact due to the non-retention of TSA.

Alkaline & acid digestion: Unresolved metabolites were released especially with 24% KOH. A major component appeared to be TSA.

F3: Suggested to be BSA. Due to matrix effects the retention time of BSA is changing considerably leading to chromatographic artefacts.

F4 & F5: The HPLC-MS analysis of these fractions gave a high molecular weight which suggests that it is possibly a natural product.

Field rotational crop studies

No field rotational crop studies were provided.

Field dissipation studies

No field dissipation studies were provided.

RESIDUE ANALYSIS

Summary of analytical methods

Methods for the analysis of fluensulfone and its breakdown products BSA, MeS, and TSA are generally the same for plant, animal, and soil matrices, though there are some differences in the extraction of BSA and TSA in eggs and milk and in the clean-up steps for fatty samples. The methods are summarized in Table 64.

Table 64 Overview of the analytical methods submitted for fluensulfone and its major metabolites

Method ID (Report)	Matrix	Analyte	Extraction	Clean-up	Separation/ Analysis/LOQ
1997W (R-23334 and R-28495) Equivalent to 2061W	Plant commodities	Fluensulfone + MeS	ACN+H ₂ O (1+1, v/v)	Filtration	LC-MS/MS Fluensulfone m/z 292 [M+H] ⁺ → 166 (q) m/z 292 → 89 (c) m/z 292 → 59 (c) LOQ: 0.01 mg/kg MeS m/z 198 [M+H] ⁺ → 120 (q) m/z 198 → 122 (q) LOQ: 0.01 mg/kg

Plant materials

For plant matrices, Method 1997W (equivalent to Method 2061W) has been developed as a suitable enforcement method by J. Marin (2010, Report R-23334) for fluensulfone, BSA, and TSA, and expanded by A. Witte (2011, Report R-28495) to include MeS. The method underwent independent validation for all four analytes by R. Bacher (2011, Report R-27478).

Residues are extracted from 10 g of sample matrix using ACN:H₂O (1:1, v/v, 50 mL) by shaking for five minutes followed by centrifugation. The extract is then split, with one aliquot for

analysis of fluensulfone/MeS and a second aliquot for analysis of BSA/TSA. Quantification of all residues is by comparison with external, matrix-matched standards.

For fluensulfone (all matrices) and MeS (non-grain/non-oily matrices), an aliquot of the extract is filtered (0.45 μm) and analysed, without further clean-up, by LC-MS/MS in positive ion spray mode. For MeS in grain and oily matrices, the extract is salted out with NaCl; the separated ACN phase is dried with MgSO_4 and an aliquot is partitioned against hexane to remove co-extracted material. The ACN phase is collected, evaporated to dryness, and the residues are reconstituted in ACN:H₂O (1:1, v/v). The resulting extract is filtered (0.45 μm) and analysed by LC-MS/MS in positive ion spray mode. Chromatography for all extracts is done on a reverse-phase C₋₁₈ column maintained at 45 °C using a gradient mobile phase that transitions from 0.1% formic acid in ACN (95%) + 0.1% formic acid in H₂O (5%) to 0.1% formic acid in H₂O (100%). Ion transitions $[\text{M}+\text{H}]^+$ for fluensulfone are m/z 292 $\rightarrow$ 166 for quantitation (q), m/z 292 $\rightarrow$ 89 for confirmation (c), and m/z 292 $\rightarrow$ 59 (c). Ion transitions for MeS are m/z 198 $\rightarrow$ 120 (q) and the corresponding chlorine isotope transition (m/z 200 $\rightarrow$ 122).

For BSA and TSA (all matrices), a 6 mL aliquot of the initial extract is concentrated to 3 mL and cleaned-up on a C₋₁₈ SPE cartridge. Eluate from the cartridge is brought to volume and analysed by LC-MS/MS in negative ion mode. Chromatography is by reverse-phase C₋₁₈ column maintained at 45 °C using a gradient mobile phase that transitions from 0.05% formic acid in ACN (95%) + 0.05% formic acid in H₂O (5%) to 0.05% formic acid in H₂O (100%). Ion transitions $[\text{M}-\text{H}]^-$ for BSA are m/z 189 $\rightarrow$ 81 (q) and m/z 189 $\rightarrow$ 80 (c). Ion transitions for TSA are m/z 198 $\rightarrow$ 89 (q) and m/z 198 $\rightarrow$ 118).

Linearity data were provided and showed linear responses ($R^2 \geq 0.992$ and generally > 0.998) from 0.2–20 ng/mL. In a few studies, linearity was demonstrated over a broader range, including up to 100 ng/mL. Accuracy and precision data, in the form of spike and recovery studies, were provided for cucumber, lemon, melon, orange flesh, peanut, pepper, tomato and wheat grain. Samples were spiked at either 0.01 or 1 mg/kg of fluensulfone, BSA, MeS, or TSA (separately). Mean recoveries for each analyte at each spiking level and for each matrix were within the generally accepted range of 70–120%. Of the 860 method validation analyses, ten had recoveries outside of the generally accepted range of 70–120%: 53% and 54% for TSA in peanut, 174% for BSA in wheat grain, and seven recoveries ranging from 121% to 170% for fluensulfone, MeS, or TSA in orange flesh or lemon. In all cases, relative standard deviations were $\leq 20\%$.

Testing of fluensulfone and the two sulfonic acid metabolites, BSA and TSA, through the FDA PAM multiresidue method protocols was conducted by T. Ballard (2012, Report R-29565) for non-fatty foods. The compounds showed poor sensitivity, poor recovery, and/or poor chromatography. Overall, the results indicate that the FDA PAM multiresidue protocols are not suitable for the detection or enforcement of fluensulfone, BSA, or TSA residues in non-fatty foods.

Animal materials

A residue analytical method for the analysis of fluensulfone and its BSA, MeS, and TSA metabolites in animal matrices has been developed by Witte (2011, Report R-28512). It is identical to the method for those analytes in plant matrices described above, with the exception of the extraction of BSA and TSA from eggs and milk. For those matrices, extraction is accomplished with ACN (neat). The method was successfully validated by R. Bacher (2012, Report R-29562).

As with the plant method, extracts (except eggs and milk) are split for separate analysis of fluensulfone and MeS or BSA and TSA. For fluensulfone/MeS, the only clean-up is filtration whereas for BSA and TSA, there is clean-up by C₁₈ SPE and filtration. The LC-MS/MS conditions and ions are the same as described above for plants. The method showed linear response from 0.2–20 ng/mL for fluensulfone and MeS, and from 0.2–15 ng/mL for BSA and TSA. Recoveries from 900 spike-and-recovery analyses for all three analytes ranged from 71–109%, with the exception of four analyses, all for fluensulfone: 122% in pork meat, 154% in kidney, and 164% for liver, and egg.

Soil

A residue analytical method for the analysis of fluensulfone and its BSA, MeS, and TSA metabolites in animal matrices has been developed by Marin (2010, Report R-23339, Method 2049W). It is identical to the method for those analytes in plant matrices described above. The method was successfully validated by R. Barker (2012, Report R-29564).

As with the plant method, extracts are split for separate analysis of fluensulfone and MeS or BSA and TSA. For fluensulfone/MeS, the only clean-up is filtration whereas for BSA and TSA, there is clean-up by C₁₈ SPE and filtration. The LC-MS/MS conditions and ions are the same as described above for plants.

Mean recoveries ranged from 78 to 114% for all analyses, with relative standard deviations of < 12%.

Stability of residues in stored samples

The stability of fluensulfone, BSA, and TSA in frozen storage has been investigated in tomato, pepper (Korpalski, S. 2011, 09-01858), cucumber and melon (Korpalski, S. 2011, 09-01859). In addition, the stability of those analytes and MeS was investigated in frozen, stored tomato puree and paste (Jones, G.L. 2011, R-23487). No dissipation of any analyte was observed during the storage periods for the various matrices. Stability was demonstrated in tomato raw agricultural commodity (RAC) for at least 469 days (ca. 15 months) and in tomato processed commodities for at least 181 days (ca. 6 months). For pepper, cucumber, and melon, residues were stable for at least 488 days (ca. 16 months).

Table 65 Storage Stability of fluensulfone, TSA and BSA in cucumber

Analyte	Storage Interval days / months	Spiking Level (mg/kg)	Percent of Nominal Spiking Level

USE PATTERN

Table 71 Good agricultural practices (GAPs) proposed for fluensulfone ^a

Crop and/ or Situation	Pests or Group of Pests Controlled	Application Method Kind	Growth Stage & Season	No.	Interval Between Applications (min)	Rate (kg ai/ha, min–max)	PHI (days)
U.S.A Registration							
Cucurbit	Root-knot,	Drip irrigation,	Pre-planting	1	N/A	1.92–2.8	N/A

Crop and/or Situation	Pests or Group of Pests Controlled	Application Method Kind	Growth Stage & Season	No.	Interval Between Applications (min)	Rate (kg ai/ha, min–max)	PHI (days)
vegetables & fruiting vegetables	root-lesion and cyst nematodes	Band application, Broadcast spray	(minimum of 7 days before transplanting) ^b				

^a Representative formulation is an EC containing 480 g/L (4 lb/gal) of fluensulfone.

^b Only outdoor uses are permitted.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received data from supervised residue trials conducted on cucumber, summer squash, cantaloupe, tomato, and pepper conducted in the USA and Canada. For all samples, analyses were conducted for fluensulfone, BSA, and TSA, and analysis of MeS was conducted for at least some samples from each crop. The reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples; dates from critical events during the study, including application, harvest, storage, and analysis; as well as detailed information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations. Samples were analysed by Method 1997W (equivalent to Method 2061W) described above. The results are supported by concurrent recoveries ranging, on average for each analyte and crop, from 81–120% for all commodity × analyte combinations except for fluensulfone in dry tomato pomace, which averaged 131% in one study. Samples were stored, frozen, for the following durations: cucumber = 10 months, squash = 10 months, melons = 9 months, pepper = 7 months, and tomato = 7 months. The storage durations are less than or equal to those for which residues have been demonstrated to be stable.

The field trial study designs included control plots. All measured residues from control plots were < 0.01 mg/kg (i.e., < LOQ) and are not included in the summary tables in this evaluation.

Supervised trials for fluensulfone:

Commodity	Crop	Table
Fruiting vegetable, cucurbit	Cucumber (VC 0424)	Table 72

Applic. Type BCS = broadcast spray

Residue n.a. = Not analysed

In a magnitude-of-the-residue study by Chevalier (2011, Report R-23486), muskmelon were grown under protected conditions in Southern Europe (Greece, Italy, and Spain) in soil that had been treated with fluensulfone by drip irrigation, at a rate of ca. 4.0 kg ai/ha, 7 days prior to transplanting. The melons were harvested at maturity, 62–79 days after application as well as for residue decline (up to 98 days after application), and stored frozen until preparation for analysis. Preparation consisted of separating the melon samples into their pulp and peel components, homogenizing the fractions, and

then storing them frozen prior to analysis. Analysis was by Method 1977W and the equivalent Method 2061W.

Table 75 Residues of fluensulfone, BSA, MeS, and TSA in melon pulp, peel, and whole fruit following treatment by drip irrigation seven days pre-transplant

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of the residue during processing

High-temperature hydrolysis

High-temperature hydrolysis of fluensulfone, BSA, MeS, and TSA was investigated by G. Morlock (2011, R-28467). In the study, fluensulfone, BSA, MeS, and TSA were spiked into buffered solutions, in duplicate, at a target concentration of 1 mg/L. The spiked solutions were put into conditions, in the dark, simulating pasteurisation (90 °C, pH 4, 20 min.); baking, brewing, boiling (100 °C, pH 5, 60 min); and sterilisation (120 °C, pH 6, 20 min.). Prior to and after processing, an aliquot from each sample was collected and preserved with acetonitrile. Samples were stored for not more than 17 days, refrigerated (ca. 4 °C) prior to analysis. Analysis consisted of diluting an aliquot of sample with water (fluensulfone, MeS) or acetonitrile/water (BSA, TSA) followed by HPLC-MS/MS determination. Procedural recoveries from samples spiked at 0.1 or 1.0 mg/L ranged from 88 to 102% with standard deviations of not more than 11% across all four compounds and at both spiking levels.

Table 78 Results of high-temperature hydrolysis studies with fluensulfone, BSA, MeS, and TSA (G. Morlock, 2011, R-28467)

	pH		Mass, g		
Analyte	Start	End	Start	End	Recovery
50 mM Citric Acid Buffer, 90 °C, 20 min.					
Fluensulfone	4.03	4.01	224.9	224.9	100.0
	4.03	4.00	225.7	225.7	100.0
TSA	4.02	4.00	224.5	224.4	100.0

Residues after processing

The fate of fluensulfone and its BSA, MeS, and TSA metabolites during processing of raw tomato into processed tomato products was investigated by Jones (2011, Report AA100707) by Burn and Winner (2012, Report FOZ1001), and by Jones (2013, Report R-29577). In all studies, samples of processed commodities were generated using procedures reflective of commercial practices and all samples were analysed by methods equivalent to Method 1977W or Method 2061W.

In Jones 2011, tomatoes were transplanted into plots that had received treatment with fluensulfone seven days prior to transplanting at a rate of 7.93 or 8.02 kg ai/ha. Tomatoes were harvested at maturity from the second trial only (8.02 kg ai/ha) and processed into juice, puree, and paste using simulated commercial practices. RAC and processed commodities were assayed for fluensulfone, BSA, MeS, and TSA. All residues were < 0.01 mg/kg in all samples except for parent fluensulfone at 0.01 mg/kg in tomato juice. Given the results and that other studies are available, further information on processing practices and derivation of processing factors are not addressed in this evaluation.

In Burn and Winner, tomatoes were transplanted in to plots which had received fluensulfone seven days prior to transplanting at a rate of either 3.93 or 7.86 kg ai/ha. Tomatoes were harvested at maturity and processed into peeled, canned, sundried, juice, puree, paste, wet pomace, and dry pomace processed commodities using simulated commercial practices. Raw tomato and processed tomato samples were analysed by a method equivalent to Method 2061W.

Peeled tomatoes were made steaming tomatoes, with stems removed, in a steamer pot for six minutes. After steaming, the skins were removed manually and the tomato cores were removed with a standard kitchen coring tool.

Canned tomatoes were made by placing portions of the peeled tomatoes into containers, topping the containers off with juice from the whole tomato, fitting lids to the containers, and boiling in a water-filled pot for 45 minutes. The canned tomatoes were then cooled rapidly to prevent overcooking.

Juice, puree, paste, and wet pomace were made as follows: Whole tomato samples were chopped in a food processor at low speed. The resulting homogenate was strained using a press and a gauze bag to remove coarse components (skins, seeds, etc.). The material in the bag made up the wet pomace fraction and the strained liquid made up the juice fraction. An aliquot of juice was concentrated, by rotary evaporation in vacuo at 90 °C, to a moisture content of 86% to form puree, and a separate aliquot of juice was concentrated in the same fashion to a moisture content of 72% to form paste. Dry pomace was made by drying wet pomace in an oven to a moisture content of < 10%.

For sundried tomatoes, whole tomato samples were quartered lengthwise and composited into samples containing at least 1 quarter from 12 different tomatoes. The wedges were laid out onto a tray and lightly covered with salt (NaCl, ca. 10–15 g per kg fresh sample). The samples were dried in the sun over a 5-day period. Samples were checked daily for water content and were considered to be suitably dried when they had dehydrated to < 20% of their original weight.

Residues of fluensulfone were < 0.01 mg/kg in all samples. Quantifiable residues of BSA, MeS, and TSA occurred in RAC tomatoes from at least one of the treatment rates. Residues of BSA and TSA were concentrated, relative to the residues in the RAC, in wet and dry pomace. In addition, BSA showed concentration in sundried tomato. MeS was concentrated in dry pomace from the lower treatment rate only.

In a second study by Jones (2013, R-29577), tomatoes were planted into plots treated at a rate of either 12 kg ai/ha or 20 kg ai/ha seven days prior to transplanting. Tomatoes were harvested from one plot at the higher treatment rate and processed into juice, puree, paste, and wet and dry pomace using simulated commercial practices. Residues of fluensulfone, BSA, MeS, and TSA were assayed using Method 2061W.

Prior to processing, tomatoes were washed (52–57 °C, 3–5 min), hand culled, and suitable fruits were trimmed of defects and/or off-colour areas. Cleaned tomatoes were chopped to a fine consistency and processed through a pulper/finisher with a 2.4 mm screen. Material passing through the screen underwent a hot-break process and was then passed through a pulper/finisher fitted with a 0.84 mm screen. An aliquot of the material passing through the screen was heated (85–91 °C, 3 min), placed into cans, pressure cooked (121–124 °C, 40–45 seconds), and cooled in a water bath (16–27 °C, 28–32 min). The resulting juice fraction was then placed into frozen storage. Separate aliquots of the juice fraction were vacuum-evaporated to form puree (8–24% solids) and paste (24–30% solids). Puree and paste samples were heated, canned, and cooled, as above for juice (no pressure cooking). Material not passing through the screens was collected as wet pomace, of which an aliquot was dried (54–71 °C, 20–24 hrs) to form dry pomace.

Figure 6 Material balance and processed commodity flowchart for processed tomato commodities (copied without alteration from Jones 2013, Report R-29577)

Residues of fluensulfone and MeS were < 0.01 ppm in all commodities. Residues of BSA and TSA were quantifiable in all commodities and showed concentration, relative to the raw fruit, in dry pomace and paste, and a slight concentration in BSA in puree.

Residues in animal commodities

No feeding studies depicting transfer of residues from animal feeds to animal commodities were provided.

APPRAISAL

Fluensulfone is a non-fumigant nematicide in the fluoroalkenyl class of pesticides. Fluensulfone shows activity in multiple nematicide physiological systems. It was considered for the first time by the 2013 JMPR for toxicology and by the 2014 JMPR for residues. The 2013 JMPR established an ADI of 0–0.01 mg/kg bw and an ARfD of 0.3 mg/kg bw.

The IUPAC name for fluensulfone is 5-chloro-1,3-thiazol-2-yl 3,4,4-trifluorobut-3-en-1-yl sulfone.

Fluensulfone with ^{14}C radiolabelling in the thiazole ring or in the ethane bridge between the sulfone and trifluorobutene moieties was used in the metabolism and environmental fate studies. In this appraisal, these positions are referred to as the Th and Bu labels, respectively.

The following abbreviations, along with IUPAC names and structures, are used for the metabolites discussed in this appraisal:

BSA	3,4,4-trifluorobut-3-ene-1-sulfonic acid	<chem>OS(=O)(=O)CC/C=C(F)F</chem>

Butene sulfinic acid	3,4,4-trifluorobut-3-ene-1-sulfinic acid	
MeS	2-methylsulfonyl-1,3-thiazole	
TSA	5-chloro-1,3-thiazole-2-sulfonic acid	
Thiazole mercapturate	2-acetamido-4-(1,3-thiazole-2-sulfonyl)butanoic acid	
Thiazole glucuronides (α and β isomers)	Name not specified	

Animal metabolism

The Meeting received studies elucidating the metabolism of fluensulfone in laboratory animals (evaluated by the 2013 Meeting), lactating goats, and laying hens.

In rats, absorption of fluensulfone administered by gavage at 5 mg/kg bw is rapid, with maximal plasma concentrations achieved within 4 hours. At 5 and 500 mg/kg bw, the extent of oral absorption is high (> 80%). Fluensulfone is widely distributed in the body. High concentrations of both butene- and thiazole-labelled material were found in the liver and kidney. The labelled material was rapidly excreted via urine (> 70%), with faecal excretion accounting for no more than 5–13%. Absorbed fluensulfone was extensively metabolized, with almost no unmetabolized parent compound detected. Other than low amounts of thiazole sulfonic acid, no other faecal metabolites were present at levels above 5% of the administered dose. The parent compound probably reacts with glutathione and cleaves, giving rise to thiazole mercapturate, thiazole glucuronide, and butene sulfinic acid, the major urinary metabolites.

In goats dosed for five consecutive days at approximately 28.8 mg/animal/day (10.5 ppm in the diet), most of the recovered radioactivity was in urine and GI tract/faeces, with only 10.7% (Th-14C) or 3.5% (Bu-14C) of the applied dose (AD) accounted for in tissues and body fluids. In excreta, the major identified residues were trifluorobutene sulfinic acid and the MeS metabolite. In other matrices, the highest levels of radioactivity were associated with liver (max. 2.6 mg eq./kg, 1.7% AD), kidney (max 1.4 mg eq./kg, 0.2% AD), and milk fat (2.0 mg eq./kg, 0.31% AD). Seventy-five to

ninety percent of the radioactivity in the goat matrices was extracted with a combination of solvent extraction and alkaline digestion. No BSA, TSA, or fluensulfone was detected in any goat matrix. Radioactivity in milk and tissues was primarily associated with glucose (0.039–0.24 mg/kg; 4–17% TRR), lactose (0.036–0.21 mg/kg; 4–63% TRR), proteins/amino acids (0.015–1.2 mg/kg; 5–37% TRR), and triglycerides/fatty acids (0.009–1.1 mg/kg; 7.6–52% TRR), and the radioactivity appears to be due to incorporation of the radiolabelled carbon.

In hens dosed for seven consecutive days at 1.25 mg/animal/day (9.8 ppm in the diet), total radioactive residues (TRR) in excreta accounted for approximately 80% of the dosed material for both label positions. Total radioactivity in eggs did not plateau within the eight dosing days of the hen study. Radioactive residues in eggs were not identified. Most residues in eggs were associated with aqueous phases in the extraction schemes; however, 0.18 mg eq./kg from the butane label (27% TRR) was extracted with hexane:acetone. Fluensulfone was a major residue (0.009–0.041 mg/kg; 21–55% TRR) in poultry fat; otherwise, parent fluensulfone was not observed in any matrix. Comparison of extraction of radioactivity from liver samples treated with and without protease enzyme indicates that ca. 0.16 mg/kg (24%) of the radioactivity was associated with proteins and/or amino acids and approximately 3% (0.016 mg/kg) was identified as TSA. Incorporation of the radioactivity into triglycerides was noted in both fat matrices and in eggs. In eggs, triglyceride accounted for 7% and 27% of the TRR for the thiazole and butene labels, respectively. In fat matrices, triglycerides accounted for 7–12% and 79–87% of the TRR for the thiazole and butene labels, respectively.

Overall, the animal metabolism studies show that fluensulfone is well absorbed and that the majority (75–90%) of the dosed radioactivity is excreted. Results from rat, goat, and hen studies indicate that fluensulfone is cleaved at the sulfonyl bridge in all three animals; however, the identification of different residues in the studies suggests that there may be different metabolic pathways. In both poultry and goats, fluensulfone can be expected to break down and be incorporated almost entirely into natural products. Based on the residue profile in poultry and the observed incorporation of radioactivity into natural components, the Meeting is of the opinion that the lack of a residue plateau in egg is not of concern.

Plant metabolism

The Meeting received studies depicting the metabolism of fluensulfone in tomato, lettuce, and potato. All of the studies were conducted with fluensulfone which was radiolabelled, separately, in the thiazole ring and the ethane bridge between the sulfonyl and trifluorobutene moieties.

To investigate the metabolism of fluensulfone on tomato, fluensulfone was applied at a rate of 4.07 kg ai/ha to soil. Later that same day, tomato seedlings were planted. Mature fruits were harvested 87 days after treatment. Total radioactive residues in tomato were higher in samples treated with Bu-¹⁴C-labelled material (0.52 mg eq./kg) than those from Th-¹⁴C treatment (0.27 mg eq./kg). The majority (88.7% Th-¹⁴C; 91.3% Bu-¹⁴C) of the radioactivity was extracted with acetonitrile:water

(ACN:H₂O). TSA made up 0.12 mg/kg (45.4% TRR), with an additional 0.06 mg eq./kg (21.2% TRR) as salts/related compounds. BSA occurred at 0.22 mg/kg (41.6% TRR) with salts/related compounds making up 0.13 mg eq./kg (26.5% TRR). No other compounds, including parent fluensulfone, were identified in tomato.

Lettuce seeds were planted into soil and then fluensulfone was applied at a rate of 4.07 kg ai/ha. Samples were collected 49 days and 64 days after application to obtain immature and mature lettuce, respectively. Contrary to the results with tomato, TRR were higher from treatment with Th-¹⁴C-labelled material (6.1–7.1 mg eq./kg) than with Bu-¹⁴C-labelled material (1.5–2.4 mg eq./kg) and were similar in immature and mature foliage. The majority of the radioactivity was extracted with ACN:H₂O, with higher extraction efficiency from samples treated with the Th-¹⁴C label. Following treatment with Th-¹⁴C-labelled material, 3.57 mg/kg and 4.34 mg/kg (67.5% and 70.6% TRR) was identified as TSA in immature and mature leaves, respectively. An additional 1.39 mg eq./kg and 0.41 mg eq./kg (17.8% and 6.6% TRR) in immature and mature leaves, respectively, was determined to be salts and/or other forms of TSA. Following treatment with Bu-¹⁴C-labelled material, BSA occurred at 0.49 mg/kg (23.8% TRR) in immature leaves and at 0.49 mg/kg (37.6% TRR) in mature leaves. As with TSA, salts and other forms occurred for BSA and constituted, in total, 0.75 mg eq./kg (36.0% TRR) in immature foliage and 0.29 mg eq./kg (22.1% TRR) in mature foliage. Fluensulfone occurred at trace levels (0.009 mg/kg, 0.008 mg/kg) in immature lettuce from the Th-¹⁴C and Bu-¹⁴C treatments, respectively. Aside from BSA and TSA, no other metabolites of fluensulfone were identified.

Potato seed pieces were planted just prior to application of fluensulfone to soil at a rate of 4.04 kg ai/ha (Th-¹⁴C) or 4.13 kg ai/ha (Bu-¹⁴C). Immature (70 days after treatment) and mature (106 days after treatment) tubers were harvested and analysed. For immature and mature tubers, respectively, TRR were 0.32 and 0.44 mg eq./kg from the Th-¹⁴C treatment and 0.22 and 0.17 mg eq./kg from the Bu-¹⁴C treatment. Extraction with ACN:H₂O efficiently released residues: 91.9% TRR (Th-¹⁴C, immature tuber), 91.7% TRR (Th-¹⁴C, mature tuber), 76.9% TRR (Bu-¹⁴C, immature tuber), and 79.1% TRR (Bu-¹⁴C, mature tuber). Fluensulfone was found at trace levels (0.005 mg/kg) from both label treatments in mature tubers only. Otherwise, the only identified residues were BSA, TSA, and their salts and/or related compounds. BSA constituted 0.069 mg/kg (30.7% TRR) and 0.042 mg/kg (25.8% TRR) in immature and mature tubers, respectively. Salts and related forms of BSA provided an additional 0.041 mg eq./kg (17.8% TRR; immature tubers) and 0.035 mg eq./kg (21.4% TRR; mature tubers). TSA occurred at 0.21 mg/kg (63.0% TRR) and 0.31 mg/kg (65.3% TRR) in immature and mature tubers, respectively. Salts and related forms of TSA gave an additional 0.028 mg eq./kg (8.4% TRR; immature tubers) and 0.025 mg eq./kg (5.3% TRR; mature tubers).

Fluensulfone was extensively metabolised in all of the studies, with the only major residues being the BSA and TSA metabolites. A few chromatographic fractions contained radioactivity in

excess of 10% TRR. Investigation of these fractions indicated that the residues were associated with the BSA or TSA metabolites, as salts of the sulfonic acids or as related forms of the metabolites. The only major residues in the harvested matrices were the BSA and TSA metabolites and, with the exception of trace levels of fluensulfone in immature lettuce and mature potato, no parent compound was detected.

Environmental fate in soil

Fluensulfone is stable to hydrolysis under accelerated conditions (50 °C, pH 4, 7, 9) but is prone to photolysis [DT₅₀ of 21 days (Th-¹⁴C) or 35 days (Bu-¹⁴C) in soil], showing first-order kinetics. In an aerobic soil metabolism study, major residues following treatment with fluensulfone were BSA, TSA, and MeS, depending on the duration of incubation. Fluensulfone had DT₅₀ estimates ranging from 7 to 17 days across six soils, all following first-order kinetics. BSA formed from fluensulfone generally accumulated for the first ca. 1 month of incubation followed by dissipation (DT₅₀ 18–26 days). Residues of TSA accumulated continuously over the incubation period, reaching maxima of 49–74% of the applied radioactivity at the 120-day sampling. Residues of MeS began to be observed after the first 2–4 weeks of incubation, reaching a maximum of not more than 8% of the applied radioactivity; residues of MeS declined to 0% of the applied radioactivity between the 50- and 120-day sampling times, depending on the soil. In a separate study, the DT₅₀ estimates for the TSA and MeS metabolites under aerobic soil conditions are 421 and 33 days, respectively. Field dissipation studies were not provided.

Confined rotational crop studies were conducted with radish, lettuce, and wheat at plant-back intervals (PBIs) of 30, 120, and 360 or 390 days. Fluensulfone, radiolabelled as either the Th-¹⁴C or Bu-¹⁴C, was applied to soil at a rate of approximately 4 kg ai/ha. Lettuce was replanted at 390 days after application due to crop failure at the 360-day PBI. Following treatment with Th-¹⁴C-labeled material, TRR generally declined sharply from 30 to 120 days and then remained relatively consistent between the 120 and the 360/390-day PBIs. (e.g., wheat hay: 27 mg eq./kg at 30-Day PBI, 9.4 mg eq./kg at 120-Day PBI, 10.8 mg eq./kg at 360-Day PBI) As with primary crops, the major residues were the BSA and TSA metabolites. A low level of the parent compound was observed in lettuce, radish root, radish foliage, and wheat forage, hay, and straw (but not grain). Fluensulfone, when found, was typically 1 to 2 orders of magnitude less than the BSA or TSA residue levels. In all cases, residues of fluensulfone and BSA were not quantifiable after the 120-day PBI whereas residues of TSA persisted at quantifiable levels for at least one year, ranging from 0.13 mg eq./kg (immature lettuce) to 11 mg eq./kg (wheat hay).

Overall, fluensulfone can be expected to dissipate rather rapidly in the environment, with a concomitant increase in residues of BSA, TSA, and, to a much lesser extent, MeS. BSA residues should then decline; however, TSA appears to be stable for an extended period. The Meeting concluded from the soil metabolism and confined rotational crop studies that TSA may accumulate in

soils following repeated uses of fluensulfone and may occur in follow-on crops at plant-back intervals exceeding one year after treatment.

Methods of residue analysis

The Meeting received analytical methods for the analysis of fluensulfone, BSA, MeS, and TSA in plant and animal matrices. The methods are essentially identical for all samples and the LOQ for all matrices and analytes, defined as the lower limit of method validation, is 0.01 mg/kg.

Extraction of residues is accomplished with ACN:H₂O (1:1, v/v) or ACN (BSA and TSA in eggs only); the extract is then split for analysis of fluensulfone and MeS by one set of procedures and for analysis of BSA and TSA by a second set. For fluensulfone and MeS, there is no clean-up of the extract beyond filtration (except hexane partitioning for analysis of MeS in fatty/oily samples). Residues of fluensulfone and MeS are determined by reverse-phase LC-MS/MS in positive ion spray mode. For BSA and TSA, an aliquot of the initial extract is concentrated and then cleaned-up using C-18 SPE. Residues are determined by reverse-phase LC-MS/MS in negative ion spray mode.

The solvent used for extraction is the same as, or very similar to, that used in the metabolism studies and showed adequate extraction efficiency of incurred residues.

Testing of fluensulfone and the two sulfonic acid metabolites, BSA and TSA, through the FDA PAM multiresidue method protocols demonstrated that the compounds showed poor sensitivity, poor recovery, and/or poor chromatography. Overall, the results indicate that the FDA PAM multiresidue protocols are not suitable for the detection or enforcement of fluensulfone, BSA, or TSA residues in non-fatty foods.

Stability of residues in stored analytical samples

The Meeting received data depicting the stability of residues of fluensulfone, BSA, and TSA in tomato, pepper, cucumber, and melon. In addition, the stability of those analytes and MeS was investigated in frozen, stored tomato puree and paste. No dissipation of any analyte was observed during the storage periods for the various matrices. Stability was demonstrated in tomato raw agricultural commodity (RAC) for at least 469 days (ca. 15 months) and in tomato processed commodities for at least 181 days (ca. 6 months). For pepper, cucumber, and melon, residues were stable for at least 488 days (ca. 16 months).

Definition of the residue

Studies depicting the nature of the residues in animals consistently show fluensulfone to be cleaved at the sulfonyl moiety, presumably via glutathione conjugation, resulting in both halves of the molecule having a sulfonyl functional group. With the exception of poultry fat, fluensulfone was not observed in any animal commodity. In livestock, the majority of the radiolabel was excreted. Retained fluensulfone is extensively metabolized, with the radioactivity being associated primarily with sugars,

amino acids, and fatty acids. MeS and butene sulfinic acid were identified in livestock studies, but were observed only in excreta. In the rats, significant residues were thiazole mercapturate, thiazole glucuronide, BSA, TSA, and butene sulfinic acid. MeS, observed in some field trial samples, was not identified in the rat metabolism study.

Based on the livestock metabolism studies, a residue definition potentially suitable for enforcement by the typical criteria is possible only for poultry fat and poultry liver, which were the only matrices in the animal metabolism studies with quantifiable residues of a fluensulfone-specific compound (fluensulfone in fat and TSA in liver). Although fluensulfone was a major residue in poultry fat (up to 55% TRR), the available residue data indicate that quantifiable residues of the parent compound are not expected in plants; thus exposure to fluensulfone via livestock diets is unlikely, making the parent compound an unsuitable marker for enforcement in any livestock commodity. The other potential marker, TSA, occurred only as a minor component in poultry liver (2.7% TRR). Based on the results of the metabolism studies and on the residue profiles observed in crop metabolism studies, confined rotational crop studies, and supervised residue trials, the Meeting determined that a residue definition for livestock commodities is not necessary.

In both plant and rotational crop metabolism studies, fluensulfone appears to follow the same glutathione-mediated pathway observed in livestock; however, in plants quantifiable residues of the BSA and TSA metabolites were consistently observed. Parent fluensulfone was identified only at trace levels in immature lettuce, mature potato, and rotational lettuce, radish foliage, and wheat hay, forage and straw at short PBIs (30 days). In target crops, BSA ranged from 0.071–1.24 mg/kg (43.6–68.1% TRR) and TSA ranged from 0.17–4.75 mg/kg (66.6–85.3% TRR). In rotational crops, BSA was detected in all matrices except wheat grain at the 30-day PBI (0.004–1.4 mg/kg) and in most matrices at the 120-day PBI (0.001–0.43 mg/kg), and was undetected (< 0.001 mg/kg) by the 360/390-day PBI, except wheat straw at 0.012 mg/kg. In contrast, TSA was detected in all rotational crop matrices at all PBIs, ranging from 0.086 mg/kg to 16 mg/kg across all samples.

In crop field trials, fluensulfone was detected in only one sample (summer squash at 0.017 mg/kg). Across all crops, residues of BSA ranged from < 0.01 to 0.27 mg/kg and TSA ranged from < 0.01 to 0.71 mg/kg. MeS ranged from < 0.01 to 0.08 mg/kg and was less than both BSA and TSA in the corresponding sample. In all trials with only pre-plant applications (per GAP), MeS was < 0.01 mg/kg in all samples of cantaloupe, pepper, and tomato. Although MeS was not found in the plant or rotational crop metabolism studies, it was observed in supervised residue trials in cucumber (< 0.01–0.079 mg/kg) and summer squash (< 0.01–0.050 mg/kg).

The Meeting determined that fluensulfone is NOT a suitable marker for compliance with MRLs in crops. Both BSA and TSA are suitable markers based on results of supervised field trials. The confined rotational crop study, however, demonstrates a potential for TSA to carry over into succeeding crops. Therefore, given that quantifiable residues of fluensulfone are not expected in plant commodities, that a separate analysis is required for the analysis of fluensulfone and BSA/TSA, and

that residues of TSA may occur from previous crop cycle treatments with fluensulfone, the Meeting determined that BSA is the most suitable marker for MRL compliance. A validated method exists for analysis of BSA in plant commodities. The Meeting defined the BSA metabolite as the residue definition for compliance in plants.

Regarding the toxicity of the BSA, TSA, and MeS metabolites, the JMPR has concluded that TSA is unlikely to be of any toxicological relevance; data are insufficient at this time to make a definitive toxicological determination regarding the relevancy of BSA and MeS.

For BSA, the JMPR has determined that the ADI and ARfD for fluensulfone could be used as a screening evaluation of exposure to BSA. Based on a comparison of toxicity data between BSA and fluensulfone, the evaluation may be made directly, without a correction for molecular weight. If additional uses are considered in the future, the use of the fluensulfone points of departure to evaluate exposure to BSA may need to be re-evaluated.

For MeS, the JMPR has determined that the IEDI (0.07 µg/kg bw/day) for MeS should be compared to the Cramer class III TTC value of 1.5 µg/kg bw/day and that the IESTI (3.2 µg/kg bw/day)² should be compared to the single-exposure TTC for Cramer class III compounds of 5 µg/kg bw proposed by EFSA. The IESTI is somewhat refined in that for melon, the specific HR (0.01 mg/kg) from melon field trials was used rather than the HR for the fruiting vegetables, Cucurbits group (0.053 mg/kg). On the basis of these comparisons, the Meeting concluded that MeS is not considered to be a relevant metabolite for the crops under consideration. If additional uses are considered in the future, this conclusion may need to be re-evaluated.

Given the residue profile in crops and taking into consideration the available information on the toxicities of the metabolites, the Meeting determined that the residue definition for dietary exposure from crops is BSA. In lieu of BSA-specific toxicological points of departure, dietary intake estimates for BSA should be compared to the ADI and ARfD for fluensulfone, with no correction for molecular weight.

Definition of the residue for compliance with the MRLs and dietary intake for plant commodities: *BSA {3,4,4-trifluorobut-3-ene-1-sulfonic acid}*.

Definition of the residue for compliance with the MRLs and for dietary intake for animal commodities: *Not necessary*

Results of supervised residue trials on crops

Fluensulfone is registered in the USA for use on cucurbit vegetables and on fruiting vegetables. For all crops, the cGAP is an application to the soil at 2.8 kg ai/ha made seven days prior to transplanting

² The estimate of 3.2 µg/kg bw is refined, using the observed HR for melon (0.01 mg/kg) rather than the HR for the fruiting vegetables, Cucurbits group (0.053 mg/kg), which resulted in a maximum dietary intake estimate of 5.3 µg/kg bw.

crops into the field. Application may be made by broadcast spray to the soil, by banded spray, or by drip irrigation. The applied material must be mechanically incorporated 15–20 cm into the soil profile for spray applications or by sufficient volume for drip irrigation application.

The Meeting received supervised residue trial data for cucumber, summer squash, cantaloupe, pepper, and tomato. The trials were conducted in North America (USA and Canada). All trials were conducted at a target application rate of 3.9 kg ai/ha, which reflects a nominal exaggeration of 39% relative to the cGAP. Therefore, the Meeting decided to scale residue values for all analytes from trials otherwise meeting the cGAP to an application rate of 2.8 kg ai/ha. Residues scaled to < 0.01 mg/kg were maintained at < 0.01 mg/kg. Reported values are field trial averages unless otherwise noted.

Residues of fluensulfone were < 0.01 mg/kg in all samples.

Fruiting vegetables, Cucurbits

In cucumber, mean field trial residues of BSA (unscaled) from independent field trials treated 7 days prior to transplant (n = 7) were: < 0.01, 0.01 (2), 0.063, 0.07, 0.17, and 0.219 mg/kg.

Application rates for these trials ranged from 3.72 kg ai/ha to 4.11 kg ai/ha. Scaled to an application rate of 2.8 kg ai/ha, the residues of BSA are: < 0.01 (3), 0.041, 0.045, 0.114, and 0.137 mg/kg.

In summer squash, mean field trial residues of BSA (unscaled) from independent field trials treated 7 days prior to transplant (n = 8) were: < 0.01, 0.05, 0.06, 0.082, 0.186, 0.196, 0.214, and 0.247 mg/kg.

Application rates for these trials ranged from 3.80 kg ai/ha to 4.14 kg ai/ha. Scaled to an application rate of 2.8 kg ai/ha, the residues of BSA are: < 0.01, 0.032, 0.038, 0.051, 0.115, 0.12, 0.133, and 0.149 mg/kg.

In melon, mean field trial residues of BSA (unscaled) from independent field trials treated 7 days prior to transplant (n = 8) were: < 0.01 (3), 0.021, 0.025, 0.032, 0.049, and 0.064 mg/kg.

Application rates for these trials ranged from 3.85 kg ai/ha to 4.11 kg ai/ha. Scaled to an application rate of 2.8 kg ai/ha, the residues of BSA are: < 0.01 (3), 0.013, 0.016, 0.019, 0.030, and 0.040 mg/kg.

Noting that the GAP in the USA is for the cucurbit vegetables crop group, which is equivalent to the Codex fruiting vegetables, Cucurbit group, and that the BSA residue data from cucumbers, summer squash, and melons are not significantly different by the Kruskal-Wallis test, the Meeting determined that the residues from the trials are similar and is estimating a group maximum residue level for fruiting vegetables, Cucurbits based on the following scaled BSA residue data set (n = 23): < 0.01 (7), 0.013, 0.016, 0.019, 0.030, 0.032, 0.038, 0.040, 0.041, 0.045, 0.051, 0.114, 0.115, 0.120, 0.133, 0.137, and 0.149 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for BSA on fruiting vegetables, Cucurbits; the HR is 0.16 mg/kg (from a single sample) and the STMR is 0.032 mg/kg.

Fruiting vegetables, other than Cucurbits

In chilli pepper, mean field trial residues of BSA (unscaled) from independent field trials treated 7 days prior to transplant (n = 3) were: 0.040, 0.041, and 0.184 mg/kg.

Application rates for these trials ranged from 3.98 kg ai/ha to 4.10 kg ai/ha. Scaled to an application rate of 2.8 kg ai/ha, the residues of BSA are: 0.025, 0.025, 0.116 mg/kg.

In sweet pepper, mean field trial residues of BSA (unscaled) from independent field trials treated 7 days prior to transplant (n = 8) were: 0.048, 0.055, 0.063, 0.070, 0.073, 0.082, 0.136, and 0.232 mg/kg.

Application rates for these trials ranged from 3.84 kg ai/ha to 410 kg ai/ha. Scaled to an application rate of 2.8 kg ai/ha, the residues of BSA are: 0.030, 0.034, 0.041, 0.045 (2), 0.050, 0.083, and 0.146 mg/kg.

In tomato, mean field trial residues of BSA (unscaled) from independent field trials treated 7 days prior to transplant (n = 20) were: < 0.01 (3), 0.013, 0.023, 0.026, 0.029, 0.034, 0.042, 0.072, 0.074, 0.078, 0.087, 0.088, 0.094, 0.173, 0.198, 0.231, 0.269, and 0.273 mg/kg.

Application rates for these trials ranged from 3.64 kg ai/ha to 4.12 kg ai/ha. Scaled to an application rate of 2.8 kg ai/ha, the residues of BSA are: < 0.01 (4), 0.014, 0.016, 0.018, 0.021, 0.026, 0.045, 0.046, 0.049, 0.054, 0.055, 0.061, 0.108, 0.132, 0.140, 0.168, and 0.169 mg/kg;

Noting that the GAP in the USA is for the fruiting vegetables crop group, which is equivalent to the Codex group fruiting vegetables, other than Cucurbits except sweet corn and mushroom, and that the residue data from sweet pepper, chilli pepper, and tomato are not significantly different by the Kruskal-Wallis test, the Meeting determined that the residues from the trials are similar and is estimating a group maximum residue level for fruiting vegetables, other than Cucurbits except sweet corn and mushroom based on the following scaled BSA residue data set: (n = 31): < 0.01 (4), 0.014, 0.016, 0.018, 0.021, 0.025, 0.025, 0.026, 0.030, 0.034, 0.041, 0.045 (3), 0.046, 0.049, 0.050, 0.054, 0.055, 0.061, 0.083, 0.108, 0.116, 0.132, 0.140, 0.146, 0.168, and 0.169 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for BSA on fruiting vegetables, other than Cucurbits except sweet corn and mushroom; the HR is 0.17 mg/kg (from a single sample) and the STMR is 0.045 mg/kg.

Based on the maximum residue level of fruiting vegetables, other than Cucurbits except sweet corn and mushroom (0.3 mg/kg) and a dehydration factor of 7, the Meeting estimated a maximum residue level of 2 mg/kg for BSA in chilli pepper (dry), an HR of 1.2, and an STMR of 0.32.

Fate of residues during processing

High-temperature hydrolysis

The Meeting received a study investigating the high-temperature hydrolysis of fluensulfone, BSA, MeS, and TSA. Samples of aqueous buffered solutions were spiked with fluensulfone, BSA, MeS, or TSA at ca. 1 mg/L and put under conditions simulating pasteurisation (90 °C, pH 4, 20 min.); baking, brewing, boiling (100 °C, pH 5, 60 min); and sterilisation (120 °C, pH 6, 20 min.). Solutions were analysed by HPLC-MS/MS prior to and after processing. All four analytes were shown to be stable under all three conditions, with overall recoveries ranging from 87 to 118% of the initial concentration.

Residues after processing

The Meeting received data depicting the concentration/dilution of residues during processing of tomato into canned, juice, puree, paste, wet and dry pomace, peeled, and sun-dried processed commodities. Processed commodities were derived using simulated commercial practices. Of the three studies that were submitted, two were suitable for deriving processing factors (in one study, all residues were < 0.01 mg/kg). In those two studies, residues of fluensulfone were < 0.01 mg/kg in all samples and processing factors for the parent compound could not be derived.

Crop	Processed commodity	BSA processing factors	Best processing factor estimate (average)	STMR-P, mg/kg	HR-P, mg/kg
Tomato	RAC	--	--	STMR = 0.045	HR = 0.17
	Canned	0.33	0.33	0.015	0.056
	Dry pomace	6.6, 9.3, 17	11	0.50	1.9
	Peeled	0.33	0.33	0.015	0.056
	Sundried	1.67, 2	1.8	0.081	0.31
	Juice	0.67, 0.83	0.75	0.034	0.13
	Paste	1, 1, 3.54	1.8	0.081	0.31
	Puree	0.67, 1.38	1.0	0.045	0.17
	Wet pomace	0.66, 3, 4	2.6	0.12	0.44

Based on the maximum residue estimate for fruiting vegetables, other than Cucurbits except sweet corn and mushroom (0.3 mg/kg) and the processing factor of 1.8 for both dried tomato and tomato paste, the Meeting recommends a maximum residue level of 0.5 mg/kg for BSA in dried tomato and 0.5 mg/kg for BSA in tomato paste.

Residues in animal commodities

The Meeting has determined that residue definitions for compliance and dietary intake are not necessary for animal commodities and that residues in animal commodities are not expected.

RECOMMENDATIONS

Definition of the residue for compliance with the MRLs and dietary intake for plant commodities: *3,4,4-trifluorobut-3-ene-1-sulfonic acid (BSA)*. Note that for dietary intake, exposure estimates should be compared to the ADI and ARfD for fluensulfone, with no correction for molecular weight.

Definition of the residue for compliance with the MRLs and for dietary intake for animal commodities: *Not necessary*.

Commodity		Recommended MRL, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
CCN	Name	New	Previous		
VC 0045	Fruiting vegetables, Cucurbits	0.3	–	0.032	0.16
VO 0050	Fruiting vegetables, other than Cucurbits except sweet corn and mushroom	0.3	–	0.045	0.17
HS 0444	Peppers chilli, dried	2.1	–	0.32	1.2
VW 0448	Tomato paste	0.5	–	0.081	0.31
DV 0448	Tomato, dried	0.5	–	0.081	0.31

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of BSA were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the current Meeting. The ADI for fluensulfone is 0–0.01 mg/kg bw. The calculated IEDIs for BSA were 0–3% of the maximum fluensulfone ADI. The Meeting concluded that the long-term intakes of residues of BSA, when fluensulfone is used in ways that have been considered by the JMPR, are unlikely to present a public health concern.

Short-term intake

The International Estimated Short-Term Intakes (IESTI) of BSA were calculated for food commodities and their processed commodities using HRs/HR-Ps or STMRs/STMR-Ps estimated by the current Meeting. The ARfD for fluensulfone is 0.3 mg/kg bw. The calculated maximum IESTI for BSA was 7% of the fluensulfone ARfD for all commodities. The Meeting concluded that the short-term intake of residues of BSA, when fluensulfone is used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

FLUFENOXURON (275)

The first draft was prepared by Ms. Monique Thomas. Pest Management Regulatory Agency, Canada

EXPLANATION

Flufenoxuron is a benzoylurea insect growth regulator with high levels of acaricidal activity. Flufenoxuron kills pest mites and insects through interference with chitin production during cuticle development in mite and insect juvenile stages. Flufenoxuron has limited to no effect on adult mites and insects. It is registered for use in a variety of crops worldwide.

IDENTITY

ISO common name: Flufenoxuron

Chemical name

IUPAC: N-{4-[2-chloro-4-(trifluoromethyl)phenoxy]-2-fluorophenyl}-N'-(2,6-difluorobenzoyl)urea

CAS: N-[[[4-[2-chloro-4-(trifluoromethyl)phenoxy]-2-fluorophenyl]amino]carbonyl]-2,6-difluorobenzamide

CAS Registry No: 101463-69-8

CIPAC No.: 470

Synonyms and Trade Name: WL115110, Cascade

Structural formula:

Molecular formula: $C_{21}H_{11}ClF_6N_2O_3$

Molecular mass: 488.8 g/mol

Formulation

Flufenoxuron is commercially marketed as an emulsifiable concentrate containing 10% flufenoxuron.

Specification

Flufenoxuron has not been evaluated by the Joint Meeting of Pesticide Specifications.

METABOLISM AND ENVIRONMENTAL FATE

The metabolism and distribution of flufenoxuron in plants and animals was investigated using ¹⁴C-labelled test materials as shown below:

Fluoroaniline-U-¹⁴C

Difluoroamide-U-¹⁴C

Common chemical names, code names and structures of the parent and metabolites are captured below:

Code	Structure	Occurrence
Flufenoxuron WL115110 <i>N</i> -{4-[2-chloro-4-(trifluoromethyl)phenoxy]-2-fluorophenyl}- <i>N'</i> -(2,6-difluorobenzoyl)urea		Rat Lactating goat Laying hen Grape Apple Tomato Chinese cabbage Soil Hydrolysis study

Code	Structure	Occurrence

Reg. No. 102719 2,6 difluorobenzamide		Rat Hydrolysis study
Reg. No. 206925 2,6-difluorobenzoic acid		Rat Hydrolysis study
Reg. No. 4964847 1-{3-[2-chloro-5-(trifluoromethyl)phenoxy]-2-fluorophenyl}-5-fluoro-2,4(1H,3H)-quinazolinedione		Hydrolysis study

Animal metabolism

The Meeting received information on the fate of [^{14}C]flufenoxuron in a lactating goat and laying hens. The lactating goat metabolism study was carried out with [^{14}C]flufenoxuron uniformly labelled at the fluoroaniline ring while the laying hen metabolism study was carried out with uniformly ^{14}C -labelled difluoroamide- and fluoroaniline-flufenoxuron. Metabolism in laboratory animals (rat) was summarised and evaluated by the WHO panel of the 2014 JMPR.

Lactating goat

The metabolism of [^{14}C]flufenoxuron was investigated in one lactating goat, weighing 73 kg, was dosed orally by gavage with 2-fluoroaniline-[U- ^{14}C]-ring-labelled flufenoxuron once daily for 4 consecutive days at a dose level of 10 mg/day equivalent to 10 ppm in the diet. Milk production

ranged from 1.2–2.8 L/day. During the treatment period, milk was collected twice daily while urine and faeces were collected once daily. At sacrifice (within 24 hours after the last dose) samples of liver, kidney, muscle (hind leg and dorsal) and fat (deep body fat store along spine and renal) were collected.

The major route of elimination of the radioactivity was via the faeces which accounted for 18% of the total administered radioactivity (TAR); while urine accounted for 2.5% of the TAR and milk accounted for 8.3% of the TAR. Overall, the tissue burden was low, accounting for < 2% of the TAR. No further justification was provided for the low overall recovery of administered radioactivity (33% of the TAR).

The total radioactive residues (TRRs) were highest in fat (1.6 mg eq/kg), followed by liver (0.37 mg eq/kg), kidney (0.13 mg eq/kg) and muscle (0.076 to 0.1 mg eq/kg).

Table 1 Radioactive residue in organs and tissues

Organ/tissue	TRR [mg eq/kg]
Liver	0.37
Kidney	0.13
Skeletal muscle	
Hind leg	0.076
Dorsal	0.1
Deep body fat	1.6
Renal fat	1.6
Bile	0.26 mg eq/L
Whole blood	0.029 mg eq/L

Milk residues peaked on day 4 (average of 0.27 mg eq/L) with the highest concentrations of radioactivity detected in the cream fraction (accounting for 82–93% of the TRR in whole milk) and the lowest found in whey (1.3–5.7% of the TRR).

Table 2 ¹⁴C-Residues in milk of goat dosed with 10 mg/day of 2-fluoroaniline-[U-¹⁴C]-ring-labelled flufenoxuron

Day	Time (hours) ^a	TRR (mg eq/L)
1	7	0.27
2	23	0.09
	31	0.39
3	47	0.13
	55	0.23
4	71	0.16
	79	0.37
5	95	0.23

^a Time after administration of first dose

Samples of tissues and milk were further analysed for determination of the distribution and composition of the total radioactivity. Liver and kidney samples were homogenised with ethyl acetate/methanol, muscle and fat samples were homogenised with dichloromethane while milk samples were mixed with potassium oxalate, ethanol and diethyl ether, all prior to partitioning with hexane and acetonitrile.

Aliquots of the acetonitrile phases of milk, liver, kidney, muscle and fat were mixed with appropriate amounts of the reference compound and subjected to HPLC/UV analysis.

Table 3 Characterisation of ¹⁴C residues in tissues and milk of goat dosed with 2-fluoroaniline-[U-¹⁴C]-ring-labelled flufenoxuron

Sample	% TRR Initial extraction efficiency	Acetonitrile/ hexane partition		Final recovery in acetonitrile fraction [%]
		% TRR in hexane fraction	% TRR in acetonitrile fraction	
Liver	93.4	3.8	88.5	82.8

Sample	% TRR Initial extraction efficiency	Acetonitrile/ hexane partition		Final recovery in acetonitrile fraction [%]
		% TRR in hexane fraction	% TRR in acetonitrile fraction	
Kidney	91.4	16.1	89.8	82.0
Muscle	66.2	9.8	114.5	63.5
Fat	99.8	1.5	115.3	107.4
Milk	98.3	0.0	81.1	81.1

Extraction of the samples collected recovered 64–107% of the TRR. HPLC/UV analysis of the extracts showed no evidence of cleavage of the flufenoxuron molecule or any metabolism of the parent substance in the goat. Hence, the parent compound remained intact with no other substances being detected in the analytical chromatograms.

The nature of the radioactivity in fat analysed after a 3–4 month storage period at -20°C was examined by HPLC. No differences were noted in the metabolic profile.

Laying Hen

Study 1

Laying hens were dosed once daily for 14 consecutive days with flufenoxuron, uniformly labelled in the difluoroamide or fluoroaniline rings, at 13–14 ppm feed, equivalent to 0.78–0.85 mg/kg bw. Eggs were collected twice daily, in the morning before and in the afternoon after administration, whilst excreta was collected once daily. The animals were sacrificed approximately 23 h after the last dose and the liver, muscle and fat were collected and pooled per dose group. Liquid samples were measured directly by LSC while solid samples were combusted prior to analysis by LSC.

Excreta accounted for 72–78% of the TAR. Although no plateau was reached in eggs during the dosing period (14 days), the radioactivity recovered in eggs amounted to 1.0–1.3% of the TAR (0.5–0.8 mg eq/kg). Among all the tissues analysed, radioactive residues were highest in fat (5.0–5.3 mg eq/kg) followed by liver (0.6–1.1 mg eq/kg) and muscle (0.3–0.4 mg eq/kg). The total recovery of radioactivity was 82% and 77% in the difluoroamide-label and fluoroaniline-label groups, respectively.

Table 4 Recovery of radioactive residues in laying hens

Matrix	Difluoroamide label		Fluoroaniline label	
	% TAR	mg eq./kg	% TAR	mg eq./kg
Excreta	78.41		71.59	
Eggs	0.98		1.28	
Blood	0.02	0.113	0.40	1.269
Liver	0.11	0.577	0.24	1.056
GI-Tract (skin)	0.47	0.504	0.39	0.369
GI-Tract (contents)	0.06	0.252	0.06	0.213
Muscle	0.58	0.326	0.71	0.364
Adipose tissue	1.33	5.041	1.85	5.318
Subtotal organs	2.57		3.65	
Cage wash	0.13	–	0.11	–
Total	82.09	–	76.66	–

Extraction of radioactive residues from tissues and organs was initially performed with methanol, with the extractability ranging from 91–102% and 88–99% of the TRR for the difluoroamide- and fluoroaniline-labels, respectively. While the lowest extractability occurred with the liver from the fluoroaniline-label (88% of the TRR), microwave extraction of the liver post-extraction solid (PES) released another 8% of the TRR. Further characterisation according to polarity of residues was completed by partitioning with ethyl acetate/ water and acetonitrile/iso-hexane (for

fat, eggs and muscle) where the majority of the radioactivity was recovered in the ethyl acetate phase (93–101% and 82–104% of the TRR, difluoroamide- and fluoroaniline-label, respectively).

Table 5 Distribution of ^{14}C -residues in eggs and tissues

Label	Sample	TRR [mg/kg]	ERR ^a [mg/kg] (%TRR)	PES ^b [mg/kg] (%TRR)	Recovery [%] ^c

^a ERR = Extracted Radioactive Residue (methanol)

^b PES = Post-Extraction Solid

^c Sum of all extracts and the residue

^d Calculated value from ERR and PES

^e Another 7.9% of the TRR was extracted by microwave treatment

For the difluoroamide-label, the parent was the only analyte identified in eggs, muscle, fat and liver ranging from 0.28 mg eq/kg (86.5% of the TRR, muscle) to 4.6 mg eq/kg (91.4% of the TRR, fat).

For the fluoroaniline-label, while the parent compound and the metabolite Reg. No. 4064702 were both identified in the eggs, muscle, fat and liver, the parent accounted for the majority of the TRRs (70–91%). The lowest level of parent was found in muscle with 0.30 mg eq/kg and the highest level in fat with 4.8 mg eq/kg. In eggs and liver, Reg. No. 4064702 was present at 0.10 mg eq/kg and 0.13 mg eq/kg (12.0% and 12.6% of the TRR), respectively. Reg. No. 4064702 was detected in muscle and fat as a minor metabolite amounting to 0.02 mg eq/kg and 0.05 mg eq/kg, respectively (5.5% and 1.0% of the TRR). The formate derivative of Reg. No. 241208 was released from the PES of liver after microwave treatment in the presence of formic acid/acetonitrile. The radioactivity associated with this derivative amounted to 0.04 mg eq/kg (3.3% TRR). The Meeting could not confirm whether the metabolite Reg. No. 241208 is an actual in-vivo metabolite or an artefact formed during microwave treatment.

Table 6 Identification of total radioactive residues in eggs and tissues

Study 2

Five groups (groups 1–5 and 7–10) of three laying hens each (White Leghorn hybrids, 1.4–2.1 kg) were dosed orally by gavage with 2-fluoroaniline-[U-¹⁴C]-ring-labelled flufenoxuron once daily for seven consecutive days at a dose level of 10 mg/kg feed (corresponding to 0.5 mg/kg bw). One group of six untreated hens (group 6) served as a background control group.

Excreta from every group of hens was combined and sampled at 24 h intervals during administration. Eggs of individual hens were collected daily before each administration. After the final administration, before sacrifice, eggs and excreta were collected. Hens were sacrificed 22 hours after the final dosage or 2, 9, 16, and 34 days after the last dose to investigate the depuration behaviour of the flufenoxuron, liver, kidney, muscle (composite of breast and thigh muscle), gizzard (without lining and contents), heart, omental fat and skin were sampled. The content of the gizzard was added to the residual carcass.

On average, 26% of the TAR was excreta-related with eggs, sampled from 0–166 h after the first administration, accounting for 5% of the TAR. At sacrifice, the highest amount of radioactive residues was detected in fat (47% of the TAR), followed by skin (12% of the TAR), muscle (4% of the TAR), liver (2% of the TAR), kidney (0.3% of the TAR), heart and gizzard. The recovery of radioactivity amounted to 96% of the TAR.

Table 7 Balance of radioactivity (means of 15 hens) after seven daily doses of 0.5 mg/kg [¹⁴C]-flufenoxuron sacrificed 22 hr after final dosage

^a After incubation at 37 °C.

Extraction of the samples collected recovered > 90% of the TRR. HPLC/UV analysis of the extracts showed that flufenoxuron was not extensively metabolized and accounted for the majority of the radioactivity in egg yolks, liver, kidney, muscle, gizzard and heart while it was the only compound detected in fat and skin. Hydrolysis of the benzoyl urea bond resulted in the formation of fluoroaniline-label specific minor metabolites Reg. No. 4064702 and Reg. No. 241208.

The metabolite Reg. No. 4064702 was detected in yolks, liver, kidney, muscle, gizzard, and heart at 6–22% of the TRR. The minor metabolite Reg. No. 241208 was only detected in liver and kidney ($\leq 4\%$ of the TRR). The Meeting noted that liver and kidney were the only matrices that were incubated for 16 hours at 37 °C in 0.07 M phosphate buffer at pH 7.5 prior to extraction. However, the Meeting could not confirm that this metabolite is an artefact of the analytical procedure.

Additionally, one to three unknown radioactive fractions in yolks, liver and kidney extracts were detected (all below 10% of the TRR). In liver, three unknown fractions were characterized that were less polar than the reference items. The unknown fraction from yolks and kidney had a similar TLC-behaviour.

Table 9 Identification of total radioactive residues in eggs and tissues (%TRR)

Identity	Yolks	Liver	Kidney	Muscle	Gizzard	Heart	Fat	Skin
Flufenoxuron	84.9	66.3	59.6	90.4	89.5	90.3	98.2	97.2
REG. NO. 4064702	6.3	10.4	21.6	9.3	10.2	9.3	n.d.	n.d.
REG. NO. 241208	n.d.	3.7	2.5	n.d.	n.d.	n.d.	n.d.	n.d.
Total Identified	91.2	80.4	83.7	99.7	99.7	99.6	98.2	97.2
Total characterized (number of fractions)	8.8 (1)	2.9–7.6 (3)	8.9 (1)	–	–	–	–	–
Total Unidentified	–	4.0	7.4	0.3	0.3	0.4	1.8	2.8
TOTAL	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

The depuration study indicated that the radioactivity in egg yolks and muscle decreased steadily up to day 34. In kidney and liver, the decrease in radioactivity was more prominent from day 16 to day 34 of the depuration phase yet in fat, the decrease in radioactivity occurred most rapidly from day 2 to day 9 and from day 16 to day 34. These results demonstrated that radioactive residues are not retained in eggs, organs and tissues after cessation of dosing.

Overview of metabolism in livestock

In the lactating goat metabolism study, the parent flufenoxuron remained intact and was the only residue identified in milk and tissues.

In the laying hen metabolism studies, while flufenoxuron was the predominant residue in eggs and organs/tissues, cleavage of the benzoyl urea bond was observed to a limited extent resulting in the formation of minor metabolites Reg. No. 4064702 (eggs and tissues) and Reg. No. 241208 (liver and kidney).

Plant metabolism

Metabolism studies on tomato, apple, grape and Chinese cabbage were made available to the Meeting.

Grape

Grape-vine plants, variety Muller-Thurgau, grown outdoor and protected with plastic covers after application, were separately treated with [difluorobenzamide- $U-^{14}C$]- and [fluoroaniline-ring- $U-^{14}C$]flufenoxuron formulated as flowable concentrate formulations. Two foliar sprays were made during fruit development at a rate of 0.04 kg ai/ha/application with a 40-day retreatment interval. Mature samples of stalks and fruit (from grape clusters) were collected 28–29 days after last treatment (DAT), while leaves were collected at 15 DAT (immature) and 28–29 DAT (mature).

Total radioactive residues (TRRs) in leaves from the applications using difluorobenzamide-label were 2.7 mg eq/kg at 15 DAT and declined to 1.8 mg eq/kg at 29 DAT (Table 10). TRRs in mature fruit and stalks (29 DAT) were 0.014 mg eq/kg and 0.16 mg eq/kg, respectively. TRRs in leaves from applications using the fluoroaniline-label declined from 2.3 mg eq/kg at 15 DAT 1.4 mg eq/kg at 28 DAT. TRRs in mature fruit and stalks (28 DAT) were 0.012 mg eq/kg and 0.11 mg eq/kg, respectively. Overall, the distribution of radioactivity was relatively similar among both radiolabels.

Homogenized samples of fruit, leaf and stalk samples were extracted three times with methanol (MeOH) and twice with water. After each extraction step, the liquid phase was separated from the post extraction solid (PES) by centrifugation. The extracts and the dried PES were analysed by combustion for the determination of the residual radioactive residues. Aliquots of the MeOH extracts were evaporated to dryness, reconstituted in water and partitioned three times with hexane followed by three partition steps of the remaining aqueous phase with ethyl acetate. Aliquots of the organic and aqueous phases were analysed by LSC. Residues were identified by reverse-phase HPLC-UV and the identity of parent flufenoxuron was confirmed by HPLC with a Polymeric Reversed Phase (PRP-1) column.

As reported in Tables 10 and 11, approximately 95–97% of the TRR (0.012–2.6 mg eq/kg) was extracted from the grape matrices for both radiolabels. In all fruit, leaf and stalk samples (both labels), parent flufenoxuron was the only compound identified at 50–97% of the TRR (0.007–2.2 mg eq/kg). Polar unknowns comprised up to 40–46% of the TRR in mature grape samples (0.005–0.006 mg eq/kg) for both radiolabels. Unextracted residues in all leaf, fruit and stalk samples comprised $\leq 5\%$ of the TRR (< 0.11 mg eq/kg), resulting in overall accountabilities of 99–100%.

The only metabolic reaction observed in grape matrices was the breakdown of flufenoxuron to mainly polar metabolites.

Apple

Flufenoxuron uniformly labelled in the fluoroaniline ring, formulated as a dispersible concentrate, was sprayed on 10 apple trees (var. Cox's Orange Pippin), maintained in glasshouses. The trees were treated during fruit development, when fruit was approximately 20 mm in diameter, with a single application at a rate of 0.1 kg ai/hL. Samples of immature fruit were harvested 0 days (4 h post-treatment) and 46 days after treatment (DAT), and mature fruit samples were collected at 99 DAT.

Immediately after harvest, all fruit samples (0, 46 and 99 DAT) were washed sequentially with acetonitrile (ACN) and hexane. Total radioactivity was determined in the washes and the fruit by combustion/LSC. At DAT 99 four additional apples were harvested; two of these were not washed and used for autoradiography while two other apples were washed as described above and separated into peel, pulp and seeds prior to analysis.

For the characterization/identification of residues, only the surface washes from the 0 and 99 DAT samples were prepared. Washed fruit samples were extracted three times with ACN:water (7:3, v/v) and centrifuged. The supernatants were combined and partitioned twice with dichloromethane (DCM). The DCM fraction was dried under a stream of nitrogen, and resuspended in DCM for TLC analysis. For HPLC-UV analysis, the DCM was removed under nitrogen and the residue was resuspended in ACN:water (7:3, v/v). The identity of parent flufenoxuron was confirmed by HPLC with a Polymeric Reversed Phase (PRP-1) column.

Total radioactive residues (TRRs) in immature fruit were 2.6 mg eq/kg (0 DAT) and declined to 0.16 mg eq/kg (46 DAT) and 0.06 mg eq/kg (99 DAT), likely due to the increasing size of the fruit as it matured (Table 13). The surface washes accounted for 77–96% of the TRRs with unextracted residues comprising 0.3–2.5% of the TRR (0.001–0.008 mg eq/kg), resulting in accountabilities of 93–100%. Parent flufenoxuron was the only compound identified in the surface washes (74–93% of

the TRRs; 0.043–2.4 mg eq/kg) and fruit extracts (3–16% of the TRRs; 0.01–0.08 mg eq/kg). There were no residues other than the parent that were identified in the apple samples.

For the two apples separated into peel, pulp and seeds and those subjected to autoradiography, the same trend was observed whereby the majority of the radioactivity remained on the peel with limited translocation of the TRRs into the pulp and the seeds.

Tomato

[U-Aniline- ^{14}C]flufenoxuron mixed in approximately equal proportions with [aniline- ^{15}N] and formulated as an emulsifiable concentrate, was applied as a single broadcast foliar application to tomato plants (var. Moneymaker) maintained in an outdoor uncovered enclosure. The application was made during fruit development at a rate of 0.125 kg ai/ha and tomato fruit was harvested at 0 and 28 days after treatment (DAT).

Tomato fruit samples were surface washed with ACN:water (7:3, v/v) five times prior to extraction. The washed fruit were homogenized and extracted once with ACN:water (7:3, v/v) and filtered. The surface washes and extracts were diluted with water and partitioned three times with DCM. The organic phase was concentrated, then analysed by thin-layer chromatography (TLC). Radioactivity in surface washes and extracts were determined by LSC while the unextracted solid residues were subjected to combustion analysis.

Total radioactive residue (TRR) in/on tomato fruit declined from 0.38 mg eq/kg on day 0, to 0.17–0.2 mg eq/kg by day 28 (Table 15). The total extracted residues (surface washes and fruit extracts) from 0 DAT to 28 DAT, accounted for 94–99% of the TRR (0.16–0.38 mg eq/kg), mainly from the surface wash ($\geq 94\%$ of the TRRs). Unextracted residues comprised 1.1–5.8% of the TRR (0.004–0.012 mg eq/kg). Only sample II (28 DAT; 0.2 mg eq/kg) underwent identification/characterization of TRRs. Radio- TLC of the extracted radioactivity showed the parent flufenoxuron as the only identified residue, accounting for 91% of the TRR (0.18 mg eq/kg).

Chinese cabbage

[U-Aniline-¹⁴C]flufenoxuron mixed in approximately equal proportions with [aniline-¹⁵N] flufenoxuron, formulated as an emulsifiable concentrate, was applied as a single foliar application at a rate equivalent to 0.10 kg ai/ha to Chinese cabbage plants (grown outdoors) during leaf development. Cabbage plants were harvested at 0 and 28 days after treatment (DAT).

Samples of wrapper leaves were surface washed with ACN:water (7:3, v/v) five times prior to extraction. The washed leaves were homogenized, extracted (once for 0 DAT samples and twice for 28 DAT samples) with ACN:water (7:3, v/v) and filtered. The surface washes and extracts were diluted with water and partitioned three times with DCM. The organic phase was concentrated, then analysed by thin-layer chromatography (TLC). Radioactivity in surface washes and extracts were determined by LSC while the unextracted solid residues were subjected to combustion analysis.

Total radioactive residue (TRR) in/on cabbage wrapper leaves declined from 5.5–7.0 mg eq/kg (average 6.3 mg eq/kg) on day 0, to 0.33–0.36 mg eq/kg (average 0.35 mg eq/kg) by day 28. The total extracted residues (surface washes and extracts from the washed leaves) accounted for 94–97% of the TRR (0.32–6.8 mg eq/kg). However, at 0 DAT, the surface wash represented the majority of the extractable residues while at the 28 DAT, the leaf extracts accounted for much of the extractable radioactivity. Unextracted residues comprised 2.6–5.9% of the TRR (0.01–0.21 mg eq/kg). Only the 28-DAT sample (0.36 mg eq/kg) underwent identification/characterization of residues. Radio- TLC of the extracted radioactivity showed the parent flufenoxuron as the only identified residue, accounting for 93% of the TRR (0.34 mg eq/kg).

Overview of metabolic pathway in plants

The grape, apple, tomato and cabbage metabolism studies indicated that parent flufenoxuron was the only residue identified in all the tested primary crop matrices, and was found at > 90% of the TRR except grapes, where parent accounted for 50% of the TRR. No other metabolites were identified and no other residues were characterized (other than polar unknowns). The metabolism data (including autoradiography of the apple samples) indicated that the majority of radioactivity remained on the leaves or surface of the fruit, with limited translocation.

Environmental fate

The Meeting received information on, aerobic and anaerobic degradation in soil, photolysis on soil and pH based degradation. In conformance with the FAO manual 2009, only studies on aerobic degradation in soil were considered for the current evaluation. The fate and behaviour of flufenoxuron in the environment was investigated using amide-[U-¹⁴C]-ring-labelled-flufenoxuron.

Study 1

The rate of aerobic degradation of flufenoxuron in three soils at a temperature of 20 °C was investigated [Goodyear and Gross, 2001, ENV 01-030]. Samples of test soils (50 g dry weight equivalent at 45% maximum water holding capacity (MWHC)), sieved to 2 mm were dispensed into flasks and treated with amide-[U-¹⁴C]-ring-labelled-flufenoxuron at a nominal rate of 0.15 µg ai/g, corresponding to a field application rate of 150 g ai/ha. The treated soils were incubated in the dark at 20 ± 2 °C with moistened carbon dioxide free air drawn through the flasks for up to 120 hours. Volatiles in effluent air were trapped successively in ethanediol, 2% paraffin in xylene and 2 M sodium hydroxide. Samples were taken at 0, 2, 7, 14, 30, 59, 90 and 120 days after treatment (DAT). Trapping solutions were sampled and replaced on the same days.

Flufenoxuron was the only residue present at each sampling interval. The flufenoxuron concentration decreased steadily in all three soil types. At day 0, flufenoxuron represented > 99% TAR and decreased to 22–52% TAR after 120 days of incubation.

Study 2

The aerobic degradation rate of 2-fluoroaniline-[U-¹⁴C]-ring-labelled-flufenoxuron was investigated in two types of soils, while the degradation of the flufenoxuron-derived soil metabolite, ¹⁴C-Reg. No. 4064702, was investigated in four different soils [Stephen and Ebert, 2003, 83303]. Samples of test soils (40% MWHC) were dispensed into glass bottles, treated at a nominal rate of 0.05 mg ai/kg,

corresponding to a field application rate of 40 g ai/ha, and incubated in the dark at 20 ± 2 °C. Samples were taken at 0, 3, 7, 14, 30, 57, 91 and 119 days after treatment (DAT).

The amounts of extractable residues, in both soils treated with radiolabelled flufenoxuron, decreased to $\leq 50\%$ of the total applied radioactivity while the bound residues increased to 38.8–43.8% TAR. No formation of CO_2 was noted. Following treatment of four soils with the metabolite Reg. No. 4064702, less than 25.5% TAR was extractable after 119 days of incubation. The bound residues reached levels of 65–80% TAR at the end of the incubation period. In two of the soils, slow mineralization was observed, reaching 2–8% TAR at the end of incubation while in the other two soils, there was no evidence of CO_2 evolution.

When treated with radiolabelled flufenoxuron, the metabolite Reg. No. 4064702, representing the fluoroaniline moiety after cleavage of the flufenoxuron molecule, was identified by chromatographic comparison with the ^{14}C -labelled reference compound. The highest concentration of this metabolite was reached after 30 days of incubation, accounting for 4.1–8.3% TAR. Flufenoxuron decreased to 45.8–51.0% TAR in the soil after 119 days. While other peaks could be observed in the chromatograms at 119 DAT, all were below the limit of quantification (0.001 mg/kg). The DT_{50} was calculated to be in the range of 115–122 days (Table 24).

In all four tested soils treated with Reg. No. 4064702, the metabolite degraded relatively quickly reaching $< 50\%$ TAR after 57 days of incubation and 16–24% TAR after 119 days. According to the chromatograms of the extracts from sampling days 57, 91 and 119, two degradation products were detected and present at concentrations close to the LOQ. One of these appeared to be the metabolite Reg. No. 241208, DT_{50} values were in the range of 47–59 days (Table 24).

Residues in Rotational Crops

METHODS OF RESIDUE ANALYSIS

The meeting received analytical method descriptions and validation data for flufenoxuron in plant and animal commodities and in soil and water. For the majority of the methods, residues of flufenoxuron are measured by HPLC-MS/MS with two specific mass transitions or with HPLC-UV at 254–260 nm for each analyte. All methods were validated at the determined LOQs, ranging from 0.01–0.05 mg/kg depending on the matrix. A summary of the analytical methods for plant and animal commodities and environmental media is provided below.

A number of scientific papers report the validation of the QuEChERS multiresidue method using GC-MS/MS for flufenoxuron in various plant commodities.

Plant materials

Method RLA 12675 involves extraction of flufenoxuron residues from finely chopped fruit with dichloromethane. An aliquot of the extract is evaporated to dryness, reconstituted in cyclohexane, and then partitioned with water. An aliquot of the cyclohexane phase is taken, evaporated to dryness, reconstituted in acetonitrile:methanol:water (58:10:32, v/v/v), and analysed by LC-MS/MS using the positive ionization mode monitoring ion transitions m/z 498→158 (for quantitation) and m/z 498→141 (for confirmatory purposes).

The applicability of the method was confirmed in an independent laboratory by Schulz (2004, 2004/1000759) and Saha (2008, 2008/7012012). In both laboratories, parent flufenoxuron was analysed with a validated LOQ of 0.05 mg/kg (Table 27).

Animal materials

Method SAMS 486-1 involves treating a sample of milk with potassium oxalate solution and ethanol followed by extraction with diethyl ether and hexane. The diethyl ether is removed by evaporation and the hexane is partitioned with acetonitrile. The acetonitrile is exchanged for a mixture of hexane, ethanol and acetic acid and cleaned-up by normal phase HPLC. Residues of flufenoxuron are determined by reverse-phase HPLC with UV detection at 254 nm.

The applicability of the method was confirmed by an independent laboratory by Skorczynski (1997, RES 97-027) where parent flufenoxuron was analysed with a validated LOQ of 0.01 mg/kg (Table 29).

Table 29 Independent laboratory recovery results of method SAMS 486-1

Matrix	Fortification level [mg/kg]	No. of tests	Range of Recoveries [%]	Mean Recovery [%]
Milk	0.01	2	84–85	85
	0.02	2	89–110	100

Method SAMS 458-1, involves extracting residues of flufenoxuron in fat with methylene chloride and sodium sulphate, followed by evaporation to dryness, then re-dissolving the residue in hexane followed by solid-phase extraction clean-up and reversed-phase HPLC-clean-up. Determination of residues of flufenoxuron is performed by normal-phase HPLC with UV-detection at 254 nm.

The applicability of the method was confirmed in an independent laboratory by Skorczynski (1997, RES 97-037) where parent flufenoxuron was analysed with a validated LOQ of 0.05 mg/kg (Table 30).

Table 30 Independent laboratory recovery results of method SAMS 458-1

	0.1	2	77–81	79

STABILITY OF PESTICIDES IN STORED SAMPLES

Plant materials

The storage stability of flufenoxuron has been investigated in various plant matrices for a storage period of up to 36 months.

The storage stability of flufenoxuron was investigated in cottonseed, orange, grape and apple for up to 36 months (Gillard, D.F., 1993a, FX-326-004), in lettuce for 27 months (Edwards, 2000?a, 2000/1021958; Farrell, 1996a, FX-726-003) and in watermelon peel and pulp for 25–26 months (Edwards, 2000b, 2000/1021961; Edwards, 2000c, 2000/1021962).

Homogenised samples were weighed into glass jars and fortified individually at levels of 0.1 mg/kg (cottonseed, orange, grape and apple) and 0.5 mg/kg (lettuce, watermelon peel and pulp). After fortification, the solvent was allowed to evaporate. In addition, untreated samples of each sample material were prepared for control and recovery experiments. Subsequently the jars were closed and stored deep frozen until analysis (except for the day 0 samples). At each sampling interval, 2–3 fortified and two control samples were removed from the deep-freezer. Subsequently, one of the control samples of each sample material was freshly fortified with flufenoxuron to determine the concurrent recoveries. Fortification levels were at the same magnitude as the spiked storage samples.

The grape and apple samples were analysed according to the Analytical Method SAMS 423-3. Briefly, flufenoxuron is extracted from the samples by blending with methylene chloride and sodium sulfate. An aliquot of the extract was concentrated to dryness and cleaned up by solid phase extraction prior to HPLC analysis.

The cottonseed and orange samples were analysed according to the Analytical Method SAMS 454-1 where flufenoxuron was extracted by blending with acetone:hexane (v:v) and sodium sulphate. An aliquot of the extract was concentrated to dryness, reconstituted in acetonitrile and partitioned with hexane. The acetonitrile phase was cleaned up by solid phase extraction prior to HPLC analysis.

Lettuce samples were analysed using Analytical Method RLA 12466.00V while watermelon peel and pulp samples were analysed using Analytical Method RLA 12482.00V. No description was provided of either method.

No significant degradation of the flufenoxuron residues was observed in cottonseed, orange, grape and apple up to 36 months of storage, in lettuce for 27 months and watermelon (pulp and peel) for up to 26 months (Table 31).

Animal Materials

For animal matrices, the storage stability of flufenoxuron has been investigated for a storage period of up to 12 months (Lewis 1993a, FX-326-003).

The freezer stability of flufenoxuron in various animal matrices was investigated over a period of one year (53 weeks). Untreated bovine muscle, liver, kidney, fat and milk and hen skin, egg yolk and egg white samples were fortified with radiolabelled flufenoxuron at three different concentrations. The samples were stored at -19 °C. All beef and hen skin samples were analysed according to the Analytical Method SAMS 457-2 with a slight modification for extracting heparin-treated blood. Egg yolk and egg white samples were analysed according to the Analytical Method SAMS 492-1. Cow's milk samples were analysed based on the Analytical Method SAMS 486-1. Residues were analysed by TLC, HPLC-UV and LSC.

No significant degradation of the flufenoxuron residues was observed in any of the animal matrices except egg whites where a steady decline was noted by 53 weeks (31% dissipation).

USE PATTERN

Flufenoxuron is a new benzoylurea type of acaricide/insecticide which inhibits chitin biosynthesis in nymphal mites and caterpillars. Flufenoxuron is registered in Brazil and in Japan as an emulsifiable concentrate (EC).

The Meeting received the registered label from Brazil for orange, apple and from Japan for tea in the original languages as well as the English translations.

Table 33 List of uses of flufenoxuron

Crop	Country	Application			Application rate per treatment			PHI [days]
		Method	No. per season	Application interval [days]	kg ai/hL	Water L/ha	kg ai/ha	
Orange	Brazil	spray	2	30	0.003–0.005	—	—	15
Apple	Brazil	spray	—	—	0.01	1200–2000	—	35
Tea	Japan	spray	2	7–14	0.0025	2000–4000	0.05–0.1	7

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue levels were reported as measured. Application rates were always reported as flufenoxuron equivalents. When residues were not quantifiable they are shown as below the LOQ, e.g., < 0.01 mg/kg.

Application rates and spray concentrations have generally been rounded to two significant figures.

All samples were analysed using either an HPLC-UV method (254 nm) which involved extraction with DCM and sodium sulphate and a validated LOQ of 0.05 mg/kg or an HPLC/MS/MS method involving extraction with methanol/water/HCl and partitioning in water cyclohexane with an LOQ of 0.01 mg/kg.

Laboratory reports included method validation including batch recoveries at fortification levels bracketing the LOQ, 10× LOQ and 100× LOQ. Dates of analyses or duration of residue sample storage were also provided. These storage intervals were covered by the storage stability studies on parent in high oil, high acid and high water content matrices.

Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables as residues in control samples were below the method LOQ. Residue data are recorded unadjusted for % recovery. Where multiple samples were taken from a single plot or where multiple analyses were conducted for the same sample, the average value is reported, with the individual

values captured in brackets. Residues from trials conducted according to critical GAP are underlined and have been used for the estimation of maximum residue levels, STMR and HR values.

Crop	Field/Greenhouse	Treatment Type	Countries	Table
Orange	Field	Foliar spray	Brazil, Greece, Italy, South Africa	34
Apple	Field	Foliar spray	Chile	35
Tea	Field	Foliar spray	Japan	36

Oranges

Eleven supervised residue trials were conducted during 1986, 2007 and 2011 on oranges grown in Brazil and treated once or twice with a soluble concentrate (SL) or dispersible concentrate (DC) formulation of flufenoxuron at rates of 0.003–0.005 kg ai/hL. Oranges were harvested 0–28 days following the last application. In the 1986 trials, residues are reported in peel and pulp based on ratios of 37% peel and 63% pulp. For the remaining trials, the residues are reported on a whole fruit basis.

Five additional orange trials, involving application of a DC formulation, were also conducted in Greece (two; 1996), Italy (one, 1996) and South Africa (two; 1989). The number of applications and treatment rates for Greece, Italy and South Africa were 2× 0.005 kg ai/hL, 2× 0.008 kg ai/hL and 1× 0.005 kg ai/hL, respectively. Oranges were harvested 0–28 days following the last application and separated into peel and pulp prior to analysis.

Melons

Melons, grown in Brazil during the 2010 season, received four applications of a DC formulation of flufenoxuron at 0.01 kg ai/hL, with 4–7 day re-treatment intervals, and harvested 0–10 days following the last application. For some trials, residues in pulp and peel were determined from whole fruit, based on a ratio of 40% peel and 60% pulp.

Tomato

Tomatoes, grown in Spain during the 2008 season and maintained under protective cover, were treated twice with a DC formulation of flufenoxuron at 0.12–0.13 kg ai/ha and 14 day re-treatment interval. Mature tomatoes were harvested 0–7 days following the last application.

During the 2008 season, field tomatoes grown in Brazil were treated with four applications of a DC formulation of flufenoxuron at 0.01 kg ai/hL and a 7-day re-treatment interval. Tomatoes were harvested 0–7 days following the last application.

Tea

Eleven trials conducted on tea, grown in Japan during the 2005–2007 growing seasons, were treated twice or five times with an EC formulation of flufenoxuron at a rate of 0.0025 kg ai/hL. The re-treatment intervals were not specified in the study report. Tea leaves were harvested 1–14 days following application. On the day of sampling, tea leaves were processed in accordance with the standard green tea processing procedure and individually tightly sealed in a tea can prior to transportation

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of residue during processing

The hydrolysis of flufenoxuron under processing conditions was investigated by Hassink, J. (2003/1000985). [Difluorobenzamide-ring-U-¹⁴C]-flufenoxuron and [fluoroaniline-ring-U-¹⁴C]-flufenoxuron were diluted in sterile buffered aqueous solution at a nominal concentration of 1 µg ai/L, which corresponds to approximately 50% of the water solubility (at pH 4). Incubation was done at three representative sets of hydrolysis conditions: 90 °C, pH 4 for 20 minutes (pasteurisation); 100 °C, pH 5 for 60 minutes (baking, brewing and boiling) and 120 °C, pH 6 for 20 minutes (sterilisation).

Parent compound and potential hydrolysis products were identified and quantified by HPLC-UV.

Thin layer chromatography was used for confirmation of the identity of the test item by co-chromatography with the non-labelled reference item. Material balances were established for each set of hydrolysis conditions.

Figure 1 Pathway of hydrolysis of flufenoxuron

Residues after processing

The fate of flufenoxuron during processing of raw agricultural commodity (RAC) was investigated in tomatoes and tea using commercial processing procedures. As a measure of the transfer of residues into processed products, a processing factor (PF) was used, defined as:

$$PF = \frac{\text{Total residue in processed product (mg/kg)}}{\text{Total residue in raw agricultural commodity (mg/kg)}}$$

If residues in the RAC were below the LOQ, no processing factor could be derived. In case of residues below the LOQ, but above the LOD in the processed product, the numeric value of the LOQ was used for the calculation. If residues in the processed product were below the LOD, the numeric value of the LOQ was used for the calculation but the PF was expressed as “less than” (e.g. < 0.5).

A summary of all processing factors for flufenoxuron relevant for the estimation of maximum residue levels of the dietary intake is given in Table 41.

Tomato

Study 1

During the 2002 growing season, four field trials were conducted in field tomatoes in different representative growing areas in southern France and Spain (Smalley R., 2003a; 2003/1004346). The treatment program consisted of three foliar applications of a 100 g/L DC formulation of flufenoxuron at a rate of 0.62 kg ai/ha/application. The tomatoes were harvested 6–7 days following the last application, washed and processed according to commercial practices into pomace, juice, sauce and canned tomatoes.

All samples were analysed for flufenoxuron according to method RLA 12675. The limit of quantitation (LOQ) was 0.05 mg/kg.

Samples of processed commodities were stored for up to 600 days prior to analysis of flufenoxuron which is within the demonstrated storage interval for the parent compound in high oil, high acid and high water content matrices.

In the following table, the residues found in processed products are summarised.

Table 41 Residues of flufenoxuron in processed tomato commodities and calculation of processing factors

^b n.a. = sample was not analysed

^c Raw juice is also added to peeled tomatoes during the process of canning

Study 2

A processing study was conducted in Southern France to determine the residue levels of flufenoxuron and the metabolites Reg. No. 4064702, Reg. No. 102719, Reg. No. 206925, Reg. No. 241208, Reg. No. 4064703 and Reg. No. 4964847 in tomato RAC and processed fractions including canned tomatoes, tomato puree and tomato juice (Ertus, C., 2013; ANADIAG).

The treatment program consisted of a single foliar application of a 100 g/L formulation of flufenoxuron at a rate of 0.5 kg ai/ha made 7 days prior to harvest at the growth stage BBCH 89.

The tomatoes were washed and processed according to the following commercial practices:

For juice production, approximately 8 kg of tomatoes were roughly cut and blended. The mixture obtained was filtered through a fine sieve to separate the juice from peels and seeds. The Brix degree and the pH of the raw juice were determined and the raw juice was heated to 95 °C for 5 minutes. Subsamples of pasteurized juice were stored frozen until analysis.

For production of tomato puree, a juice sample was concentrated under vacuum and gentle heating to 60 °C until reaching a Brix degree of 12. The obtained puree was pasteurized by heating to 95 °C for 5 minutes in a can.

For canning, approximately 2 kg of tomatoes were submerged for about 60 seconds in boiling water and transferred into cold water for 20 seconds to crack the peel. After peeling, subsamples were transferred into glass preserving jars, which were filled up with water, closed and submitted to sterilization. After cooling, canned tomatoes were blended and subsamples were stored frozen until analysis.

All samples were analysed for flufenoxuron and the metabolites according to a method adapted from 'Flufenoxuron: Development and Validation of an Analytical Method for Determination and Confirmation of BAS 307I (Flufenoxuron) and its Degradates in Grape—PTRL Europe Study No.P/B1206G'. Briefly, residues were extracted using a mixture of methanol, water and HCl. The centrifuged extract was analysed by LC/MS/MS. The limit of quantification (LOQ) was reported to be 0.01 mg/kg.

Samples of processed commodities were stored for up to 33 days prior to analysis of flufenoxuron and all metabolites which is within the demonstrated storage interval for the parent compound in high oil, high acid and high water content matrices.

In the following table, the residues found in processed products are summarised.

Table 42 Residues of Flufenoxuron and associated metabolites in processed tomato commodities and calculation of processing factors

^a Only processing factors for flufenoxuron were reported as residues of all other metabolites were not detected above the limit of quantitation (0.01 mg/kg).

Tea

Two residue trials were conducted in 1990 in Kyoto and Kagoshima, Japan (Class, T., 2007a). Flufenoxuron was applied either once or twice at a rate of 0.0025 kg ai/hL and leaves were harvested 7–14 days following application.

An infusion was prepared from the treated dried green tea leaves by adding 360 mL boiling water to 6 g tea and leaving to stand for five minutes.

Dried tea (green) leaves and tea infusion were analysed using the HPLC-UV method titled Pesticide Residue Analysis for Crop (Shell Corporation, 1996). In summary, the method involves extracting flufenoxuron residues with acetone, in the presence of zinc acetate. The filtrates were extracted with ethyl acetate and subjected to hexane/acetonitrile partition after which the acetonitrile phase is purified using a florisil cartridge prior to HPLC–UV analysis. The limit of quantitation for both tea leaves and tea infusion was reported as 0.02 mg/kg, each.

Samples of tea leaves and tea infusion were stored for up to 108 days prior to analysis of flufenoxuron which is within the demonstrated storage interval for parent in high oil, high acid and high water content matrices.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

For the estimation of residues of flufenoxuron in animal matrices lactating cow and laying hen feeding studies were submitted to the Meeting.

Lactating dairy cattle

Residues of flufenoxuron in lactating cows were investigated by Gilland Pack (1993). Flufenoxuron was administered orally to fifteen lactating Friesian dairy cows (three cows/control and treatment group and a depuration group consisting of three cows), between 4–7 years of age and in the weight range of 466–602 kg, for 90 consecutive days. Based on a feeding rate of approximately 20 kg/day, dose levels were 1.75, 5.25 and 17.5 mg/kg feed corresponding to 0.07, 0.21 and 0.7 mg/kg bw/day. Animals were dosed twice daily at half of the daily rate at each milking. The average daily milk production ranged from 13–21 kg starting 14 days prior to dosing up to the last day of dosing. The fat content of milk samples taken on days 7, 28, 56 and 90 of the study ranged from 2.5–4.3%.

Milk was collected twice daily. At the end of the dosing period, two composite milk samples were taken for processing to pasteurized milk, cream, skimmed milk and acid whey.

Three animals from the highest dose level group and one control animal were monitored for flufenoxuron residues over a 40-day depuration phase. Milk from these animals was sampled during the depuration period.

Approximately one day after the last day of dosing, the animals, with the exception of the cows of the depuration group, were sacrificed and liver, kidney, composite muscle (pectoralis/adductor muscle of thigh) and perirenal fat (perirenal/omental) were collected for analysis.

Analysis of the samples of milk and milk products was performed using the Analytical Method SAMS 486-1 with minor modifications. The limit of quantitation of this method for flufenoxuron in milk and milk products was reported to be 0.001 mg/L based on acceptable concurrent recoveries. Analysis of the bovine tissues was carried out in duplicate according to a slightly modified version of the Analytical Method SAMS 457-2. The lowest limit of method validation for flufenoxuron in animal tissues is 0.10 mg/kg for muscle, liver and kidney and 0.30 mg/kg for fat based on acceptable concurrent recoveries.

Residues of flufenoxuron in milk are presented in the following table:

Table 44 Residues of Flufenoxuron in milk after administration of Flufenoxuron at 1.75, 5.25 or 17.5 mg/kg feed/day

^a Mean values of three animals

^b Mean values of six animals, three animals during depuration phase

Pasteurised milk, cream, skimmed milk and acid whey were prepared from pooled control milk (group A) and from pooled milk from the high-dose group (D) at the end of the 90 day dosing period. The mean results of the analyses of those milk products for both treatment groups are summarised in Table 45.

Table 45 Mean residues of Flufenoxuron in milk products after 90 days of dosing.

Product	Mean residues of flufenoxuron in milk products [mg/L]	
	Group A (Control)	Group D (17.5 mg/kg diet)
Raw Milk	0.001	5.5
Pasteurized Milk	0.012	6.4
Cream	0.007	28
Skimmed Milk	< 0.001	0.18
Acid Whey	< 0.001	0.06

Analysis of milk obtained from the high dose group showed that pasteurization had no effect on the levels of flufenoxuron in milk. Residues in cream were concentrated by a factor of 1.5. In skimmed milk and acid whey, residues were reduced compared to the raw milk.

The mean residue levels and individual sample residues in tissues are summarized in Table 46 for each treatment group.

^a Only one control animal was sacrificed at the end of the 90-day dosing period

^b Mean of three animals; for each animal two separate analyses were conducted for each tissue

Laying hen

Seventy five white female Leghorn laying hens (three subgroups per control and treatment group, five hens per subgroup; the depuration group consisted of three subgroups of five hens/subgroup), aged 8–9 months and weighing 1303–1896 g, were dosed orally (gavage) once daily with flufenoxuron for 50 consecutive days at 1, 3 and 10 mg/kg feed, based on a daily consumption of 150 g/bird/day, equivalent to 0.15, 0.45 and 1.5 mg/kg bw/day. The average lay efficiency was 0.5 egg/hen/day.

Eggs were collected daily and separated into yolks and whites then pooled by subgroup (of five hens), resulting in three replicate daily samples per treatment group.

Fifteen animals from the top dose group and ten animals from the control group were monitored for flufenoxuron residues over a 40-day depuration phase. Eggs from these animals were sampled during the depuration period.

One day after the last day of dosing (day 40), the birds, with the exception of those of the depuration group, were sacrificed and samples of skin, muscle (breast, leg and thigh pooled), fat and liver (total organs) were taken separately for analysis and subdivided into two subsamples per subgroup.

The egg and tissue samples were analysed for residues of flufenoxuron using Analytical Method SAMS 492-1 and Analytical Method SAMS 457-2, respectively. The limit of quantitation for flufenoxuron is 0.25 mg/kg in egg yolk and 0.05 mg/kg in egg white and tissues based on acceptable concurrent recoveries. The liver samples were also analysed for the metabolite Reg. No. 4064702 using the HPLC/UV Analytical Method 01791.PCC with a limit of quantitation 0.03 mg/kg.

Egg white and yolk samples were analysed separately. Unless otherwise identified, in the majority of cases, no residues of flufenoxuron in egg white exceeded 0.05 mg/kg. The mean residue levels and range of residues in egg yolks are summarized in Table 47.

Table 47 Residues of Flufenoxuron in egg yolks.

Study Day	Mean (range) residues for flufenoxuron in egg yolks (mg/kg)

90	< 0.25 ^b	–	–	2.27 (2.07–2.47) ^c

^a The sample of Group B collected on Day 14 was the only egg sample in which Flufenoxuron was also detected in egg white (group mean residue of 0.13 mg/kg, but detected only in one out of three subgroups (subgroup B2)); in each other egg white sample analysed (Day –3 to Day 50), the Flufenoxuron concentration was below 0.05 mg/kg

^b During the depuration period, only the eggs of one control subgroup (5 hens) were analysed

^c During the depuration period, only the eggs of 15 hens at the highest dose level were analysed

The mean and range of residue concentrations of flufenoxuron in hen tissues are listed in Table 48.

Table 48 Residues of Flufenoxuron in tissues

Tissue type	Mean (range) residues of Flufenoxuron in tissues [mg/kg]

APPRAISAL

Flufenoxuron is a benzylurea insect growth regulator used to kill mites and insects, through interference with chitin production during cuticle development in mite and insect juvenile stages, on various orchard crops, fruiting vegetables and tea. It was considered for the first time by the 2014 JMPR for toxicology and residues.

The Meeting received information on physical chemical properties, livestock and plant metabolism, environmental fate, analytical methods, storage stability, supervised residue trials, use patterns, processing and livestock feeding.

The IUPAC name of flufenoxuron is N-{4-[2-chloro-4-(trifluoromethyl)phenoxy]-2-fluorophenyl}-N'-(2,6-difluorobenzoyl)urea and the CA name is N-[[[4-[2-chloro-4-(trifluoromethyl)phenoxy]-2-fluorophenyl]amino]carbonyl]-2,6-difluorobenzamide.

Common chemical names, code names and structures of the parent and metabolites are captured below:

Code	Structure	Occurrence
Flufenoxuron WL 115110		Rat Lactating goat Laying hen Grape Apple Tomato Chinese cabbage Soil Hydrolysis study
Reg. No. 4064702		Rat Laying hen Soil Hydrolysis study
Reg. No. 241208		Rat Laying hen Hydrolysis study
Reg. No. 4064703 (chloride salt of Reg. No. 241208)		Hydrolysis study
Reg. No. 102719		Rat Hydrolysis study

Code	Structure	Occurrence
Reg. No. 206925		Rat Hydrolysis study
Reg. No. 4964847		Hydrolysis study

Flufenoxuron uniformly labelled in either the fluoroaniline or difluoroamide rings was used in the metabolism and environmental fate studies.

Fluoroaniline U-¹⁴C

Difluoroamide U-¹⁴C

Animal metabolism

Information was available on the metabolism of flufenoxuron in laboratory animals, lactating goats and laying hens.

Metabolism studies in rats demonstrated that unchanged flufenoxuron accounted for the majority of the total applied radioactivity (TAR) in faeces, with minor metabolites (less than 1% of the TAR) identified as 2-amino-5-(2-chloro- α,α,α -trifluoro-p-tolyoxy)-3-fluorophenol (Reg. No. 4110959), Reg. No. 4064702, Reg. No 241208, Reg. No 102719 and Reg. No. 206925. For organs and tissues, parent flufenoxuron was the main component observed.

In the lactating goat metabolism study, one goat received four daily doses of 2-fluoroaniline-[U-¹⁴C]-ring-labelled flufenoxuron at a rate equivalent to 10 ppm in the diet (10 mg/day). The animal was sacrificed 24 hours after administration of the last dose. While the majority of the radioactivity was excreted via the faeces (18% of the TAR) and urine (2.5% of the TAR), milk and tissues accounted for $\leq 10\%$ of the TAR. Total recovered radioactivity was low (33%). No explanation for the low recovery was evident.

The total radioactive residues (TRRs) were highest in fat (1.6 mg eq/kg), followed by liver (0.37 mg eq/kg), kidney (0.13 mg eq/kg) and muscle (0.076 to 0.1 mg eq/kg). Milk residues peaked on day 4 (average of 0.27 mg eq/L) with the highest concentrations of radioactivity detected in the cream fraction (accounting for 82–93% of the TRR in whole milk) and the lowest found in whey (1.3–5.7% of the TRR). Following solvent extraction, residue extractabilities were 66–100%. In milk

and all tissues sampled, the flufenoxuron molecule remained intact with no other metabolites being detected.

Two studies on metabolism in laying hens were available. In the first study, the laying hens received 14 daily doses of flufenoxuron, uniformly labelled in the difluoroamide or fluoroaniline rings, at 13–14 ppm in the feed. The animals were sacrificed approximately 23 h after the last dose. Excreta accounted for 72–78% of the TAR. No plateau was reached in eggs during the dosing period (14 days); however, the radioactivity in eggs and tissues amounted to 1.0–1.3% and 2.6–3.6% of the TAR, respectively. Among all the tissues analysed, radioactive residues were highest in fat (5.0–5.3 mg eq/kg) followed by liver (0.6–1.1 mg eq/kg) and muscle (0.3–0.4 mg eq/kg). The total recovery of radioactivity was 82% and 77% in the groups administered the difluoroamide- and fluoroaniline-labelled flufenoxuron, respectively.

Solvent extraction released 91–102% and 88–99% of the TRRs for the difluoroamide- and fluoroaniline-label, respectively. While the lowest extractability occurred in the liver of the fluoroaniline-labelled study (88% of the TRR), microwave extraction of the liver post-extraction solid (PES) sample released another 8% of the TRR. For the difluoroamide-label, the parent was the only analyte identified in eggs, muscle, fat and liver ranging from 0.28 mg eq/kg (86.5% of the TRR, muscle) to 4.6 mg eq/kg (91.4%, fat).

For the fluoroaniline-label, the parent compound accounted for the majority of the TRRs (70–91%) in the eggs, muscle, fat and liver. The lowest level of parent was found in muscle (0.30 mg eq/kg) with the highest observed in fat (4.8 mg eq/kg). In eggs and liver, Reg. No. 4064702 was present at 0.10 mg eq/kg and 0.13 mg eq/kg (12.0% and 12.6% of the TRR, respectively) while in muscle and fat, Reg. No. 4064702 was a minor metabolite amounting to 0.02 mg eq/kg and 0.05 mg/kg, respectively (5.5% and 1.0% of the TRR). The formate derivative of Reg. No. 241208 was released from the PES of liver after microwave treatment in the presence of formic acid/acetonitrile. The radioactivity associated with this derivative amounted to 0.04 mg eq/kg (3.3% TRR). The Meeting could not confirm whether the metabolite Reg. No. 241208 is an actual in-vivo metabolite or an artefact formed during microwave treatment.

In the second study, laying hens received seven consecutive daily doses of flufenoxuron uniformly labelled in the fluoroaniline ring at a rate equivalent to 10 ppm in the diet. Hens were sacrificed 22 hours following administration of the last dose. To investigate the depuration behaviour of flufenoxuron, four groups of three laying hens each were sacrificed at 2, 9, 16, and 34 days after the last administration.

On average, 26% of the TAR was excreta-related with eggs, sampled from 0–166 h after the first administration, accounting for 5% of the TAR. At sacrifice, the highest amount of radioactive residues was detected in fat (47% of the TAR), followed by skin (12% of the TAR), muscle (4% of the TAR), liver (2% of the TAR), kidney (0.3% of the TAR), heart and gizzard (combined 0.2% TAR). The recovery of radioactivity amounted to 96% of the TAR.

Solvent extraction (including incubation of liver and kidney samples at 37 °C) released 91–102% of the TRRs). The parent compound was the predominant analyte detected in yolks, liver, kidney, muscle, gizzard and heart while it was the only compound detected in fat and skin. The metabolite Reg. No. 4064702 was detected in yolks, liver, kidney, muscle, gizzard, and heart at 6–22% of the TRR, while the minor metabolite Reg. No. 241208 was only detected in liver and kidney at ≤ 4% of the TRR, the only matrices that were incubated for 16 hours at 37 °C in 0.07M phosphate buffer at pH 7.5 prior to extraction

In the depuration study, radioactivity in egg yolks decreased steadily from a mean of 0.02 mg eq./kg, 2 days after cessation of dosing to 0.006 mg eq/kg on depuration day 34. Similarly, radioactivity in muscle decreased from 0.28 mg eq/kg to 0.06 mg eq/kg, during this same interval. In kidney and liver, the decrease in radioactivity was more prominent from day 16 to day 34 of the depuration phase (kidney; 0.48 mg eq/kg to 0.17 mg eq/kg and liver; 0.89 mg eq/kg to 0.42 mg eq/kg) yet in fat, the decrease in radioactivity occurred most rapidly from day 2 to day 9 (13.18 mg eq/kg to 6.00 mg eq/kg) and from day 16 to day 34 (4.6 mg eq/kg to 1.97 mg eq/kg). These results

demonstrate that radioactive residues are not retained in eggs, organs and tissues after cessation of dosing.

In both laying hen studies, the metabolic pattern was comparable with unchanged flufenoxuron accounting for the majority of the radioactivity, representing $\geq 60\%$ of the TRRs in eggs and tissues. The minor metabolites Reg. No. 4064702 (eggs and tissues) and Reg. No. 241208 (liver and kidney), resulting from the cleavage of the benzoyl urea bond, were also observed to a limited extent ($\leq 12\%$ of the TRRs; except in the kidney where Reg. No. 4064702 represented 22% of the TRRs).

The Meeting concluded that in the lactating goat metabolism study, the parent flufenoxuron remained intact and was the only residue identified in milk and all tissues. In the laying hen metabolism studies, while flufenoxuron was the predominant residue in eggs and tissues, cleavage of the benzoyl urea bond was observed to a limited extent resulting in the formation of the metabolites Reg. No. 4064702 (eggs and tissues) and Reg. No. 241208 (liver and kidney), which were also identified in the rats.

Plant metabolism

The Meeting received metabolism studies for flufenoxuron following foliar applications of either [difluorobenzamide- U - ^{14}C]- or 2-fluoroaniline-[U - ^{14}C]-ring-flufenoxuron to grape, apple, tomato and Chinese cabbage.

Two foliar sprays were made to grape vines, grown outdoor and protected with plastic covers after application, during fruit development; at a rate of 0.04 kg ai/ha/application, with a 40-day retreatment interval, resulting in a total rate of 0.08 kg ai/ha. Immature leaves were collected at 15 DAT (days after last treatment) while mature leaves, stalks and fruit (from grape clusters) were harvested 28–29 DAT. TRRs in leaves declined from 2.3–2.7 mg eq/kg at 15 DAT to 1.4–1.8 mg eq/kg at 29 DAT. TRRs in mature fruit and stalks were 0.012–0.014 mg eq/kg and 0.11–0.16 mg eq/kg, respectively. Solvent extraction released approximately 95–97% of the TRR (0.012–2.6 mg eq/kg) from the grape matrices. Flufenoxuron was the only compound identified in all fruit, leaf and stalk samples (50–97% of the TRR; 0.007–2.2 mg eq/kg). Polar unknowns comprised up to 40–46% of the TRR in mature grape samples (0.005–0.006 mg eq/kg) with unextracted residues in all leaf, fruit and stalk samples accounting for $\leq 5\%$ of the TRR (< 0.11 mg eq/kg).

Ten apple trees, maintained in glasshouses, were sprayed with flufenoxuron, uniformly labelled in the fluoroaniline ring. A single application of the dispersible concentrate was made to trees, during fruit development, at a rate of 0.01 kg ai/hL. Samples of immature fruit were harvested 0 days (4 h post-treatment) and 46 days after treatment (DAT), and mature fruit samples were collected at 99 DAT. TRRs in immature fruit were 2.6 mg eq/kg (0 DAT) and declined to 0.16 mg eq/kg (46 DAT) and 0.06 mg eq/kg (99 DAT). The radioactivity in the combined acetonitrile and hexane surface washes decreased with increasing DAT, from 96% of the TRRs at 0 DAT to 77% of the TRRs at 99 DAT, with a corresponding increase in TRRs in fruit extracts (3.7% TRR at 0 DAT to 23% of the TRRs at 99 DAT), demonstrating limited translocation. The parent flufenoxuron accounted for the majority of the TRRs in surface washes (74–93%; 0.043–2.4 mg eq/kg) and in fruit extracts (3–16% of the TRRs; 0.01–0.08 mg eq/kg).

A single broadcast foliar application of 2-fluoroaniline-[U - ^{14}C]-ring-flufenoxuron, formulated as an emulsifiable concentrate, was made to tomato plants, maintained outdoor, during fruit development at a rate of 0.125 kg ai/ha. Tomato fruit was harvested at 0 and 28 DAT. TRRs in/on tomato fruit declined from 0.38 mg eq/kg on day 0, to 0.2 mg eq/kg by day 28. The total extracted residues (ACN:water surface washes and fruit extracts) from 0 DAT to 28 DAT, accounted for 94–99% of the TRR (0.16–0.38 mg eq/kg), mainly from the surface wash ($\geq 94\%$ of the TRRs). Flufenoxuron was the only identified residue in the mature tomato sample (91% of the TRRs).

2-Fluoroaniline-[U - ^{14}C]-ring-flufenoxuron, formulated as an emulsifiable concentrate, was applied once to Chinese cabbage plants, grown outdoor, during leaf development, as a foliar application, at a rate equivalent to 0.10 kg ai/ha. Cabbage plants were harvested at 0 and 28 DAT.

TRRs in/on cabbage wrapper leaves declined from 6.3 mg eq/kg on day 0 to 0.35 mg eq/kg by day 28. At 0 DAT, the surface wash represented the majority of the extracted residues (84% of the TRRs; 5.3 mg eq/kg) while at the 28 DAT, the leaf extracts accounted for a greater fraction of the extractable radioactivity (76% of the TRRs; 0.27 mg eq/kg). The parent flufenoxuron was the only identified residue in mature cabbage leaves (93% of the TRRs).

The Meeting concluded that the metabolism of flufenoxuron in grape, apple, tomato and Chinese cabbage is consistent among all crops, where parent flufenoxuron remained intact. No other metabolites were identified and no other residues were characterized (other than polar unknowns). The Meeting agreed that the majority of radioactivity remained on the leaves or surface of the fruit, with limited translocation.

Environmental fate in soil

The Meeting received information on aerobic degradation in soil.

In these studies, the fluoroaniline-specific metabolite, Reg. No. 4064702, was the only metabolite identified, reaching a maximum concentration after 30 days of incubation (4.1–8.3% TAR). The predominant residue, flufenoxuron, decreased to 45.8–51.0% TAR in the soil after 119 days, resulting in a calculated DT_{50} for flufenoxuron of 115–122 days. Considering the persistence of flufenoxuron, it is desirable that confined rotational crop and field accumulation studies be submitted.

Methods of residue analysis

The Meeting received analytical methods for the analysis of flufenoxuron in plant and animal commodities. The basic principle for plant commodities employs extraction by homogenisation with dichloromethane, methanol/water/HCl or acetone followed by partitioning with water/cyclohexane. For animal matrices, flufenoxuron residues are extracted by homogenization with various non-polar organic solvents followed by liquid partitioning and/or clean-up by normal-phase or reverse-phase HPLC prior to analysis. Residues of flufenoxuron are measured by HPLC-MS/MS with two specific mass transitions or with HPLC-UV at 254–260 nm. The applicability of the proposed enforcement methods was confirmed in various independent laboratories where parent flufenoxuron was analysed with validated LOQs of 0.05 mg/kg for plant and animal commodities and eggs, and 0.01 mg/kg for milk.

The multiresidue method DFG S-19 was tested, for the analysis of flufenoxuron in animal matrices only, and found to be unsuitable.

A number of scientific papers report the validation of the QuEChERS multi-residue method using GC-MS/MS for flufenoxuron in various plant commodities.

The Meeting concluded that the available enforcement analytical methods are suitable for determining residues of flufenoxuron in plant and animal commodities with LOQs, ranging from 0.01–0.05 mg/kg depending on the matrix.

Stability of residues in stored analytical samples

Based on the storage stability data submitted, the Meeting concluded that no significant dissipation of flufenoxuron residues was observed in cottonseed, orange, grape, and apple after 36 months of storage, in lettuce after 27 months and in watermelon (pulp and peel) after 26 months.

The Meeting agreed that no degradation of flufenoxuron residues was observed in animal matrices stored for up to 53 months of storage, except egg whites, where flufenoxuron residues were determined to be stable for up to 4 months.

Definition of the Residue

In the lactating goat metabolism study, flufenoxuron was the only residue identified in tissues and milk with no other metabolites detected. Similarly, in the laying hen metabolism studies, flufenoxuron

accounted for the majority of the radioactivity in eggs, muscle, fat, liver and kidney (60–104% of the TRRs).

Therefore, the Meeting recommends the residue definition for compliance with MRL for animal commodities as flufenoxuron.

The Log K_{ow} of flufenoxuron is 4. In the goat metabolism study, highest levels of the parent compound were observed in fat and cream, while in the laying hen metabolism studies, the highest concentrations of flufenoxuron were observed in the fat ($\leq 98\%$ of the TRRs). These findings were supported by the livestock feeding studies, where the average ratio for cream/skim milk was ≥ 155 and ≥ 112 for egg yolks/egg whites. Further to this, residues in fat were 24–30-fold higher than those in muscle.

In light of this, the Meeting concluded that the residue is fat soluble.

The metabolite Reg. No. 4064702 was also identified in laying hen muscle, fat, liver, kidney and eggs (1–22% of the TRRs) with the highest levels observed in liver and kidney. The minor metabolite Reg. No. 241208 was also observed but only in liver and kidney (2.5–3.7% of the TRRs) which were the only matrices that were subject to microwave extraction (liver only) or incubation at 37 °C in 0.07M phosphate buffer at pH 7.5 prior to extraction (liver and kidney), and hence considered a potential artefact of the analytical procedure.

The toxicity of the minor metabolite Reg. No. 241208, found in laying hen matrices, was considered to be covered by toxicity studies on flufenoxuron since this metabolite was seen in the rat. The metabolite Reg. No. 4064702, also observed in eggs and tissues of laying hens, and observed in the rat, was determined to be more acutely toxic than the parent flufenoxuron based on the LD₅₀. However, according to the poultry feeding study, residues of this metabolite in liver are not expected to exceed 0.04 mg/kg at the lowest feeding level of 1 ppm. Hence, as there are no poultry feed items derived from the proposed crops, the dietary exposure to this metabolite from poultry matrices is unlikely.

The Meeting recommends the residue for dietary intake for animal commodities as parent only.

The fate of flufenoxuron in plants was investigated following foliar application to tomato, apple, grape and Chinese cabbage. In all plant commodities tested, flufenoxuron was the predominant residue accounting for > 90% of the TRR, with the exception of grape, where flufenoxuron accounted for 50% of the TRR. No other metabolites were identified and no other residues were characterized (other than polar unknowns).

According to the hydrolysis study, simulating typical processing conditions (pH 4, 5 and 6 with 90 °C, 100 °C and 120 °C for 20, 60 and 20 minutes), flufenoxuron was degraded to various metabolites including: Reg. No. 102719 (8–32%), Reg. No. 4064702 (4%) and Reg. No. 4964847 (4–9%). All metabolites, except Reg. No. 4064702 and Reg. No. 4964847 are considered to be covered by toxicity studies on flufenoxuron, since they were seen in the rat. The absorption, distribution, metabolism and excretion studies in rat demonstrated that Reg. No. 4064702 was more acutely toxic than the parent flufenoxuron. Conversely, no toxicity information is available on metabolite Reg. No. 4964847, Reg. No. 4064702. Nevertheless, in the tomato processing study where these metabolites were measured in juice, purée and canned tomatoes, none were detected (< 0.01 mg/kg)

The Meeting recommended the following residue definition for flufenoxuron:

Definition of the residue for compliance with MRL and for estimation of dietary intake for plants and animal commodities: *flufenoxuron*

The Meeting considers the residue fat soluble.

Results of supervised residue trials on crops

The Meeting received supervised residue trials from Brazil, Europe and South Africa where flufenoxuron was applied to oranges, apples, pears, melons and tomatoes and Japanese trials on tea.

Oranges

The critical GAP in Brazil for flufenoxuron on oranges is up to two foliar applications of 0.005 kg ai/hL, with a re-treatment interval of 30 days and a PHI of 15 days. Sixteen supervised field trials were conducted in Greece, Italy, South Africa and Brazil.

Four of the trials were conducted in Brazil according to the critical GAP. Residues in whole oranges at the 15-day PHI were: 0.09, 0.11, 0.13 and 0.16 mg/kg.

Five trials in Brazil were conducted at 2×0.002 – 0.003 kg ai/hL with a PHI of 15 days, representing 0.4 – $0.6 \times$ the critical GAP in Brazil. The residues in whole fruit were 0.03, 0.05, 0.07, 0.08 and 0.10 mg/kg. The Meeting agreed to use the proportionality approach to scale the residues at the 15-day PHI according to an application rate of 0.005 kg ai/hL. The rank order of scaled residues in whole fruit was ($n = 5$): 0.08 (2), 0.13 (2), and 0.17 mg/kg.

When combining all the residue data, residues in whole oranges were 0.08 (2), 0.09, 0.11, 0.13 (3), 0.16 and 0.17 mg/kg and residues in pulp were 0.03, 0.04, 0.05 (3), 0.06, 0.08 (2) and 0.10 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg, and a median residue of 0.13 mg/kg for residues of flufenoxuron in whole oranges. For orange pulp, the Meeting estimated an STMR of 0.05 mg/kg.

Apples

The Brazil critical GAP for flufenoxuron on apples is a single foliar application at 0.01 kg ai/hL and a PHI of 35 days.

Three trials on apples were available from Chile where trees were treated at 0.015–0.02 kg ai/hL with PHIs of 35–36 days, representing 1.5 – $2 \times$ the critical GAP in Brazil. The residues in the fruit were 0.17, 0.43 and 0.52 mg/kg. The Meeting agreed to use the proportionality approach to scale the residues at the PHIs of 35–36 days according to the application rate of 0.01 kg ai/hL. The ranked order of the scaled residues were: 0.08, 0.22 and 0.35 mg/kg ($n=3$).

In two trials conducted in Chile in accordance with Brazilian GAP, flufenoxuron residues were 0.07 and 0.45 mg/kg.

The Meeting concluded that the number of trials available was insufficient to estimate a maximum residue level for residues of flufenoxuron in apples.

Melons

There is no GAP in Brazil for flufenoxuron on melons; therefore, the Meeting could not recommend a maximum residue level.

Tomatoes

There is no GAP in Brazil for flufenoxuron on tomatoes; therefore, the Meeting could not recommend a maximum residue level.

Tea

The critical GAP for flufenoxuron in Japan for tea is up to two foliar applications of 0.025 kg ai/hL at a re-treatment interval of 7–14 days and a PHI of 7 days.

In seven of the eleven trials conducted in Japan and matching the critical GAP, residue levels in tea (green) were: 2.37, 2.48, 3.95, 4.58, 6.02, 6.23 and 11.8 mg/kg.

The Meeting estimated a maximum residue level of 20 mg/kg and a STMR of 4.58 mg/kg for residues of flufenoxuron in tea, green, black (black, fermented and dried).

Fate of residues during processing

Nature of residues

The Meeting received information on the hydrolysis of flufenoxuron uniformly labelled in the fluoroaniline and difluoroamide rings where typical processing conditions were simulated (pH 4,5 and 6 with 90 °C, 100 °C and 120 °C for 20, 60 and 20 minutes).

In duplicate samples of sterile buffer solution flufenoxuron (accounting for 63–93% of the TAR) was seen to hydrolyse to various metabolites, however, none accounted for greater than 10% of the TAR, with the exception of Reg. No. 102719, present at 32% of the TAR, following hydrolysis conditions simulating baking, boiling and brewing procedures.

Level of residues

The Meeting also received information on the fate of flufenoxuron residues during the processing of the raw agricultural commodities like tomato to juice, pomace, puree and canned tomatoes and tea to infusion. While the magnitude of the residues of Reg. No. 102719 in tea infusion was not elucidated, in the tomato processing study, the residues of flufenoxuron metabolites, including Reg. No. 102719, Reg. No. 4064702 and Reg. No. 4964847 in all processed tomato commodities were below the LOQ (0.01 mg/kg). However, in the absence of a critical GAP in Brazil for flufenoxuron on tomatoes, the tomato processing study was not relied upon to derive processing factors, STMR-P values and to estimate maximum residue levels for tomato processed commodities.

The processing factor obtained in the tea processing study and the estimated STMR-P value for the dietary intake calculation is summarized below:

Raw agricultural commodity	STMR, mg/kg	Processed commodity (food)	Processing factor	STMR-P (mg/kg)
Tea (green)	6.02	Infusion	0.0065 (median)	0.04

Residues in animal commodities

Farm animal feeding studies

The Meeting received information on the residue levels arising in animal tissues and milk when dairy cows were fed flufenoxuron for 90 days at levels equivalent of 1.75, 5.25 and 17.5 ppm in the diet. Three animals from the highest dose level group were monitored for flufenoxuron residues over a 40-day depuration phase.

At the lowest dose tested, flufenoxuron residues in milk increased steadily over the 90-day period, from 0.0243 mg/kg on day 2 to 0.64 mg/kg on day 90, however, in the mid and high dose groups, residues seemed to plateau on day 56 (at 1.6 mg/kg) and day 70 (at 5.5 mg/kg), respectively. Analysis of milk obtained from the high dose group showed that pasteurization had no effect on the levels of flufenoxuron in milk. Residues in cream were concentrated by a factor of 1.5. In skimmed milk and acid whey, residues were lower than those of raw milk.

In all tissues tested, except subcutaneous fat, residues of flufenoxuron were dose dependant, increasing with increasing dose. In subcutaneous fat, residues were 0.8 mg/kg, 9.3 mg/kg and 8.7 mg/kg, in the low, mid and high dose groups, respectively.

The residue depuration study demonstrated that flufenoxuron residues in milk decreased slowly within the 40 days of cessation of dosing, from 5.1 mg/kg on day 91 to 0.9 mg/kg on day 130. In tissues, flufenoxuron residues decreased on average by 80% by day 130.

The Meeting also received information on the residues in tissues and eggs of laying hens when dosed with flufenoxuron for 50 days at levels equivalent to 1, 3, 10 ppm in the diet. Fifteen animals from the top dose group were monitored for flufenoxuron residues over a 40-day depuration phase.

At all feeding levels, no residues of flufenoxuron in egg white exceeded 0.05 mg/kg. However, residues in egg yolks did not reach a plateau but rather increased steadily over the 50-day period.

Residues of flufenoxuron in liver, muscle, skin and fat increased with increasing feeding level.

During the depuration study, flufenoxuron residues in egg yolks decreased more rapidly than in cattle milk over the same duration, from 32.5 mg/kg on day 51 to 2.3 mg/kg on day 90.

Farm animal dietary burden

As there is no information on citrus dry pulp, the only potential cattle feed item derived from the proposed crops and there are no poultry feed items, the Meeting did not calculate farm animal dietary burdens.

Therefore, the Meeting estimated maximum residue levels of 0.05* mg/kg for flufenoxuron in meat (from mammals other than marine mammals), edible offal (mammalian), mammalian fat (except milk fats) and 0.01* mg/kg for milks. STMRs and HRs for dietary intake estimation are 0 mg/kg for meat (from mammals other than marine mammals), edible offal (mammalian), mammalian fat (except milk fats) and milks.

The Meeting did not estimate maximum residue levels, STMRs or HRs for poultry matrices.

The residue in animal commodities is considered fat soluble.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake, animal and plant commodities): *flufenoxuron*

The residue is fat soluble.

CCN	Commodity Name	MRL mg/kg	STMR or STMR-P mg/kg	HR or HR-P mg/kg
FC 0004	Oranges, Sweet, Sour	0.4	0.13	–
	Orange pulp	–	0.05	–
DT 1114	Tea, Green, Black (black, fermented and dried)	20	4.58	–
	Tea infusion	–	0.04	–
MO 0105	Edible offal (mammalian)	0.05*	0	–
MM0095	Meat (from mammals other than marine mammals)	0.05*	0	–
MF 0100	Mammalian fats (except milk fats)	0.05*	0	–
ML 0106	Milks	0.01*	0	–

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intake (IEDI) for flufenoxuron was calculated based on the recommendation for STMRs for raw and processed commodities (tea infusion) in combination with consumption data for corresponding food commodities. These results are shown in Annexe 3.

The IEDI of the 17 GEMS/Food cluster diets, based on the estimated STMRs represented 0% of the maximum ADI of 0.04 mg/kg bw, expressed as flufenoxuron. The Meeting concluded that the

long-term intake of flufenoxuron residues from uses considered by the Meeting is unlikely to present a public health concern.

Short-term intake

No ARfD was considered necessary. The Meeting concluded that the short-term intake of flufenoxuron residues from uses considered by the Meeting is unlikely to present a public health concern.

FLUOPYRAM (243)

The first draft was prepared by Mr David Lunn, Food Safety Authority, Wellington, New Zealand

EXPLANATION

Fluopyram, a pyridylethylamide broad spectrum fungicide was evaluated for the first time by the 2010 JMPR, where an ADI of 0–0.01 mg/kg bw and an ARfD of 0.5 mg/kg bw were established, residue definitions were proposed and maximum residue levels were recommended for a limited number of uses where GAP information was available. New GAP and supporting information were evaluated by the 2012 JMPR and a number of additional maximum residue levels were recommended.

The 2010 JMPR also established residue definitions for fluopyram:

- For plant products (compliance with MRLs and dietary intake assessment): *fluopyram*
- For animal products (compliance with MRLs): *sum of fluopyram and 2-(trifluoromethyl)benzamide, expressed as fluopyram*
- For animal products (dietary intake assessment): *sum of fluopyram, 2-(trifluoromethyl)benzamide and the combined residues N-{(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl benzamide and N-{(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl}-2-trifluoromethyl benzamide, all expressed as fluopyram.*

The 45th Session of the CCPR (2013) listed fluopyram for further evaluation by the 2014 JMPR for additional MRLs and the current Meeting received new GAP information and new supporting residue information from the manufacturer for plum, peach, apricot, raspberry, onion, leek, Brussels sprouts, cabbage, cauliflower, melon, lettuce, asparagus and oilseed rape.

New residue information was also provided for watermelon and currants but because no GAP information was available for these crops, these data were not evaluated by the Meeting.

The Meeting also considered residue information provided to the 2010 JMPR for peach, raspberry, onion, leek, Brussels sprouts, cabbage, cauliflower, melon, lettuce and oil seed rape.

USE PATTERNS

Information on GAP in a number of countries in Europe, North America, Southern Africa, Peru, China and South Korea was provided to the Meeting for foliar applications to a range of fruit, vegetable, nut and oil seed crops. This information is summarised in Table 1.

Table 1 Registered uses of fluopyram-SC formulations (including co-formulations with tebuconazole, trifloxystrobin and triadimenol)

RESIDUES RESULTING FROM SUPERVISED TRIALS

The Meeting reviewed supervised field trial information provided to the 2012 JMPR and received new information on supervised field trials involving applications of fluopyram to the following crops.

Crop Group	Commodity	Country	Table No.
Stone fruit	Apricots	Europe	2
	Peaches	Europe	3
	Plums	Europe	4
Berries and other small fruit	Currants	Europe	5
	Raspberries	Europe, USA	6–7
Bulb vegetables	Bulb onions	Europe, USA	8–9
	Leek	Europe	10
	Broccoli	Europe	11–12
Brassicas	Brussels sprouts	Europe	13
	Cabbage, head	Europe	14
	Cauliflower	Europe	15
Fruiting vegetables, cucurbits	Melons (except watermelons)	Europe, Australia, USA	16–19
	Watermelons	Europe	20
Leafy vegetables	Lettuce	Europe, USA	21–23
Stalk and stem vegetables	Asparagus	Europe	24
Oilseeds	Oilseed rape	Europe, USA	25–26
Animal feeds	Oilseed rape forage	Europe	27

The supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation including procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for recovery.

When multiple applications were made to a crop, the application rate, spray concentration and spray volume were not always identical from one application to the next. If the variation was small, only the final values for application rate, concentration and spray volume were recorded. For larger variations all values were recorded.

Intervals of freezer storage between sampling and analysis were recorded for all trials and were covered by the conditions of the freezer storage stability studies reviewed by the 2010 JMPR.

Results from replicated field plots are presented as individual values and have not been corrected for concurrent method recoveries unless indicated. When residues were not detected they are shown as below the LOQ (e.g. < 0.01 mg/kg). Residues and application rates have been rounded to two significant digits (or if close to the LOQ, rounded to one significant digit). Average values have been calculated from the residue results prior to rounding and the results from trials conducted according to the maximum GAP and used for the estimation of maximum residue levels have been (underlined).

In addition to the description and details of the field trials and analytical methods, each report includes a summary of the method validation, procedural recoveries, and in most cases, concurrent recoveries in stored frozen samples.

In the trials, where multiple analyses are conducted on a single sample, the average value is reported and where duplicate samples have been analysed, both the individual results and the average value have been reported. Where results from separate plots with distinguishing characteristics such as different formulations, varieties or treatment schedules were reported, results are listed for each plot, and the highest value has been used in calculations of MRLs and STMRs.

Stone fruits

Apricots

Results from supervised trials from Europe on apricots were provided to the Meeting. In the trials, fluopyram (SC formulations) were applied twice at 0.21–0.25 kg ai/ha or three times at 0.125 kg ai/ha. In all trials, the treatments were made at 6–8 day intervals to mature, full-sized trees, as foliar sprays using knapsack atomiser or airblast single-nozzle sprayers to apply 1000–1500 L water/ha.

Samples of at least 1.1 kg fruit or 24 fruit (without stalks) were frozen within 24 hours of sampling and stored at –18 °C for up to 582 days before whole fruit analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 81–111%.

Peach

Results from supervised trials from Europe on peaches were provided to the Meeting. Some of the trials conducted in 2006 and 2007 were also provided to the 2010 JPPR. In the trials, fluopyram (SC formulations) were applied twice at 0.21–0.25 kg ai/ha or three times at 0.125 kg ai/ha. In all trials, the treatments were made at 7–10 day intervals to mature, full-sized trees, as foliar sprays using knapsack atomiser or airblast single-nozzle sprayers to apply 900–1500 L water/ha (with lower rates of 300–750 L/ha in three trials).

Samples of at least 1.3 kg fruit or 24 fruit (without stalks) were frozen within 24 hours of sampling and stored at –18 °C for up to 527 days before whole fruit analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 79–115%.

Plums

Results from supervised trials from Europe on plums were provided to the Meeting. In these trials, fluopyram (SC formulations) were applied twice at 0.25 kg ai/ha, or three times at 0.125 kg ai/ha. In all trials, the treatments were made at 6–8 day intervals to mature, full-sized trees, as foliar sprays using knapsack atomiser or airblast single-nozzle sprayers to apply 1000–1500 L water/ha. At two sites, 1–2 fluopyram sprays were also applied to separate plots at different times over flowering and to immature fruit.

Samples of at least 1 kg fruit or 24 fruit (without stalks) were frozen within 24 hours of sampling and stored at -18 °C for up to 524 days before whole fruit analysis for fluopyram using

LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 74–107%.

Berries and other small fruit

Currants

Results from supervised trials from Europe on currants were provided to the Meeting. In the German trials, two applications of fluopyram (SC formulations) were made 7–10 days apart to outdoor currants 0.2 kg ai/ha using knapsack atomiser single-nozzle sprayers to apply 300–1000 L/ha. In the Belgian and the Netherlands trials, currants grown under plastic cover were treated with two applications of 0.2 kg ai/ha, applied 7 days apart using knapsack atomiser or hand lances to apply 1000 L/ha.

Samples of at least 0.5 kg fruit were frozen within 24 hours of sampling and stored at -18 °C for up to 234 days before whole fruit analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–2.0 mg/kg fluopyram ranged from 93–107%. In one trial, higher recovery rates of 122–181% were reported in samples spiked at the lower levels of 0.01–0.1 mg/kg, but were 106–107% in the samples spiked at 1.0 mg/kg.

Raspberries

Results from supervised trials from Europe on raspberries grown in the field and under plastic cover were provided to the Meeting. In the German and French field trials, two applications of 0.2 kg ai/ha fluopyram (SC formulations) were made 7–10 days apart using knapsack atomiser single-nozzle sprayers to apply 300–1000 L/ha. In the Belgian and the Netherlands trials, crops grown under plastic (top) cover were treated twice at 0.2 kg ai/ha, 7 days apart using knapsack atomiser or hand lances to apply 900–1000 L/ha.

Samples of at least 0.5 kg fruit were frozen within 24 hours of sampling and stored at –18 °C for up to 234 days before whole fruit analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–2.0 mg/kg fluopyram ranged from 93–107%. In one trial, higher recovery rates of 122–181% were reported in samples spiked at the lower levels of 0.01–0.1 mg/kg, but were 106–107% in the samples spiked at 1.0 mg/kg.

Bulb vegetables

Onion, bulb

Results from supervised trials from Europe on bulb onions were provided to the Meeting. Trials conducted in 2006 and 2007 were also provided to the 2010 JMPR. In the trials, one or two applications of 0.1 kg ai/ha or 0.2 kg ai/ha (or in some earlier trials one application of 0.5 kg ai/ha) fluopyram (SC formulations) were made 6–8 days apart, using knapsack single-nozzle or mini-boom sprayers (3–12 nozzles) to apply 200–800 L/ha.

Samples of at least 1.5 kg or 24 bulbs were frozen within 24 hours of sampling, and stored at –18 °C for up to 398 days before analysis for fluopyram using LC/MS/MS Method 00984. The

reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 81% and 106%.

Studies RA-2517, RA-2518, RA-2567, RA-2568 were also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 105]

Results from supervised trials from USA on bulb onions were provided to the Meeting. Trials conducted in 2007 were also provided to the 2010 JMPR. In the trials, one or two applications of 0.25 kg ai/ha fluopyram (SC formulations) were made 5 days apart, using knapsack sprayers or tractor-mounted 4-row boom sprayers to apply about 120–280 L/ha. In the 2009 trials, additional plots were treated with fluopyram plus adjuvant.

Duplicate samples of at least 2 kg dry bulbs were frozen within 1 hour of sampling and stored frozen for up to 267 days before analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–0.5 mg/kg fluopyram ranged from 94% to 106%.

Study RAGML001 was also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 106]

Leek

Results from supervised trials from Europe on leeks were provided to the Meeting. In these trials fluopyram (SC formulations) foliar sprays were applied either once or twice (13–14 days apart) at 0.2 kg ai/ha or three times at 0.15 kg ai/ha (21–22 days apart), using knapsack mini-boom sprayers (3–12 nozzles) to apply 300–600 L/ha (200 L/ha in one trial). The trials involving two applications, conducted in 2006 and 2007 were also provided to the 2010 JMPR.

Samples of at least 1 kg or 24 plants (without roots) were frozen within 24 hours of sampling and stored at -18 °C for up to 391 days before analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–2.0 mg/kg fluopyram ranged from 71% to 118%.

Brassica vegetables

Broccoli

Results from supervised trials from USA on broccoli were provided to the 2010 Meeting. In these trials, two foliar applications of 0.24–0.26 kg ai/ha fluopyram (SC 500 formulation), tank-mixed with trifloxystrobin (SC) in 122–186 L of water were applied to broccoli plants 5 days apart using knapsack sprayers or tractor-mounted boom sprayers. Plot sizes in these trials ranged from 53–159 square metres.

Duplicate samples of (at least 12 broccoli heads and stems) were taken from each plot, frozen within 4 hours of sampling, held in frozen storage for up to 448 days before analysis for fluopyram using LC/MS/MS Method GM-001-P07-01 (LOQ of 0.01 mg/kg).

Study RAGMP076 was also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 111]

Results from supervised trials from Europe on broccoli were provided to the Meeting. These trials were also provided to the 2010 JMPR. In these trials, two applications of fluopyram + tebuconazole (SC 200+200) at rates 0.2 kg ai/ha fluopyram in 300–800 L/water/ha of were made at 14–21 day intervals as foliar sprays using knapsack sprayers with hand-held booms (4–12 flat fan or hollow cone nozzles). Plot sizes in these trials ranged from 50–100 square metres.

Unreplicated samples of 12–20 broccoli heads were taken from each plot, frozen within 24 hours of sampling and stored at -18 °C or below for up to 335 days before analysis for fluopyram and its BZM, PAA and PCA metabolites using LC/MS/MS Method 00984 or Method 00984/M001 (LOQs were 0.01 mg/kg for each analyte).

Brussels sprouts

Results from supervised trials from Europe on Brussels sprouts were provided to the Meeting. These trials were also provided to the 2010 JMPR. In the trials, two foliar sprays of 0.2 kg ai/ha fluopyram (SC formulations) were applied 14–15 days apart using knapsack or wheelbarrow mini-boom sprayers (3-12 nozzles) to apply 300–800 L/ha.

Samples of at least 1 kg of sprouts were frozen within 24 hours of sampling and stored at –18 °C for up to 253 days before analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 89% to 110%.

Cabbage, head

Results from supervised trials from Europe on head cabbages (red, white or round) were provided to the Meeting. In these trials fluopyram (SC formulations) foliar sprays were applied either twice at 0.2 kg ai/ha (14 days apart) or three times at 0.15 kg ai/ha (20–21 day intervals) using knapsack mini-boom sprayers (3–12 nozzles) to apply 300–600 L/ha (800 L/ha in one trial). The trials conducted in 2006 and 2007 and involving two fluopyram applications were also provided to the 2010 JMPR.

Samples of at least 12 units (min 10 kg of whole heads or two opposing quarter-heads) were frozen within 24 hours of sampling and stored at –18 °C for up to 307 days before analysis of heads (plus wrapper leaves) for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg fluopyram ranged from 84% to 110%.

Cauliflower

Results from supervised trials from Europe on cauliflower were provided to the Meeting. The 2006 and 2007 trials were also provided to the 2010 JMPR. In these trials, two applications of fluopyram (SC formulations) at rates 0.2 kg ai/ha fluopyram in 300–800 L water/ha of were applied at 13–15 day intervals as foliar sprays using knapsack sprayers with a single solid cone nozzle hand lance or hand-held booms (3–12 flat fan or hollow cone nozzles). Plot sizes in these trials ranged from 66–162 square metres.

Unreplicated samples of 12 cauliflower curds were taken from each plot, frozen within 24 hours of sampling and stored at -18 °C or below for up to 14 months before analysis for fluopyram using LC/MS/MS Method 00984 or Method 00984/M001. The reported LOQ was 0.01 mg/kg.

^aAnalysis of the whole plant, without roots

Studies RA-2525, RA-2526, RA-2571, RA-2572 were also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 114]

Fruiting Vegetables (Cucurbits)

Melons (except watermelon)

Results from supervised trials from Europe on greenhouse melons were provided to the Meeting. In the trials conducted in 2006 and 2007, also provided to the 2010 JMPR, and in the 2008 trials, two applications of 0.3 kg ai/ha fluopyram (SC 500 formulations) in 500–1000 L water/ha were applied at 7 day intervals to mature plants. In the 2010 trials, three foliar sprays of 0.1 kg ai/ha (SC formulations) were applied in 500–1000 L of water/ha at 14-day intervals. Applications were made using knapsack or wheel barrow sprayers with 1–3 solid-cone or hollow-cone nozzles or with mini-booms (2–12 nozzles).

Unreplicated samples of at least 12 fruit were taken from each plot, some of the larger fruit were sub-sampled in the field, with 4/12 segments frozen within 24 hours of sample collection and stored at -18 °C or below for up to 418 days before analysis of whole fruit, peel and pulp for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 1.0 mg/kg ranged from 82–108% in whole fruit, 91–114% in peel and 93–133% in pulp.

Studies RA-2587, RA-2680 were also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 122]

Results from supervised trials from Europe on outdoor melons were provided to the Meeting. These trials, conducted in 2006 and 2007, were also provided to the 2010 JMPR and involved two applications of 0.25–0.3 kg ai/ha fluopyram (SC formulations) in 500–1000 L/water/ha, applied at 7 day intervals to mature plants using knapsack or wheel barrow sprayers with 1–3 solid-cone or hollow-cone nozzles or with mini-booms (3–10 nozzles).

Unreplicated samples of at least 12 fruit were taken from each plot, some of the larger fruit were sub-sampled in the field, with 4/12 segments frozen within 24 hours of being sampled, and stored at -18 °C or below for up to 313 days before analysis of whole fruit, peel and pulp for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 1.0 mg/kg ranged from 85–106% in whole fruit, 81–103% in peel and 93–132% in pulp.

Studies RA-2508, RA-2587, RA-2588, RA-25890 also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 123]

Results from supervised trials from Australia on outdoor melons were provided to the Meeting. These trials involved three applications of 0.075, 0.125 or 0.19 kg ai/ha fluopyram (SC 500 formulations) in 300–1000 L/water/ha, made at 5 day intervals to mature plants using motorised knapsack hand-held booms or bike-mounted 5 metre booms.

Unreplicated samples of 3–4 fruit were taken from each plot, frozen within 24 hours of sampling and stored at -18 °C or below for up to 308 days before analysis of whole fruit for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 1.0 mg/kg ranged from 80–119%.

Results from supervised trials from the USA on musk melons were provided to the 2010 Meeting. In these trials, two applications of 0.24–0.26 kg ai/ha (SC 500 formulation) were applied to melon plants either by foliar application or by drip line irrigation. In both plots the interval between applications was 5 days.

In the plots treated by foliar application, CO₂ plot sprayers or backpack sprayers were used to apply 139–172 L/spray mix/ha. In the drip line irrigation treated plots, fluopyram concentrations

equivalent to 16–29 kg ai/100 L were applied at rates of 3.3–6.1 L per emitter per hour, to achieve an application rate equivalent to 0.25 kg ai/ha.

Duplicate samples of mature melons (12 fruit from 12 areas within each plot) were taken from each plot, frozen within 3.5 hours of sampling and held in frozen storage for up to 219 days before being analysed for fluopyram using LC/MS/MS Method GM-001-P07-01 (LOQ 0.01 mg/kg).

Study RAGMP082 was also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 120]

Watermelon

Results from supervised trials from Europe on outdoor watermelons were provided to the Meeting. In these trials, two applications of 0.25 kg ai/ha fluopyram (SC 500 formulations) were applied in 500–1000 L/water/ha at 7 day intervals to mature plants using knapsack mini-booms (1–8 nozzles).

Unreplicated samples of at least 12 fruit were taken from each plot, some of the larger fruit were sub-sampled in the field, with 4–6/12 segments frozen within 24 hours of sampling and stored at -18 °C or below for up to 338 days before analysis of whole fruit, peel and pulp for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 1.0 mg/kg ranged from 97–109% in whole fruit, 86–106% in peel and 93–110% in pulp.

*Leafy vegetables**Lettuce, leaf and head*

Results from supervised trials from Europe on field and protected lettuce were provided to the Meeting. Trials conducted on outdoor crops and on indoor lettuce in 2006 and 2007 were also provided to the 2010 JMPR. In these trials, two foliar applications of fluopyram (SC 500 formulations) were applied to head or leaf lettuce (non-hearting) at a rate of 0.25 kg ai/ha in 300–1000 L of water and 7 days apart in the greenhouse trials and in 200–800 L water and 7–10 days apart in the field trials. Application was by knapsack sprayers and hand-held booms with 3–12 flat fan or hollow-cone nozzles.

In the more recent trials on protected lettuce, either two applications of 0.2 kg ai/ha, 7 days apart or one application of 0.3 kg ai/ha were applied in 300–1000 L spray mix/ha using knapsack and mini-boom (3–8 nozzle) sprayers.

Unreplicated samples of at least 12 lettuce heads were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 520 days before analysis for fluopyram using LC/MS/MS Methods 00984 or 00984-M001. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 20.0 mg/kg ranged from 72–120%.

Leaf=non-hearting lettuce, whole plant sampled with roots and main stalk removed

Studies RA-2509, RA-2510, RA-2592, RA-2593 were also provided to the 2010 JMPR [2010 JMPR Fluopyram

Evaluation: Table 138]

Results from supervised trials from USA on outdoor lettuce were provided to the Meeting. The trials conducted in 2007 and 2008 were also provided to the 2010 JMPR. In the trials, two foliar applications of fluopyram (SC 500 formulation) were applied to leaf lettuce or head lettuce plants at 0.24–0.26 kg ai/ha in 110–190 L of water, 4–7 days apart, using CO₂ pressurised plot sprayers or knapsack sprayers.

At each site, additional plots were treated with two narrow (3–15 cm) band spray applications of 0.24–0.26 kg ai/ha in 23–180 L of water over the top of the row, the first just after transplanting and the second being 1–5 weeks later, at the 5-leaf growth stage (BBCH 15) with treatment intervals ranging from 7 to 35 days.

In the trials conducted in 2009, a single application of 0.25 kg ai/ha (SC formulations) was applied to leaf lettuce, with and without added surfactant, using CO₂ pressurised plot sprayers or knapsack sprayers to apply 180–300 L spray mix/ha.

Duplicate samples (lettuce leaves or lettuce heads with wrapper leaves) were taken from each plot, frozen within 4 hours of sampling, held in frozen storage for up to 429 days before analysis for fluopyram using LC/MS/MS Method GM-001-P07-01.

The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 10.0 mg/kg ranged from 87–101%.

Stalk and stem vegetables

Asparagus

Results from supervised trials from Europe on asparagus were provided to the Meeting. In these trials, two applications of 0.15–0.2 kg ai/ha fluopyram (SC formulations) in 300–800 L/water/ha of were applied at 10–11 day intervals to mature ferns (just prior to senescence) as foliar sprays using knapsack and hand lance or mini-boom (4–12 nozzle) sprayers.

Unreplicated samples of at least 1 kg or 24 spears (with soil removed and in some trials, trimmed to 20 cm length) were taken from each plot, frozen within 24 hours of sampling and stored at -18 °C or below for up to 187 days before analysis for fluopyram using LC/MS/MS Method 00984. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01 to 1.0 mg/kg ranged from 72–99%.

Oilseeds

Rape seed

Results from supervised trials on winter and summer rape in Europe were provided to the Meeting. The trials conducted in 2006 and 2007 were also provided to the 2010 Meeting. In these trials, two applications of fluopyram (SC 500 formulation or as a 250 SC formulation, in combination with prothioconazole) were applied to rape plants at BBCH 63 (30% flowers open) and again, 14–39 days later, at BBCH 73 (30% pods at full size), as foliar sprays using knapsack sprayers with spray booms (3–12 flat fan nozzles), applying 0.125 kg ai/ha in 200–400 L/water/ha. Plot sizes in these trials ranged from 48–563 square metres.

Unreplicated samples of mature seeds (min 1 kg), pods and seeds (min 0.7 kg) and/or plants (min 2 kg green material, including pods and seeds) were taken from each plot, frozen within 24 hours of sampling and stored at -18 °C or below for up to 15 months before analysis using LC/MS/MS Method 00984 (with minor variations). The reported LOQ was 0.01 mg/kg.

Studies RA-2609, RA-2616, RA-2610, RA-2617 were also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 177]

Results from supervised trials from USA on oilseed rape (canola) were provided to the Meeting. These trials were also provided to the 2010 Meeting. In these trials, two applications of 0.242–0.256 kg ai/ha (SC 500 formulation) were applied to canola, 13–14 days apart from flowering as foliar sprays using CO₂ plot sprayers or knapsack sprayers with hand-held spray booms, field sprayers or tractor-mounted spray booms to apply 92–184 L/spray mix/ha. Plot sizes in these trials ranged from 70–210 square metres.

Duplicate samples of rape seed (min 1 kg) were taken from at least 12 areas within each plot, frozen within 3 hours of sampling and held in frozen storage for up to 516 days before analysis for fluopyram using LC/MS/MS Method GM-001-P07-01, with a reported LOQ of 0.01 mg/kg.

Animal feeds

Rape forage

Results from supervised trials on winter and summer rape in Europe were provided to the Meeting. The trials conducted in 2006 and 2007 were also provided to the 2010 Meeting. In these trials, two applications of fluopyram (SC 500 formulation or as a 250 SC formulation, in combination with prothioconazole) were applied to rape plants at BBCH 63 (30% flowers open) and again, 14–39 days later, at BBCH 73 (30% pods at full size), as foliar sprays using knapsack sprayers with spray booms (3–12 flat fan nozzles), applying 0.125 kg ai/ha in 200–400 L/water/ha. Plot sizes in these trials ranged from 48–563 square metres.

Unreplicated samples of pods and plants (min 2 kg green material, including pods and seeds) were taken from each plot, frozen within 24 hours of sampling and stored at –18 °C or below for up to 15 months before analysis using LC/MS/MS Method 00984 (with minor variations). The reported LOQ was 0.01 mg/kg.

Table 27 Residues in oilseed rape plants from supervised trials in France, Germany, Italy and UK, involving two foliar applications of fluopyram (SC formulations)

Studies RA-2609, RA-2616, RA-2610, RA-2617 were also provided to the 2010 JMPR [2010 JMPR Fluopyram Evaluation: Table 177]

FATE OF RESIDUES IN STORAGE AND IN PROCESSING

Magnitude of the residue in processing

Information was provided to the 2010 JMPR on the residue distribution of fluopyram in peel and pulp (melons), on the effects of trimming, washing and cooking of strawberries, blueberries, cabbage, broccoli, summer squash, lettuce, spinach, Mustard greens, celery and on the effects of simulated commercial processing on residues of fluopyram and metabolites in oranges, apples, plums, grapes, tomatoes, potatoes, sugar beet, soya beans, wheat, maize, peanut, rape seed, cotton seed and sunflower seed.

Processing factors derived by the 2010 JMPR of relevance to the commodities considered for maximum residue levels, dietary intake or livestock dietary burden estimation by the current meeting are summarized below:

Table 28 Summary of selected processing factors for fluopyram

Raw agricultural commodity	Processed commodity	Calculated processing factors ^a	Processing factor (mean or median)
Melons & Watermelon	Pulp	< 0.02, < 0.05, 0.05, < 0.06, < 0.06, < 0.07, < 0.08, < 0.09, 0.09, < 0.11, < 0.13, < 0.13, < 0.13, 0.13, 0.13, < 0.17, < 0.17, < 0.2, < 0.2	< 0.11
Cabbage	Washed heads	0.17, 0.25, < 0.5, < 0.5	< 0.36
	Cooked washed heads	< 0.17, < 0.25, < 0.5, < 0.5	< 0.36
Lettuce	Trimmed heads ^b	0.01, 0.02, 0.02, 0.03, 0.09, 0.34	0.03 (median)
	Trimmed heads ^b	0.02, 0.02, 0.03, 0.05, 0.19, 0.2	0.09
	Washed leaves	0.24, 0.85	0.55
Broccoli	Washed heads	0.8	0.8
	Cooked washed heads	0.62	0.62
Plums	Washed fruit	0.49	0.49
	Dried fruit	1.1	1.1
Rape seed	Oil (crude)	1.0, 1.3, 1.3, 2.1	1.4
	Oil (refined)	0.01, 0.64, 0.83, 1.0, 1.7	0.71
	Meal	0.29, 0.34, 0.67, 0.75, 1.4	0.69

^a Each value represents a separate study where residues were above the LOQ in the RAC. The factor is the ratio of the total

residue in the processed item divided by the total residue in the RAC.

^b Wrapper leaves removed

APPRAISAL

Fluopyram, a pyridylethylamide broad spectrum fungicide was evaluated for the first time by the 2010 JMPR, where an ADI of 0–0.01 mg/kg bw and an ARfD of 0.5 mg/kg bw were established, residue definitions were proposed and maximum residue levels were recommended for a number of uses where GAP information was available. New GAP and supporting information were evaluated by the 2012 JMPR and a number of additional maximum residue levels were recommended.

Residue definitions established by the 2010 JMPR are:

For plant products (compliance with MRLs and dietary intake assessment): *fluopyram*

For animal products (compliance with MRLs): *sum of fluopyram and 2-(trifluoromethyl)benzamide, expressed as fluopyram*

For animal products (dietary intake assessment): *sum of fluopyram, 2-(trifluoromethyl)benzamide and the combined residues N-[(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl]-2-trifluoromethyl benzamide and N-[(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl]-2-trifluoromethyl benzamide, all expressed as fluopyram.*

New GAP information and supporting residue data were provided by the manufacturer for evaluation by the Meeting.

Supervised residue trials on crops

The Meeting received new supervised trial data for foliar applications of fluopyram (SC formulations) on plum, peach, apricot, raspberry, onion, leek, Brussels sprouts, cabbage, cauliflower, melon, lettuce, asparagus and oilseed rape and noted that data for some of these crops had also been provided to the 2010 JMPR. New supervised trial data were also provided for watermelon and currants, but because no GAP information was available for these crops, these data were not considered by the Meeting.

The results from these new trials and those previously reported by the 2010 JMPR and either matching critical GAP or where the results can be proportionally adjusted (scaled) to reflect GAP application rates were used to estimate maximum residue levels, STMRs and HRs for a number of commodities for which GAP information was available. The proportionality approach was used to scale the results from trials where the application rates range from $0.33 \times \text{GAP}$ to $4 \times \text{GAP}$ and where all other parameters matched the critical GAP). Frozen sample storage times in the new trials were within the storage intervals considered acceptable by the 2010 JMPR.

Stone fruit

Results from supervised field trials on apricots, peaches and plums conducted in Europe were considered by the Meeting, including some data for peaches that were also provided to the 2010 JMPR.

Peaches (sub-group 003C)

The critical GAP for apricots is in Greece, up to two applications of 0.15 kg ai/ha, 7–14 days apart with a PHI of 3 days. No trials were available matching this GAP. In trials from Europe where apricots were treated with 2×0.21 –0.25 kg ai/ha fluopyram, residues at 3 DALA (days after the last application) were: 0.16, 0.2, 0.33, 0.38, 0.43, 0.46, 0.58 and 0.95 mg/kg. When proportionally adjusted to the 0.15 kg ai/hL GAP application rate (scaling factors of 0.6–0.75), fluopyram residues in apricots from these trials were: 0.12, 0.14, 0.22, 0.26, 0.27, 0.28, 0.35 and 0.69 mg/kg (n=8).

For peaches, the 2012 JMPR recommended a maximum residue level of 0.4 mg/kg based on trials from Southern Europe proportionally adjusted to the GAP in Turkey (0.005 kg ai/hL, PHI 3 days).

The Meeting was advised that new GAP existed in Europe, with a new critical GAP (Greece) of up to two applications of 0.15 kg ai/ha, 7–14 days apart and a PHI of 3 days. No trials were available matching this new GAP. In trials from Europe where peaches were treated with 2×0.21 –0.25 kg ai/ha fluopyram, residues at 3 DALA were: 0.2, 0.26, 0.28, 0.28, 0.31, 0.36, 0.63 and 0.73 mg/kg. When proportionally adjusted to the 0.15 kg ai/ha GAP application rate (scaling factors of 0.6–0.75), fluopyram residues in peaches from these trials were: 0.12, 0.16, 0.17, 0.17, 0.19, 0.22, 0.45 and 0.53 mg/kg (n=8).

The Meeting noted that the medians of the data sets for apricots and peaches differed by less than 5-fold and agreed to consider a group maximum residue level for peaches (subgroup 003C) since GAP exists in Europe for all crops within this subgroup. In deciding on the data set to use for estimating a group maximum residue level, since a Mann-Whitney U-test indicated that the residue populations for apricots and peaches were not different it was agreed to combine the results to give a data set of 0.12, 0.12, 0.14, 0.16, 0.17, 0.17, 0.19, 0.22, 0.22, 0.26, 0.27, 0.28, 0.35, 0.45, 0.53 and 0.69 mg/kg (n=16).

The Meeting estimated a group maximum residue level of 1 mg/kg, an STMR of 0.22 mg/kg and an HR of 0.69 mg/kg for fluopyram on peaches (subgroup 003C) and to recommend withdrawal of the previous maximum residue level recommendation of 0.4 mg/kg for peach.

Plums (sub-group 003B)

The critical GAP for plums is in Greece, up to three applications of 0.1 kg ai/ha with a PHI of 3 days. In trials from Europe matching the GAP in Greece, residues were: 0.08, 0.1, 0.1, 0.13, 0.13, 0.14, 0.16, 0.18, 0.2, 0.2 and 0.22 mg/kg (n=11).

The Meeting estimated a sub-group maximum residue level of 0.5 mg/kg, an STMR of 0.13 mg/kg and an HR of 0.22 mg/kg for fluopyram on plums (subgroup 003B).

Berries and small fruit

Results from supervised trials on outdoor and protected raspberries conducted in Europe and outdoor raspberries were provided to the Meeting.

Cane berries

The critical GAP for small berries (including blackberries and raspberries) is in South Africa, up to two applications of 0.25 kg ai/ha, 10–14 days apart, with a PHI of 3 days. In trials from Europe where protected raspberries were treated with 2×0.2 kg ai/ha fluopyram, residues at 3 DAT were: 0.51, 0.69, 0.7 and 1.2 mg/kg (n=4).

Since the South African GAP does not exclude use on protected crops the Meeting agreed to use the European trial results on protected raspberries matching the GAP in South Africa to estimate a maximum residue level of 3 mg/kg, an STMR of 0.7 mg/kg and an HR of 1.2 mg/kg for fluopyram on raspberries and agreed to extrapolate these estimations to blackberries.

Bulb vegetables

Results from supervised field trials on bulb onions and leeks in Europe and bulb onions in USA were considered by the Meeting, including some data that were also provided to the 2010 JMPR.

Onion (bulb)

The critical GAP in Northern Europe for bulb onions is in Germany, a maximum of two applications of 0.1 kg ai/ha, with a PHI of 7 days. In trials in Europe matching the GAP in Germany, fluopyram residues in onion bulbs were: < 0.01 (3), < 0.01, 0.01, 0.02, 0.03 and 0.04 mg/kg (n=8).

GAP for bulb onions exists in Southern Europe (Greece and Spain), a maximum of one application of 0.2 kg ai/ha with a PHI of 7 days. In trials in Europe matching this GAP, fluopyram residues in onion bulbs were: < 0.01 (6), 0.03 and 0.04 mg/kg (n=8).

The Meeting agreed to use the results matching the GAP in Germany to estimate a maximum residue level, noting that this would accommodate the GAP in Greece and Spain.

The Meeting estimated a maximum residue level of 0.07 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.04 mg/kg for fluopyram on onion (bulb).

Garlic

The Meeting noted that the GAP for onions in Greece and Spain also applied to garlic and agreed to extrapolate the results of the European onion trials matching this GAP to garlic and estimated a maximum residue level of 0.07 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.04 mg/kg for fluopyram on garlic.

Leek

The critical GAP for leeks is in Germany and Switzerland, a maximum of one application of 0.2 kg ai/ha, with a PHI of 21 days. In trials in Europe matching this GAP, fluopyram residues in leeks were: < 0.01 (4), 0.01, 0.03, 0.06 and 0.07 mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.07 mg/kg for fluopyram on leek.

Brassica vegetables

Results from supervised field trials on broccoli, Brussels sprouts, head cabbage and cauliflower in Europe were considered by the Meeting, including some data that were also provided to the 2010 JMPR.

Broccoli

The critical GAP for broccoli (flowerhead brassicas) is in Germany, a maximum of two foliar applications of 0.18 kg ai/ha, with a PHI of 14 days. In trials on broccoli in Europe matching this GAP, fluopyram residues in broccoli were: < 0.01, < 0.01, 0.02, 0.03, 0.05, 0.05, 0.06, 0.13 and 0.14 mg/kg (n=9).

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.05 mg/kg and an HR of 0.14 mg/kg for fluopyram on broccoli.

Cauliflower

In trials on cauliflowers in Europe matching the GAP in Germany for cauliflower (flower head Brassicas), up to two foliar applications of 0.18 kg ai/ha, with a PHI of 14 days. fluopyram residues were: < 0.01 (4), 0.01 (5), 0.02, 0.05, 0.05 and 0.05 mg/kg (n=13).

The Meeting estimated a maximum residue level of 0.09 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.05 mg/kg for fluopyram on cauliflower.

Brussels sprouts

The critical GAP for Brussels sprouts is in Germany, a maximum of two foliar applications of 0.18 kg ai/ha, with a PHI of 14 days. In trials in Europe matching this GAP, fluopyram residues in Brussels sprouts were: 0.01, 0.04, 0.04, 0.04, 0.04, 0.05, 0.07, 0.07, 0.07, 0.09, 0.14 and 0.15 mg/kg (n=12).

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.06 mg/kg and an HR of 0.15 mg/kg for fluopyram on Brussels sprouts.

Cabbages, head

The critical GAP for head cabbages is in Germany, a maximum of two foliar applications of 0.18 kg ai/ha, with a PHI of 14 days. In trials in Europe matching this GAP, fluopyram residues in cabbage heads were: < 0.01 (4), 0.01, 0.01, 0.01, 0.02, 0.02, 0.04 and 0.08 mg/kg (n=11).

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.08 mg/kg for fluopyram on cabbage, head.

Fruiting vegetables, Cucurbits

Results from supervised field trials on protected melons and on field melons in Europe, USA and Australia were considered by the Meeting, including some data that were also provided to the 2010 JMPR.

Melons (except watermelon)

The critical GAP for melons is in South Korea, up to three applications of 0.225 kg ai/ha, 10 days apart, with a PHI of 3 days. Since this GAP does not exclude use on protected crops, the Meeting agreed to consider the data from trials on protected melons in Europe involving three applications of 0.1 kg ai/ha where residues at 3 DAT were < 0.01, 0.02, 0.07 and 0.12 mg/kg. When the results of three of these trials where residues were found above the LOQ are proportionally adjusted to the South Korean GAP (scaling factor of 2.25), fluopyram residues in these trials are: 0.05, 0.06 and 0.27 mg/kg.

The Meeting agreed that these data were not sufficient to estimate a maximum residue level for fluopyram on melons (except watermelon).

*Leafy vegetables, including brassica leafy vegetables**Lettuce*

The critical GAP for lettuce is in Netherlands, up to two applications of 0.25 kg ai/ha, 7 days apart, with a PHI of 7 days.

In outdoor lettuce trials in Europe matching this GAP, fluopyram residues in head lettuce were 0.12, 0.13, 0.57, and 0.63 mg/kg and in leaf lettuce were 0.18, 0.18, 0.25, 0.26, 0.27, 0.53, 0.61, 0.62 and 0.93 mg/kg.

In protected lettuce matching the GAP in Netherlands, fluopyram residues in head lettuce were 0.23, 1.4, 1.9, 2.1, 2.5 and 7.7 mg/kg and in leaf lettuce were 0.16, 0.81, 0.92, 1.2, 2.3, 2.7, 3.8, 4.4, 7.2 and 8.4 mg/kg.

The Meeting noted that highest residues were in protected lettuce and since the data sets for leaf and head lettuce were not from different populations (Mann Whitney), agreed to use the combined data set for protected head and leaf lettuce to estimate maximum residue levels for leaf and head lettuce.

The combined data set of results from the protected lettuce trials matching the GAP in Netherlands is: 0.16, 0.23, 0.81, 0.92, 1.2, 1.4, 1.9, 2.1, 2.3, 2.5, 2.7, 3.8, 4.4, 7.2, 7.7 and 8.4 mg/kg (n=16).

The Meeting estimated maximum residue levels of 15 mg/kg, STMRs of 2.2 mg/kg and HRs of 8.4 mg/kg for fluopyram on lettuce, head and lettuce, leaf.

*Stalk and stem vegetables**Asparagus*

The critical GAP for asparagus is in Switzerland, up to two applications of 0.2 kg ai/ha, applied to mature ferns prior to senescence, about 6 months or more before the new spears emerge. In four European trials matching this GAP, fluopyram residues in the new spears were all < 0.01 mg/kg.

The Meeting estimated a maximum residue level of 0.01 (*) mg/kg, an STMR of 0 mg/kg and an HR of 0 mg/kg for fluopyram on asparagus.

*Oilseeds**Rape seed*

The critical GAP for oilseed rape is in Ukraine, up to two applications of 0.113 kg ai/ha with a PHI of 30 days. Fluopyram residues in rape seed from European trials matching this GAP were: 0.07, 0.1, 0.14, 0.25, 0.27, 0.27, 0.29, 0.33, 0.34, 0.35, 0.38, 0.38, 0.46, 0.46 and 0.61 mg/kg (n=15).

The Meeting estimated a maximum residue level of 1 mg/kg and an STMR of 0.33 mg/kg for fluopyram on rape seed.

*Animal feeds**Oilseed rape, forage*

The Meeting noted that the GAP for fluopyram in Europe is for use on oilseed rape over the flowering period or at early maturity (up to 30 days before harvest). The use of oilseed rape as a forage crop is normally earlier in the season, up to about BBCH 39, prior to the first application of fluopyram and the Meeting concluded that the reported GAP for fluopyram is not relevant for the use of oilseed rape as an animal forage crop.

Fate of residues during processing

The 2010 JMPR reported that fluopyram was stable under conditions simulating pasteurisation, boiling and sterilisation and also estimated processing factors and STMR-Ps for a range of commodities. Relevant processing factors and STMR-Ps for the commodities considered at this Meeting and used for dietary intake risk assessment or for estimating livestock animal burdens are summarised below.

Summary of relevant processing factors and STMR-P values for fluopyram residues

Raw agricultural commodity	Processed commodity	Processing factors ^a (mean or median)	RAC (mg/kg)		STMR-P (mg/kg)	HR-P (mg/kg)
			STMR	HR		
Cabbage			0.01	0.14		
	Cooked washed heads	< 0.36			0.004	0.05
Plums			0.13	0.22		
	Dried fruit	1.1			0.14	0.24
Rape seed			0.33			
	Oil (refined)	0.71			0.23	
	Meal	0.69			0.23	

^a The processing factor is the ratio of the total residue in the processed item divided by the total residue in the RAC.

Animal commodity maximum residue levels

Cattle

The two new cattle feed commodities considered by the Meeting (rape meal and cabbage leaves) increased these dietary burdens by less than 1.5% and the Meeting agreed that the maximum residue levels, STMRs and HRs estimated by the 2012 JMPR for animal commodities did not need to be revised.

Poultry

The new poultry feed commodity considered by the Meeting (rape meal) increased the maximum dietary burden by less than 1% and increased the mean dietary burden by 11%. The Meeting agreed that the maximum residue levels and HRs estimated by the 2012 JMPR for poultry commodities did not need to be revised.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with the MRL and for the estimation of dietary intake for plant commodities: *fluopyram*

Definition of the residue for compliance with the MRL for animal commodities: *Sum of fluopyram and 2-(trifluoromethyl) benzamide, expressed as fluopyram*

Definition of the residue for the estimation of dietary intake for animal commodities: *Sum of fluopyram, 2-(trifluoromethyl)benzamide and the combined residues N-[(E)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl]-2-trifluoromethyl benzamide and N-[(Z)-2-[3-chloro-5-(trifluoromethyl)pyridin-2-yl]ethenyl]-2-trifluoromethyl benzamide, all expressed as fluopyram.*

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) for fluopyram were calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available. The results are shown in Annex 3.

The International Estimated Daily Intakes of fluopyram for the 17 GEMS/Food regional diets, based on estimated STMRs were 3–20% of the maximum ADI of 0.01 mg/kg bw (Annex 3 to the 2014 Report). The Meeting concluded that the long-term intake of residues of fluopyram from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short-term Intakes (IESTIs) for fluopyram were calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available (Annex 4 to the 2014 Report).

For fluopyram the IESTI varied from 0–100% of the ARfD (0.5 mg/kg bw) and the Meeting concluded that the short-term intake of residues of fluopyram from uses considered by the Meeting is unlikely to present a public health concern.

GLUFOSINATE-AMMONIUM (158)

First draft prepared by Dr D.J. MacLachlan, Department of Agriculture, Australia

EXPLANATION

Glufosinate-ammonium is a herbicide or desiccant. It was first evaluated for residues and toxicology by the 1991 JMPR and re-evaluated (T, R) by the 2012 JMPR. The ADI of glufosinate-ammonium was 0–0.01 mg/kg bw and the ARfD was 0.0 1mg/kg bw. The compound was listed by the 45th Session of CCPR for the JMPR to consider a revised use-pattern for use on soya bean. The residue definition for compliance with MRL and for estimation of dietary intake (for animal and plant commodities) is the sum of glufosinate, 3-[hydroxy(methyl)phosphinoyl]propionic acid and N-acetyl-glufosinate, calculated as glufosinate (free acid).

For the current evaluation the Meeting received critical data required for the estimation of MRLs for soya beans.

RESIDUE ANALYSIS***Stability of pesticide residues in stored analytical samples***

The 2012 JMPR evaluated data on the storage stability of glufosinate-ammonium residues (and metabolites) in plant commodities that included soya bean. The studies concluded residues of glufosinate, NAG and MPP are stable under frozen conditions for at least 24 months in glufosinate-tolerant soya bean seed and for at least 12 months in glufosinate tolerant soya bean hay. The longest storage interval in the current trials was 5.4 months.

USE PATTERN

In the United States the registered use of glufosinate-ammonium for weed control in/on glufosinate-tolerant soya bean was recently amended. Up-dated information on the corresponding label recommendations and the supported use pattern is given in Table 1.

The critical GAP consists in two spray applications before the beginning of bloom, first at the rate of 0.74 kg ai/ha and then at the rate of 0.59 kg ai/ha with a minimum interval of 5 days between the two applications. The pre-harvest interval is 70 days.

The previous label suggested that it was possible to apply at the beginning of bloom and this point now has been specified since the growth stage at the time of application significantly impacts the residues in mature seed at harvest.

Table 1 GAP information on the use of glufosinate-ammonium in/on glufosinate-tolerant soya bean

Crop	Country	Use	Application			PHI
			Rate kg ai/ha	Spray volume L/ha	No.	
LLSoya bean	United States	Post-emergence and up to, but not including, the bloom growth stage	0.45-0.74 for 1 st 0.45-0.59 for 2 nd (max 1.3 kg ai/ha/season)	94-187 L/ha (> 94 L/ha air)	1-2	70 ^a

^a Do not graze the treated crop or cut for hay. Do not use nitrogen solutions as spray carriers. A silicone-based antifoam agent may be added if needed. Do not apply through any type of irrigation system. Sequential applications should be at least 5 days apart.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised residue trials of foliar treatments of glufosinate-ammonium for soya beans (Oakes 2013 TK011619).

Residues, application rates and spray concentrations have been rounded to two figures. Residue data are recorded unadjusted for percentage recoveries or for residue values in control samples. Where multiple analyses were conducted on a single sample, the average value is reported. Residues from the trials conducted according to critical GAP have been used for the estimation of maximum residue levels, STMR and HR values. Those results are underlined.

Table 2 Summary of sprayers, plot sizes and field sample sizes in the supervised trials

Crop	Location	Year	Sprayer	Plot size (m ²)	Sample size (kg)	Sample to analysis interval (months)
Soya	USA	2012	Backpack sprayer	56 m ²	≈2.3	4.9-5.0
Soya	USA	2012	Backpack sprayer	35 m ²	≈0.45	4.0-4.1
Soya	USA	2012	Backpack sprayer	74 m ²	≈2.3	5.1-5.2
Soya	USA	2012	Backpack sprayer	93 m ²	≈2.3	4.5-4.6
Soya	USA	2012	Tractor mounted sprayer	93 m ²	≈2.3	5.3-5.4
Soya	USA	2012	Tractor mounted sprayer	93 m ²	≈2.3	4.7-4.8

Six residue trials with glufosinate-tolerant soya bean (SYHT0H2 event) were conducted in the USA during the 2012 growing season. In each trial the treated plot received two applications of glufosinate-ammonium at the nominal rates of 0.74 kg ai/ha and 0.59 kg ai/ha, respectively, using an SL formulation. The first application was conducted at the growth stages BBCH 12–13 while the second application was conducted 7 to 15 days later, at the growth stages BBCH 14–59. Duplicate samples of soya bean seed were taken at the earliest commercial harvest which was between 86 and 110 days after the last application. Samples were stored frozen for a maximum of 5.4 months before analysis.

APPRAISAL

Glufosinate-ammonium is a herbicide or desiccant. It was first evaluated for residues and toxicology by the 1991 JMPR and re-evaluated (T, R) by the 2012 JMPR. The ADI of glufosinate-ammonium was 0–0.01 mg/kg bw and the ARfD was 0.0 1mg/kg bw. The compound was listed by the 45th Session of CCPR for the JMPR to consider residues in soya bean following a revision to the use-pattern.

The residue definition for compliance with MRL and for estimation of dietary intake (for animal and plant commodities) is the sum of glufosinate, 3-[hydroxy(methyl)phosphinoyl]propionic acid and N-acetyl-glufosinate, calculated as glufosinate (free acid).

For the current evaluation the Meeting received critical data required for the estimation of MRLs for soya beans.

Stability of residues in stored analytical samples

The 2012 JMPR evaluated data on the storage stability of glufosinate-ammonium residues (and metabolites) in plant commodities that included soya bean. The studies concluded residues of glufosinate, NAG and MPP are stable under frozen conditions for at least 24 months in glufosinate-tolerant soya bean seed and for at least 12 months in glufosinate tolerant soya bean hay. The longest storage interval in the current trials was 5.4 months.

Results of supervised residue trials in crops

Soya beans, tolerant

The Meeting received field trials performed in the USA involving glufosinate tolerant soya beans. GAP for USA is for (1) one application pre-planting or pre-emergence at 0.59–0.74 kg ai/ha with additional applications from post-emergence to the early bloom growth stage at 0.45–0.59 kg ai/ha with a maximum seasonal rate of 1.3 kg ai/ha/year or (2) post-emergence only with applications from post-emergence to the early bloom growth stage at 0.41–0.50 kg ai/ha with a maximum seasonal rate of 0.91 kg ai/ha/year. The PHI is 70 days. Post-emergent application leads to higher residues.

The use pattern specifies both a last growth stage for application (before the bloom growth stage) and a PHI. The Meeting noted that the interval between the last application and harvest varies significantly depending on the trial location and the soya bean cultivar and that the growth stage at last application was the critical parameter in determining compliance with GAP rather than the PHI.

In trials previously reported by the 2012 JMPR and new trials made available to the current meeting approximating the revised critical GAP in the USA total residues (glyphosate+NAG+MPP) in soya bean seeds were (n=24): 0.04, 0.08, 0.08, 0.1, 0.18, 0.18, 0.19, 0.22, 0.3, 0.3, 0.32, 0.32, 0.32, 0.36, 0.39, 0.4, 0.45, 0.5, 0.51, 0.54, 0.65, 0.75, 1.09, 1.3 mg/kg. The Meeting estimated a median residue of 0.32 mg/kg for use in calculating livestock dietary burdens and a maximum residue level of 2 mg/kg for soya bean, dry to replace its previous recommendation of 3 mg/kg.

Residues for estimation of dietary intake (glufosinate + $0.1 \times [\text{NAG} + \text{MPP}]$) residues were (n=24): 0.02, 0.02, 0.03, 0.04, 0.05, 0.05, 0.07, 0.08, 0.09, 0.09, 0.09, 0.09, 0.09, 0.10, 0.11, 0.11, 0.13, 0.13, 0.14, 0.14, 0.19, 0.25, 0.35 and 0.39 mg/kg. The Meeting estimated an STMR and HR of 0.09 and 0.39 mg/kg respectively for soya bean (dry) for use in calculation of dietary intake.

Fate of residues during processing

Processing factors reported by the 2012 JMPR are used to calculate median residues for aspirated grain fractions, hulls, meal and oil that are used in calculation of livestock dietary burden and also for oil used in calculation of the IEDI and IESTI for glufosinate-ammonium.

Summary of selected processing factors for glufosinate-ammonium

Raw commodity	Processed commodity	Individual PF	Best estimate PF	Median or STMR _{RAC} (mg/kg)	Median or STMR _{RAC} × PF (mg/kg)
Soya bean	Aspirated grain fraction	2.73 8.89	5.81	0.32	1.86
	Hulls	3.15, 11.4	7.275		2.33
	Meal	1.22	1.22		0.39
	Oil	< 0.11 < 0.12 <0.22 < 0.9	< 0.17	0.09	< 0.015

Animal commodity maximum residue levels

The minor changes to the estimated soya bean and soya bean processed commodity levels do not result in significant differences in livestock dietary burdens. The Meeting agreed it is not necessary to make new estimates and recommendations for livestock commodities.

RECOMMENDATIONS

On the basis of the data obtained from supervised residue trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for (compliance with the MRL and for estimation of dietary intake) for animal and plant commodities: *sum of glufosinate, 3-[hydroxy(methyl)phosphinoyl]propionic acid and N-acetyl-glufosinate, calculated as glufosinate (free acid)*

The residue is not fat soluble.

Table of recommendations.

Commodity		Recommended MRL (mg/kg)		STMR or STMR-P (mg/kg)	HR (mg/kg)
CCN	Name	New	Previous		
VD 0541	Soya bean (dry)	2	3	0.09	-

DIETARY RISK ASSESSMENT**Long-term intake**

The Meeting noted that the reduction in the recommended maximum residue level for soya beans would result in lower IEDIs than those previously estimated for glufosinate-ammonium by the 2012 JMPR. The present meeting concluded that the long-term intake of glufosinate-ammonium resulting from the uses considered by the current JMPR is unlikely to present a public health concern.

Short-term intake

The WHO Panel of the 2012 JMPR established an Acute Reference Dose (ARfD) of 0.01 mg/kg bw for glufosinate-ammonium. The IESTI was calculated for soya bean and related commodities using STMR, STMR-P and HR values estimated by the current Meeting. The IESTIs represented 0 to 10% of the ARfD of 0.01 mg/kg bw. The Meeting concluded that the short-term intake of residues of glufosinate-ammonium resulting from uses that have been considered by the JMPR is unlikely to present a public health concern.

IMAZAMOX (276)

The first draft was prepared by Professor Mi-Gyung Lee, Andong National University, Republic of Korea

EXPLANATION

Imazamox is an imidazolinone herbicide used for the control of a wide spectrum of grassy and broadleaf weeds. The mode of action of imazamox is the inhibition of acetohydroxy acid synthase (AHAS), an enzyme involved in the synthesis of essential amino acids (leucine, isoleucine and valine) for the development of the plant.

At the 45th session of the CCPR (2013), it was scheduled for evaluation as a new compound by the current JMPR. Imazamox has been registered in various countries worldwide.

The Meeting received information on physical and chemical properties, animal and plant metabolism, environmental fate, analytical methods, storage stability, use patterns, supervised trials and processing studies.

CL 152795		2-[(1-carbamoyl-1,2-dimethylpropyl) carbamoyl]-3,5-pyridinedicarboxylic acid		impurity present in dosing solution in animal metabolism study

The metabolism and distribution of imazamox in animals and plants and the fate of imazamox in the environment were investigated using the following radiolabelled compounds (* indicates position of radiolabelling).

[pyridine-6-¹⁴C]-imazamox[pyridine-6-¹⁴C]-CL 263284[pyridine-6-¹⁴C]-CL 312622

Animal metabolism

The Meeting received information on the metabolism of imazamox in ruminants (lactating goats), poultry (laying hens) and laboratory animals (rat). Metabolism studies on rats were reviewed in the framework of toxicological evaluation by the current JMPR and relevant information is summarized below.

Rat

Imazamox administered to rats orally was primarily eliminated as unchanged test compound via the urine and secondly via the faeces. Biliary excretion was not an important route of elimination. Elimination was very efficient and occurred rapidly within 6–48 hours post-dose. In addition, the ratio of enantiomers did not change, demonstrating a similar absorption and excretion rate for the individual enantiomers of imazamox in the rat [Chiu 1995a, ID-440-003; Chiu 1996a, ID-440-004; Thiaener & Lutz 2012a, 2011/1080475].

Lactating goats

Imazamox

Lactating goats were orally given single daily doses of [pyridine-6-¹⁴C]-imazamox for seven consecutive days at a level of either 2.08 or 11.6 ppm in the feed [Johnson 1994a, ID-440-002]. Radiolabelled imazamox was administered orally in gelatin capsules with lactose carrier to lactating goats. Mean feed consumption was 1890 and 1721 g per day for the low and high dose goats during the treatments. The milk, urine, faeces, and blood were collected daily starting one day before the first dosing for each animal group and continued throughout the dosing period. Kidney, liver, leg and loin muscle, and omental fat samples were collected approximately 20 hours after the last dosing. All samples were analysed for radioactivity content.

Samples were analysed by LSC or combustion followed by LSC. The validated detection limit of the radioassay method was approximately 0.01 mg eq/kg for milk, blood, and all tissues. Radioactivity in kidney and urine extracts was characterized using HPLC. Aliquots of the radioactive components isolated from kidney and urine were analysed by GC-MS for confirmation.

During treatment, the total radioactive residues (TRR) in the daily blood and milk samples were less than 0.01 mg eq/kg regardless of the treatment dose levels. The TRR in liver, leg and loin muscle, and omental fat were less than 0.01 mg eq/kg regardless of dose level. The imazamox-derived TRR in the kidney was 0.02 mg eq/kg from the goat dosed at 2.08 ppm and 0.06 ppm from the goat dosed at 11.6 ppm.

Elimination of ¹⁴C radioactivity in the urine accounted for 91.2% and 64.8% of the total dose for the low and high doses, respectively. The radioactivity excreted in the faeces represented 14.8% and 24.0% of the total dose for the low and high doses, respectively. Total recovery of radioactivity in urine and faeces was 106.0% and 88.8% for the low and high doses, respectively.

Radioactive residues from kidney of the high dose goat were extractable (99%) with methanol/water (80:20, v/v). Analysis of the extract by reverse-phase HPLC showed that 89% of the

extractable TRR was attributable to imazamox. The identity of this compound was confirmed by GC-MS. The other radioactivity detected was distributed throughout the chromatogram at levels near background.

That imazamox parent is the only significant compound in tissues is supported by results for urine. Reverse-phase HPLC of goat urine showed 91% of radioactivity was imazamox (confirmed by GC-MS). A radioactive peak containing approximately 5% of the radioactivity recovered from the HPLC column occurred at a shorter retention time than imazamox and the remaining radioactivity occurred as minor components (< 0.5% of radioactivity). The component with a shorter retention time was isolated using HPLC fraction collection, partitioned from the mobile phase using dichloromethane, and reanalysed using HPLC. Of the radioactivity recovered from the HPLC column, 70% was imazamox (confirmed by GC-MS). The most likely explanation for this is that imazamox formed a weak complex with a component in the urine matrix, causing the shorter retention time. This then dissociated during isolation, giving imazamox.

In summary, orally administered imazamox in the goat is mainly excreted in urine. At highly exaggerated dose rates, there were no detectable imazamox-derived residues in milk during and after treatment, nor in tissues except kidney 20 hours after the last dose. The kidney contained 0.02 and 0.06 mg eq/kg total radioactive residue from the low and high dose ^{14}C -treated goats, respectively. This was mostly imazamox. Unaltered parent accounted for most of the excreted residue.

CL 263284

A ruminant metabolism study was conducted with [pyridine-6- ^{14}C]-CL 263284 [Kao 1994a, IA-440-001]. Dose levels for the goats, administered orally in gelatin capsules, were 0, 2.33 or 14.5 mg/kg feed daily for seven days. Samples of blood, milk and excreta were collected daily. After seven days of dosing, the goats were sacrificed (approximately 20 hours after the last dose) and the tissues kidney, liver, muscle and fat were collected. Samples were analysed by LSC or combustion followed by LSC. The validated detection limit of the radioassay method was approximately 0.01 mg eq/kg. Kidney, urine and faeces samples were additionally analysed via HPLC-MS.

TRR levels in most control samples and most tissue samples (muscle, fat and liver) from the low and high dose treated goat and from all milk samples were non-detectable (< 0.01 mg eq/kg). The control sample from kidney showed a residue of 0.01 mg eq/kg and the kidney sample from the high dose goat was at 0.03 mg eq/kg.

Elimination of ^{14}C radioactivity via urine accounted for 14.6% and 18.2% of the total cumulative dose at low dose and high dose, respectively (81.7% and 67.8% via faeces). The recovery of radioactivity in urine and faeces totalled 96.3% and 86.0% at low dose and high dose, respectively.

All milk and all tissue samples contained less than 0.01 mg eq/kg of TRR, the detection limit, except the kidney samples from goat treated at the high dose rate.

Radioactive residues were extracted from kidney using methanol as solvent. The main radioactivity was observed in the extract (91%) and only minor amounts were detected in the PES (9%). The kidney extract was analysed by HPLC to determine the nature of the radioactive residue. The administered compound (CL 263284) was the minor radioactive residue (9% TRR, < 0.01 mg/kg). One further peak was present in the chromatogram (M1; 78% TRR, 0.02 mg eq/kg). M1 was further characterized by treatment with β -glucuronidase, sulfatase or buffer alone. M1 showed to be a very labile component and was easily degraded to CL 263284 under non-enzymatic or enzymatic hydrolysis. Because M1 was converted to CL 263284 in buffer (0.2 M potassium phosphate, pH 6.8) alone, it is likely that M1 was the parent compound weakly coupled with kidney endogenous components. It is suspected that M1 is a salt or conjugate of CL 263284 that is readily dissociated in aqueous solutions such as buffer.

HPLC analysis of the faeces extract of goat treated at high dose showed that 96% of the radioactivity had a retention time corresponding to that of CL 263284 reference standard. HPLC analysis of the faeces extract of goat treated at low dose showed that the major component had a retention time at 9 minutes which is the same as the M1 component found in the high dose kidney.

The M1 component was very labile and was easily converted to CL 263284 under aqueous, acidic conditions or incubated with β -glucuronidase and sulfatase.

The results of this lactating goat study showed that the administered compound was excreted without retention or accumulation in milk. Of the edible tissues only kidney showed detectable residues and these were identified as the administered compound CL 263284 and a labile metabolite that converted to CL 263284 in aqueous solution. This shows a very low transfer of CL 263284-derived residues from animal feed into tissues and milk of lactating ruminants.

CL 312622

Lactating goats were orally treated with a mixture of [pyridine-6- ^{13}C] and [pyrindine-6- ^{14}C]-radiolabelled imazamox metabolite (CL 312622) [Tsaltz 1999a, ID-440-006]. The three goats were dosed for five consecutive days with the nominal dietary equivalent of 0 ppm (control), 3.1 ppm (low dose) and 33 ppm (high dose) in the feed. Milk, urine and faeces samples were collected daily and edible tissues (muscle, fat, liver and kidney) were collected at sacrifice (approximately 22 hours after the last dose). Samples were analysed by LSC or combustion followed by LSC. The specific radioactivity afforded a validated detection limit of 0.006 mg eq/kg CL 312622 equivalents in the tissues, milk, urine and faeces.

TRR levels in all tissue and milk samples were non-detected (< 0.006 mg eq/kg), except kidney (0.025 mg eq/kg) and liver (0.009 mg eq/kg) of goats treated at high dose (33.4 mg/kg feed). Elimination of ^{14}C radioactivity via urine accounted for 8.5% and 7.0% of the total cumulative dose at low dose and high dose, respectively (90.4% and 90.0% via faeces). The recovery of radioactivity in urine and faeces totalled 98.9% and 97.0% at low dose and high dose, respectively.

Radioactive residues were extracted from kidney using acetone/water (3:1, v/v) as solvent. The overall recovery in the extractable portion was $> 100\%$ (by comparison with the TRR obtained by combustion); no radioactivity was observed in the PES. The kidney extract was analysed by HPLC to determine the nature of the radioactive residue. The administered CL 312622 was the predominant radioactive residue (60.0%). The impurity known to be present in the dosing solution (CL 152795) was also found in the extract at 11.0% of TRR.

Minor polar unknowns (total 10.3% of TRR) and non-polar unknowns (total 11.9% of TRR) were also present in the kidney extract. Since these fractions were equivalent to 0.003 mg eq/kg and contained multiple components, no further characterization was attempted.

Radioactive residues were extracted from liver according to a modification of the kidney extraction procedure. The percent extractable radioactivity was 98.7% and the percent TRR in the PES by combustion/LSC analysis yielded residues less than the validated detection limit.

The concentrated extract was analysed by HPLC after solid phase extraction (SPE) clean-up. The administered CL 312622 was present at 38.2% of TRR in the liver. The impurity known to be present in the dosing solution (CL 152795) was also found in the liver extract at 19.0% of the TRR as determined by HPLC. Polar radioactive components were present in the liver extract at 31.2% of the TRR. The majority of that fraction (22.9%) was not retained by the SPE cartridge, indicating it to be very polar material. Some non-polar metabolites were also present at a total concentration of 11.3% of the TRR. Since these fractions were equivalent to 0.003 mg eq/kg or lower and contained multiple components, no further characterization was attempted.

Data on the distribution of the recovered radioactivity from the kidney and the liver extract, as determined by HPLC, are summarized in table below.

Table 1 Distribution of radioactivity in high dose goat kidney and liver goat treated with [^{14}C]-CL 312622 (ID-440-006)

Compound	Kidney (0.025 mg eq/kg)		Liver (0.009 mg eq/kg)	
	% TRR	mg eq/kg	% TRR	mg eq/kg
CL 312622	60.0	0.015	38.2	0.003
CL 152795	11.0	0.003	19.0	0.002

Polar unknowns	10.3	0.003	31.2	0.003
Non-polar unknowns	11.9	0.003	11.3	0.001

Kidney and liver of goat administered with 33.4 mg/kg feed

CL 152795: impurity present in dosing solution

The results of this CL 312622 study showed that the administered compound (CL 312622) and the CL 152795 compound (present as an impurity in the dosing solution) were excreted with minimal retention by the kidney and the liver at the exaggerated dose of 33.4 ppm in the feed. There was no accumulation in any other edible goat tissue or in the milk. There were no residues found in the tissues or milk of the low dose treated goat.

Laying hens

Imazamox

Laying hens were orally dosed with [pyridine-6-¹⁴C]-imazamox [Johnson 1994b, Johnson 1994b, (IA-440-002)]. Feeding levels for each group consisting of eight white Leghorn hens were 0, 2.11 and 10.2 ppm in the feed daily by gelatin capsule for seven consecutive days. Eggs were collected twice daily and blood and the tissues (liver, kidney, muscle, and skin with adhering fat) were collected for analysis approximately 22 hours after the last dose. Samples were analysed by combustion followed by LSC. The validated detection limit of the radioassay method was approximately 0.01 mg eq/kg for eggs, blood and all tissues.

Residues in eggs, blood, skin with adhering fat, muscle, liver, and kidney tissues were all less than 0.01 mg eq/kg. Recovery of ¹⁴C in excreta collected over the 7 day treatment period averaged 85.5% of the total administered dose at 2.11 ppm feeding level and 84.8% at 10.2 ppm feeding level.

The results of this study indicate that imazamox-related residues do not accumulate in eggs or edible tissues of poultry. Orally administered imazamox was mainly eliminated from the hen through excreta. No detectable (< 0.01 mg eq/kg) [¹⁴C]imazamox-derived residues in eggs or edible tissue were found.

CL 263284

A poultry metabolism study was conducted with [pyridine-6-¹⁴C]-radiolabelled imazamox metabolite CL 263284 [Afzal 1994a, IA-440-002]. Hens of each group containing eight animals were dosed orally by gelatin capsules at 0, 2.14 and 10.9 ppm in the feed daily for seven days. Eggs and excreta were collected daily. After seven days of dosing, the hens were sacrificed and the tissues (liver, kidney, muscle and skin with adhering fat) and blood were collected for analysis approximately 22 hours after the last dose. Samples were analysed by combustion followed by LSC. The validated detection limit of the radioassay method was 0.01 mg eq/kg CL 263284 equivalents in the tissues, eggs and excreta.

Total recovery of radioactivity in excreta was 85.3% and 88.6% for the low and high dose, respectively. Residues in all tissues, blood and eggs were less than 0.01 mg eq/kg, the validated detection limit.

The results of this study indicate that the administered CL 263284-related residues do not accumulate in eggs or edible tissues of poultry. Orally administered imazamox was mainly eliminated from the hen through excreta. No detectable (< 0.01 mg eq/kg) ¹⁴C-CL 263284-derived residues in eggs or edible tissue were found.

CL 312622

Laying hens were orally treated with a mixture of [pyridine-6-¹³C] and [pyridine-6-¹⁴C]-radiolabelled imazamox metabolite CL 312622 [Afzal 1999a, ID-440-005]. The eight hens (Hy Line W-36, White Leghorn) by each group were dosed for five consecutive days with 0 ppm feed (control), 0.13 ppm feed (low dose) and 10.5 ppm feed (high dose). Eggs were collected twice daily and bile and the edible tissues (muscle, liver and skin with adhering fat) were collected at sacrifice approximately 22

hours after the last dose. Samples were analysed by combustion followed by LSC. The validated detection limit of the radioassay method was 0.01 mg/kg CL 312622 equivalents in the tissues, eggs and excreta. Detection of CL 312622-related residues in excreta extract was accomplished by HPLC-UV. The radioactivity was quantitated by LSC.

With the exception of high dose composite bile sample (0.018 mg eq/kg), residue in tissues (liver, muscle and skin with adhering fat), eggs and bile were all less than or equal to the validated detection limit (0.006 mg/kg) of the radioassay. Recovery of ^{14}C in excreta collected over the five day treatment period averaged 87.5% and 90.9% of the total administered dose from the low dose (0.13 ppm feed) and high dose (10.5 ppm feed), respectively. These data showed that the administered CL 312622 or derived residues as well as CL 152795 (present as an impurity in the dosing solution) were excreted without retention or accumulation in eggs and edible poultry tissues.

The extremely low residues in eggs and edible tissues precluded further characterization. The high dose day-2 excreta sample was extracted with methanol. The extractability of ^{14}C residue was 91.2%. The extracted ^{14}C residue was analysed by HPLC. The major component of the extractable residue was unchanged CL 312622, accounting for 76.7% of the extractable radioactive residue. The polar dosing solution impurity (CL 152795) accounted for approximately 6.5% of the ERR. All other components were insignificant and no single component exceeded 5% of the TRR.

Table 2 Distribution of radioactivity in high dose hen excreta of day 2 treated with [^{14}C]-CL 312622 (ID-440-005)

Compound	Excreta (9.2 mg eq/kg)	
	% TRR	mg eq/kg
CL 312622	70.0	7.0
CL 152795	5.9	0.6
Non-polar unknowns / Methyl ester	2.0	0.2

Excreta of hen administered with 10.5 ppm.

Plant metabolism

The Meeting received information on the fate of imazamox in oilseed rape, soya bean, pea, maize, wheat and alfalfa.

Oilseed rape

Study 1

A metabolism study was conducted to investigate the amount of imazamox residues and the nature of its degradation products in summer oilseed rape after foliar application [Radzom 2013a, 2011/1281377]. Oilseed rape (imidazolinone herbicide-tolerant variety: Salsa CL) was sown into ten plastic containers (total test area, external size = 2.4 m²) filled with sandy loam soil, which were located in climatic chambers (phytotrons). The phytotrons simulated the natural climatic conditions of a typical rapeseed-growing area.

Under the indoor condition, the crop was treated once with [imidazolinone-5- ^{14}C , 3- ^{15}N]-imazamox at growth stage BBCH 10–18 with a rate of 0.075 kg ai/ha. Labelled ^{14}C , ^{15}N -imazamox and unlabelled ^{12}C -imazamox were mixed at a ratio of 2:1 (^{14}C , ^{15}N -imazamox: ^{12}C -imazamox). Blank formulation (40 g ai/kg blank formulation), adjuvant BAS 160 00 S (1 L/ha) and water was added. The application solution was monitored for purity by HPLC and the isotope pattern was determined by mass spectrometry. The formulation in a spray volume of 216 L/ha was applied with an automatic spray track. Forage samples were taken 12 days after treatment (BBCH 39). At harvest (90 DAT, BBCH 89), mature oilseed rape pods and straw were cut off with scissors. Hull and seed were separated using a thresher. All samples were stored in a freezer at approximately $-18\text{ }^{\circ}\text{C}$ or below. The storage conditions stayed the same until analysis

started and during the whole period of the metabolism study. Extracts were stored in a refrigerator or, for longer periods, in a freezer.

The plant material (forage, straw, hull and seed) were extracted with methanol and water. The combined extracts were measured by LSC. The residual radioactive residues after solvent extraction were combusted. On the other hand, a sequential solubilisation procedure was applied for the PES of rape straw, hull and seed. The residues were extracted with aqueous ammonia solution (1%) and subsequently by treatment with protease (only seed) and with cellulase and macerozyme. The extracts and residues were analysed by LSC.

Methanol extracts of rape forage, straw and hull were directly investigated by LC-MS. Peak assignment in the other samples was done by comparing the metabolite patterns with those of the extracts investigated by MS-analysis and by comparison of the retention times of the identified components (CL 263284, CL 312622) with the ^{14}C -signals of the quantitative and confirmatory HPLC analyses. Additionally, a co-chromatography experiment with the reference items CL 312622 and CL 263284 was performed with the water extract of rape straw. In order to investigate, if cleavage of the imazamox ring systems occurs, reference item dimethylhydantoin was studied with respect to its chromatographic properties to check for similar degradation products. According to retention time comparison, in the HPLC chromatograms of oilseed rape matrices no corresponding signals were detected and therefore no formation of cleavage products was observed.

The TRR of rape forage was 1.004 mg eq/kg, straw 1.100 mg eq/kg, hull 2.448 mg eq/kg, seed 0.149 mg eq/kg, when determined by direct combustion.

Table 3 Total radioactive residues (TRR) in oilseed rape samples following foliar application of [^{14}C , ^{15}N]-imazamox (2011/1281377)

Radioactive residues in treated oilseed rape			
Matrix	Days after treatment	TRR determined by direct combustion (mg eq/kg)	TRR calc. (mg eq/kg)
Forage	12	1.004	0.889
Straw	90	1.100	1.134
Hull	90	2.488	2.527
Seed	90	0.149	0.152

The extractability of rape forage with methanol and water was 97.7% TRR (0.868 mg eq/kg) with the major part of the residues extracted with methanol (0.823 mg eq/kg, 92.6% TRR). The extractability of rape straw and hull with methanol and water was 77.6% TRR (0.879 mg eq/kg) and 78.8% TRR (1.991 mg eq/kg), respectively. The major part of the residues was also extracted with methanol (50.5% TRR in straw and 57.7% TRR in hull). From rape seed, 58.3% TRR (0.089 mg eq/kg) was extracted by solvent extraction (methanol and water), with more radioactivity was extracted with water (34.3% TRR) than with methanol (24.0% TRR).

Table 4 Distribution of residues of [^{14}C , ^{15}N]-imazamox in oilseed rape samples (2011/1281377)

Matrix	Days after treatment	TRR calc. ^a mg eq/kg	Extracts				total		PES	
			methanol extract		aqueous extract		mg eq/kg	%TRR	mg eq/kg	%TRR
			mg eq/kg	%TRR	mg eq/kg	%TRR				
Forage	12	0.889	0.823	92.6	0.045	5.0	0.868	97.7	0.021	2.3

Analysis of the methanol extract of rape forage resulted in a pattern of two major and four minor peaks, of which three were identified by direct LC-MS analysis of the methanol extract. One of the two prominent peaks was identified as metabolite CL 263284 and accounted for 0.476 mg eq/kg (53.5% TRR). Parent compound imazamox was the second most abundant component and accounted for 0.373 mg/kg (41.9%). Metabolite CL 312622 was identified at 8.6% TRR. The remaining components were detected at levels below 1.1% TRR and characterised by their chromatographic properties. The same methanol extract was additionally analysed using HPLC that confirmed the metabolite pattern of the quantitative analysis. The respective water extract and the residue obtained after solvent extraction were not further investigated due to their low amounts of radioactive residues. In the extracts, 104.0% of the total radioactive residues were identified and 7.1% were characterised by HPLC analysis or their extractability with water.

Analysis of the methanol extract of rape straw resulted in a pattern of one main peak and seven minor peaks. The main peak was identified as metabolite CL 263284 and accounted for 0.398 mg eq/kg (35.1% TRR). The metabolite CL 312622 was identified at a level of 0.071 mg eq/kg (6.3% TRR). Parent compound imazamox was not detected. The remaining components were detected at levels below 3.7% TRR. HPLC analysis of the water extract of rape straw yielded a pattern of three peaks. The most abundant peak corresponded to the metabolite CL 312622 (0.212 mg eq/kg, 8.7% TRR). The second most abundant component was metabolite CL 263284, which accounted for 0.066 mg eq/kg (5.8% TRR). The PES was further solubilised with ammonia, and a mixture of macerozyme and cellulase. The first solubilisation step with aqueous ammonia solubilised a portion of 0.069 mg eq/kg (6.1% TRR) of the radioactive residues, which may have been incompletely extracted with methanol and water or weakly associated with insoluble plant material. In the subsequent solubilisation step, the NH_4OH residue was incubated with a mixture of macerozyme and cellulase which released 0.045 mg eq/kg (4.0% TRR). Analysis of the ammonia extract resulted in the identification of CL 263284 and metabolite CL 312622, which accounted for up to 1.5% of the TRR. In the supernatant obtained after treatment with macerozyme and cellulase, CL 263284 (1.3% TRR) was identified. In the extracts of rape straw, 66.0% of the total radioactive residues were identified and 14.4% TRR were characterised by HPLC. In the PES, additional 3.9% TRR were identified and 5.9% TRR were characterised by their HPLC elution behaviour.

Analysis of the methanol extract of rape seed hull resulted in a pattern of one main peak and five minor peaks. The main peak was identified as metabolite CL 263284 and accounted for 1.321 mg eq/kg (52.3% TRR). The metabolite CL 312622 was identified at a level of 0.084 mg eq/kg (3.3% TRR). The remaining components were detected at levels below 1.4% TRR and characterised by their chromatographic properties. Likewise, in the water extract again the main constituent was CL 263284 at 0.348 mg eq/kg (13.8% TRR) detected. CL 312622 was identified at 0.049 mg eq/kg (1.6% TRR). The remaining five minor peaks were detected at levels at or below 2.0% TRR and characterised by their chromatographic properties. The residue after solvent extraction was further solubilised with ammonia, and a mixture of macerozyme and cellulase. The first solubilisation step with aqueous ammonia solubilised a portion of 0.114 mg/kg (4.5% TRR) and subsequent solubilisation step with macerozyme and cellulase released 0.082 mg eq/kg (3.2% TRR). Analysis of

the ammonia extract resulted in the identification of CL 263284 and metabolite CL 312622, which accounted for up to 2.4% of the TRR. In the supernatant obtained after treatment with macerozyme and cellulase, CL 263284 (1.8% TRR) was identified. In the extracts of rape hull, 71.0% of the total radioactive residues were identified and 8.3% TRR were characterised by HPLC. In the PES, additional 4.7% TRR were identified and 2.0% TRR were characterised by their HPLC elution behaviour.

Analysis of the methanol extract of rape seed resulted in a pattern of two peaks. The peak at 24.8 min was identified as metabolite CL 263284 and accounted for 0.020 mg eq/kg (13.3% TRR). One polar component eluted at 3.4 min and was detected at 0.017 mg eq/kg (11.1% TRR). In the confirmatory HPLC chromatogram the peak eluting in the polar region was split up into three components each below or equal to 0.009 mg eq/kg (5.9% TRR). For further investigation, the polar fraction was isolated by SPE fractionation and analysed by HPLC. Both chromatograms confirmed that the polar fraction consist of at least two components. In the water extract the main constituent was identified as CL 263284 at 0.027 mg eq/kg (17.8% TRR). CL 312622 was identified at 0.004 mg eq/kg (2.8% TRR). The remaining non-identified components were detected at levels of up to 0.007 mg eq/kg (4.3% TRR). The residue after solvent extraction was further solubilised with ammonia, protease and a mixture of macerozyme and cellulase. The first solubilisation step with aqueous ammonia solubilised a portion of 0.015 mg eq/kg (9.8% TRR) and solubilisation with protease and macerozyme/cellulase released 11.9% TRR and 4.8% TRR, respectively. An aliquot of the concentrated protease solubilisate was analysed and some minor components below or equal to 0.003 mg eq/kg (1.9% TRR) eluting in the polar region were detected. In the ERR, 33.8% of the total radioactive residues were identified and 24.2% were characterised by HPLC. In the PES, additional 9.4% TRR were characterised by HPLC analysis of the protease supernatant. In addition, 14.6% TRR were characterised by solubilisation with aqueous ammonia and a mixture of macerozyme and cellulase.

In order to analyse whether one enantiomer of imazamox and CL 263284 was preferably metabolised in oilseed rape, enantiomer-specific analyses were performed in all four matrices (forage, straw, hull and seed). For the test item and the unlabelled reference item CL 263284 the ratio of enantiomer 1 to enantiomer 2 was found to be approximately 50:50. For the determination of the enantiomer ratio in the different matrices, the parent compound imazamox and metabolite CL 263284 were isolated from the methanol extracts and analysed using HPLC. The enantiomer ratio of imazamox in forage was found to be about 30:70 and the enantiomer ratio of its metabolite CL 263284 was found to be between approximately 40:50 in forage and straw and about 60:40 in hull and seed.

Study 2

A metabolism study was conducted with [pyridine-6-¹⁴C]-imazamox and [pyridine-6-¹³C]-imazamox [McDonnell 1995a, ID-640-003]. The in-life phase of the study was conducted by the EnviroQuest facilities in Minto, Manitoba, Canada in imidazolinone-resistant oilseed rape variety NS 1471. The oilseed rape was maintained under normal outdoor agronomic practices for the region. The test substance was applied as a single post-emergence broadcast spray to a 5.6 m² plot of established oilseed rape seedlings (3- to 4-leaf stage). The application rate was 0.020 kg ai/ha. Plants samples were collected after application on the day of treatment (0 DAT). Seed was collected at maturity (82 DAT). All samples were frozen within 3 hours of the time of sampling and were kept until assay in a freezer, at approximately -20 °C. The crop samples were processed, extracted and analysed within 14 to 42 days of harvest. Plant samples were combusted using an oxidizer and the radioactive residues were assayed by LSC.

The immature oilseed rape foliage sample (0 DAT) was extracted with water/methanol (2:8, v/v). The extract was subjected to radioassay and HPLC analysis. The harvest seeds were processed to oilseed rape oil and the resultant meal. A finely ground seed sample was extracted twice with hexane. The hexane extract was evaporated and the remaining oily residue was presumed to be rape oil, while the air dried PES (post extraction solid) was presumed to be the meal. Radioactive residues in the oil and seed were assayed by LSC.

The TRR in canola foliage (0 DAT) was 2.14 mg eq/kg. The presence of [^{14}C]imazamox (91.9% TRR) was confirmed by comparison of retention time with that of known analytical standard. There were no peaks of radioactivity comprising greater than 2% impurity in the radio-profile.

In the seed, the TRR was below the detectable amount of radioactivity, 0.002 mg eq/kg. The TRR in the canola oil was below the detectable amount of radioactivity (< 0.004 mg eq/kg). No detectable TRR was present in the oil meal.

Study 3

A small plot field study on the metabolic fate of imazamox in oilseed rape was conducted during the oilseed rape-growing season in 1998 [Roman 1999b, ID-640-009]. The field phase of this study was conducted in outdoor fenced-off research plots at EnviroQuest, Minto, Manitoba, Canada where imidazolinone-tolerant oilseed rape variety 45A71 received a single post-emergence treatment with [pyridine-6- ^{14}C]-imazamox. Plot A was treated at a rate of 0.051 kg ai/ha. Plot B was treated at a rate of 0.089 kg ai/ha. The test solution was sprayed evenly over the entire plot of the oilseed rape at the 3 to 4-leaf stage. The spray volume of 280.5 L/ha and the application timing simulated the actual field use conditions.

Oilseed rape plant specimens were sampled directly after the application (0 DAT), foliage was sampled at 22 DAT and the last sampling of seeds and straw took place at 78 DAT. Green plants (0 and 22 DAT) were cut into small pieces and then ground into a fine powder with dry ice. Straw collected at later sampling intervals was first homogenized in dry ice. The seed was manually cleaned of any remaining chaff. The resulting chaff was combined with straw and processed as part of the straw sample. The seed samples were ground into a fine powder. All processed samples were stored frozen until used. The crop samples were processed, extracted, and analysed within 9 to 401 days of harvest. Rape plant and soil samples were combusted and radioactive residues were quantitated by LSC.

Finely ground oilseed rape samples were extracted three times with methanol/water (80:20, v/v) and then once with a solvent mixture of methanol/acetone/water (1:1:1, v/v/v). The radioactive residues in the combined extracts (neutral organo-extractable) were assayed by LSC. The extract was analysed for the radioactive components by HPLC. Oilseed rape seed from plot treated at a 0.089 kg ai/ha was extracted with hexane. The resulting extracts were assayed by LSC.

The remaining non-neutral organo-extractable residues in all crop samples were extracted once with 2% HCl in methanol/water (4:1). The remaining residues in straw samples were further treated with *Penicillium* cellulase and subsequently by 6 N HCl reflux. The extracts and hydrolysates were analysed by combustion.

The TRR in the rape foliage taken at 0 DAT was 2.208 mg eq/kg at a rate of 0.051 kg ai/ha (low rate) and 3.943 mg eq/kg at a rate of 0.089 kg ai/ha (high rate). The level of the radioactive residues, at the low and high rate, declined to 0.040 mg eq/kg and 0.130 mg eq/kg at 22 DAT but increased to 0.088 mg eq/kg and 0.178 mg eq/kg in the straw presumably due to dehydration. The concentration of the TRR in the mature seed (78 DAT) was relatively low as 0.004 mg eq/kg at a low rate and 0.006 mg eq/kg at a high rate.

Table 6 Total radioactive residues (TRRs) in oilseed rape plant, foliage, straw and seed samples after application of [^{14}C]-imazamox

TRR calc.: sum of extracted + PES

Neutral organo-extractable: the extraction was done with 20% aqueous methanol three times followed by methanol/acetone/water once.

n.d.: Not detected, < 0.001 mg eq/kg

In plant, forage, straw and seed, 62.1% to 98.6% of the TRR were extracted with aqueous organic solvent mixtures. The majority (57.0–97.4% TRR) was extracted with 80% aqueous methanol three times and with methanol/acetone/water (1:1:1, v/v/v). Increase in extractability by acidic organic solvent (2% HCl in methanol) was small (1.17–5.17% TRR). The unextracted radioactivity from rape plant, foliage and straw accounted for 1.4 % to 19.5% of the TRR. In the seed, the extractability of the residues was 62.1% (0.003 mg eq/kg) of the TRR. The radioactivity remaining in seed accounted for 37.9% (0.002 mg/kg) of the TRR. In the dry straw, Penicillin cellulose and 6 N HCl reflux released 2.0–2.5% TRR and 7.4–9.4% TRR, respectively. A small extractability by enzyme treatment suggested that the presence of glycosidic linkages of the residue with endocons in the oilseed rape samples is insignificant. Due to the very low residue levels (0.002–0.004 mg eq/kg) in the enzyme hydrolysates of straw sample, no attempts were made to further characterize the nature of the residues.

In rape plant at 0 DAT, residue level of the unchanged imazamox was 1.726 mg /kg or 3.068 mg /kg (78% TRR in both). Imazamox accounted for 21% or 16% TRR in forage (22 DAT), 2% TRR in straw (78 DAT). Imazamox was extensively metabolized in the late growing and matured oilseed rape plants.

Each of the metabolites (CL 189215, CL 263284 and CL 312622) was found in rape at 0 DAT as a minor with none exceeding 2.6% of the TRR. At 22 DAT and 78 DAT, the hydroxymethyl metabolite CL 263284 accounted for 37.4% or 36.0% in forage and 49.6% or 46.4% in straw. Its glucoside CL 189215 and di-acid metabolite CL 312622 were present in very low level (below 8.6% TRR, 0.003 mg eq/kg).

Soya bean

A small-plot field study was conducted in an outdoor, fenced-off research area during the growing season of soya bean [Chiu 2000b, ID-640-010]. [pyridine-6-¹⁴C]-imazamox was applied as a single post-emergence on soya bean plants var., Hartz 5566 at the three-to-four trifoliate stage. The [pyridine-6-¹⁴C]-imazamox was diluted with non-radiolabelled imazamox and [pyridine-6-¹³C]-imazamox. The radiolabelled imazamox was formulated for application as the ammonium salt in aqueous solution and was sprayed at a rate of 0.39 kg ai/ha. Crop samples were collected at 0, 29, 60, and 153 days after treatment. Plant samples were stored frozen from sampling until analysis for a maximum period of 448 days.

Soya bean matrices were ground with dry ice. The TRR were determined by direct LSC or combustion for all needed samples (plant tissues, non-extractable residues, extracts, fractions from HPLC). The validated detection limit of the radioassay was 0.002 mg eq/kg.

Finely ground soya bean samples were extracted with methanol/water (80:20, v/v) and then partitioned three times with dichloromethane. The unextractable solids were blended with methanol, and the methanol rinse was analysed separately. To determine the potential for residues to accumulate in soya bean oil, the 153 DAT soya bean seed sample was blended with hexane and fractionated. Both fractions, hexane and residues, were assayed by oxidative combustion and LSC analysis.

The PES from soya bean straw and seed (after solvent extraction) were subjected to acid hydrolysis. The PES was stirred in the presence of 2% HCl in methanol/water (1:1) solution. The mixture was filtered. The filtrate was extracted with ethyl acetate if needed (> 0.01 mg eq/kg). The PES was subjected to reflux in the presence of 6 N HCL and subsequently of 1 N NaOH. If needed, the basic filtrate was extracted with ethyl acetate.

The amount of ^{14}C radioactivity present in the extracts and in the post-extraction solids was determined either by direct counting in a liquid scintillation counter or by oxidative combustions of aliquots. Distribution of radioactivity in the extractable fractions of soya bean samples was analysed by HPLC-UV at 254 nm and TLC.

Table 10 Distribution of residues of [^{14}C]-imazamox in soya bean samples (ID-640-010)

			Extracts						PES

DAT: Days after treatment

TRR calc: sum of extracted + PES, equal to TRR determined by direct combustion.

^a Residues from three times extraction with dichloromethane, after extraction with aqueous methanol solution (methanol/water, 80:20, v/v). Residue in the methanol rinse (washing of the remaining solids after extracting with the aqueous methanol) was added.

^b Residues in the aqueous layer from extraction of three times with dichloromethane

The largest amount of [pyridine-6- ^{14}C]-imazamox-derived radioactivity appeared in the forage (54.9 mg eq/kg at 0 DAT, 0.56 mg eq/kg at 29 DAT and 0.13 mg/kg at 60 DAT), whereas smaller amounts of residues were noted in the harvest straw and seed, 0.08 mg eq/kg and 0.02 mg eq/kg, respectively.

The TRR in soya bean seed oil extracted with hexane was detectable at 0.002 mg eq/kg. No additional analysis was carried out due to the extremely low radiocarbon content.

Although the radioactive residue in the 0, 29 and 60 DAT forage samples was readily extractable, the extractability of the 153 DAT samples had decreased significantly. By the 153 DAT sampling, the extractability had decreased to 40.99% for straw and 35.30% for seed (8% extractability for seed when hexane was used, < 0.01 mg eq/kg).

The majority of radioactive residues in 0 DAT treated soya bean was extracted into dichloromethane (85.21% of the TRR). In the other samples, smaller amounts of residues were extracted into dichloromethane (excluding residues from methanol rinse): 4.09% TRR in 29 DAT forage, 3.06% TRR in 60 DAT forage, 1.56% TRR in straw and 4.28% TRR in seed.

The unextracted radioactivity in the PES from soya bean straw and seed were 59.01% (0.04 mg eq/kg) and 64.70% of TRR (0.02 mg eq/kg), respectively. By acid and base digestion, 52.96% TRR (0.03 mg eq/kg) and 56.79% TRR (0.01 mg eq/kg) were released from the straw and seed marc, respectively.

The parent imazamox declined from 41.81 mg/kg at 0 DAT to 0.06 mg/kg (10.69% TRR) at 29 DAT in forage. The glucoside metabolite CL 189215 increased from 0.05 mg eq/kg (0.09% TRR) at 0 DAT to 0.20 mg eq/kg (35.84% TRR) at 29 DAT. However, CL 263284 and CL 312622, showed a decrease in concentration from 0 DAT to 29 DAT in forage, that is, 0.28 mg eq/kg (0.51%) to 0.05 mg eq/kg (10.07% TRR) for CL 263284 and 0.18 mg eq/kg (0.33% TRR) to 0.04 mg eq/kg (8.35% TRR) for CL 312622, respectively.

In forage at 60 DAT, residue levels of the three components (imazamox, CL 263284 and CL 312622) were very low at 0.01 mg eq/kg (5.89–11.07% TRR) and CL 189215 was found only at 0.04 mg eq/kg, although it accounted for 31.87% TRR. Three non-polar and three polar unknowns were detected but none exceeded 0.01 mg eq/kg or 10% of TRR individually.

In straw and seed at 153 DAT, no or little residues of parent imazamox and the metabolites were found.

Pea

Field peas (variety: Express) were treated post-emergence at the three to four node stage (thirty days after planting) with [pyridine-6-¹⁴C]-imazamox formulated as the ammonium salt at 0.040 kg ai/ha [Chiu 1995c, ID-640-004]. The in-life phase of this study was conducted outdoors in a sandy loam soil. The plots were equipped with removable plastic-covered “All” farms to exclude excessive rainfall, when required.

The whole plants were taken at 0 and 20 DAT. At 61 DAT, foliage/vine, pea, pea shell and pea pod at immature state were sampled. Mature pea and hay were harvested at 84 DAT. All samples were stored in a freezer at approximately –20 °C until used. The crop samples were analysed within 12 to 188 days of harvest. TRR for all samples were analysed by combustion and LSC.

A subsample of the 0 DAT treated plant tissue was extracted twice with methanol/water (8:2, v/v). The PES was air-dried and combusted prior to radioanalysis. Similarly a subsample of the 0 DAT control plant tissue treated with the blank formulation was spiked with [¹⁴C]imazamox and extracted as above.

A subsample of 20 DAT immature pea plant tissue was extracted twice with methanol/water (8:2, v/v). The PES was subjected to microwave extractions with 20% aqueous methanol solution and then 2% HCl in 20% aqueous methanol. Subsequently, reflux with 0.2 N NaOH in 20% aqueous methanol was made.

A subsample of 61 DAT immature pea sample was extracted twice with methanol/water (8:2, v/v). The combined filtrate was concentrated and stored in the refrigerator overnight. A precipitate which formed was removed. The filtrate was further concentrated, followed by precipitation with an equal volume of acetonitrile/methanol (1:1).

A subsample of harvest pea sample (84 DAT) was extracted twice with methanol/water (8:2, v/v). The combined filtrate was concentrated resulting in a thick oily residue. This residue was

washed with acetonitrile/methanol (1:1), resulting in some precipitation. After the acetonitrile/methanol-soluble phase was decanted, the precipitate was reconstituted in water. The water-soluble fraction was concentrated, adjusted to pH 3, and then introduced onto a solid phase extraction (SPE) column.

A subsample of the harvest pea hay sample (84 DAT) was extracted twice with methanol/water (8:2, v/v). The PES was subjected to microwave extractions with 2% HCl in 20% aqueous methanol, and then 0.2 N NaOH in 20% aqueous methanol.

The extracts were assayed by combustion and LSC. HPLC and TLC analysis was made for characterization and identification.

The TRR in whole plant sampled at 0 DAT was determined to be 1.1 mg eq/kg. The TRR in immature pea plants at 20 DAT had decreased to 0.035 mg eq/kg, most probably associated with growth dilution. No detectable residues above the validated limit of the radioanalysis method (0.01 mg eq/kg) were seen in any plant tissues (foliage, pea, shell, and immature pea pod) sampled at 61 DAT. At harvest (84 DAT), the dry pea and pea hay contained small but detectable TRR, 0.01 mg eq/kg and 0.05 mg eq/kg, respectively.

Table 12 TRR in various pea matrices after application of [¹⁴C]imazamox

Matrix	Days after treatment	TRR determined by direct combustion (mg eq/kg)
Whole plant	0	1.12
Whole plant	20	0.035
Foliage/vine	61	< 0.01
Immature pea	61	< 0.01
Immature pea shell	61	< 0.01
Immature pea pod	61	< 0.01
Harvest pea	84	0.01
Harvest pea hay	84	0.05

The radioactive residues from 0 DAT whole pea plant samples with the aqueous methanol solution extracted up to 99% (1.1 mg eq/kg) of the TRR. In whole pea plant fortified with a predetermined amount of [¹⁴C]imazamox, nearly 100% of the TRR was recovered.

From immature green peas (61 DAT) and harvested pea samples (84 DAT), approximately 61% of the TRR (< 0.01 mg eq/kg) and 39.2% of the TRR (0.004 mg eq/kg) were extracted, respectively. No further extractions of the PES were pursued due to the low radioactive residue.

From 20 DAT pea plants and 84 DAT hay samples, 65.4% of the TRR (0.023 mg eq/kg) and 58.4% (0.029 mg eq/kg) of the TRR were extracted respectively. More extractions under acidic and basic condition released nearly all of the remaining residues in the post extraction solids.

Table 13 Distribution of residues of [¹⁴C]imazamox in pea samples

Matrix	DAT	TRR calc.	Extracts, organo-extractable		PES	
		(mg eq/kg)	(mg eq/kg)	(%TRR)	(mg eq/kg)	(%TRR)
Whole plant	20	0.035	0.023	65.4	0.012	34.6
Hay	84	0.05	0.029	58.4	0.021	41.6
Peas	84	0.01	0.004	39.2	0.006	60.8

TRR calc: sum of extracted + PES

Organo-extractable means the residues extracted with methanol/water (8:2, v/v).

In all pea samples, the parent imazamox, CL 263284, and CL 189215 were found at or below the limit of detection (0.01 mg eq/kg), except hay (0.02 mg eq/kg, 66.3% TRR).

Table 14 Metabolites detected in pea matrices following foliar application of [^{14}C]imazamox

Alfalfa

The [pyridine-6- ^{14}C]-imazamox was applied once post-emergence to alfalfa (variety, WL 414) [Wu 1998b, ID-640-008]. The test substance (formulated as an ammonium salt) was applied once at a rate of 0.13 kg ai/ha onto four plots: plot B (established crop, breaking dormancy, at the 3rd trifoliate stage), plot D (newly seeded crop, at the 3rd trifoliate stage), plot F (newly seeded crop, late treatment at 5 days after the 1st cut) and plot H (newly seeded crop, late treatment at early bud stage).

The alfalfa forage and hay samples were taken from all four plots at the day of the application (0 DAT), 26 DAT (plots B, D and F), 45 or 74 DAT (1st cut; plots B and D, respectively); 87, 111 or 25 DAT (2nd cut, plots B, D and F, respectively) and 87, 157 or 53 DAT (3rd cut, plots B, D and F, respectively). Mature alfalfa seeds were sampled 74 DAT from plot H.

Forage and hay samples were taken from the three plots (B, D and F). In plot H, forage and seed were sampled at 0 DAT and 74 DAT, respectively. In the all plots, forage was sampled at 0–157 DAT and hay was takes 2–3 days later. All samples were stored frozen at approximately $-20\text{ }^{\circ}\text{C}$.

The TRR in green plants (forage), hay and seeds was determined by combustion and LSC except forage sample collected at 0 DAT. The 0 DAT forage was determined by solvent extraction followed by combustion due to very small size sample and the expected high radioactivity.

Ground alfalfa samples were extracted with methanol/acetone/water (1:1:1, v/v/v). The seed extract was additionally subjected to hexane partition. The PES were re-extracted three times with the acidic extraction solvent (methanol/water/HCl, 40:9:1, v/v/v), except several alfalfa samples due to high extractability and a very low residue level (0.003 mg eq/kg). The residual solids derived from the acidic methanol/water extraction (forage, hay or seed) were treated with cellulase and by 6 N HCl reflux.

The methanol/acetone/water extract of the alfalfa hay was treated with β -glucosidase or with 1 N NaOH for base hydrolysis.

The extracts were assayed by direct LSC or by combustion and characterized by HPLC. Structural characterization of the parent compound and the major metabolites was performed by LC-MS.

The TRR in forage at 0 DAT were 15.28 mg eq/kg (plot B), 10.28 mg eq/kg (plot F), 14.00 mg eq/kg (plot D) and 6.51 mg eq/kg (plot H). At 26 DAT, the radioactive residues declined significantly to 0.34 mg eq/kg (plot B) and 0.67 mg eq/kg (plot D), respectively. The TRR in forage of 1st, 2nd and 3rd cut from the all plots were found at relatively low levels, < 0.01 mg eq/kg to 0.21 mg eq/kg. The TRR levels in hay were three to five times higher than those of forage.

In forage and hay samples, the extracted residues from solvent extraction ranged from 74.9 to 98.8% of the TRR. The most (65.3–98.8%) was derived from methanol/acetone/water solvent extraction. The acidified aqueous methanol (2% HCl in 80% methanol) extracted an additional 1.2 to 14.2% of the TRR (0.001–0.090 mg eq/kg) in the forage and hay. As the result, the residual radioactive residues in PES were 0.001 to 0.252 mg eq/kg. In alfalfa seed, 72.7% TRR was extracted from the organic solvent extractions (15% TRR from acidified aqueous methanol extraction).

The radioactive residues in PES were released by enzyme treatment and acid hydrolyses. The results suggested the presence of glycosidic linkages of the residue with endocons in the alfalfa samples. After cellulase hydrolysis, the PES (greater than 0.05 mg eq/kg) were subjected to acid hydrolysis (6 N HCl reflux). The acid hydrolysis step released about 60% of the radioactive residues (equivalent to 8–9% of TRR or 0.033–0.056 mg eq/kg) while about 40% (equivalent to 6% of TRR or 0.022–0.039 mg eq/kg) remained bound. The results indicated that the labelled carbon has been incorporated into undefined plant constituents.

n.e.: not extracted

At 0 DAT, the unchanged imazamox parent accounted for the majority of the TRR (79.7–86.6%, 5.64–12.98 mg/kg) in forage from all plots. All other components at 0 DAT, including CL 189215, CL 263284 and CL 312622 were found to be minor (each at < 2% of the total residue). Imazamox was extensively metabolized in alfalfa and accounted for only 3–6% TRR (0.019–0.023 mg/kg) in forage of plot B and D (only data available) at 26 DAT. The metabolites included

CL 189215 (14–20% TRR, 0.048–0.132 mg eq/kg), CL 263284 (14–23% TRR, 0.079–0.095 mg eq/kg) and CL 312622 (18–22% TRR, 0.075–0.119 mg eq/kg) at 26 DAT.

In the 1st and 2nd cut hay (plot B, D and F), imazamox was found at very low level of 2–6% TRR (0.001–0.036 mg/kg). Relatively, the residue levels of the three main metabolites were high: CL 189215 12–31% TRR (0.005–0.208 mg eq/kg), CL 263284 12–15% TRR (0.006–0.105 mg eq/kg) and CL 312622 4–26% TRR (0.002–0.186 mg eq/kg). In seed collected at 74 DAT, residue levels of parent and the three main metabolites were very low at < 0.001 mg eq/kg or 0.001 mg eq/kg.

The metabolite profile of the alfalfa hay based on HPLC analysis shows that the incurred [¹⁴C]imazamox-derived residues in the alfalfa hay are stable when stored frozen for about 13 months. The quantitative distribution of imazamox and metabolites CL 189215, CL 263284, CL 312622 and the very polar components peak in the sample analysed within one month after sampling is similar to those found in the sample analysed at about 13 months after sampling.

Maize

Study 1

A metabolism study of imazamox in maize (imidazolinone-tolerant variety, Pioneer hybrid 3571 IR) was conducted in an outdoor, fenced-off research area on sandy loam soil in Lucama, North Carolina, during the growing season 1996 [Zulalian 1997c, ID-640-006]. The radiolabelled imazamox was a mixture prepared from [pyridine-6-¹⁴C]-imazamox, [pyridine-6-¹³C]-imazamox and non-isotopically labelled imazamox. The radioactive test substance formulated as an aqueous ammonium salt solution was applied as a post-emergence broadcast application 0.13 kg ai/ha to maize plants at the 4–8 leaf growth stage. Samples of maize plants were harvested at 0 DAT (immature maize plant), 14 DAT (immature plant), 30 DAT (early forage), and 62 DAT (late forage). At maturity (100 DAT), collected field samples were separated with fodder (stalks, husks, cobs) and grain. The maize samples were ground with dry ice and stored frozen. The samples were subjected to oxidative combustion and LSC. All control samples were < 0.004 mg eq/kg. The crop samples were analysed within 44 days.

Green plant, forage and fodder samples were extracted three times with methanol/water (80:20, v/v). The PES was rinsed with methanol and the rinsate was combined with the extracts. A grain sample was extracted three times with hexane. The PES was extracted three times with methanol/water (80:20, v/v).

The methanol/water extracts were partitioned three times with dichloromethane. The dichloromethane and aqueous fractions were separated. For the 14 DAT, 30 DAT and 62 DAT forage and 100 DAT fodder samples, the PES (after partitioning with dichloromethane) were extracted once with methanol/water/hydrochloric acid (130:18:2, v/v/v).

TRR in extracts and residual radioactive residues were analysed by combustion and LSC. Distribution of radioactivity in the extracts was analysed by HPLC-UV at 254 nm. Imazamox and the metabolite CL 263284 were isolated and identified by mass spectral analysis. The other components of the residue were identified by comparison of HPLC retention time.

The TRR in immature maize plant at 0 DAT was 8.2 mg eq/kg and rapidly decreased to 0.41 mg eq/kg (14 DAT). At 30 DAT and 62 DAT, the TRR in early and late forage were 0.087 mg eq/kg and 0.078 mg eq/kg, respectively. In maize fodder and grain at maturity (100 DAT), the TRR were 0.047 mg eq/kg and 0.021 mg eq/kg, respectively.

Of the TRR in the various maize substrates, between 48% and 98% (0.014–8.0 mg eq/kg) was extracted with methanol/water (80:20, v/v) and between 2% and 52% (0.006–0.17 mg eq/kg) remained unextracted. Negligible radioactivity (0.4–0.6% of the TRR, < 0.001 mg eq/kg) was extracted from the grain with hexane indicating the imazamox-derived residues did not concentrate in the maize oil.

The additional extraction with acidic extraction solvent (methanol/water/HCl, 80:18:2) released more residues in maize samples up to approximately 56% to 98% of the TRR (0.013–8.0 mg eq/kg). Approximately 2% to 44% (0.006–0.021 mg eq/kg [¹⁴C]imazamox equivalents) remained in the post extraction solids.

Table 18 Distribution of TRR following solvent partitioning and extraction of residues of [¹⁴C]imazamox in maize samples

Matrix	DAT	TRR calc. (mg eq/kg)	Extracts								PES	
			dichloromethane extract (mg eq/kg)	(%TRR)	aqueous extract (mg eq/kg)	(%TRR)	methanol/water/ HCl extract (mg eq/kg)	(%TRR)	total (mg eq/kg)	(%TRR)	(mg eq/kg)	(%TRR)

After extraction with methanol/water (80:20, v/v), followed by partitioning with dichloromethane

TRR calc.: sum of extracted + PES, equal to TRR determined by direct combustion.

Additional radioactivity was released from the PES at 62 DAT as follows. The PES was extracted at elevated temperature and pressure in an ASE 200 Accelerated Solvent Extractor to recover 0.016 mg/kg [¹⁴C]imazamox equivalents (20.5% of the TRR) and only 0.003 mg/kg [¹⁴C]imazamox equivalents (3.8% of the TRR) remained in the PES following this more vigorous procedure. This indicated there were no significant bound residues in the maize forage.

^a Replicate 1, 0.4% (< 0.004 mg/kg) was hexane-soluble.

^b Replicate 2, 0.6% (< 0.004 mg/kg) was hexane-soluble.

The unchanged parent imazamox amounted to 5.3 mg/kg (65% TRR) at 0 DAT plant, 0.073 mg/kg (18% TRR) at 14 DAT plant and less than 0.01 mg/kg (2–9% of the TRR) thereafter.

CL 263284 was identified as the major metabolite in maize, accounting for 0.24 mg eq/kg (3% TRR) at 0 DAT plant, but only 0.007 mg eq/kg (15% TRR) in maize fodder and only 0.004 mg eq/kg (20% TRR) in grain. The residue levels of glucose conjugate (CL 189215), the di-acid (CL 312622) and the hydroxy-acid (CL 354825) were < 0.001–0.003 mg eq/kg (2–5% TRR) in fodder and grain. Many polar and nonpolar compounds (minimum 4 polar and 3 nonpolar) were found at 0.012 mg eq/kg or less (1–14% TRR) individually since 30 DAT.

Study 2

The metabolism study of imazamox in maize (Pioneer hybrid 3571 IR, Imidazolinone-tolerant variety) was conducted in an outdoor, fenced-off research area on sandy loam soil in Lucama, North Carolina, during the 1996 growing season [Zulalian 1997d, ID-640-007]. The radio impurity amounting to approximately 3% was identified as the di-acid (CL 312622). The radiolabelled imazamox was a mixture prepared from [pyridine-6- ^{14}C]-imazamox, [pyridine-6- ^{13}C]-imazamox and non-isotopically labelled imazamox. The radioactive test substance was formulated as an aqueous ammonium salt solution and applied as a pre-emergence broadcast treatment (one day after seeding) at a rate of 0.14 kg ai/ha. Samples of maize plants were taken at 14 DAT (immature maize plant), 30 DAT (early maize forage) and 62 DAT (late maize forage). At maturity (112 DAT), the fodder (stalks/husks/cobs) and grain were collected. The samples were ground with dry ice and stored frozen. TRR was analysed by oxidative combustion and LSC. The detection limit was < 0.004 mg eq/kg. The crop samples were analysed within 24 days.

The extraction method with methanol/water (80:20, v/v) and dichloromethane was the same with that of above study. The PES of immature maize plant (14 DAT) was extracted once with methanol/water/hydrochloric acid (80:18:2, v/v/v). A grain sample was extracted three times with hexane. The PES was extracted three times with methanol/water (80:20, v/v). The extracts and post extraction solids were analysed by combustion and LSC. Distribution of radioactivity in the extractable fractions of maize samples was analysed by HPLC-UV detector set at 254 nm. Imazamox and the metabolite CL 263284 were isolated and identified by mass spectral analysis. The other components of the residue were identified by retention times by HPLC.

The TRR in immature maize at 14 DAT was 0.16 mg eq/kg and decreased to 0.027 mg eq/kg in early forage (30 DAT) and further to 0.011 mg eq/kg in late forage (62 DAT). In harvest fodder and grain (112 DAT), the TRR were 0.012 mg eq/kg and 0.010 mg eq/kg, respectively.

In the various maize substrates, 40% to 89% (0.004–0.13 mg eq/kg) of the TRR was extracted with methanol/water, and 17% to 60% (0.005–0.028 mg eq/kg) remained in the post extraction solid

(for 14 DAT maize, including 7% TRR released from acidic solvent extraction). Negligible radioactivity (2.1% of the TRR, < 0.001 mg eq/kg) was extracted from the grain with hexane indicating the imazamox-derived residues did not concentrate in the maize oil.

Since the TRR in the extracts of the 62 DAT and 112 DAT maize samples were insufficient for identification/characterization, the extracts were not carried through the solvent partitioning procedures.

Table 20 Distribution of TRR following solvent partitioning and extraction of residues of [¹⁴C]imazamox in maize samples

Matrix	DAT	TRR calc.	Extracts								PES	
			dichloromethane extract		aqueous extract		methanol/water/HCl extract		total			
		(mg eq/kg)	(mg eq/kg)	(%TRR)	(mg eq/kg)	(%TRR)	(mg eq/kg)	(%TRR)	(mg eq/kg)	(%TRR)	(mg eq/kg)	(%TRR)
Green plant	14	0.158	0.044	28.0	0.075	47.2	0.011	6.9	0.13	82.1	0.028	17.9
Early forage	30	0.027	0.007	25.5	0.015	57.1			0.022	82.6	0.005	17.3
Late forage	62	0.011							0.009	88.8	0.002	21.2
Fodder	112	0.012							0.005	40.3	0.007	59.7
Grain	112	0.010							0.004	43.6	0.006	56.4

TRR calc.: sum of extracted + PES, equal to TRR determined by direct combustion.

Extracts of grain includes hexane extract, approximately 2% TRR (< 0.001 mg eq/kg).

The unchanged parent imazamox amounted to 0.049 mg/kg (31% TRR) at 14 DAT maize plant and 0.010 mg/kg (37% TRR) at 30 DAT forage. CL 263284 was identified as the major metabolite in maize, accounting for 12% TRR (0.019 mg eq/kg) at 14 DAT plant and 19% TRR (0.005 mg eq/kg) at 30 DAT forage. The identification of imazamox and CL 263284 was confirmed by LC-MS analysis. The residue levels of the metabolites (identified by HPLC retention time) glucose conjugate (CL 189215), the di-acid (CL 312622) and the hydroxy-acid (CL 354825) were between 0.003 (2% TRR) and 0.008 mg eq/kg (5% TRR) at 14 DAT and below < 0.001 mg eq/kg (less than 4% of the TRR) at 30 DAT. The remaining radioactive residue was characterized as multiple polar and nonpolar water-soluble metabolites (0.001–0.016 mg eq/kg, 0.6–10% TRR individually). The only significant components of the residue in maize were imazamox and CL 263284.

Wheat

Study 1

Spring wheat (imidazolinone-tolerant variety: AP603 CL) was sowed into ten plastic containers filled with loamy sand soil, which was conducted in climatic chambers, the phytotrons simulated the natural climatic conditions for a typical spring, [Grosshans *et al.*, 2012b, 2012/1064722]. The crop was treated once with [imidazolinone-5-¹⁴C, 3-¹⁵N]-imazamox at a rate of 0.76 kg ai/ha at growth stage BBCH 13–24. The application formulation (including the test item: unlabelled imazamox (2:1 ratio), blank formulation and adjuvant Dash EC) was applied with an automatic spray track at a spray volume of 219 L/ha. Samples of wheat forage and hay were taken 8 days (BBCH 39) after application. Harvest of wheat plants and sampling of straw and grain was accomplished 62 days after application. Eighty wheat plants were thinned out. One half of the plants was minced and frozen as forage, the other half was minced and dried at room temperature. Wheat ears and straw (GS 89) were cut off and the straw was minced. Afterwards, ears were separated into chaff and grain using a thresher. The chaff was mixed to the straw. All samples were stored in a freezer at –18 °C or below. The samples were stored in a refrigerator or in a freezer. Radioassay was performed by combustion and LSC.

The samples were extracted with methanol and water. The residual radioactive residues were extracted twice with 1% ammonia, and then treated with the enzymes in order of macerozyme/cellulase, α -amylase/ β -amylase/amyloglucosidase, and tyrosinase/lactase. After the tyrosinase incubation the PES were extracted once with 1 N HCl, thereafter refluxed with 6 N HCl. The extracts and PES were assayed by LSC. The residues in the extracts were characterized or identified by HPLC. For enantiomer-specific analysis, an aliquot of wheat forage, hay or grain was extracted with methanol and water and then the methanol extract was extracted three times with ethyl acetate, subsequently the ethyl acetate phase partitioned with water (acidified with formic acid to pH 2). The water phase was fractionated using HPLC and the fractions were subjected to enantiomer-specific analysis using HPLC.

There were no major differences between measured TRR and calculated TRR (ERR plus PES). Here, the calculated TRR values were set to 100% TRR for all matrices. For the wheat forage, hay, straw and grain, the TRR were 1.6 mg eq/kg, 8.0 mg eq/kg, 3.2 mg eq/kg and 1.4 mg eq/kg, respectively.

Table 22 Distribution of residues of [¹⁴C]imazamox in wheat samples (2012/1064722)

TRR cal.: sum of extracts + PES

The extractability of wheat forage and hay with methanol and water was very high and accounted for 92.5% and 91.6% of the TRR. The major part of the residues was extracted with methanol (forage: 89.0% TRR, hay: 75.0% TRR). The extractability of wheat straw and grain with methanol and water was high and accounted for 79.6% and 86.9% of the TRR. For straw, the major part of the residues was extracted with methanol (61.3% TRR), whereas for grain virtually equal amounts were extracted with methanol and water (methanol 43.8% TRR; water 43.1% TRR).

In wheat forage, analysis of the methanol extract using HPLC resulted in a pattern of six peaks, of which four were identified. The main peak was identified as the parent compound imazamox and accounted for 1.046 mg/kg (65.3% TRR). Metabolite CL 263284 was the second most abundant component and accounted for 0.286 mg eq/kg (17.9% TRR). The metabolites CL 312622 and

CL 189215 were identified at levels of up to 6.7% TRR. In the water extract, the parent compound imazamox was the main constituent at 0.033 mg/kg (2.1% TRR). The remaining components CL 263284, CL 312622 and CL 189215 were identified at levels of up to 0.6% TRR. No signals corresponding to the reference items Reg. No. 60967 (5,5-dimethylimidazolidine-2,4-dione [or 5,5-dimethylhydantoin]; CAS Nr 77-71-4) and Reg. No. 199553 (5-isopropyl-5-methyl-2,4-imidazolidinedione [or iPr-Me-Hydantoin]; CAS-N 5455-35-6)—putative cleavage products of imazamox, imidazoline moiety- were detected in the solvent extracts using HPLC. The residue after solvent extraction was further solubilized. Analysis of the ammonia solubilizate identified imazamox and metabolite CL 263284, which accounted for up to 0.4% of the TRR. In the ERR, 94.5% of the total radioactive residues were identified and 4.1% were characterized. In the PES, additional 3.9% of the TRR were identified and characterized.

In wheat hay, analysis of the methanol extract resulted in a pattern of five peaks, of which four were identified. The parent compound imazamox accounted for 4.056 mg/kg (50.6% TRR). The second most abundant component was metabolite CL 263284, which accounted for 1.689 mg eq/kg (21.1%). The metabolites CL 312622 and CL 189215 were identified at levels of up to 4.2% TRR. In the water extract the same components as in the methanol extract were identified. The parent compound imazamox accounted for 0.910 mg/kg (11.4% TRR). The remaining components CL 263284, CL 312622 and CL 189215 were identified at levels of up to 2.8% TRR. No signals corresponding to the reference items Reg. No. 60967 and Reg. No. 199553 (putative cleavage products of imazamox, imidazoline moiety) were detected in the solvent extracts using HPLC. The ammonia solubilizate contained imazamox and metabolite CL 263284, which accounted for up to 0.4% of the TRR. In the ERR, 96.0% of the total radioactive residues were identified and 1.0% were characterized. In the PES, additional 6.5% of the TRR were identified and characterized.

In wheat straw, the methanol extract showed a pattern of eleven peaks, of which four were identified. The metabolite CL 263284 accounted for 1.041 mg/kg (32.6% TRR). CL 189215 and CL 312622 were 0.394 mg/kg (12.3% TRR) and 0.396 mg/kg (12.4% TRR), respectively. The parent compound imazamox accounted for 6.1% TRR. In the water extract, the same components as in the methanol extract were identified. Likewise, the main constituent was CL 263284 at 0.172 mg eq/kg (5.4% TRR). The remaining components imazamox, CL 189215 and CL 312622 were identified at levels of up to 4.6% TRR. In the solvent extracts up to four non-identified peaks (up to approximately 1% TRR) eluted prior to metabolite CL 189215. It was not possible to assign the peaks to putative cleavage products of imazamox (imidazoline moiety) by HPLC-MS experiments. The ammonia solubilizate contained imazamox, metabolite CL 263284 and CL 312622 at up to 1.2% of the TRR. In the ERR, 78.0% of the TRR were identified and 10.5% were characterized. In the PES, additional 13.7% of the TRR were identified and characterized.

In wheat grain, analysis of the methanol extract of wheat grain resulted in a pattern of eleven peaks, of which three were identified. The parent compound imazamox accounted for 0.577 mg/kg (40.8% TRR) and the metabolites CL 263284 and CL 189215 were identified at levels of up to 3.5% TRR. In the water extract the same components as in the methanol extract were identified. The parent compound imazamox accounted for 0.473 mg/kg (33.5% TRR). The remaining components CL 263284 and CL 189215 were identified at levels of up to 3.0% TRR. In the solvent extracts up to four non-identified peaks (up to approximately 1% TRR) eluted prior to metabolite CL 189215 using HPLC. It was not possible to assign similar peaks to putative cleavage products of imazamox (imidazoline moiety) by HPLC-MS experiments. In the ammonia solubilizate the parent compound imazamox accounted for 0.026 mg/kg (1.8% TRR). In the ERR, 83.4% of the TRR were identified and 5.5% were characterized. In the PES, additional 10.1% of the TRR were identified and characterized.

The ratio of enantiomer 1 to enantiomer 2 for the test item was approximately 1:1. For the parent compound and metabolite CL 263284 isolated from methanol extracts of four matrices (forage, hay, straw and grain), the enantiomer ratio of each compound was found to be approximately 1:1 in all matrices, thus remained unchanged during metabolism of imazamox in wheat.

^a The extracts (methanol + aqueous) for these samples were combined and analysed by HPLC

n.d.: Not detected

The radioactive residues in wheat samples were initially extracted with methanol and water and analysed by HPLC at 102–126 days (forage), 102–129 days (hay), 45–75 days (straw) and 47–160 days (grain), after sampling. After 324 days (forage), 323 days (hay), 326 days (straw) and 327 days (grain), re-analysis with the methanol and water extract confirmed the initial metabolic patterns. Otherwise, re-extraction from straw and grain was performed 362 days and 336 days, respectively after sampling. The metabolic patterns of the initial analyses remained. During the storage of sample extracts or straw and grain samples over approximately one year, no changes in the metabolic patterns were found.

Study 2

In another wheat study, [pyridine-6-¹⁴C]-imazamox was applied post-emergence to imidazolinone-tolerant wheat (variety: Fidel selection number 2) at a rate of 0.14 kg ai/ha [Johnson 1996b, ID-640-005]. Wheat seeds were planted in a field test site under outdoor condition. Emergence was noted seven days after sowing. The wheat forage, forage of hay stage, straw (including chaff), and grain were harvested 28, 45, 70, and 70 days after treatment, respectively. Additionally, plant samples were taken the same day of treatment (0 DAT). The samples were stored in a freezer (–20 °C). Extracts were stored in a refrigerator or in a freezer. Total radioactive residues were analysed by combustion and LSC

For forage at 0 DAT, 28 and 45 DAT, the radioactive residues were extracted three times with methanol/water (8:2, v/v). The aqueous phase was partitioned three times with methylene chloride.

For wheat grain and straw, residues in the samples were extracted three times with methanol/water (8:2, v/v) and further extracted three times with a mixture of methanol/water/concentrated HCl (8:2:0.2, v/v/v). The PES were extracted with 0.5% t-octylphenoxy-polyethoxyethanol (Triton X-100) and then by 6 N HCl reflux.

Extracts were concentrated, assayed by LSC and characterized/identified by HPLC. Further, imazamox, CL 263284 and CL 312622 were identified by gas chromatography-negative ion chemical ionization mass spectrometric (GC-NICIMS) analysis.

The TRR found in 0 DAT (plant), 28 DAT (forage), 45 DAT (hay stage), straw (70 DAT) and grain (70 DAT) were 5.57 mg eq/kg, 0.102 mg eq/kg, 0.087 mg eq/kg, 0.157 mg eq/kg and 0.067 mg eq/kg, respectively. Most likely plant growth dilution resulted in the rapid decline in residue from the time of application.

The radioactive residues in the 0 DAT, 28 DAT and 45 DAT forage as well as the harvest wheat grain were readily extractable, with 97.4%, 82.3%, 75.6 and 75.2% of the TRR extracted into

methanol/water, respectively. However, only approximately 46% of TRR was extractable from the harvest wheat straw sample. For residual radioactive residues in PES from 28 DAT/45 DAT forage and wheat grain, no further characterization was made (< 0.05 mg eq/kg, 17.7–24.8% TRR).

In straw sample, 91.5% TRR was totally extracted: 46% with aqueous methanol, 6.5% with acidic aqueous methanol, 1% with Triton X-100 and 38% by 6 N HCl reflux. The PES contained only 5.0% (0.008 mg eq/kg) of the TRR.

Table 24 Distribution of residues of [^{14}C]imazamox in wheat samples (ID-640-005)

Matrix	DAT	TRR ^c mg eq/kg	Extracts						PES

^c TRR was determined after combustion.

^d Aqueous methanol

In forage at 0 DAT, the unaltered parent imazamox accounted for 91.8% (5.11 mg/kg) of the TRR. No known metabolites (CL 263284, CL 312622, CL 189215) were detected.

In 28 DAT forage, the concentration of the parent imazamox was 0.042 mg/kg (41.6% TRR) and present in both organic and aqueous phases. There was only one major radioactive peak (imazamox) in the organic phase. In the aqueous phase, there were four peaks (imazamox, CL 263284, CL 312622 and CL 189215). CL 263284 was present at 0.010 mg eq/kg (9.8% TRR). The other two metabolites identified (CL 312622 and CL 189215) were both less than 0.01 mg eq/kg (each < 10% TRR). Several minor components were detected at near background radioactivity.

In 45 DAT forage, the parent imazamox was present at 0.035 mg/kg (39.9% TRR). There was only one major radioactive peak (imazamox) in the organic phase. In the aqueous phase, there were four peaks (imazamox, CL 263284, CL 312622 and CL 189215). The three metabolites were all less than 0.01 mg eq/kg (each < 10% of TRR). Several minor components were detected at near background radioactivity.

In 70 DAT grain, imazamox was present at 0.027 mg/kg (40.3% TRR). Two other components (CL 263284 and CL 189215) were also present at less than 0.01 mg eq/kg (< 10% TRR) each; the di-acid metabolite (CL 312622) was not observed. Several minor components were detected at near background radioactivity.

In 70 DAT straw, the metabolite CL 263284 was present in the largest quantity, at 0.020 mg eq/kg (13.0% TRR), followed by imazamox at 0.015 mg/kg (9.5% TRR), and CL 312622 and CL 189215 at less than 0.01 mg eq/kg (< 10% TRR) each. There were many unknown minor components present at near background levels of radioactivity (< 0.01 mg eq/kg, < 10% TRR each). From extractions with the acidic aqueous methanol, X-100 surfactant and 6 N HCL reflux, the radioactive residues were found at 0.01 mg eq/kg (6.3% TRR), < 0.01 mg eq/kg (1.0% TRR) and 0.06 mg eq/kg (38.0% TRR), respectively. HPLC analysis of the each extract (except surfactant extract due to low radioactivity) showed several minor components at near background radioactivity.

^a Sum of the radioactivity not accounted for by the identified compounds in the initial extract and the radioactivity in the dilute acid, X-100 and 6 N acid extracts

PES after extraction with solvents like methanol and water

n.d: not detected

After 4 to 39 days after sampling, the all samples were removed from the combustion and HPLC analyses, except the 0 DAT plant sample. The 0 DAT sample was analysed by HPLC 423 days after sampling. The parent compound imazamox was only significant component in the 0 DAT sample. This indicated that the residue component in the sample was stable for more than 14 months.

Proposed metabolic pathway of imazamox in plants

The metabolism of imazamox was studied in oilseed rape, soya bean, pea, alfalfa, maize and wheat. Application was made on imidazolinone-tolerant varieties, except pea and soya bean. In all the studied crops, [pyridine-6- ^{14}C]-imazamox was treated with post-emergence application (for maize, additionally pre-emergence treatment). In oilseed rape and wheat studies, imidazolinone-labelled imazamox, [imidazolinone-5- ^{14}C , 3- ^{15}N]-imazamox, was also used.

The key step of the metabolism of imazamox was the cleavage of the methyl ether group (demethylation) resulting in metabolite CL 263284. Subsequently, oxidation of the hydroxyl group of CL 263284 generated the dicarboxylic acid metabolite CL 312622, while glycosylation led to the glucose conjugate CL 189215. Both metabolites were formed mostly in very minor amounts. In oilseed rape, soya bean, alfalfa and maize, several polar metabolites were also present. A number of nonpolar metabolites and possibly the hydroxy acid (CL 354825) were found in maize in addition.

Figure 1 Proposed metabolic pathway of imazamox in pea, soya bean, oilseed rape, wheat and alfalfa

Figure 2 Proposed metabolic pathway of imazamox in maize plant

Environmental in soil

The Meeting received information on aerobic soil degradation, photolysis on soil, hydrolysis, and confined rotational crop studies. The fate and behaviour of imazamox in the environment was investigated using [pyridine-6-¹⁴C]-imazamox, [Imidazolinone-5-¹⁴C]-imazamox, (see Figure 1).

Aerobic degradation in soil—laboratory studies

Study 1

The study was conducted using [pyridine-6-¹⁴C]-imazamox on a New Jersey (sandy loam) soil [Ta 1997a, ID-620-018]. The test compound was applied at a rate of 0.10 kg ai/ha. The soil was maintained aerobically in the dark at 25 ± 1 °C for up to 12 months at 75% of 1/3 bar moisture. The soil characteristics were as follows: % sand, 65; % silt, 22; % clay, 13; CEC (meq/100 g), 9.1; % moisture at 1/3 bar, 14.1; % organic carbon, 1.5; pH in soil:CaCl₂ (1:1), 6.8.

The ethylene glycol and NaOH traps were radioassayed and the foam plugs were extracted with ethyl acetate before being radioassayed. The extracts, after clean up by SPE using C-18 OH and SCX cartridges, were analysed by HPLC and TLC.

Total recoveries of radioactivity ranged from 95.0% to 102% of the total applied radioactivity throughout 1 year of incubation. Imazamox degraded rapidly in soil with an initial half-life of 31 days. The parent compound was initially oxidized to CL 312622 (the di-acid metabolite). The CL 312622 was then converted to a second metabolite CL 354825 (the hydroxy acid metabolite). There were no other metabolites > 5% TAR observed. Imazamox and both metabolites were further mineralized to ¹⁴CO₂ (48.1% TAR over the year) or bound into soil (7.1% TAR at the end of 1 year incubation).

Table 26 Distribution of parent and metabolites (as % TAR) in soil treated with [¹⁴C]imazamox (ID-620-018)

Time	Parent	CL 312622	CL 354825	CO ₂	Bound residue	Others	Total
0 Time	96.3	2.3	ND	ND	1.0	0.0	99.6
1 Day	92.6	4.3	ND	0.8	1.8	0.0	99.5

365 Days	15.2	0.2	22.2	48.1	7.1	5.1	97.9

Study 2

The study was conducted using [pyridine-6-¹⁴C]-imazamox on a New Jersey (sandy loam) soil at 25 ± 1 °C for up to 12 months at 75% of 1/3 bar moisture [Ta 1995a, ID-620-008]. The test material was applied at a rate of 0.10 kg ai/ha. The soil characteristics were as follows: % sand, 53.2; % silt, 34.4; % clay, 12.4; CEC (MEQ/100 g), 5.8; % moisture at 1/3 bar, 14.1; % organic carbon, 1.7; pH in soil:CaCl₂ (1:1), 6.6. EDTA (ethylene diamine tetracetic acid-disodium salt) extraction and subsequently followed 0.5 N NaOH extraction recovered the major part of radioactivity in soil.

Total recoveries of radioactivity ranged from 90.5% to 104% of the time0 dose, through 86 days of incubation, and then slowly decreased to 81% of the TAR after 365 days.

Approximately 60% of imazamox was degraded during the first month, 69% by two months, and 77% by 365 days of aerobic incubation. The degradation pattern was biphasic, with an initial half-life of 28 days over the first two months. The DT₉₀ was greater than 365 days.

Imazamox was initially oxidized to CL 312,622 (identified by TLC, HPLC, MS and NMR). The di-acid reached a maximum concentration of approximately 44% of the applied dose at 4–6 weeks after dosing. It then decreased over the remainder of the study and accounted for less than 5% of the applied dose from 6 to 12 months. A second metabolite, CL 354,825 (identified by TLC, HPLC, MS and NMR) increased in concentration over time, and accounted for approximately 55% of the applied dose from 6 to 12 months. Ultimately imazamox and its degradates were mineralized to CO₂.

Table 27 Distribution of parent and metabolites (as % TAR) in soil treated with [¹⁴C]imazamox (ID-620-008)

Time, days	% Parent	% AC 312622	% AC 354825
0	89.9	2.9	1.0

365	12.5	2.9	54.0

Study 3

The rate of degradation of [pyridine-6-¹⁴C]-imazamox was studied on three EU soils (two silt loams [Ta and Lewis 1997a, ID-620-027]. The test material was applied to soil at a rate of 0.075 kg ai/ha. The soil moistures were maintained at approximately 45% of the maximum water holding capacity (MWHC). Soil samples were extracted three times with 0.5 M NaOH solution. The extracts were subjected to acid precipitation. After centrifugation, the humic acid fraction (precipitate) was re-dissolved in 0.5 N NaOH. The supernatant (fulvic acid fraction) was passed through a C-18 cartridge and the radioactivity was eluted with methanol:water (90:10 v/v). The extracts of one of the silt loam soils (Soil A) were further cleaned-up using a silica column. All samples were concentrated prior to chromatography by HPLC and TLC. Unextracted soil residues (humic fraction) were dried and aliquots combusted.

Table 28 Characteristics of soils used (ID-620-027)

Location	Limours (FR) Soil A	Boissy (FR) Soil B	Ponfaverger (FR) Soil C
% Sand	4.7	7.9	14.3
% Silt	79.4	74.7	60.7
% Clay	15.8	17.4	25.1
USDA Textural Class	Silt loam	Silt loam	Silty clay loam
CEC (meq/100 g)	13	12.6	18.3
% Moisture at 1/3 bar	20.4	19.4	22.2
% Organic Carbon	0.8	0.8	1.1
pH in 1:1 soil:water ratio	5.8	6.5	8.1

CEC: cation exchange capacity

Mass balance at 122 days was $\geq 96\%$ ($\geq 95\%$ at all earlier time points).

In the silty clay loam (soil C), at 20 °C, the amount of AC 299,263 decreased from 97% to 4% of applied radioactivity during the 122 day incubation period. CL 312,622, was a major metabolite at especially 14 days and 27 days (42%) but then decreased to 2% at 122 days. CL 354,825 increased to 40% at 66 days then remained at about this level for the remainder of the incubation period.

In one of the silt loams (soil B) at 20 °C, the amount of imazamox decreased from 95% of applied radioactivity to 61% at 27 days. The main degradate was CL 354,825, which increased to 33% at 66 days. CL 312,622 was a minor metabolite reaching its maximum concentration of 8% at 14 days.

In the other silt loam (soil A) at 20 °C, degradation of imazamox was much slower than either of the other soils at the same temperature. Imazamox decreased from 91% TAR at 0 day to 73% TAR at 122 days, CL 354,825 increased to 12% TAR at 122 days but amounts of CL 312,622 were < 1% throughout the incubation period.

In the silty clay loam (soil C) at 10 °C, the amount of imazamox declined from 97% TAR to 12% TAR at 122 days. CL 312,622 was the principal metabolite and increased to 45% TAR at 66 days, then remained at this level to the end of the study (42% at 122 days). Levels of CL 354,825 increased during the study and accounted for 24% at 122 days.

In the silt loam (soil B, Boissy, FR) at 10 °C, the amount of imazamox declined from 96% TAR to 42% TAR at 122 days. CL 312,622 and CL 354,825 were both formed, and accounted for 22% and 19%, respectively after 122 days.

Several minor unidentified degradation products were detected but in total accounted for < 6% of applied radioactivity at any time point. Small amounts of radioactivity were also detected in the non-absorbed fraction from the C-18 cartridges ($\leq 5\%$) and the humic acid fractions ($\leq 4\%$), but these were not characterized.

The calculated first-order DT₅₀ and DT₉₀ values are summarized as follows:

Soil	Temperature (°C)	DT ₅₀ (Days)	DT ₉₀ (Days)
C (Silty clay loam)	20	12	39
B (Silt loam)	20	44	147
A (Silt loam)	20	207	687
C (Silty clay loam)	10	42	140
B (Silt loam)	10	113	375

Imazamox was degraded in this laboratory study at rates dependent upon the soil type and temperature. In most incubation groups two major metabolites (CL 312622 and CL 354825) were present. Radiolabelled residues were also incorporated into soil bound residues (especially the humin fraction, values up to 17%). Up to 24% (1–24%) of the radioactivity was evolved as volatiles, mainly carbon dioxide, demonstrating eventual mineralization of imazamox.

Study 4

The aerobic metabolism of imazamox in soils was conducted using [Imidazolinone-5-¹⁴C]-imazamox [Ta 2012a, 2011/7002438]. Two soils of different textures: a sandy loam soil (Limbergerhof, Rheinland-Pfalz, Germany) and a loam soil (Hunterdon County in New Jersey, USA) were used. The test material was applied at the rate of 0.050 kg ai/ha (0.066 mg ai/kg) and the soil moistures were maintained to approximately 50% MWHC. The soil samples were extracted once with methanol, followed by 50% methanol in water, twice. Soils were further extracted with 0.5 N NaOH solution and then the extract was subjected to acid precipitation.

Table 29 Characteristics of soils used (2011/7002438)

Location	Bruch West (DE)	New Jersey (US)
% Sand	65.7	28
% Silt	23.1	49

Location	Bruch West (DE)	New Jersey (US)
% Clay	11.2	23
USDA Textural Class	Sandy loam	Loam
CEC (meq/100 g)	12.6	7.6
Maximum water holding capacity %	31.5	37.4
% Organic Carbon	1.38	1.16
pH in 1:1 soil:water ratio	8.1	7.1

The average total recovery of the radiolabelled material was 95.5% of the TAR for the entire samples from two soils.

From both soils, organic solvent extractable [^{14}C]-residues decreased from approximately 94.2% to 96.8% TAR at 0 days after treatment to approximately 23.4% to 40.5% TAR at 120 DAT. NaOH extracts increased from 3.2% to 3.4% at 0 DAT to 35.8% to 49.5% TAR at 120 DAT and non-extractable [^{14}C]-residues increased from approximately 0.8% to 1.6% TAR at 0 DAT to 17.7% to 22.1% TAR at 120 DAT. At 120 DAT, the total evolved $^{14}\text{CO}_2$ was 2.5 to 6.8% TAR.

The concentration of [imidazolinone-5- ^{14}C]-imazamox decreased to approximately 28.4% to 38.8% TAR at 120 DAT. There were two major (> 5% TAR) transformation products, CL 312622 and CL 354825 at maximum values of 14.8% to 30.7% TAR, and 18.1% to 28% TAR, respectively. Several minor transformation products were also observed and none of them reached concentration of > 5% TAR. Additional investigations on the potential shift of the isomer ratio of imazamox and its metabolites during soil incubation were performed. The results clearly show that the isomer ratios were almost constant over time.

The DT_{50} values of imazamox were calculated to be 38.1 days and 23.1 days in sandy loam soil (Bruch West, Germany) and loam soil (New Jersey, USA), respectively. Mineralization was observed with levels of CO_2 reaching values of 2.5% to 6.8% TAR after 120 days of incubation.

Proposed degradation pathway of imazamox in soil under aerobic condition

Imazamox was rapidly degraded in soil. Half-life of imazamox was 28–38 days or 12–207 days (depending on soil types and temperatures). In soil, two major metabolites, CL 312622 (di-acid) and CL 354825 (hydroxyl acid) were present. Imazamox was initially oxidized to CL 312,622 (the di-acid metabolite). The CL 312622 was then converted to a second metabolite CL 354,825 (the hydroxy acid metabolite). There were no other metabolites > 5% TAR observed. Parent and both metabolites were further mineralized to $^{14}\text{CO}_2$ or bound into soil.

Photodegradation on soil surface

Study 1

The photolysis of imazamox was conducted using [pyridine-6- ^{14}C]-imazamox [Ta 1995b, ID-620-004]. The test compound was applied to New Jersey (sandy loam) soil (53.2% sand; 34.4 silt; 12.4% clay; 1.7% organic carbon; pH 6.6; CEC 5.8 meq/100 g; 14.1% soil moisture at 1/3 bar) at a rate equivalent to 0.10 kg/ha (40 ppm on a soil weight basis) in photolysis chamber. Samples were irradiated continuously for up to 30 days by light from a xenon-arc lamp (filtered to remove wavelengths less than 290 nm) and maintained at 25 °C and 75% of 1/3 bar moisture during the course of the study. Soil sample was extracted two times with 0.5 M NaOH, then the extract was combusted and analysed by LSC. TLC (normal and reverse phase) and HPLC were used for identification.

Total radioactivity recovered from the irradiated samples ranged between 97.7% TAR and 101.3% TAR (105.5–109.0% TAR in control samples) throughout the experiment. These recoveries demonstrated that volatile degradates were not formed.

The 0.5 M NaOH extracts contained 96% or greater of the radioactivity initially applied to the soil. The residual radioactivity remaining in the soil after extraction ranged from 0.5% TAR to 1.3% TAR in the irradiated samples (0.8–1.2 % TAR in the control samples).

TLC analyses of the soil extracts showed that approximately 68.6% (normal phase TLC) to 73.7% (reverse phase TLC), averaging 71% of the parent compound remained intact at the end of the 30 days irradiation. The control samples were stable throughout the course of the study. The half-life was calculated to be 65 days of continuous irradiation.

There was one major product formed, CL 312,622 (the di-acid metabolite) which accounted for approximately 11.9% TAR (normal phase TLC) to 15.4% TAR (reverse phase TLC), averaging 14% TAR after 30 days. This metabolite was also found in the dark control sample, indicating that this metabolite is not photolytic specific degradate. There were at least ten other unidentified radiolabelled components, each of which represented less than 6% TAR.

Study 2

The photolysis of imazamox was conducted using [pyridine-6-¹⁴C]-imazamox or [imidazolinone-5-¹⁴C]-imazamox [McCall and Blood 2013a, 2012/7003612]. The test compound was applied to a loam soil from New Jersey at a rate of 0.050 kg/ha (0.33 ppm based on an assumed bulk density of 1.5 g/cm³ and 1 cm depth). Samples were irradiated continuously for up to 15 days at 20 °C by light from a xenon-arc lamp filtered to remove wavelengths less than 290 nm. Total irradiance during the duration of the study was 528.56 W/m⁻² which is comparable to the natural sunlight intensity in the spring at 40 ° N latitude. The loam soil characteristics were as follows: 28% sand; 48% silt; 24% clay; 1.3% organic carbon; pH 6.9; CEC 8.9 meq/100 g; 49% a maximum of water holding capacity.

Volatile residues were collected for the irradiated and the dark control samples and analysed at the soil sampling intervals. Each sample was extracted once with 40 mL methanol and two times with 40 mL methanol:water (1:1; v:v) and finally with 40 mL 0.5 N NaOH at each sampling point. The extracts were analysed by HPLC. Reference standards were used for co-chromatography for characterization in conjunction with MS/MS analysis of select samples.

The mass balance for both irradiated and dark controls for the imidazolinone label ranged from 89.3% TRR to 101.2% TAR. The cumulative volatile ¹⁴C-residues from the irradiated and dark control samples were 10.7 %TAR for the light and for the dark controls, 1.2% of the TAR. The mass balance for both irradiated and dark controls for the pyridine label ranged from 98.0% to 102.5% TAR.

In overall, extractabilities of radioactive residues were in the range of 70.7–99.9% TRR.

The DT₅₀ value of imazamox in the irradiated samples was calculated to be approximately 28.4 days (both labels, n=4) and found to be 19.7 days in the dark control samples. One minor product (< 10% TAR) observed in the irradiated samples was the di-acid CL 312,622. It accounted for a maximum level of approximately 8% TAR through the study period in both labels. In the control samples, CL 312622 accounted for a maximum of 41% TRR in the imidazolinone label, and a maximum of 25% TRR in pyridine label through the study period. There were no unique photoproducts of imazamox in soil at 20 °C.

These studies indicated that imazamox on soil surface is photodegraded and any specific metabolite is not formed under irradiation. The half-life of imazamox was 65 days or 28 days and it was slightly longer in dark control condition. One metabolite CL 312622 was present in irradiated soil as a major or minor component; however, it was not specific for photolysis.

Hydrolysis

Test solution containing imazamox at concentration of 8 µg/mL was prepared in pH 4, 7 and 9 buffers and incubated at 50 °C [Holman 1997a, ID-322-002]. The test was conducted for 5 days in the dark under sterile conditions. Additional samples buffered at pH 9 were incubated for up to 24 days at 50 °C, 10 days at 60 °C, and 4 days at 70 °C. Aliquots of the samples were analysed by HPLC.

No degradation of imazamox occurred during the test period of 5 days at 50 °C in pH 4 and pH 7 buffers, indicating that the test compound is stable to hydrolysis in these buffers.

In the sample at pH 9, considerable loss of the compound was observed. For samples at pH 9 and 50 °C, the half-life of imazamox was calculated to be 11.9 days; at 60 °C, 4.17 days; and at 70 °C, 1.70 days. Extrapolating to 25 °C, the half-life is 192 days.

There was one major hydrolysis product confirmed by LC-MS. This was identified as the carbamoyl compound CL 336554, formed from the ring opening at the nitrogen bond.

The study indicated that imazamox is hydrolytically stable at pH 4 and pH 7. However, at pH 9 at 25 °C, it hydrolyses with a half-life of 192 days, forming the hydrolysis product, carbamoyl compound CL 336554.

Metabolites and distribution in succeeding crops

Confined Rotational Crop Study

Study 1

Soya beans (variety, Hutcheson) were treated at the 4–6 leaf stage (sandy loam soil) with [pyridine-6-¹⁴C]-imazamox at a rate of 0.072 kg ai/ha (ammonium salt formulation) [Gatterdam 1994b, ID-640-002]. At 100 days after treatment (100 DAT), the soya bean crop was harvested and winter wheat (variety, Pioneer 2548) was seeded in subplot 1. At 268 DAT, maize (variety, Pioneer 3165), radish (variety, White Icicle) and lettuce (variety, Black-Seeded Simpson) were seeded (subplots 2–4), respectively. Radish and lettuce were planted in subplots 5 and 6 at 420 DAT.

Soya bean foliage was sampled at the day of treatment; fodder and seed were taken at harvest, 100 DAT. The rotational crop commodities wheat forage, maize forage (stalk, ear foliage and cob), radish leaves and lettuce plants were sampled at mid-maturity, 238, 357, 302 and 311 DAT, respectively. Wheat grain, maize seed, radish roots and lettuce plants were taken at harvest, 331, 420, 311 and 335 DAT, respectively. The study was terminated before harvesting the 420 DAT samples (radish and lettuce), thus these samples were not analysed for radioactive residues. Soil samples were taken before treatment, immediately after application, at rotational crop planting and at crop sampling (mid-maturity and harvest). Soil samples were 46 cm in depth (sections of 0–8, 8–15, 15–30, and 30–46 cm) except the pre-treatment and 0 DAT cores which were 30 cm in depth. Plant tissue and soil samples were combusted and ¹⁴C was determined by LSC.

The soil extract was analysed by HPLC-UV. The column was eluted isocratically with a mobile system consisting of acetonitrile/ tetrahydrofuran/formic acid/water (14:2:1:83, v/v/v/v). A liquid scintillation cocktail was added for LSC. The retention time of imazamox analytical standard was compared to radiochromatograms of soil extracts to verify identification of the radioactivity.

Soya bean foliage at 0 DAT contained total radioactive residues averaging 1.70 mg eq/kg. The plants at harvest (100 DAT) were collected but not analysed.

Rotational crops planted at 100 DAT (wheat) and 268 DAT (maize, radish and lettuce) showed TRRs below the limit of detection of 0.01 mg/kg at both mid-maturity and harvest intervals. Further analysis for radish and lettuce planted at 420 DAT was not performed.

Radioactive residues in treated soil (0–8 cm) at 0 DAT averaged 0.03 mg/kg. At the 100 DAT, 268 DAT and 420 DAT rotational crop intervals, there were no detectable residues in soil (< 0.01 mg eq/kg TRR).

Plant and soil samples were stored frozen from sampling until analysis. Sampling to final analysis ranged from 14 to 71 days for crops and from 8 to 147 days for soil.

The stability of the treatment solution was verified in a soil extract sample (0 DAT). Recovery of radioactivity by extraction showed 92.8% was extracted and 7.2% was unextracted. Cartridge clean-up (C₁₈ SPE) of the soil extract yielded two carbon-14 containing residues. The major fraction (approximately 90% of the cleaned up residue) showed one peak by HPLC constituting 97.3% of the recovered radioactivity. This radioactive peak coincided with imazamox on the HPLC-

UV chromatogram. The minor fraction (approximately 10% of the cleaned up residue) was not analysed due to low radioactivity.

Table 30 Total radioactive residues in crops after treatment with [^{14}C]imazamox (ID-640-002)

Study 2

A confined rotational crop study was conducted with two radiolabels-[imidazolinone 5- ^{14}C , 3- ^{15}N]-imazamox and [pyridine-3- ^{14}C , imidazolinone-3- ^{15}N]-imazamox [Funk and Possienke 2013b, 2013/1085609]. The active substance was applied to bare sandy loam soil (USDA scheme) in plastic containers at a rate of 0.075 kg ai/ha using an automatic spray track system. The nature and the level of radioactive residues were investigated in spinach (variety, Corvette F1; immature and mature), white radish (variety, April Cross; root and top) and spring wheat (variety, Thassos; forage, hay, straw and grain). For the imidazolinone label samples from the plant back intervals 31, 119 and 364 days were investigated, while for the pyridine label plant back intervals of 29, 123 and 365 days were used.

Plant samples were harvested at maturity and additional immature spinach samples as well as spring wheat forage samples (in part dried to hay) were taken 23 to 33 days and 50 to 75 days after sowing, respectively. Mature and immature spinach leaves were sampled and the roots remained in the soil. Ripe white radishes were pulled from the soil and separated into the edible parts (root) and the remaining green parts (top). Soil samples were taken after ploughing at the individual plant back intervals and after harvest of the mature crops.

All samples were stored in a freezer at -18°C or below. Prior to extraction and determination of the TRR, sample material was homogenized. Plant matrices with a sufficient level of radioactivity were extracted with solvents, while for samples with low concentrations of radiolabelled compounds the amount of the TRR was obtained only by combustion analysis. Soil samples were directly subjected to combustion.

Aliquots of homogenized plant material were extracted three times with methanol. The residue was further extracted in the same way with water (twice). The TRR included in some spring wheat hay and straw samples radioactive residue of pendimethalin, which was identified as a contamination in this study. The obtained methanol extracts of spring wheat matrices were partitioned three times with ethyl acetate for forage, hay and grain, with cyclohexane for wheat grain. For grain, further partition for the obtained ethyl acetate phase was conducted with n-hexane.

The radioactive residues in the PES (after solvent extraction with methanol and water) were subsequently extracted twice with ammonia. After ammonia extraction, the residues were dried and subsequently solubilized with different enzymes (β -glucosidase and hesperidinase; macerozyme R-10 and cellulase Onozuka R-10; α -amylase, β -amylase and amyloglucosidase). For straw, the macerozyme solubilizes were treated with yeast (fermentation). For grain, water extract derived from the solvent extraction with water two times was precipitated with acetone. The precipitate was treated with protease. The extracts were analysed by LSC and if needed, HPLC.

The calculated TRR of all extracted rotational crop matrices showed no major differences to the TRR values obtained by combustion.

At all plant back intervals, the highest TRR levels were found in spring wheat hay, straw and grain. The concentration of residues in grain decreased significantly after a plant back interval of approximately 365 days: in imidazolinone/pyridine label, respectively, 0.032/0.053 mg eq/kg at one month PBI and 0.002/0.004 mg eq/kg at one year PBI. For spinach and white radish, much lower TRR values (less than 0.01 mg eq/kg) were found in all PBI intervals and both labels.

DAT: days after treatment

^a TRR combusted. TRR calculated was not determined because of low amount of radioactivity.

^b Including a contamination of pendimethalin

Soil samples (imidazolinone label/pyridine label) were taken at 0/0 day DAT. On the days after ploughing at 31/29, 119/123 and 364/365 DAT (PBIs) and on the days after harvest of mature crops, the each labelled soil samples were taken at 74, 161, 410 DATs in spinach, 95, 179, 424 DATs in white radish and 146, 216, 501 DATs in spring wheat.

In both labels, the residue concentration in the top soil layer decreased rapidly after aging and ploughing, 0.670 mg eq/kg (0 DAT) to 0.019 mg eq/kg (31 DAT) in imidazolinone label and 0.694 mg eq/kg (0 DAT) to 0.050 mg eq/kg (29 DAT) in pyridine label. Then, the level decreased relatively in small ratio: imidazolinone label 0.013 mg eq/kg at 364 DAT and pyridine label 0.018 mg eq/kg at 365 DAT. After harvest of the mature crops, the residue levels in soil were 0.009–0.019 mg eq/kg for the all PBIs of both labels, being remained more or less stable.

The extractability of the radioactive residues with methanol and water ranged for rotational crop matrices from 17.1% to 77.1% TRR in the imidazolinone label and from 17.8% to 77.9% TRR for the pyridine label. In spring wheat grain, low extractability with both solvents was observed (less than 30% TRR). Besides, extractabilities for some forage and hay sample (pyridine label, 123 DTA) were low (less than 30% TRR). The major portions of the radioactive residues were generally extracted with methanol, except for spring wheat grain (all PBIs, both labels), hay (123 DAT, pyridine label) and straw (365 DAT, pyridine label) where similar portions were extracted with methanol and water.

In most cases, higher portions of the radioactive residues extracted with methanol were water soluble, and lower portions were found in the organic fractions (ethyl acetate phase or cyclohexane phase). In some cases, comparable portions were found in the organic phases and in the water phase.

HPLC analysis for all spring wheat matrices and plant back intervals showed a metabolite pattern with only a few peaks. Parent imazamox was identified very small in three matrices: 31 DAT grain (0.002 mg/kg, 6.2% TRR) in imidazolinone label and 29 DAT hay (0.007 mg/kg, 9.1% TRR) and 29 DAT straw (0.002 mg/kg, 2.1%) in pyridine label. The metabolite CL 263284 was found in only two matrices-29 DAT hay (0.002 mg/kg, 2.3% TRR) and 123 DAT straw (0.001 mg/kg, 5.5% TRR) in pyridine label. CL 263284 is characterized by a hydroxyl group, derived from the cleavage of the methyl ether group (demethylation) of the parent. There were degradation products in minor concentrations. These were characterized by HPLC and/or liquid-liquid partition.

^a Loss of 8.8% TRR during ammonia solubilisation for solid residue was not significant due to low amount of radioactive residues (0.004 mg/kg).

^b Loss of 16.7% TRR during ammonia solubilisation for solid residue was not significant due to low amount of radioactive residues (0.003 mg/kg).

Methanol and water extracts of rotational crop matrices were prepared within periods of 12 to 243 days after sampling for the imidazolinone label and 223 to 463 days after sampling for the pyridine label. For partition phases of the methanol extract, concentrated water extracts and supernatants from water extract incubations (after acetone precipitation and protease treatment, HPLC analysis was conducted within 28 to 458 days after extraction for imidazolinone label and 7 to 329 days after extraction for pyridine label.

With spring wheat grain (imidazolinone label PBI 31 DAT and pyridine label PBI 29 DAT samples), storage stability tests were performed for the water phase of the methanol extract.

PBI 31 DAT wheat grain sample was extracted at 176 days after sampling. The stored water phase of the methanol extract was analysed by HPLC at 220 days after extraction and re-analysed at 647 days (14 months) after extraction. For PBI 29 DAT wheat grain sample, extraction was conducted at 387 days after sampling. The water phase of the methanol extract was analysed by HPLC at 54 days after extraction and re-analysed at 344 days (9 months) after extraction. As results, water phase of the methanol extract was stable for at least 14 months.

PBI 31 DAT and 29 DAT wheat grain samples were re-extracted at 817 days (2.2 years) after sampling and 729 days (2 years) after sampling, respectively. Similar amounts of radioactive residues were extracted compared to the initial extractions (176 days after sampling for PBI 31 DAT and 387 days after sampling for PBI 29 DAT). Further, HPLC analysis for the water phase of the methanol extract showed similar HPLC patterns. Thus, residues in wheat grain frozen stored were stable for about 2 years. From these results, residues in wheat grain over the period of the study were shown to be stable.

In summary, the confined rotational crop studies (radish, lettuce, spinach, maize and wheat) showed that imazamox-derived residues from a previous use or soil treatment do not accumulate in rotational crops; only low levels of radioactive residues were observed in all rotation crop matrices at all analysed plant back intervals.

Figure 3 Proposed metabolic pathway of imazamox in rotational crops

Field rotational studies

No data submitted.

RESIDUE ANALYSIS

The Meeting received descriptions and validation data for analytical methods for imazamox and its metabolites in plant or animal matrices.

Good linearity was observed in the standard solutions with linear correlations with coefficients > 0.99. Overall, recovery values were within an acceptable level (70–120%), where the

relative standard deviations were mostly less than 20%. A brief description of the methods is given below.

Analytical methods for plant matrices

L0188/01

Imazamox and its metabolites CL 312622, CL 263284 and CL 189215 were extracted from plant matrices (grapes, green beans, dry peas, rice grain, sunflower seed, rice straw, rice whole plant) with methanol/water/1 N HCl (60:39:1, v/v/v). In case of high protein samples (e.g. peas and beans), ammonium sulphate was added to the extract. A portion of the extract was centrifuged for 5 min at 4000 rpm, filtered through a disposable syringe filter and an aliquot of the filtrate was diluted to obtain the final volume for LC-MS/MS determination against matrix matched standards. In all matrices tested the mean recovery values were between 80% and 108% and the RSDs were below 12% except one value (23% in 0.01 mg/kg fortified sunflower seed). The LOQ for each analyte was 0.01 mg/kg in all matrices tested [Lehmann 2013a, 2012/1294678; Lehmann 2013b, 2013/1177533].

Table 39 Recovery results of imazamox, CL 312622, CL 263284 and CL 189215 from plant matrices using the method L0188/01

^a Proposed for quantification

An independent laboratory validation study (ILV) of method L0188/01 for the determination of imazamox, CL 312622, CL 263284 and CL 189215 in plant matrices (grapes, green beans, dry peas, rice grain, sunflower seed, rice straw and rice whole plant) was conducted. In all matrices tested, the mean recovery values were between 76% and 110% (RSD, < 18%). The LOQ for each analyte was 0.01 mg/kg in all matrices tested [Mewis A., 2013a, 2013/1249356].

^a Proposed for quantification

This method was used in the field residue trials for beans, rice and sunflower seeds, where the procedural recoveries and LOQ levels were acceptable.

CEM-236/001

Imazamox and CL 263284 are extracted from plant matrices (peas, beans pods, whole bean, maize grain, maize ears and maize whole plant) by homogenization with methanol/water/1 M hydrochloric acid (60:39:1, v/v/v). Clean-up of the extract was achieved using liquid/liquid partition and solid phase extraction using a Bond Elut SCX cartridge. Final quantitative determination of residues was by HPLC-UV detection at 254 nm. In all tested matrices, the recovery values were in the range of 72% to 110%. The LOQ for each analyte was 0.01 mg/kg in all matrices tested [Robbins 1996a, ID-244-018; Robbins 1997a, ID-244-015; Robbins 1997b, ID-244-016; Robbins 1997c, ID-244-017].

Table 41 Recovery results of imazamox and CL 263284 from plant matrices using the Method CEM-236/001

Substance	Crop	Fortification level (mg/kg)	No. tests	Range (mg/kg)	Average recovery (%)	RSD (%)
Imazamox	Peas (fresh)	0.05–1.0	5	94–109	101	5.7
	French beans (pods)	0.05–1.0	5	73–99	88	12.5

	Maize (grain)	0.05–1.0	5	80–107	93	13.1
	Maize (ears)	0.05–1.0	5	87–104	94	6
	Maize (whole plant)	0.05–1.0	5	82–97	89	6.5
CL 263284	Peas (fresh)	0.05–1.0	5	76–98	89	10.2
	French beans (pods)	0.05–1.0	5	72–82	77	6
	French beans (whole plant)	0.05–1.0	5	72–89	79	10
	Maize (grain)	0.05–1.0	5	91–110	102	6.9
	Maize (ears)	0.05–1.0	5	82–90	86	3.5
	Maize (whole plant)	0.05–1.0	5	75–87	82	5.5

Recovery test was conducted with one test per each of five fortification levels (0.05, 0.10, 0.25, 0.50 and 1.0 mg/kg).

In the field residue trials for beans, peas and rice, this method was used with acceptable procedural recoveries and LOQ levels.

M 3076

An independent laboratory validation study of method M 3076 for the determination of residues of imazamox in canola seed was performed. Residues of imazamox were extracted from oilseed rape seed (canola) with acidic aqueous methanol. Clean-up of the extract was achieved by evaporation, liquid/liquid partition and solid phase extraction using an SCX cartridge. Final quantitative determination of residues was by capillary electrophoresis (CE). The recovery values were in the range of 74% to 85%. The LOQ for imazamox was 0.05 mg/kg in rape seed [Sweeney and Gross 1998a, ID-244-020].

Table 42 Recovery results of imazamox from rape seed using the method M 3076 (independent laboratory validation study)

Crop	Fortification level (mg/kg)	No. of tests	Recovery (%)	Average recovery (%)	RSD (%)
Oilseed rape (seeds)	0.05	2	84, 85	85	
	0.10	2	74, 85	80	
	0.50	2	79, 83	81	

M 2460

Residues of imazamox and CL 263284 are extracted from the plant samples (pea whole pod/dry seed, soya bean seed/forage/straw, rape seed, and pea vine/hay/straw) with acidic methanol-water. The extracts are subjected to suitable clean-up involving solvent partitioning and solid phase extraction. Both compounds are converted to a common methylated product and measured as one chromatographic peak representing a total imazamox-related residue. Measurement of the total imazamox-related residues is accomplished using on-column methylation and GC-NPD. Results were calculated as total imazamox-related residues by the direct comparison of peak heights to those of external standards. In all matrices tested, the recovery values were in the range of 65% to 131%. The LOQ was 0.05 mg/kg for each compound as well as for combined imazamox and CL 263284 in all matrices tested [Safarpour 1995a, ID-244-005].

Table 43 Recovery results of imazamox and CL 263284 from plant matrices using the method M 2460

Test substance	Crop	Fortification level (mg/kg)	No. of Tests	Recovery (%)	Average recovery (%)	RSD (%)
Imazamox + CL 263284	Oilseed rape (seeds)	0.05	2	85, 105	95	
		0.50	2	120, 121	121	
	Pea (vines)	0.05	2	91, 131	111	
		0.50	2	106, 116	111	
	Pea (hay)	0.05	2	90, 91	91	
	Pea (dry seed)	0.05	2	99, 102	101	
	Pea (straw)	0.05	2	65, 103	84	
	Pea (whole pod)	0.05	2	85, 100	93	
	Soya bean (forage)	0.05	2	70, 83	77	
	Soya bean (seed)	0.05	2	82, 84	83	
Imazamox	Soya bean (straw)	0.05	1	98	98	
		0.50	1	105	105	
	Oilseed rape (seeds)	0.05	2	114, 121	118	
	Soya bean (straw)	0.05	2	104, 110	107	
CL 263284	Oilseed rape (seeds)	0.05	2	124, 122	123	
	Soya bean (straw)	0.05	2	91, 94	93	

This method was used in the field residue trials for peas, soya bean and rape seeds, where the procedural recoveries and LOQ levels were acceptable.

M 3519

Imazamox, CL 263284, CL 189215 and CL 312622 were extracted from lentil seed and forage samples using an acidic methanol-water solution. An aliquot of the seed or forage sample extract was diluted with methanol and then passed through an SCX cartridge, which retained the analytes. The SCX cartridge was washed with methanol to remove co-extractives; then the residues were selectively eluted with a water-methanol solution. The eluate was evaporated to dryness and the residues were dissolved in acidic water for analysis. Measurement of the residues was accomplished by LC-MS or LC-MS/MS. In both matrices tested, the mean recovery values were between 75% and 99% (RSD, < 4%). The LOQ for each analyte was 0.05 mg/kg in lentil seed and forage [Nejad 2004a, 2004/5000274].

Table 44 Recovery results of imazamox, CL 263284, CL 189215 and CL 312622 from lentils using the method M 3519

Test substance	Crop	Fortification level (mg/kg)	No. of tests	Average recovery (%)	RSD (%)
Imazamox	Lentil (seed)	0.05	5	93	4
		0.5	5	95	2
	Lentil (forage)	0.05	5	94	2
		0.5	5	92	1

		0.5	5	95	2
	Lentil (forage)	0.05	5	94	2
		0.5	5	93	1
CL 189215	Lentil (seed)	0.05	5	89	3
		0.5	5	99	2
	Lentil (forage)	0.05	5	92	3
		0.5	5	96	3
CL 312622	Lentil (seed)	0.05	5	86	4
		0.5	5	75	2
	Lentil (forage)	0.05	5	95	4
		0.5	5	87	3

An independent laboratory validation of method M 3519 for the determination of imazamox, CL 263284, CL 189215 and CL 312622 residues in lentils (seed and forage) was performed. In both matrices tested, the mean recovery values were between 84% and 109% (RSD, < 19%). The LOQ for each analyte was 0.05 mg/kg in lentil seed and forage [Jordan J.M., 2003a, 2002/5004302].

Table 45 Recovery results of imazamox, CL 263284, CL 189215 and CL 312622 from lentils using the method M 3519 (independent laboratory validation study)

Test substance	Crop	Fortification level (mg/kg)	No. of tests	Average recovery (%)	RSD (%)
Imazamox	Lentil (seed)	0.05	5	95	16
		0.50	5	87	7
	Lentil (forage)	0.05	5	84	15
		0.50	5	88	5

		0.50	5	93	7
	Lentil (forage)	0.05	5	84	2
		0.50	5	89	6
CL 312622	Lentil (seed)	0.05	5	86	10
		0.50	5	88	6
	Lentil (forage)	0.05	5	85	11
		0.50	5	87	13

This method was used in the field residue trials for lentil, rape seeds and sunflower seeds, where the procedural recoveries and LOQ levels were acceptable.

Homogenised subsamples of straw and seed were additionally extracted according to method M 3519, QuEChERS method and DFG S19 method. For straw samples the extractability with method No. M 3519 (80.2% TRR) and QuEChERS method (64.8% TRR) was comparable to the extractability with methanol and water (77.6% TRR). For seed, method M 3519 extracted about one half (31.0% TRR) and QuEChERS method one third (17.2% TRR) of the radioactive residues extracted with methanol and water (58.3% TRR). For both matrices the DFG S19 method extracted the lowest amounts of radioactive residues with 16.9% TRR for straw and 8.0% TRR for seed. HPLC analyses of the straw and seed extracts obtained from extraction with method M 3519, QuEChERS and DFG S19

method (for straw only) showed a similar metabolite pattern compared to methanol extracts used for metabolism investigation, with CL 263284 as the main component. This data demonstrates that among the tested residues methods method M 3519 has the capability to extract the relevant residues of imazamox.

M 3515

Imazamox and CL 263284 were extracted from plant matrices (orange, grape, pea, maize grain and wheat grain) using an acidic methanol-water solution. For wheat grain, an aliquot of the sample extract was evaporated to dryness, the residue dissolved in acidic water and then passed through a C-18 cartridge, which retained the analytes. The cartridge was washed with water to remove co-extractives; then the residues were downloaded with methanol onto an SCX cartridge, which retained the analytes. For all other plant matrices, an aliquot of the sample extract was diluted with methanol then passed through an SCX cartridge, which retained the analytes. For all plant matrix samples, the SCX cartridge was washed with methanol to remove co-extractives then the residues were eluted with a water-methanol solution. The eluate was evaporated to dryness and the residues were dissolved in water for analysis. Measurement of the residues was accomplished by LC-MS. In all matrices tested, the mean recovery values were between 83% and 109% (RSD, < 12%). The LOQ for each analyte was 0.01 mg/kg in wheat grain and 0.05 mg/kg in all other matrices [Fletcher 2002a, ID-244-029].

Table 46 Recovery results of imazamox and CL 263284 from plant matrices using the method M 3515

Test substance	Crop	Fortification level (mg/kg)	No. of Tests	Average recovery (%)	RSD (%)

		overall	9	85	14

^a When one value of 55% was excluded, the average (n = 4) and the RSD

In the field residue trials for lentil and sunflower seeds, this method was used with acceptable procedural recoveries and LOQ levels.

M 3178

An independent laboratory validation study of the method M 3178 was conducted. Imazamox, CL 263284, CL 189215 and CL 312622 in alfalfa (forage, hay and seeds) were extracted from the samples with acidic water-methanol followed by filtration. For imazamox, CL 263284 and CL 189215, the extracts were cleaned up with precipitation, centrifugation and solid phase extraction (SPE) techniques using RP-102 and SCX columns. For CL 312622, the extracts were cleaned up by filtration with an ISOLUTE filtration column and SPE (C₁₈, QMA and SCX columns). Measurements of the residues were accomplished by reverse-phase HPLC with mass spectrometric detection (LC-MS) and monitoring product ions (LC-MS/MS). LC-MS/MS was used for the analysis of imazamox, CL 263284, CL 189215 and CL 312622 in alfalfa seed samples. The recovery values were between 68% and 109%, except for alfalfa seed at 10 mg/kg fortification level (59–75%). The LOQ for each analyte was 0.1 mg/kg in the all alfalfa matrices [Wickremesinhe and Safarpour 1998a, ID-244-022].

Table 48 Recovery results of imazamox, CL 263284, CL 189215 and CL 312622 from alfalfa using the method M 3178 (independent laboratory validation study)

Test Substance	Crop	Fortification level (mg/kg)	No. of tests	Recovery range (%)	Average recovery (%)	RSD (%)
Imazamox	Alfalfa (forage)	0.1–10	8	73–101	85	12
	Alfalfa (hay)	0.1–10	8	82–102	92	7.5
	Alfalfa (seeds)	0.1–10	8	59 ^a , 84–88	83	12
CL 263284	Alfalfa (forage)	0.1–10	8	80–102	87	11
	Alfalfa (hay)	0.1–10	8	76–88	84	4.9
	Alfalfa (seeds)	0.1–10	8	68 ^a , 84–109	91	13
CL 189215	Alfalfa (forage)	0.1–10	8	74–96	82	11
	Alfalfa (hay)	0.1–10	8	68, 68, 71–82	76	7.9
	Alfalfa (seeds)	0.1–10	8	59 ^a , 70–96	75	13
CL 312622	Alfalfa (forage)	0.1–10	8	77–91	86	5.6
	Alfalfa (hay)	0.1–10	8	72–84	80	5.0
	Alfalfa (seeds)	0.1–10	8	75 ^a –85	78	4.0

Recovery test was conducted with two tests per each of four fortification levels (0.1, 0.2, 0.5 and 10 mg/kg).

^a At a fortification level of 10 mg/kg

This method was used in the residue trials for soya bean and alfalfa with acceptable procedural recoveries and LOQ levels.

M 3098

An independent laboratory validation study of the method M 3098 for the determination of residues of CL 299263 and CL 263284 in wheat hay, forage, straw and grain was conducted. Imazamox and CL 263284 were extracted from wheat forage, hay, straw and grain samples with acidic water-

methanol. Samples were further purified using solid phase extraction (SPE) and liquid-liquid partitioning techniques. Measurement of imazamox and CL 263284 residues was accomplished by capillary electrophoresis (CE) using a high sensitivity- flow cell and a ultra-violet absorbance detector set at 240 nm. In all matrices tested, the recovery values were between 69% and 97%. The LOQ of each analyte was 0.05 mg/kg in wheat matrices [Xu and Nejad 1999a, ID-244-026].

Table 49 Recovery results of imazamox and CL 263284 from wheat using the method M 3098 (independent laboratory validation study)

Test Substance	Crop	Fortification level (mg/kg)	No. of tests	Range of recovery (%)	Average recovery (%)	RSD (%)
Imazamox	Wheat (forage)	0.05, 0.50	4	87–93	90	2.8
	Wheat (hay)	0.05, 0.50	4	75–89	82	7.8
	Wheat (straw)	0.05, 0.50	4	69–89	80	12
	Wheat (grain)	0.05, 0.50	4	72–87	82	8.8
CL 263284	Wheat (forage)	0.05, 0.50	4	85–88	85	2.5
	Wheat (hay)	0.05, 0.50	4	71–97	79	9.8
	Wheat (straw)	0.05, 0.50	4	74–88	81	7.5
	Wheat (grain)	0.05, 0.50	4	72–83	79	6.5

Recovery test was conducted with two tests per each of two fortification levels.

This method was used in residue trials for wheat with acceptable procedural recoveries and LOQ levels.

M 2248, M 2333 (Confirmatory method for M 2248)

M 2248: Imazamox (CL 299263) was extracted from soya bean seeds with acidic aqueous methanol using a Polytron ultrasonic extractor. The extract was cleaned up by liquid/liquid partitioning with methylene chloride, gel permeation chromatography using a Biobead S-X3 column and solid phase extraction using an SCX column. Measurement of the residue was performed by HPLC-UV at 254 nm (HPLC-UV). The mean recovery values were between 82% and 88% (RSD, < 11%). The LOQ was 0.05 mg/kg for all matrices tested [Witkonton 1994b, 1994/7003428; Witkonton 1993a, ID-244-002].

Soya bean seed samples showing positive (> 0.05 mg/kg) residues of imazamox by method M 2248 above were confirmed by LC-MS (method M 2333). The two same extracts prepared in method M 2248 were directly amenable to analysis by LC-MS. The (M+H)⁺ ion of imazamox at m/z 306⁺ was monitored for confirmation [Witkonton *et al.*, 1994a, ID-244-003]. The recovery values were 76% and 79% and the LOQ was 0.05 mg/kg.

Table 50 Recovery results of imazamox from soya bean using the method M 2248 and M 2333

Crop	Fortification level (mg/kg)	No. of tests	Average recovery (%)	RSD (%)	Reference
Soya bean (seeds)	0.05	3	88	6.8	ID-244-002 M 2248
	0.10	3	82	11	
	0.50	3	86	10	
	0.05	2	78 (mean of 76 and 79)		ID-244-003 M 2333

M 2248.01

Imazamox (CL 299263) was extracted from the samples (soya bean seed/foilage and peanut/peanut foliage) with acidic aqueous methanol using a Polytron ultrasonic extractor. The extract was cleaned up by liquid/liquid partitioning with methylene chloride and solid phase extraction using an SCX column. Measurement of the residue was performed by HPLC-UV at 254 nm. There was a major modification to the method M 2248.01: exclusion of a sample clean up procedure by gel-permeation chromatography (GPC). The mean recovery values were between 81–115%. The LOQ was

0.05 mg/kg for each matrix [[Minoura and Ohba 1996a, ID-244-007; Minoura and Ohba 1996b, ID-244-008; Minoura and Ohba 1996c, ID-244-009; Minoura and Ohba 1996d, ID-244-010].

Table 51 Recovery results of imazamox from soya bean using the method M 2248.01

Crop	Fortification level (mg/kg)	No. of tests	Range of recovery (%)	Average recovery (%)	RSD (%)	Reference
Soya bean (seeds)	0.05, 0.2	4	100.3–112.4	105.0	5.0	ID-244-007
Soya bean (foliage)	0.05, 0.1	4	87.2–115.4	101.4	11	ID-244-008
Peanut (nut in shell)	0.05, 0.2	4	90.0–109.9	101.8	9.5	ID-244-009
Peanut (foliage)	0.05, 0.1	4	80.6–104.7	94.9	12	ID-244-010

Recovery test was conducted with two tests per each of two fortification levels

An independent laboratory validation study of method M 2248.01 for the determination of imazamox residues in soya bean seed was performed. GPC clean up procedure was included in this study. The recovery values were 75% between 90% and the LOQ (0.05 mg/kg) for soya bean seed was confirmed [Witkonton 1994a, ID-244-004].

Table 66 Recovery results of imazamox from soya bean seed using the method M 2248.01 (independent laboratory validation study)

Crop	Fortification level (mg/kg)	No. of tests	Recovery (%)
Soya bean (seeds)	0.05	2	75, 81
	0.10	2	76, 86
	0.40	2	88, 90

In the field residue trials for peanut, this method was used with acceptable procedural recoveries and LOQ levels.

ABC Report 46324

Imazamox and metabolites CL 263284 and CL 312622 were extracted from sunflower seed and meal samples with an acidified methanol/water solution, filtered and concentrated. The residues were purified on a C₁₈ SPE column eluted with methanol in aqueous ammonium acetate. Residues in refined oil samples were diluted in hexane and extracted by shaking with acidified acetonitrile/water solution. Following phase separation, the lower aqueous acetonitrile layer was collected. The final chromatography analysis of imazamox residues was performed using LC-MS. The mean recovery values were between 75–109% (RSD, < 13%). The LOQ for each analyte was 0.05 mg/kg in sunflower matrices [Johnston 2003a, 2002/500411].

SOP-PA.0288

Imazamox and its metabolites CL 263284 and CL 189215 were extracted from sunflower samples using extraction solution methanol/water/1 M HCl (60:39:1, v/v/v). Final determination was performed using LC-MS/MS determination. The mean recovery values were between 76% and 106% (RSD, < 15%). The LOQ for each analyte was 0.01 mg/kg in sunflower seed [Freitas 2010a, 2010/1057139; Leite 2008a, 2010/1090461]

Table 53 Recovery results of imazamox, CL 263284 and CL 189215 from sunflower using the method SOP-PA.0288

Transition 2 (for confirmation): imazamox, 306→193 m/z; CL 263284, 292→179 m/z; CL 189215, 454→292 m/z

Analytical methods for animal matrices

D0303

Imazamox and CL 263284 were extracted from bovine tissues (liver, kidney and muscle) with acidic methanol-water solution. Following centrifugation, an aliquot of the extract was diluted with methanol and then passed through an SCX cartridge, which retained the analytes. The SCX cartridge was washed with methanol to remove co-extractives; then the residues were selectively eluted with a water-methanol solution. The eluate was evaporated to dryness and the residues were dissolved in water for analysis. Residues from milk and fat were extracted with acetonitrile in hexane. Following solvent partitioning, an aliquot of the acetonitrile extract was diluted with methanol and passed through the SCX cartridge using the same procedure as described for the tissue samples. The final detection was accomplished by LC-MS/MS. In all matrices tested, the mean recovery values were

between 69% and 121% (RSD, 25%). The LOQ for each analyte was 0.01 mg/kg for bovine matrices [Stewart 2003a, 2003/5000116; Gooding 2013a, 2013/7002842].

Table 54 Recovery results of imazamox and CL 263284 from bovine matrices using the method D0303

Test substance	Crop	Fortification level (mg/kg)	No. of tests	Average recovery ^a (%)	RSD (%)
Imazamox	Liver	0.01	5	92	25
		0.10	5	93	9

M 2503, M 2463, SOP CEM-236/002, M 2379 and M 3178.01

The methods used for storage stability studies are summarized briefly below.

M 2503: The samples were analysed by method M 2503 which determines the analytes by means of CE-UV. Residues of a soya bean sample aliquot were extracted with acidic water methanol. After filtration of the samples, one aliquot was subjected to solid phase extraction and liquid-liquid partitioning techniques. The final quantitation was performed by CE-UV (240 nm). The method has a limit of quantitation of 0.5 mg/kg for each compound in soya bean.

M 2463: The samples were analysed by Method M 2463 which determines the analytes by means of CE-UV. The validated LOQ of the method is 0.1 mg/kg per compound. Residues of the test compounds were extracted with acidic water-methanol followed by clean-up steps which included precipitation, centrifugation and solid-phase extraction techniques. Measurement of CL 263284 was accomplished by capillary electrophoresis (CE) equipped with a high sensitivity flow cell and a UV detector set at 240 nm.

SOP CEM-236/002: The samples were analysed by CEMAS SOP CEM-236/002 which determines the analytes by means of HPLC-UV. Residues of imazamox and CL 263284 were extracted by maceration with extraction solution (methanol/water/1 M hydrochloric acid). After filtration, extracts were re-suspended in methanol and hydrochloric acid before they were partitioned into dichloromethane. After evaporation to dryness, the residue was reconstituted in methanol and acetonitrile before being extracted into hexane. The hexane layer was evaporated to dryness and the residuum was re-dissolved into 0.2% hydrochloric acid. The extracts were cleaned up by solid phase extraction. The quantitation of residues was performed by HPLC-UV at 254 nm. The method has a limit of quantitation of 0.05 mg/kg for each compound in maize.

M 2379: The samples were analysed by Method M 2379 which determines the analytes by means of CE-UV. Residues of the test compounds were extracted with 1 N HCl/water/methanol solution (1:39:60, v/v/v).

M 3178.01: The samples were analysed by Method M 3178.01 which determines the analytes by means of HPLC-MS. The validated LOQ of the method is 0.1 mg/kg per compound. Residues of the test compounds were extracted with acetone/water/methanol solution (1:1:1, v/v/v) and purified by SPE techniques. Measurement of imazamox, CL 263284, CL 189215 and CL 312622 was accomplished by LC-MS.

RLA 12539, HPLC-MSD and CEM-236

The methods used for determination of incurred residues in supervised field trial samples are summarized briefly below.

RLA 12539 (wheat, ID-730-019): The whole wheat specimens were analysed for residues of imazamox using method RLA 12539 (CE-UV). The validated limit of quantitation was 0.05 mg/kg. The samples were extracted with methanol:water:HCl 1 mol/L (60:39:1, v/v/v). After clean-up by solid phase extraction, the specimen was partitioned with dichloromethane and evaporated to dryness and reconstituted in water. The final determination was performed with CE-UV at 240 nm. Mean recovery of imazamox from fortified untreated wheat whole plant, wheat grain and wheat straw, over the range 0.05 to 1.00 mg/kg, was 87%, 88% and 84%, respectively. Mean recovery of CL 263284 from fortified untreated wheat whole plant, wheat grain and wheat straw, over the range 0.05 to 1.00 mg/kg, was 81%, 77%, and 76%, respectively.

HPLC-MSD method (sunflower, sunflower seed processing, 2002/5004111): Residues of imazamox were extracted from sunflower seed and meal samples with an acidified methanol:water solution, filtered and concentrated. The residues are purified on a C₁₈ SEP column eluted with 25% MeOH in 0.05 M aqueous ammonium acetate and brought to final volume with water. Residues in refined oil samples are diluted in hexane and extracted by shaking with acidified acetonitrile:water solution. Following phase separation, the lower aqueous acetonitrile layer is collected and adjusted to final volume with water. The final analysis of imazamox residues is performed using LC-MSD. At fortification levels of 0.05, 0.1 and 0.5 mg/kg for sunflower seed and 0.05 mg/kg for refined oil and meal, recoveries were in the range of 70.8% and 113% (RSDs, 2–13%).

CEM-236 (alfalfa, ID-731-001): The specimens were analysed for imazamox and its metabolite CL 263284 with method CEM-236 quantifying each relevant analyte with a limit of quantitation of 0.05 mg/kg. For the analysis, alfalfa samples (green matter and hay) were extracted with an acidified methanol/water mixture. After clean-up of the extract by liquid/liquid partition and solid phase extraction residues were determined by UV detection after liquid chromatographic separation (HPLC-UV). In whole plant samples fortified at 0.05 mg/kg with imazamox and CL 263284 each, recovery was 82% and 72%, respectively.

Stability of residues in stored analytical samples

The Meeting received information on freezer storage stability of imazamox and its metabolites in plant commodities. Storage stability study on animal commodity was not submitted. Residues in plant commodities were generally stable for the duration of the studies.

Frozen samples were homogenized and fortified with test compound. The fortified homogenate was stored in deep freezer. After each specified period, a portion of sample was analysed for test compound. The stability results are expressed as average percentage of the nominal fortification and are not corrected for the procedural recoveries. In order to account for possible variations over the time investigated, the mean procedural recovery results are additionally given. The storage conditions, storage periods and percent remaining after each period were summarized in the table below.

Table 56 Stability of imazamox and its metabolites in frozen plant matrices

Matrix	Storage period (month)	Imazamox % remaining	Proc. rec.	CL 263284 % remaining	Proc. rec.	CL 189215 % remaining	Proc. rec.	CL 312622 % remaining	Proc. rec.

Stability of residues in stored analytical samples was investigated for imazamox, CL 263284, CL 189215 and CL 312622.

In acidic methanol water extract and final volume solution (for LC-MS/MS), the four compounds were stable for 3 days and 7 days, respectively in the matrices of rice (whole plant, grain and straw), grapes and sunflower seeds at refrigeration conditions [Lehmann 2013a, 2012/1294678; Lehmann 2013b, 2013/1177533].

Stability of calibration solutions prepared with 1% acetic acid in water was tested at 4 °C, where the four compounds were stable for 27 days [Jordan 2003a, 2002/5004302]. The mixed fortification standard solution in 10% methanol/water was stable up to one month at 4 °C with no more than 8% difference between the response of the one month old and the new fortification solution [Wickremesinha and Safarpour 1998a, ID-244-022].

Imazamox and CL 263284 in methanol or acidified water (calibration solution) were stable for 56 days and 28 days, respectively when stored under refrigeration [Stewart 2003a, 2003/5000116; Gooding 2013a, 2013/7002842]. In the study, extracts of livestock matrices in acidic methanol-water were stable for the time period tested 2 to 6 days.

USE PATTERNS

Imazamox is a systemic herbicide used for the control of grassy and broadleaf weeds. It is formulated as a liquid or granular product either a solo product or in combination with other active substances for use on legume vegetables, pulses, cereal grains, oilseeds and legume animal feeds. It is registered in a number of countries for crops with pre-emergence and post-emergence applications.

The authorized uses relevant to the supervised trials data submitted to the current Meeting and described in English are summarized in the table below.

Table 57 Registered use of imazamox relevant to the residue evaluation by the current Meeting

Crop	Country	Formulation	Application					Remarks
			Growth stage & season (crop)	No.	Water L/ha	Rate, kg ai/ha	PHI, days	
Bean	Brazil	WG 700 g/kg	Post-emergence	1	30–50 100–300	0.028–0.042	43	Add non-ionic surfactant in 0.25% v/v of mixture.
Bean(dry)	Canada	WG 700 g/kg	Early post-emergence BBCH 12–18	1	100	0.020	60	Apply with a nitrogen source and EC surfactant (0.5%, v/v).
Bean (dry)	Canada	SL 20 g/L (bentazone, 429 g/L)	Early post-emergence	1	100	0.020	60	Apply with a nitrogen source. Do not graze the treated crop or cut for hay.
Bean	Chile	WG 700 g/kg	Early post-emergence	1	150–200	0.042–0.056		
Bean (common)	Costa Rica	WG 700 g/kg	Early post-emergence	1	200–300	0.040	43	Add a non-ionic surfactant at 0.25%.
Bean (Winter and spring Faba)	France	EC 16.7 g/L (pendimethalin, 250 g/L)	Pre-emergence (within 5 days after sowing); pre-emergence of the weeds	1 (max every 2 yrs)	100–500	0.075	90	Applied on the soil. Do not roll after treatment.
Bean (Green)	Israel	EC 40 g/L	2–3 leaves			0.024		
Bean (Spring and winter field)	UK	EC 16.7 g/L (pendimethalin, 250 g/L)	Before weed emergence after sowing (pre-emergence of the crop)	1	200–300	0.075		Do not apply once the plumule is less than 13 mm from the soil surface.
Bean (Lima succulent)	USA	SL 120 g/L as free acid (ammonium sulphate)	Early post-emergence (1 st –2 nd trifoliate leaf stage)	1		0.035		A non-ionic surfactant must be added to the spray solution.
Bean, snap	USA	SL 120 g/L as free acid (amm. sulphate)	Post-emergence (at least 1 fully expanded trifoliate leaf and before the bloom stage)	1		0.035		A non-ionic surfactant must be added to the spray solution.
Bean (dry)	USA	SL 120 g/L as free acid (amm. sulfate)	Post-emergence (prior to bloom stage but after dry beans have at least 3 pairs of leaves)			0.035		An adjuvant (a surfactant or a crop oil concentrate) must be added to the spray solution.
Lentil (Clearfield)	Canada	WG 700 g/kg	Early post-emergence (2–6 leaf stage of the crop) BBCH 12–18	1	100	0.015–0.020	60	Apply with EC surfactant (0.5% v/v). Do not graze the treated crop or cut for hay within 20 days of application.
Lentil (Clearfield)	Canada	WG 35% (imazethapyr, 35%)	Early post-emergence (the 2–6 leaf stage of the crop)	1	50–100	0.015	60	Apply with EC surfactant (0.5% v/v). Do not harvest forage or cut hay for forage.

Crop	Country	Formulation	Application					Remarks
			Growth stage & season (crop)	No.	Water L/ha	Rate, kg ai/ha	PHI, days	
Lentil (Clearfield)	Canada	SL 33 g/L (imazapyr, 15 g/L)	Early post-emergence (1–9 node stage) BBCH 12–17	1	50–100	0.020	60	Apply with EC surfactant (0.5% v/v).
Lentil	France	EC 16.7 g/L (pendimethalin, 250 g/L)	Pre-emergence post-sowing of the crop	1	100–500	0.037	63	
Lentil (Clearfield)	USA	SL 120 g/L as free acid (amm. salt)	Post-emergence (2–leaf to prior to flower bud formation)	1		0.035–0.053		A non-ionic surfactant and nitrogen-based fertilizer must be added to the spray solution.
Pea (Field)	AUS	WG 700 g/kg	Early post-emergence	1	min 50	0.032	not req.	WHP: 6 weeks (grazing). Spray adjuvant and liquid ammonium sulfate should be added.
Pea (Succulent shelled peas)	Canada	SL 20 g/L (bentazone, 429 g/L)	Early post-emergence (3 to 6 node stage)	1	100	0.020	40	
Pea (Field)	Canada	WG 350 g/kg (imazethapyr, 35%)	BBCH 11–16	1	50–100	0.015	60	Apply with EC surfactant (0.5% v/v). Field peas treated may be fed to livestock 30 days after application. Do not harvest forage or cut hay for forage.
Pea (Succulent)	Canada	WG 700 g/kg	Early post-emergence (3–6 node stage)	1	100	0.020	40	Must be applied in tank mix combination with bentazone (429 g/ha) and nitrogen source (2 L/ha). Do not graze the treated crop or cut for hay.
Pea (Field)	Canada	WG 700 g/kg	Early post-emergence (3–6 node stage)	1	100	0.020	60	The same with the above
Pea (Field)	Canada	SL 20 g/L (bentazone, 429 g/L)	Early post-emergence (3–6 node stage)	1	100	0.020	60	Apply with a nitrogen source. Do not graze the treated crops or cut for hay.
Pea	Chile	WG 700 g/kg	Early post-emergence	1	150–200	0.042–0.056		–
Pea (canning)	France	EC 16.7 g/L (pendimethalin, 250 g/L)	Pre-emergence (within 3–4 days after sowing)	1 (max every 2 years)	100–500	0.075	63	Applied on the soil. Do not roll after treatment.
Pea (Winter and spring protein)	France	EC 16.7 g/L (pendimethalin, 250 g/L)	Pre-emergence post-sowing (preferred) or post-emergence (2–3 leaf stage of the culture) BBCH 12–13	1 (max every 2 years)	100–500	0.075	63	
Pea (Combining and vining pea)	UK, Ireland	EC 16.7 g/L	Before weed emergence after	1	200–300	0.075		Do not apply once the plumule is less than 13

Crop	Country	Formulation	Application					Remarks
			Growth stage & season (crop)	No.	Water L/ha	Rate, kg ai/ha	PHI, days	
		(pendimethalin, 250 g/L)	sowing					mm from the soil surface.
Pea	Israel	EC 40 g/L	2–3 leaves			0.024		
Pea (English)	USA	SL 120 g/L as free acid (amm. sulfate)	Early post-emergence	1		0.026		A non-ionic surfactant must be added to the spray solution.
Pea (dry) (field pea, southern pea (cow pea))	USA	SL 120 g/L as free acid (amm. sulfate)	Early post-emergence prior to bloom stage but after dry peas have at leaves 3 pairs of leaves	1		0.035		A non-ionic surfactant (or crop oil concentrate) must be added to the spray solution.
Peanut	AUS	WG 700 g/kg	Early post-emergence	1	min 50	0.035		WHP: 4 weeks (grazing) A spray adjuvant and liquid ammonium sulfate should be used. Do not graze or cut for stock food for 4 weeks after application.
Peanut	Israel	EC 40 g/L	3–4 true leaves			0.032		
Peanut	South Africa	SL 120 g/L	Post-emergence	1	200	0.048	50	This must only be used with a non-ionic surfactant (0.2% v/v) and ammonium sulfate solution.
Peanut	Zimbabwe	SL 120 g/L	Early post-emergence	1	200	0.036		Add an adjuvant and ammonium sulfate solution. Do not graze the treated crops or cut for hay within 20 days of application.
Rape (Clearfield winter rape)	UK	SC 17.5 g/L (metazachlor, 375 g/L)	Post-emergence BBCH 10–18	1	100	0.035		EC spreader may be used.

Alfalfa	USA	SL 120 g/L as free acid (amm. sulfate)	^e	1		0.035–0.053		

In Costa Rica, Guatemala, El Salvador, Nicaragua, and Panama, the same use is approved for common bean.

As well as UK, the same use for field bean is approved in Ireland.

In Cota Rica, Guatemala, El Salvador, Nicaragua, and Panama, the same use is approved for soya bean.

In Cota Rica and El Salvador, the same use is approved for Asian rice (Clearfield).

^a Seed-bearing fodder legumes (violet clover, white clover and crimson clover and of seed-bearing alfalfa: a) on set-up cultures at 0.067 kg ai/ha, in a single application and making sure that the application is carried out at most every 2 years. B) on a young plant culture at 0.033 kg ai/ha, between the 2 leaf and 4–5 trifoliate leaf stages. A second 0.033 kg ai/ha application may prove to be useful in certain cases. Do not exceed a maximum of two applications every 2 years.

^b Applied in post-emergence of the alfalfa: for young cultures, 0.033 kg ai/ha from the 2 trifoliate leaf stage of alfalfa; for cultures set up, a) end of autumn/beginning of winter: 0.033 kg ai/ha b) out of winter (resumption of vegetation growth): 0.033–0.067 kg ai/ha. If an application was carried out at 0.033 kg ai/ha at the end of autumn/beginning of winter, resumption is possible at the end of winter at a dosage of 0.033 kg ai/ha if this is necessary. Notes: Do not apply if the culture has been milled beforehand. At the end of the season between the last cut and the potential application, observe a min. 15 days period

^c 1) New planting: one application after germination or after the 1st cut, when the crop has 2–5 leaves 2) Established planting (from 2nd year): one application during dormancy of the crop or after the 1st cut (as soon as the alfalfa acquires 2–5 new leaves)

^d 1) Newly sown: 2–3 leaf stage 2) Established: after dormant season or 4–5 days after cutting

^e Early post-emergence 1) Seedling: application in the 2nd trifoliate stage or larger. For alfalfa grown for seed, before bud formation. 2) Established: application in the fall, winter, or in the spring to dormant or semi dormant alfalfa, or between cuttings. Any application should be made before significant alfalfa growth or regrowth (3 inches).

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received residue data from supervised field trials conducted on legume vegetables, pulses, cereal grains, oilseed and animal feeds.

Application rates and residue concentrations were reported as imazamox. Residue concentrations were recorded unadjusted for recoveries or for residue values in control samples. Where multiple samples were taken from a single plot, the calculated mean concentration is reported and used for estimation of maximum residue level. When trials were conducted in the same location, with the same or similar varieties, same or similar formulations, and same equipment, and at the same or similar timing, they are not regarded as independent and only one result from these trials was chosen for the estimation of a maximum residue level.

Analytical methods used for determination of imazamox-related residues in field trial samples were well validated through procedural recovery tests or method validation conducted previously.

Concentration of the metabolite CL 263284 was expressed as parent equivalents using conversion factor of 1.048. When calculating sum of parent and CL 263284, for values below LOQ, the LOQ was used for each analyte.

In many of the following trials, plants resistant to imidazolinone pesticides were used. That is expressed as “CL” in their variety name, which means non-GM plants showing the tolerance due to the mutation(s) of endogenous AHAS gene from conventional breeding technique.

Forage and fodder of cereal grains and grasses	Rice forage and straw, imidazolinone-tolerant	72
	Wheat forage and straw, imidazolinone-tolerant	73, 74
Miscellaneous fodder and forage crops	Rape seed forage, imidazolinone-tolerant	75

Legume vegetables

Beans

Residue field trials on beans were conducted in the European countries and USA during the growing season of 1996, 2011 and 2012. SL or EC formulation was used at various rates of 0.028–0.075 kg ai/ha with a pre- or post-emergence application. Bean seeds or other bean fractions were analysed for the determination of imazamox and the metabolites.

Peas

Residue trials on peas were conducted in EU countries and USA during the growing season of 1995–1998 and 2002–2008. SL or EC formulation was used at various rates of 0.028–0.075 kg ai/ha with a pre- or post-emergence application. Pea seeds or other pea fractions were analysed for the determination of imazamox and the metabolites.

Pea (dry)

Residue field trials on dry peas were conducted in France during the growing season of 1994 and 1996. SL or EC formulation was used at rates of 0.071–0.075 kg ai/ha with a pre-emergence application. Pea seeds or other pea fractions were analysed for the determination of imazamox and the metabolites.

^a Imazamox and CL 263284 were measured as one chromatographic peak representing a total imazamox-related residue.

Lentil

Residue trials were conducted with imidazolinone-tolerant lentils in Canada and USA during the growing season of 2001–2008. SL or WG formulation was used at rates of 0.015–0.021 kg ai/ha with a post-emergence application. Lentil seeds were analysed for the determination of imazamox and the metabolites.

Mix formulation: SC 22.4 g/L (bentazone of 480 g/L)

In the trials conducted in Canada, imazamox and CL 263284 were measured as one chromatographic peak representing a total imazamox-related residue.

^a Not independent trials

Cereals

Rice

Residue trials were conducted with rice plant water (imidazolinone-tolerance variety) in Italy in 2004–2012. SL formulation was used at various rates of 0.035–0.075 kg ai/ha at BBCH 13–31. In the all trial, the flooding was interrupted a few days before treatment. Applications were carried out on humid soil but without water in the paddy rice. Rice grain was analysed for the determination of imazamox and the metabolites.

Wheat

During the growing season of 1995–1998, residue trials were conducted with wheat of imidazolinone-tolerant variety in France, Italy, Canada and USA. Treatments were made post-emergent with various formulations at rates of 0.020–0.075 kg ai/ha. Wheat grain samples were analysed for the determination of imazamox and the metabolites.

w. plant: Whole plant without roots

^a Not independent trials

^b Not independent trials

^c Imazamox and CL 263284 were measured as one chromatographic peak representing a total imazamox-related residue.

Sunflower seed

Residue trials on sunflower seed (imidazolinone-tolerance variety) were conducted in European countries, Turkey, Argentina, Canada and USA in 2002–2012. Foliar application was made post-emergent with SL, SC or WG formulation at various rates of 0.015–0.081 kg ai/ha. Rape seed samples were analysed for residues of imazamox and the metabolites.

Table 68 Residues of imazamox in imidazolinone-tolerant sunflower from supervised field trials

Mix formulation: SC or SL 33 g/L (imazapyr of 15 g/L); WG 350 g/kg (imazethapyr 35%)

w. plant: whole plant without roots

r. plant: rest of plant without roots

MSO: methylated seed oil

^a Not independent trials due to the same trial location and close application time two days separate

^b Tank mix with imazapyr

^c Grown in 2007/2008

^d Grown in 2008/2009

Legume animal feeds

Alfalfa

Residue trials on alfalfa were conducted in Greece, Spain and USA in 1996–1999. Foliar application was made post-emergent with SL, SC or WG formulation at rates of 0.067–0.075 kg ai/ha. The forage and hay samples were collected and analysed for residues of imazamox and the metabolites.

Table 69 Residues of imazamox in alfalfa from supervised residue trials

^a Not independent trials^b Not independent trials*Wheat forage and straw*

Residue trials were conducted with imidazolinone-tolerant wheat in France, Italy, Canada and USA. Treatments were made with various formulations at rates of 0.020–0.075 kg ai/ha. The forage and straw were analysed for residues of imazamox and metabolites.

Rape seed forage

Residue trials were conducted with imidazolinone-tolerant rape plant in Germany, UK and France. Treatments were made with SC or SL formulation at rates of 0.050–0.077 kg ai/ha. The plant was analysed for residues of imazamox and metabolites.

^a Imazamox and CL 263284 were measured as one chromatographic peak representing a total imazamox-related residue.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In processing

The Meeting received information on effects of heating in water and processing on imazamox residues in soya bean, wheat and sunflower seed.

The processing factors (residue processed commodity divided by residue RAC) were calculated based on the total imazamox residues (sum of imazamox and CL 263284, expressed as imazamox). When the total imazamox residue value of the RAC was below limit of quantification, no processing factor was derived. When the total imazamox residue value of the processed commodity was below limit of quantification, the calculated processing factor is reported with a “less than” (<) symbol.

Effects on the nature of residue

To estimate the degradation behaviour of [pyridine-3-¹⁴C, imidazolinone-3-¹⁵N]-imazamox during industrial processing or household preparation, different processes (pasteurization, baking, brewing, boiling and sterilization) were simulated [Hassink 2012(a), 2011/1286214].

The test item was suspended in aqueous buffer solutions of different pH-values, to give a final concentration of ca. 0.92 µg/mL. Pasteurization was simulated by incubating the test solutions (pH 4) in a rotated round-bottom flask in a water bath for 20 min at 90 °C. For baking, brewing and boiling, the test solutions (pH 5) were treated in an Erlenmeyer flask under reflux at 100 °C for 60 min. To avoid an influence of light, the glassware was wrapped. Sterilization was performed by autoclaving the test solution (pH 6) at about 120 °C for 20 min. The total radioactivity present was determined by LSC. Characterization of the radioactivity in the buffered samples after incubation was performed by HPLC.

The recovery of total applied radioactivity (TAR) was 98.3–103.5%. Only in sterilization test, one replicate test solution showed a breakdown product of 5.8% TAR, the peak split into at least two peaks. Imazamox was stable under the simulation conditions of pasteurization, baking, boiling, brewing and sterilization.

Effects on the residue level

No residues were observed in trials with soya beans treated at exaggerated rates (0.13 kg ai/ha or 0.22 kg ai/ha) and no processing of the raw commodity was undertaken [ID-720-005, ID-720-006].

Wheat

During the 1998 growing season, a field trial was carried out in North Dakota, United States [Rodriguez 1999a, ID-730-038]. Wheat was treated with SL formulation (11.5%) and 0.25% adjuvant X-77. Trial plot received one post-emergence broadcast foliar application at a rate of either 0.20 kg ai/ha or 0.32 kg ai/ha, respectively. The applications were made when the plants were in the 5 leaf growth stage. Replicate wheat straw and grain samples were collected at crop maturity for typical wheat harvest (82 DAT). Wheat grain samples treated with 0.20 kg ai/ha were analysed for residues of imazamox and CL 263284 according to method M 3098 (CE-UV). The validated limit of quantitation was 0.05 mg/kg for imazamox and CL 263284 each. Wheat grain treated with 0.32 kg ai/ha was analysed for imazamox and CL 263284 residues according to method M 3252 (HPLC-MS; method M 3098). The validated limit of quantitation was 0.01 mg/kg for each analyte. Samples were stored frozen for a maximum of 5 months until analysis.

^a Field trial sample^b Mean residue for five subsamples (0.031, 0.030, 0.027, 0.027, 0.026 mg/kg)*Sunflower seed*

During the 2000 growing season, one field trial was carried out in Minot, ND, US. Sunflowers were treated with SL formulation (11.78%) and a formulation containing imazapyr. Trial plot received one foliar tank-mix application at a rate of either 0.056 kg ai/ha or 0.11 kg ai/ha of imazamox. Another one plot received a single foliar application of imazamox alone at 0.14 kg ai/ha. All spray solutions included methylated seed oil (1.0% v/v). The applications were made post-emergence when the plants were 30 to 46 cm tall (6 to 8 leaf growth stage). Replicate sunflower seed RAC samples were harvested at normal crop maturity, 88 days after treatment and processed according to simulated commercial practices into meal and refined oil. Sunflower samples were analysed for residues of imazamox, CL 263284 and CL 312622 using a developed HPLC-MSD method. The validated limit of quantitation was 0.05 mg/kg for each analyte. Samples were kept in frozen storage from collection until analysis for a maximum period of 7 months.

Processing factors were not derived as residue concentrations of sunflower seed (RAC) were all < LOQ.

^a tank mix with imazapyr

During the 2008 growing season, one field trial was carried out in SK, Canada [Norris 2009(a), 2008/7019225]. Clearfield Sunflowers were treated with a single foliar application of SL formulation (33% imazamox and 15% imazapyr) at 0.10 kg ai/ha. The applications were made broadcast post-emergence targeting stem elongation (BBCH 33-39) to late flowering growth stages (BBCH 69), at 70 days prior to the harvest of mature (dry) seed. The sunflower samples were analysed for residues of imazamox and CL 263284 using method M 3519 (LC-MS/MS) with a limit of quantitation of 0.05 mg/kg. Samples were stored after harvest for a maximum of 157 days prior to analysis.

Residues from sampled two bulks

Mix formulation: SL 33 g/L (imazapyr of 15 g/L).

During the 2007 growing season, one field trial was carried out in ND, USA [Johnston 2009a, 2008/7008101]. Clearfield sunflowers were treated with a single foliar application of WG formulation (35% imazamox and 35% imazethapyr) at 0.075 kg ai/ha of imazamox. The applications were made post-emergence when the sunflowers were at flower buds visible to late flowering growth stages, at 59 days prior to the harvest of mature (dry) seed. Sunflower samples were analysed for residues of imazamox and CL 263284 using method SOP-PA.0288 (LC-MS/MS) with a limit of quantitation of 0.05 mg/kg. Seed samples were stored frozen after harvest or fraction collection for a maximum of 239 days prior to analysis.

APPRAISAL

Imazamox is an imidazolinone herbicide registered in many countries to control a wide spectrum of grass and broadleaf weeds. At the Forty-fourth Session of the CCPR (2012)³, it was scheduled for evaluation as a new compound by the 2014 JMPR.

The Meeting received information on the physical and chemical properties, animal and plant metabolism, environmental fate, analytical methods, storage stability, use patterns, supervised trials and processing studies.

The following abbreviated names were used for the metabolites discussed below.

Code (MW)	IUPAC chemical name	Structure
CL 299263 (305) Imazamox; BAS 720 H	(<i>RS</i>)-2-(4-isopropyl-4-methyl-5-oxo-2-imidazolin-2-yl)-5-methoxymethylnicotinic acid	
CL 263284 (291) M715H001	5-(hydroxymethyl)-2-(4-isopropyl-4-methyl-5-oxo-2-imazolin-2-yl) nicotinic acid	
CL 189215 (453.5) M715H002	5-[(β-glucopyranosyl oxy) methyl]-2-(4-isopropyl-4-methyl-5-oxo-2-imidazolin-2-yl) nicotinic acid	
CL 312622 (305) M720H002	2-(4-isopropyl-4-methyl-5-oxo-2-imidazolin-2-yl)-3,5-pyridine-dicarboxylic acid	
CL 354825 (277)	5-hydroxy-6-(4-isopropyl-4-methyl-5-oxo-2-imidazolin-2-yl)-nicotinic acid	
CL 336554 (323)	2-[(1-carbamoyl-1,2-dimethylpropyl) carbamoyl]-5-(methoxymethyl)-nicotinic acid	

³ REP12/PR-Appendix XIII

Code (MW)	IUPAC chemical name	Structure
CL 152795	2-[(1-carbamoyl-1,2-dimethylpropyl) carbamoyl]-3,5-pyridinedicarboxylic acid	

Animal metabolism

The Meeting received metabolism studies on imazamox, CL 263284 (hydroxymethyl) and CL 312622 (dicarboxylic acid) orally administered to lactating goats and laying hens.

Imazamox

Lactating goats were orally administered single daily doses of [pyridine-6-¹⁴C]-imazamox, via gelatin capsules, for seven consecutive days at either 2.1 or 12 ppm. Kidney, liver, leg and loin muscle, and omental fat samples were collected approximately 20 hours after the last dosing.

In the goat the imazamox was mainly excreted in urine (92% of the low dose and 65% of the high dose) and via faeces (14.8% of the low dose and 24.0% of the high dose). Unaltered parent accounted for most of the excreted residue. The total radioactive residues in the daily blood and milk samples and tissues (liver, leg, loin, omental fat) were less than 0.01 mg eq./kg regardless of the treatment dose levels. In the kidney, the TRR was 0.02 mg eq./kg at a dose level of 2.1 ppm and 0.06 mg eq./kg at a dose level of 12 ppm. This was mostly imazamox (89% TRR).

CL 263284

A ruminant metabolism study was conducted with [pyridine-6-¹⁴C]-CL 263284. Dose levels for the goats, administered orally in gelatin capsules, were either 2.3 or 15 ppm daily for seven days. Samples of blood, milk and excreta were collected daily. After seven days of dosing, the goats were sacrificed (approximately 20 hours after the last dose) and the tissues kidney, liver, muscle and fat were collected.

Elimination of ¹⁴C radioactivity via faeces accounted for 82% and 68% of the total cumulative dose at the low dose and high dose, respectively. TRR levels in most tissue samples (muscle, fat, liver) from the low and high dose treated goat and all milk samples were < 0.01 mg eq./kg. The kidney showed a residue of 0.03 mg eq./kg at the 15 ppm dose, which comprised minor component CL 263284 (9% TRR, < 0.01 mg/kg) and very labile component M1(salt or conjugate of CL 263284; 78% TRR, 0.02 mg eq./kg).

CL 312622

Lactating goats were orally treated with a mixture of [pyridine-6-¹⁴C, ¹³C]-CL 312622. The three goats were dosed for five consecutive days with either 3.1 or 33 ppm. Milk, urine and faeces samples were collected daily. Edible tissues (muscle, fat, liver and kidney) were collected at sacrifice (approximately 22 hours after the last dose).

About 90% of the total cumulative dose was excreted via the faeces. TRR levels in all tissues and milk samples were < 0.006 mg eq./kg, except kidney (0.025 mg eq./kg) and liver (0.009 mg eq./kg) of goats treated at the high dose level (33 ppm).

In the kidney sample, CL 312622 was the predominant radioactive residue (60% TRR). The impurity (CL 152795) present in the dosing solution was found at 11% of TRR. Minor polar unknowns (total 10% of TRR) and non-polar unknowns (total 12% of TRR) were also present in the kidney extract, composed with fractions of 0.003 mg eq./kg with multiple components. In the liver, CL 312622 was present at 38% of TRR (impurity, CL 152795, 19% TRR) and polar and nonpolar (31% and 11% TRR, respectively) fractions were equivalent to 0.003 mg eq./kg or lower, containing multiple components.

In summary imazamox and its metabolites (CL 263284 and CL 312622) each was mainly excreted unchanged through urine and faeces in lactating goats. There was no accumulation in any other edible goat tissue or in the milk (< 0.01 mg eq./kg) except kidney. Kidney mostly contained the unchanged administered compound.

Metabolism of imazamox in laying hens

Imazamox

Laying hens were orally dosed with [pyridine-6- ^{14}C]-imazamox at a dose level of either 2.1 or 10 ppm for seven consecutive days. Eggs were collected twice daily and blood and the tissues (liver, kidney, muscle, and skin with adhering fat) were collected for analysis approximately 22 hours after the last dose. About 85% of the total dose administered at the low and high dose was in the excreta. Residues in eggs, skin with adhering fat, muscle, liver and kidney tissues were all less than 0.01 mg eq./kg.

CL 263284

A poultry metabolism study was conducted with [pyridine-6- ^{14}C]-CL 263284. Hens were dosed orally at a dose level of either 2.1 or 11 ppm by gelatin capsules for seven days. Eggs and excreta were collected daily. The hens were sacrificed and the tissues (liver, kidney, muscle and skin with adhering fat) were collected approximately 22 hours after the last dose. About 87% of the total dose administered at the low and high dose was eliminated via excreta. Residues in all tissues and eggs were less than 0.01 mg eq./kg.

CL 312622

Laying hens were orally treated with a mixture of [pyridine-6- ^{13}C]-CL 312622 and [pyridine-6- ^{14}C]-CL 312622. Hens were dosed for five consecutive days with a dose level of either 0.13 or 10.5 ppm. Eggs were collected twice daily and the edible tissues (muscle, liver and skin with adhering fat) were collected at sacrifice approximately 22 hours after the last dose.

About 89% of the total dose administered at the low dose and high dose was eliminated via the excreta. Residues in tissues (liver, muscle and skin with adhering fat) and eggs were all 0.006 mg eq./kg or below. There was no retention or accumulation in eggs or edible poultry tissues.

In summary, in laying hens, imazamox, its metabolites (CL 263284 and CL 312622) were mainly eliminated unchanged through excreta. No residues (< 0.01 mg eq./kg) in eggs or edible tissues were found.

Plant metabolism

The Meeting received information on the fate of imazamox in oilseed rape, soya bean, pea, maize, wheat and alfalfa.

The metabolic fate of imazamox in imidazolinone-tolerant oilseed rape was investigated in one indoor and two outdoor studies. In one of the outdoor studies, a mixture of [pyridine-6- ^{14}C]-imazamox and [pyridine-6- ^{13}C]-imazamox was post-emergence treated at 0.02 kg ai/ha. Residues in plant at 0 DAT and seed at 82 DAT were 2.1 mg eq./kg and < 0.002 mg eq./kg, respectively (not further identified for component in plant and seed).

In the other two studies (indoor or outdoor), either [pyridine-6- ^{14}C]-imazamox or [imidazolinone-5- ^{14}C , 3- ^{15}N]-imazamox was applied post-emergence at rates of 0.051–0.089 kg ai/ha (outdoor) or 0.075 kg ai/ha (indoor), respectively. TRR in plant at 0 DAT were 2.2–3.9 mg eq./kg. Residues in forage (12–22 DAT) ranged from 0.04 mg eq./kg to 0.89 mg eq./kg. In straw and seed (78–90 DAT), residues were 0.088–1.1 mg eq./kg and 0.004–0.15 mg eq./kg, respectively. The majority of residues (80–99% TRR) in forage and straw samples were extracted with aqueous methanol or acidic aqueous methanol. Extractability in seeds was relatively low, 58–80% TRR.

In both labels, major components of the residues in forage were imazamox (16–42% TRR) and CL 263284 (36–54% TRR). In straw, major components were CL 263284 (44–50% TRR) and CL

312622 (up to 26% TRR); imazamox, < 2% TRR. In rape seed, major components of the residues were CL 263284 (up to 31%) or CL 189215 (up to 21%); imazamox, present at up to 13%.

The metabolic fate of [pyridine-6-¹⁴C]-imazamox in soya bean under outdoor field was studied with post-emergence treatment at a rate of 0.39 kg ai/ha. TRR in plant at 0 DAT was 55 mg eq./kg. Residues in forage (29–60 DAT) ranged from 0.13 mg eq./kg to 0.56 mg eq./kg. In straw and seed (153 DAT), residues were 0.08 mg eq./kg and 0.02 mg eq./kg, respectively. The majority of residues in forage (86–97%) were extracted with aqueous methanol and dichloromethane. Acidic and/or basic digestion for straw and seed samples extracted up to 53% and 57% of residues, respectively.

A major component of the residue in soya bean forage (29–60 DAT) was CL 189215 (32–36% TRR); imazamox, CL 263284 and CL 312622 each, present at 6–11% TRR. In soya bean seed, CL 263284 was a major component, representing 12% TRR.

Field peas were treated post-emergent, under outdoor growing conditions, with [pyridine-6-¹⁴C]-imazamox at a rate of 0.040 kg ai/ha. TRRs in whole plant at 0 DAT and 20 DAT were 1.1 mg eq./kg and 0.035 mg eq./kg, respectively. At 61 DAT, residues in all of the samples (pea foliage, immature peas, pea shells and pea pods) were < 0.01 mg eq./kg. In pea and pea hay (84 DAT), residues were 0.01 mg eq./kg and 0.05 mg eq./kg, respectively. The aqueous methanol extracted 61–99% of the TRR in whole plant. From the hay and peas, 58% and 39% of the TRR was extracted, respectively.

In pea hay, imazamox was present at 0.02 mg eq./kg (66% TRR) and other components (CL 263284, CL 189215) were negligible ($\leq$ 0.01 mg eq./kg).

Alfalfa was treated, post-emergent, in plots at different ages of crop and timing of application under outdoor conditions with [pyridine-6-¹⁴C]-imazamox at a rate of 0.13 kg ai/ha. TRR in alfalfa plants at 0 DAT was 6.5–15 mg eq./kg. Residues in forage (26 DAT) ranged from 0.18 mg eq./kg to 0.67 mg eq./kg. Residues in forage (1st, 2nd, 3rd cut at 26–111 DAT) and hay (1st, 2nd, 3rd cut at 28–160 DAT) were < 0.01–0.21 mg eq./kg and 0.02–0.83 mg eq./kg, respectively. The majority (65–99% TRR) of residues in forage and hay were extracted with a solvent mixture of methanol/acetone/water.

Residue components in alfalfa forage (26 DAT) were: imazamox, 3–6% TRR and CL 263284, CL 189215 and CL 312622, 14–26% TRR. For forage and hay samples, 1st, 2nd, 3rd cut, composition of the compounds were similar to those in forage at 26 DAT.

The metabolic fate of imazamox on imidazolinone-tolerant maize was investigated in two outdoor studies. Radiolabelled imazamox, either [pyridine-6-¹⁴C]-imazamox or a mixture of [pyridine-6-¹⁴C]-imazamox and [pyridine-6-¹³C]-imazamox was post- or pre-emergence (one day after seedling) treated at rates of 0.13–0.14 kg ai/ha. Residues in forage (14, 30 and 62 DAT) ranged from 0.011 mg eq./kg to 0.41 mg eq./kg. In fodder and grain (100–112 DAT), TRRs were 0.012–0.047 mg eq./kg and 0.010–0.01 mg eq./kg, respectively. 40–98% of the TRR in maize samples were extracted with aqueous methanol (40% TRR in fodder).

Major components of the residues in maize forage were imazamox (18–31% TRR) and CL 263284, (12–23% TRR). In fodder, CL 263284 was present at 15% TRR, < 1–7% TRR in the other components. In grain, major components were CL 263284 (20% TRR) and CL 189215 (15% TRR) with imazamox at low level, < 5% TRR.

The metabolic fate of imazamox on imidazolinone-tolerant spring wheat was investigated under indoor and outdoor conditions. Radiolabelled imazamox, [pyridine-6-¹⁴C]-imazamox or [imidazolinone-5-¹⁴C, 3-¹⁵N]-imazamox was post-emergence applied at rates of 0.14 or 0.76 kg ai/ha. Residues in forage (8–28 DAT) ranged from 0.10 mg eq./kg to 1.6 mg eq./kg. In straw and grain (62–70 DAT), residues were ranged in 0.16–3.2 mg eq./kg and 0.067–1.4 mg eq./kg, respectively. The 53–93% TRR in all wheat samples was extracted with methanol and water or acidic aqueous methanol (53% in straw).

Major components of the residues in spring wheat forage were imazamox (42–67% TRR) and CL 263284 (10–18% TRR). In straw, CL 263284 was most abundant (13–38% TRR). The other

components, imazamox (8–10% TRR), CL 189215 (3–15% TRR) and CL 312622 (6–17% TRR) were found at lower levels. In wheat grain, imazamox was most abundant component (40–70% TRR, 0.027–1.1 mg eq./kg); CL 263284 (7–10% TRR) and CL 189215 (3–4% TRR) were present at relatively low levels and CL 312622 was not detected.

The key step of the metabolism of imazamox in plant was the cleavage of the methyl ether group (demethylation) resulting in metabolite CL 263284. Subsequently, oxidation of the hydroxyl group of CL 263284 generated the dicarboxylic acid metabolite CL 312622, while glycosylation led to the glucose conjugate CL 189215.

In conclusion, in the edible portions of most treated food crops harvested at maturity, no or a very small residue of imazamox or its metabolites are expected to be found. However, for certain crops such as wheat, it is considered that the residues may be detected in wheat grain. In animal feed crops, imazamox, CL 263284, CL 189215 and CL 312622 are expected to be found above the LOQ.

Environmental fate

The Meeting received information on aerobic soil metabolism, photodegradation on the soil surface, hydrolysis and residues in succeeding crops.

Aerobic soil metabolism

Imazamox applied in sandy loam soil degraded rapidly. In three studies, half-life of imazamox was 28–38 days in sandy loam soil treated with imazamox at 0.050–0.10 kg ai/ha. However, in another study, half-life of imazamox treated in combinations of soil type (silty clay loam and silt loam) and temperature (10 °C and 20 °C) was in a range of 12–207 days (DT₉₀, 39–687 days). Imazamox was shown to be moderately persistent in aerobic soil. In all the studies, dicarboxylic acid (CL 312622) and hydroxy acid (CL 354825) metabolites were the major residue components. The parent and both metabolites were ultimately mineralized to CO₂.

Residues in succeeding crops

In a confined rotational crop study, [pyridine-6-¹⁴C]-imazamox was applied once to soya beans at the 4–6 leaf stage, in a sandy loam soil, at a rate of 0.072 kg ai/ha. One-hundred days after treatment, the soya bean crop was harvested. On the day of harvest, winter wheat was seeded into a subplot (100-day plant-back interval; PBI) of the treated field. Maize, radish, and lettuce were seeded into separate subplots at a 268-day PBI. Total radioactive residues were < 0.01 mg eq./kg in all rotational crops.

In another study, radiolabelled imazamox, either [imidazolinone-5-¹⁴C, 3-¹⁵N]-imazamox or [pyridine-3-¹⁴C, imidazolinone-3-¹⁵N]-imazamox were applied to bare sandy loam soil in plastic container followed by sowing spinach, white radish and spring wheat at PBIs of 1 month, 4 month and 1 year.

In spinach and white radish, residues were < 0.01 mg eq./kg at any PBIs. However, in spring wheat samples (forage, hay, straw, grain), total residues (TRR) were: 0.008–0.078 mg eq./kg at one month PBI (grain, 0.032–0.053 mg eq./kg), 0.004–0.132 mg eq./kg at four month PBI (grain 0.019–0.035 mg eq./kg) and < 0.001–0.052 mg eq./kg at one year PBI (grain, 0.002–0.004 mg eq./kg). In wheat grain at one month PBI, residues of imazamox and CL 263284 were 0.001–0.005 mg eq./kg.

In conclusion, residues of imazamox and the metabolites are expected to be less than 0.01 mg eq./kg in succeeding crops.

Photodegradation

Soil photolysis of [pyridine-6-¹⁴C]-imazamox was studied in a sandy loam soil, surface treated at a rate equivalent to 0.10 kg ai/ha and exposed for 30 days to artificial sunlight. The 92% imazamox at time-0 decreased to 74% imazamox at the end of the 30 days irradiation. A half-life of imazamox was calculated to be 65 days. A degradate, dicarboxylic acid CL 312622 (2% TAR in dark control), was formed at about 14% of the total residues after 30 days irradiation.

Imazamox is photodegraded with a half-life of 65 days on the surface of soil. Any degradate specific for photolysis was not found.

Hydrolysis

Imazamox is used for rice production. In the hydrolysis study under different pH conditions, imazamox was stable at pH 4, pH 7 and pH 9.

Methods of analysis

The Meeting received description and validation data for analytical methods for residue analysis of imazamox and its metabolites in various plant and animal commodities.

In general, the methods involved extraction of residues with acidic methanol-water solution, clean-up procedure by mainly solvent partitioning and solid phase extraction, and determination by HPLC-UV or LC-MS/MS. In the case of milk and fat, acetonitrile in hexane is used for the extraction step. Some methods employ capillary electrophoresis-UV or GC-NPD, in case of use of GC-NPD, where combined determination for imazamox-related residues is possible by converting to a common methylated product.

A number of specific methods for plant matrices were found suitable for analysis of imazamox, CL 263284, CL 189215 and CL 312622 with LOQ ranging 0.01–0.05 mg/kg for these analytes except that it was 0.1 mg/kg for alfalfa.

For animal matrices, one method determined by LC-MS/MS was submitted and found suitable for analysis of imazamox and CL 263284 with LOQs of 0.01 mg/kg for bovine matrices and poultry egg.

No multi-residue methods were submitted.

Stability of residues in stored analytical samples

The stability of imazamox and its metabolites during frozen storage of samples was investigated in a range of plant matrices for which supervised residue trials were submitted.

Compounds tested were imazamox, CL 263284, CL 189215 and CL 312622. Each compound was spiked to matrices at 0.1 to 1 mg/kg.

All of the compounds tested were found to be stable (> 70% remaining) at least during the storage periods tested: for imazamox, 3.6 years in soya bean (seed, forage and hay), 4 years in wheat (grain, straw, forage and hay), 2 years in maize (grain, ear and immature plant), 1.5 years in rape seed and 1.5 years in alfalfa (hay, forage and seed); for CL 263284, 3.6 years in soya bean (seed, forage and hay), 10 months in processed soya bean products, 4 years in wheat (grain, straw, forage and hay), 2 years in maize (grain, ear and immature plant) and peanut (hull and nutmeat) and 1.5 years in alfalfa (hay, forage and seed); for CL 189215, 10 months in soya bean seed and processed soya bean products, 2 years in peanut (hull and nutmeat) and 1.5 years in alfalfa (hay, forage and seed); and for CL 312622, 1.5 years in alfalfa (hay, forage and seed).

Definition of the residue

In metabolism studies of imazamox and the metabolites (CL 263284, CL 312622) in goats and hens, the compounds were mostly excreted (85–106%) unchanged through urine and faeces. In hen, no detectable residues were found in eggs or edible tissue. In goat, there were no detectable residues in milk and tissues except kidney. Residue in the kidney was predominantly the administered parent. Therefore, no residues of imazamox and related compounds are expected in livestock tissues, milk or eggs at expected livestock dietary burdens of less than 3 ppm.

The log P_{ow} for imazamox is 0.73 suggesting imazamox residues are not fat soluble.

In confined crop rotation studies, any imazamox related residues in succeeding crops were not detected above more than 0.01 mg/kg.

In primary crops, imazamox is either not found or found at very low levels ($< 30\%$ TRR, < 0.01 mg eq./kg) in non-tolerant food commodities and imidazolinone-tolerant food commodities (tolerant rape seeds, soya bean seeds, pea seeds, alfalfa, tolerant maize seeds). Imidazolinone-tolerant wheat grain, is the only food commodity, where parent is found at significant levels ($40\text{--}74\%$ TRR, $0.027\text{--}1.1$ mg eq./kg). Among the metabolites found, CL 263284 is the most predominant metabolite, although present at low levels in food commodities (up to 31% TRR, maximum 0.092 mg eq./kg). In supervised trials imazamox and CL 263284 are found at levels above the LOQ in food commodities (lentil seeds, sunflower seeds). In feed commodities (tolerant rape forage or straw, soya forage or straw, pea forage or hay, alfalfa forage or hay, tolerant maize forage or fodder, wheat forage, hay or straw), imazamox ($1.5\text{--}67\%$ TRR, $< 0.01\text{--}5.0$ mg eq./kg) and CL 263284 are more prominent ($8\text{--}54\%$ TRR, $< 0.01\text{--}1.9$ mg eq./kg).

Parent and CL 263284 are the only two compounds expected to be found in food commodities. Metabolite CL 263284 can also arise in plant commodities as a result of treatment with imazapic, another imidazolinone herbicide. Since CL 263284 cannot be seen as a marker for imazamox, the Meeting decided to define the residue for enforcement/monitoring as parent only.

Parent and CL 263284 are considered relevant for dietary risk assessment as the toxicity of CL 263284 is similar to that of imazamox in rat. Therefore, the Meeting decided to define the residue for dietary risk assessment as the sum of parent and CL 263284, expressed as imazamox.

The Meeting agreed the following residue definitions:

Definition of the residue for plant and animal commodities for compliance with the MRL: imazamox.

Definition of the residue for plant and animal commodities for the estimation of dietary intake: sum of imazamox and 5-(hydroxymethyl)-2-(4-isopropyl-4-methyl-5-oxo-2-imazazolin-2-yl) nicotinic acid (CL 263284), expressed as imazamox.

Residue is not fat-soluble.

Should imazamox be used on crops other than cereals, pulses and oilseeds, the residue definition may need to be revised.

Results of supervised residue trials on crops

The Meeting received supervised trial data for imazamox on legume vegetables (beans and peas), pulses (bean, pea, lentil and soya bean), cereals (rice and wheat), oil seed crops (peanut, rape and sunflower) and alfalfa.

In below, a maximum residue level was estimated based on residue concentration of imazamox. Total residue means sum of parent compound and CL 263284. Concentration of CL 263284 was expressed as parent equivalents (conversion factor, 1.048).

Legume vegetables

Beans

Residue trials on beans were performed in Denmark, Germany, France, the UK, Greece, Italy, Spain and the USA. The GAP for beans in Chile is a single early post-emergent application at 0.056 kg ai/ha with no PHI specified.

In six trials on French beans conducted in Italy (1×0.050 kg ai/ha at post-emergence) matching the Chile GAP, residues in bean pods with seeds were: parent < 0.05 (6) mg/kg and metabolite < 0.05 (6) mg/kg. Total residues in the bean pods with seeds were ($n=6$): < 0.1 (6) mg/kg.

In other six trials from USA (1×0.050 kg ai/ha at post-emergence) matching the Chile GAP, residue concentrations of imazamox (only measured) were < 0.05 (6) mg/kg in pods with seeds of snap beans.

Three trials conducted in France, the UK and Italy involved an earlier application timing and a higher rate (1×0.075 kg ai/ha at pre-emergence). Residues in pods with seeds of common bean (flageolet bean) were: parent < 0.01 (3) mg/kg, metabolite < 0.01 (3) mg/kg. Total residues in the bean pods with seeds were < 0.02 (3) mg/kg.

The Meeting considered that there was no expectation of residues above LOQ in bean pods with seeds. The Meeting estimated a maximum residue level of 0.05^* mg/kg and an STMR of 0 mg/kg for beans, except broad bean and soya bean (green pods and immature seeds).

Peas

Residue trials on peas were performed in Italy, France, Spain, the UK, Germany and the USA. The GAP for peas in France is for a single pre-emergent application post sowing per every 2 years, treating on soil at 0.075 kg ai/ha with a PHI of 63 days.

In nine trials conducted in Italy and France approximating the French GAP (1×0.068 – 0.075 kg ai/ha at pre-emergence, 70–110 day PHI), residues in pea seeds were: parent < 0.05 (9) mg/kg and metabolite < 0.05 (9) mg/kg. Total residues in pea seeds were ($n=9$): < 0.1 (9) mg/kg.

Another ten trials were conducted in Italy and Spain with post-emergence treatments at 0.050 – 0.052 kg ai/ha in eight trials and 0.073 – 0.075 kg ai/ha in two trials. The total residues were all < 0.1 (10) mg/kg.

The Meeting estimated a maximum residue level of 0.05^* mg/kg and an STMR of 0 mg/kg for peas, shelled (succulent seeds).

Pulses

Bean (dry)

Residue trials on dry beans were performed in France, Germany, Netherlands, the UK, Italy, Greece, Spain and the USA. The GAP for dry bean in the UK is a single pre-emergence application to soil at a rate of 0.075 kg ai/ha.

In four trials from France, the UK and Italy (1×0.075 kg ai/ha at pre-emergence, 91–108 day PHIs), approximating the UK GAP, residues in common bean seeds were: parent < 0.01 (4) mg/kg and metabolite < 0.01 (4) mg/kg. Total residues in seed of common beans were < 0.02 (4) mg/kg. In these trials, the total residues in whole plants harvested early (PHIs of 32–48 days) were < 0.02 mg/kg.

In two trials from the USA applied at a post-emergence timing and at a rate comparable to the UK GAP (1×0.070 kg ai/ha, 61–98 day PHIs), residue concentrations of the parent compound were also below LOQ, < 0.05 (2) mg/kg.

Pea (dry)

The GAP for dry peas in France is a single pre- or post-emergence application every 2 years at a rate of 0.075 kg ai/ha with a PHI of 63 days. A total of ten trials were conducted in France at the GAP rate (1×0.075 kg ai/ha at pre-emergence) but with longer PHIs (106–129 days). The residues measured for each compound or combined total residue were: parent < 0.05 (5) mg/kg, metabolite < 0.05 (5) mg/kg and total residue < 0.1 (10) mg/kg.

Lentil (dry)

Residue trials for lentil were available from Canada and the USA. In Canada, imazamox is approved for use in imidazolinone-tolerant lentils with a single early post-emergent application at a rate of 0.020 kg ai/ha (plus adjuvant) with a PHI of 60 days.

In a total of fourteen trials (1×0.015 – 0.021 kg ai/ha at post- or early post-emergent timings and a 60 day, or shorter, PHI (without use of an adjuvant), residues in imidazolinone-tolerant lentils

were: imazamox < 0.05 (9), 0.056, 0.060, 0.065, 0.12, 0.12 mg/kg and metabolite < 0.05 (14) mg/kg. Total residues were: < 0.1 (9), 0.11 (3), 0.17, 0.17 mg/kg.

Soya bean (dry)

Residue trials on soya bean were performed in France, Germany, Italy and Canada. The GAP for soya bean in Brazil is for a single post-emergence application at a rate of 0.049 kg ai/ha (plus adjuvant) with a PHI of 70 days.

In nine trials conducted in France, Germany and Italy (1×0.042–0.045 kg ai/ha at post- or early post-emergence, 69–104 days of PHI, with or without adjuvant) approximating the Brazilian GAP, residues in soya bean seeds were: imazamox < 0.01 (7) mg/kg and metabolite < 0.01 (7) mg/kg. Total residues were < 0.02 (7) mg/kg. Of which five trials showed no effect of adjuvant on the level of residue in dry seed.

In two trials conducted in Canada at an exaggerated rate of 0.070–0.071 kg ai/ha (single post-emergence application, 106–112 day PHIs), total residues were all < 0.05 (2) mg/kg.

The Meeting estimated a maximum residue level of 0.05* mg/kg and an STMR of 0 mg/kg for bean and pea in dry, respectively.

For lentil (dry), the Meeting estimated a maximum residue level of 0.2 mg/kg and an STMR of 0.1 mg/kg.

For soya bean (dry), the Meeting estimated a maximum residue level of 0.01* mg/kg and an STMR of 0 mg/kg.

Cereals

Rice

Residue trials on imidazolinone-tolerant rice were performed in Italy and Spain. The use pattern in Spain is twice post-emergence treatment at a rate of 0.035 kg ai/ha with an interval of 14–21 days and no PHI, applying on imidazolinone-tolerant rice plant in water or dry planted.

In a total of six trials on imidazolinone-tolerant rice (2×0.035–0.038 kg ai/ha at BBCH 13–14 and BBCH 25–31, 10–12 day interval) from Italy and Spain matching the Spain GAP, residues in rice grain were: imazamox < 0.01 (6) mg/kg and metabolite < 0.01 (3), 0.02, 0.03 (2) mg/kg. Total residues were: < 0.02 (3), 0.030, 0.040 (2) mg/kg.

The Meeting estimated a maximum residue level of 0.01* mg/kg and an STMR of 0.025 mg/kg for rice.

Wheat

Residue trials on imidazolinone-tolerant wheat were performed in France, Italy, Canada and the USA. The GAP for wheat (imidazolinone-tolerant) in Argentina is a single early post-emergence application at 0.070 kg ai/ha with no PHI.

In a total of twelve trials from France (eight trials), Italy (four trials) and USA (one trial) (1×0.067–0.075 kg ai/ha at post-emergence) matching the GAP, residues in imidazolinone-tolerant wheat grain were: imazamox < 0.05 (13) mg/kg and metabolite < 0.05 (13) mg/kg. Total residues were < 0.1 (13) mg/kg.

The Meeting considered that there is no expectation of residues above the LOQ for wheat grain and agreed to estimate a maximum level of 0.05* mg/kg and an STMR of 0.1 mg/kg for wheat.

Oilseeds

Peanuts

Five trials were conducted in Brazil with a single post-emergence application (BBCH 71–79) at a rate of 0.056 kg ai/ha with a PHI of 43–50 days without use of an adjuvant, matching the GAP for peanut in South Africa (1×0.048 kg ai/ha plus adjuvant) at post-emergence with a PHI 50 days. The residues in peanut kernels were: imazamox < 0.01 (5) mg/kg and metabolite < 0.01 (5) mg/kg. Total residues were < 0.02 (5) mg/kg.

Although only a relatively small number of trials were available, there is no expectation of residues above the LOQ in peanuts. The Meeting estimated a maximum residue level of 0.01* mg/kg and an STMR of 0 mg/kg.

Rape seed

Residue trials on imidazolinone-tolerant oilseed rape were conducted in France, Germany, the UK and Canada and Argentina. The GAP for imidazolinone-tolerant rape in Chile is a single early post-emergence application at a rate of 0.056 kg ai/ha with no PHI. In six trials from Germany, France and Argentina (1×0.050 kg ai/ha at post-emergence) matching the Chile GAP, residues in rape seed (imidazolinone-tolerant variety) were: imazamox < 0.01 (2), < 0.05 (4) mg/kg and metabolite < 0.01 (2), < 0.05 (4) mg/kg. Total residues were < 0.02 (2), < 0.1 (4) mg/kg.

In another eighteen trials from France, Germany and the UK, an exaggerated rate of 0.073–0.079 kg ai/ha did not lead to above LOQ (< 0.05 mg/kg) for total residues in seeds of imidazolinone-tolerant oilseed rape.

The Meeting considered that there is no expectation of residues above the LOQ in rape seeds.

The Meeting estimated a maximum residue level of 0.05* mg/kg, an STMR of 0 mg/kg for rape seed.

Sunflower seed

Residue trials on imidazolinone-tolerant sunflower were conducted in France, Germany, UK, Italy, Spain, Argentina, Canada and USA. In Canada, critical GAP for sunflower (imidazolinone-tolerant) is a single early post-emergence application at a rate of 0.015 kg ai/ha with a specified PHI of 60 days and an addition of adjuvant.

A total of six trials conducted in Canada and USA (1×0.015–0.019 kg ai/ha at PHIs of 58–68 days with or without adjuvant) approximated the Canadian GAP. The residues in seeds of imidazolinone-tolerant sunflower were: imazamox < 0.05 (2), 0.05 (2), 0.07, 0.14 mg/kg and metabolite < 0.05, 0.06, 0.10, 0.16, 0.17, 0.19 mg/kg. Total residues were: < 0.1, 0.13, 0.15, 0.22, 0.25, 0.30 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg and an STMR of 0.19 mg/kg for sunflower seed.

Legume animal feeds

Alfalfa

Residue trials on alfalfa were performed in Greece, Spain and USA. The GAP for alfalfa in France is a single post-emergence application at a rate of 0.067 kg ai/ha with a PHI of 30 days.

In a total of seven trials from Greece, Spain and USA (1×0.067–0.075 kg ai/ha at PHIs of 26–30 days) matching the French GAP, residues in alfalfa forage were as received basis: imazamox < 0.1 (7) mg/kg and metabolite < 0.1 (7) mg/kg. Total residues in alfalfa forage were < 0.2 (7) mg/kg. For alfalfa hay, residues were as received basis: imazamox < 0.1 (5) mg/kg and metabolite < 0.1 (3), 0.19, 0.29 mg/kg. Total residues were < 0.2 (3), 0.32, 0.41 mg/kg in hay.

The Meeting estimated a median residue of 0 mg/kg and a highest residue of 0.2 mg/kg for alfalfa forage.

For alfalfa hay, the Meeting estimated a maximum residue level of 0.1* mg/kg, a median residue of 0.20 mg/kg and a highest residue of 0.41 mg/kg.

Pea vines (green) and pea fodder

Five trials approximating the French GAP for pea (single pre-emergence post-sowing per every 2 years at 0.075 kg ai/ha) were conducted in France with PHIs of 88–110 days. Residues in pea vines, (pods + haulm) on an as received basis, were: imazamox < 0.05 (5) mg/kg and metabolite < 0.05 (5) mg/kg. Total residues in pea vines were < 0.1 mg/kg.

Ten trials approximating the French GAP for field pea (single pre- or post-emergence application per every 2 years at a rate of 0.075 kg ai/ha) were conducted in France with PHIs of 106–120 days. Residues in pea fodder (straw or pods + haulm) on an as received basis, were: imazamox < 0.05 (5) mg/kg and metabolite < 0.05 (4), 0.17 mg/kg. Total residues were < 0.05 (5), < 0.1(4) and 0.22 mg/kg.

The Meeting estimated a median residue of 0.1 mg/kg and a highest residue of 0.1 mg/kg for pea vines. For pea fodder, the Meeting estimated a maximum residue level of 0.05* mg/kg, a median residue of 0.075 mg/kg and a highest residue of 0.22 mg/kg.

Soya bean, forage and fodder

Four trials were conducted in France and Germany approximating the Brazil GAP for soya bean (1×0.049 kg ai/ha). Residues in soya bean forage harvested at 27–28 PHIs were as received basis: imazamox < 0.01 (4) mg/kg and metabolite < 0.01 (4) mg/kg. Total residues were < 0.02 (4) mg/kg. For fodder, residues were as received basis: imazamox < 0.01 (4) mg/kg and metabolite < 0.01 (2), 0.01, 0.05 mg/kg. Total residues were < 0.02 (2), 0.02, 0.06 mg/kg in soya bean fodder.

For soya bean forage, the Meeting estimated a median residue of 0.02 mg/kg and a highest residue of 0.02 mg/kg.

For soya bean fodder, the Meeting estimated a maximum residue level of 0.01* mg/kg, a median residue of 0.02 mg/kg and a highest residue of 0.06 mg/kg.

Forage and fodder of cereal grains and grasses

Rice straw and fodder

In six trials conducted in Italy and Spain matching the Spain GAP (post-emergence treatment on imidazolinone-tolerant rice plant, water or dry planted, 2× 0.035 kg ai/ha, 14–21 day interval), residues in imidazolinone-tolerant rice straw (77–90 day PHIs) were as received basis: imazamox < 0.01 (6); metabolite < 0.01 (3), 0.01, 0.02 (2) mg/kg. Total residues were < 0.02 (3), 0.02, 0.03 (2) mg/kg in straw.

The Meeting estimated a maximum residue level of 0.01* mg/kg, a median residue of 0.02 mg/kg and an highest residue of 0.03 mg/kg in rice straw.

Wheat forage and straw

Trials on imidazolinone-tolerant wheat were conducted in Canada approximating the GAP for imidazolinone-tolerant wheat in Canada (single early post-emergence application at 0.020 kg ai/ha). In Canada, grazing and cutting for hay are not permitted within 4 days and 42 days of application, respectively. Five trials for forage (7, 14 day PHIs) and four trials (42, 56 day PHIs) for hay and five trials (72–90 PHIs) for straw matched the Canadian GAP on feedstuffs.

Residues in imidazolinone-tolerant wheat forage were as received basis: imazamox < 0.05 (2), 0.05, 0.13, 0.15 mg/kg; metabolite < 0.05 (5) mg/kg. Total residues were < 0.1 (2), 0.10, 0.20, 0.23 mg/kg.

Residues in imidazolinone-tolerant wheat hay were as received basis: imazamox < 0.05 (4) mg/kg; metabolite < 0.05 (4) mg/kg. Total residues were < 0.1 (4) mg/kg.

Residues in imidazolinone-tolerant wheat straw were as received basis: imazamox < 0.05 (5) mg/kg; metabolite < 0.05 (5) mg/kg. Total residues were < 0.1 (5) mg/kg.

For wheat forage, the Meeting estimated a median residue of 0.1 mg/kg and a highest residue of 0.23 mg/kg.

For wheat hay and straw, the Meeting estimated a maximum residue level of 0.05* mg/kg, a median residue of 0 mg/kg and a highest residue of 0.1 mg/kg.

Miscellaneous Fodder and Forage crops

Rape seed forage

In four residue trials on imidazolinone-tolerant oilseed rape conducted in France and Germany, matching the GAP of Chile for oilseed rape (imidazolinone-tolerant rape, a single early post-emergence application, 0.056 kg ai/ha), residues in whole plants without roots (12–19 day PHIs) on an as received basis were: imazamox, 0.05, 0.12, 0.14 0.19 mg/kg; metabolite 0.52, < 0.05, 0.21, 0.28 mg/kg. Total residues were: 0.10, 0.33, 0.42 and 0.71, mg/kg.

The Meeting estimated a median residue of 0.38 mg/kg and an highest residue of 0.71 mg/kg for rape forage.

Fate of residues during processing

High temperature hydrolysis

The hydrolysis of [pyridine-3-¹⁴C, imidazolinone-3-¹⁵N]-imazamox was investigated in aqueous buffer solutions. After pasteurization (20 minutes at 90 °C, pH 4), baking/brewing/boiling (60 minutes at 100 °C, pH 5) and sterilization (20 minutes at 120 °C, pH 6), 98–104% of the applied radioactivity remained in the test solutions, where the detectable radioactive component was unchanged imazamox only. Imazamox was stable under such simulated processing conditions.

Processing

Information on processing of wheat and sunflower seed were available for an estimation of maximum residue level and STMR-P for the processed product. Estimated processing factors, maximum residue levels and STMR-Ps are summarized below. A maximum residue level and STMR-P value for processed product were calculated with imazamox residue and STMR value (total residue of imazamox and CL 263284), respectively.

RAC and processed product	RAC		Pf, best estimate (individual Pf)		Processed product	
	Estimated maximum residue level (mg imazamox/kg)	STMR (mg total/kg)	Imazamox	Total residue	Estimated maximum residue level (mg imazamox/kg)	STMR-P total residue (mg total/kg)
Wheat	0.05*	0.1				
Wheat germ			2.7	2.2	0.1	0.22
Wheat bran, unprocessed			3.9	3.4	0.2	0.34
Wheat flour			1.2	1.2	0.06	0.12
Wheat asp. grain fraction			1.0	1.0		0.10
Wheat by products (middling, shorts)			2.4 (1.6, 3.2)	2.1 (1.5, 2.6)		0.21
Sunflower seed	0.3	0.19				
Sunflower seed meal			2.3	2.5 (1.9, 3.0)		0.48
Sunflower refined oil				< 0.5 (< 0.2, < 0.5)		0.095

The Meeting estimated maximum residue levels of 0.1 mg/kg for wheat germ and 0.2 mg/kg for wheat bran, unprocessed.

Residues in animal commodities

Farm animal feeding studies

Information on farm animal feeding studies was not submitted.

Estimation of dietary burdens

Dietary burden calculations for beef cattle and dairy cattle and poultry are provided below. The dietary burdens were estimated using the OECD diets listed in Appendix IX of the 2009 edition of the FAO Manual.

Summary of livestock dietary burden (ppm of dry matter diet)

	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.230	0.178	0.821	0.463	2.37 ^a	1.27 ^c	0.217	0.193
Dairy cattle	0.670	0.404	0.0749	0.0433	1.50 ^b	0.765 ^d	0.256	0.197
Poultry broiler	0.278	0.278	0.179	0.179	0.200	0.200	0.052	0.023
Poultry layer	0.278	0.278	0.75 ^e	0.478 ^f	0.188	0.188	0.072	0.072

^a Highest maximum beef cattle dietary burden suitable for MRL estimates for mammalian meat

^b Highest maximum dairy cattle dietary burden suitable for MRL estimates for milk

^c Highest mean beef cattle dietary burden suitable for STMR estimates for mammalian meat

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for milk

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs.

^f Highest mean poultry dietary burden suitable for STMR estimates for poultry meat and eggs

Animal commodity maximum residue levels

Maximum estimated dietary burdens for beef cattle and dairy cattle were 1.4 and 1.1 ppm, respectively. These dietary burdens were similar to the dose rates in the metabolism studies in lactating goats (< 0.01 mg eq./kg at 2.1 ppm for imazamox; < 0.01 mg eq./kg at 2.3 ppm for CL 263284). As no residues in cattle meat and milk are expected, the Meeting estimated a maximum residue level of 0.01* mg/kg and HR and STMR of 0 in each animal commodity: milk, meat (mammalian except marine mammals) and edible offal and fat.

In poultry, the maximum dietary burden, 0.75 ppm was 3 times lower than dose rates in metabolism studies in laying hens (< 0.01 mg eq./kg at 2.1 ppm for imazamox and CL 263284 each). The Meeting estimated a maximum residue level of 0.01* mg/kg and HR and STMR of 0 for poultry meat, poultry edible offal, poultry fat and eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant and animal commodities for compliance with the MRL: *imazamox*

Definition of the residue for plant and animal commodities for estimation of dietary intake: *sum of imazamox and 5-(hydroxymethyl)-2-(4-isopropyl-4-methyl-5-oxo-2-imazazolin-2-yl) nicotinic acid (CL 263284), expressed as imazamox*

Residue is not fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The ADI for imazamox is 0–3 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for imazamox were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the present JMPR. The results are shown in Annex 3 of the 2014 JMPR Report. The IEDIs were 0% of the maximum ADI. The Meeting concluded that the long-term intake

of residues of imazamox from uses considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The ARfD for imazamox is 3 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for imazamox were calculated for the food commodities for which STMRs or HRs were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4. The IESTIs were 0% of the ARfD for children and the general population.

The Meeting concluded that the short-term intake of residues of imazamox from uses considered by the present Meeting are unlikely to present a public health concern.

MESOTRIONE (277)

The first draft was prepared by Professor Eloisa Dutra Caldas

University of Brasilia, Brasília/DF, Brazil

EXPLANATION

Mesotrione is a systemic pre-emergence and post-emergence herbicide for the selective contact and residual control of broadleaf weeds. It is rapidly absorbed by green plant tissue or taken up through the soil during emergence. It acts by inhibiting the enzyme 4-hydroxyphenolpyruvate dioxygenase (HPPD), leading to a reduction of carotenoids causing bleaching symptoms in the plant. Mesotrione was scheduled for the evaluation as a new compound by the 2014 JMPR at the 45th Session of the CCPR (2013). Metabolism studies on animal and plants, environmental fate studies, analytical methods and residue trials on berries, okra, sweet corn, soya bean and tolerant soya bean, asparagus, rhubarb maize, millet, oat, rice, sorghum, sugarcane and linseed were submitted for evaluation.

IDENTITY

ISO Common Name Mesotrione
 Chemical name IUPAC: 2-(4-mesyl-2-nitrobenzoyl)cyclohexane-1,3-dione
 CAS (104206-8): 2-[4-(methylsulfonyl)-2-nitrobenzoyl]-1,3-cyclohexanedione

Structural formula

Molecular formula: C₁₄H₁₃NO₇S
 Molecular mass: 339.3

PHYSICAL AND CHEMICAL PROPERTIES

Mesotrione pure material (> 99%) was used for colour, physical state, odour, melting point, pH and spectroscopic characterisation, and also for density, aqueous solubility, dissociation constant, octanol/water partition coefficient and vapour pressure determinations. Colour, odour, solubility in organic solvents, density, pH and surface tension determinations for mesotrione technical material were conducted with material containing 96.7% mesotrione.

Properties of pure mesotrione

Property	Results	Reference; Report
Melting point	165.3 °C with decomposition	Goodman, 1996; RR95-077B
Density at 20 °C	1.49 g/cm ³	
Vapour pressure at 20 °C	< 5.7 × 10 ⁻⁶ Pa	
Volatility at 20 °C	Henry's law constant: < 5.1 × 10 ⁻⁷ Pa/m ³ /mol.	
Physical state, colour, odour	Odourless pale yellow solid (room temperature)	
Solubility in water at 20 °C	0.16 g/L (unbuffered water) 2.2 g/L at pH 4.8 (buffered water) 15 g/L at pH 6.9 (buffered water) 22 g/L at pH 9 (buffered water)	
Partition coefficient n-octanol/ water at 20 °C	log P _{OW} : 0.11 in unbuffered water 0.90 at pH 5 < -1.0 at pH 7 and 9	
pH at 20 °C	3.38 at 25.4 °C in 1% aqueous solution	

Property	Results	Reference; Report
Hydrolysis in water at 25 °C	Less than 10% degradation of mesotrione (1 µg/ml) occurred during the test period of 30 days in the pH of 4–9 at both 25 and 50 °C.	Miles & Powell, 1995; RJ1776B
Photochemical stability in water	The photolysis half-life and rate constant in sterile aqueous buffer solutions at pH 7 at 25 °C were 83.7 days and 8.40×10^{-3} /day, respectively at 37°56' latitude local sunlight, or 92 days at 50°N. No degradates exceeding 10% of the applied radioactivity were observed during the photolysis of [^{14} C-phenyl] mesotrione. The major degradation product was carbon dioxide (^{14} CO ₂), the others were present at levels < 5% of the applied radioactivity. Recovery ranged from 92.2 to 101.8%. Recovery of 92.2% was only observed prior to trapping volatiles formed during photolysis of [^{14} C-cyclohexane] mesotrione. The average recovery of applied radioactivity after trapping volatiles was 95.4%.	Eya, 1995; RR94-071B
Dissociation constant at 20 °C	pK _a =3.12	Goodman, 1996; RR95-077B

Technical grade material (Goodman, 1996; RR96-004B)

Property	Results
Physical state, colour, odour	Light tan or sand coloured opaque solid with slight odour. sweet (not pungent)
Solubility in organic solvents at 20 °C	Acetone 76.4 g/L Acetonitrile 96.1 g/L 1,2-Dichloroethane 82.7 g/L Ethyl acetate 16.6 g/L Heptane < 0.3 g/L Methanol 3.6 g/L Toluene 2.7 g/L Xylenes 1.4 g/L
Density	The density at 20 °C: 1.46 g/ml; bulk density at 23.3 °C: 0.56 g/mL
pH	The pH of a 1% solution: 3.42 at 24.8 °C
Surface tension at 20 °C	Aqueous solution, 90% saturated: 72.5 mN/m (without indication of surface activity)

METABOLISM AND ENVIRONMENTAL FATE

The fate and behaviour of mesotrione in animals, plants, and soils were investigated using the following [^{14} C] labelled test materials:

Concentrations of radioactivity are expressed as mg mesotrione equivalents/kg throughout. The chemical structures of the major degradation compounds arising from the metabolism of mesotrione are presented in the following table.

Degradation compounds from metabolism of mesotrione in plants and animals

Compound Name	Structure	Found in:
4-Hydroxy-mesotrione 4-hydroxy-2-[4-(methylsulphonyl)-2-nitrobenzoyl]-1,3-cyclohexanedione		Livestock, plant
5-Hydroxy-mesotrione 5-hydroxy-2-[4-(methylsulphonyl)-2-nitrobenzoyl]-1,3-cyclohexanedione		Livestock, plant
MNBA 4-(methylsulphonyl)-2-nitrobenzoic acid		Livestock, plant
AMBA (2-amino-4-(methylsulphonyl)-benzoic acid)		Livestock, plant
MBA 4-(methylsulphonyl) benzoic acid		Livestock, plant

Animal metabolism

Cow

Two metabolism studies were conducted in lactating cows, one with [phenyl-U-¹⁴C]-mesotrione (Powell & Marples, 1996; RJ 1890B) and one with [cyclohexane-2-¹⁴C]-mesotrione (Hand, 1995; RJ 1830B). The studies used similar dosing regimens, sampling protocol and analysis. In each study, one lactating cow was dosed orally with [¹⁴C]mesotrione for 7 consecutive days at a nominal rate of 10 ppm in the diet (450–650 kg cow, 20 kg feed intake per day). Milk and excreta were collected daily; the cows sacrificed 16 hours after the final dose and tissues taken for analysis. Milk production was around 20 L per day.

Tissue samples were homogenised in sequence in the presence of solvents such as hexane, acetonitrile/hexane, dichloromethane, acetonitrile, acetonitrile/water (1:9) and 2% sodium dodecyl sulphate (SDS). Each of the extracts was radioassayed. Extracts were partitioned in diethyl ether and water, ethyl acetate and water, hexane and water or hexane and acetonitrile. Solubilised protein was denatured with acetone. Hydrolyses of proteins and extracts were conducted to characterise the bound and/or conjugated residues, using a variety of enzymes, including papain (to hydrolyse ester and peptide bonds) and β-glucuronidase (to hydrolyse glucuronides). Subsamples of the milk extract were submitted to chemical hydrolysis using either 1 M HCl or 1 M NaOH. Protein hydrolysate samples

were derivatized with isobutyl chloroformate to facilitate the chromatography. Residues in tissues were determined by combustion analysis. Normal or reserve phase TLC and HPLC radiochromatograms were used to characterise the components.

Table 1 shows the total radioactive residues found in tissues, milk and excreta (Hand, 1995, Powell & Marples, 1996). Over 90% of the administered dose was found in excreta, mostly in faeces. Liver and kidney contained the highest residues (about 0.1 mg/kg eq.). Residues in muscle were below 0.01 mg/kg eq and reached 0.08 mg/kg eq in milk, with a plateau at day 5 in the cyclohexane experiment (Table 2).

Table 1 Radioactive residues in lactating cow tissues, milk and excreta after oral administration of [¹⁴C]mesotrione

^a TRRs was calculated from the summation of fractions obtained from various complex extraction schemes required to determine the nature of this type of residue

^b Consists of three components, the largest represents 2% (0.002 mg/kg) liver and 2.6% (0.003 mg/kg) kidney

^c Consists of two components, largest represents 0.9% (< 0.001 mg/kg)

^d Consists of two components, largest represents 1.4% (0.001 mg/kg)

^e Consists of five components resulting from 6 N HCl and subsequent derivatization (largest 0.2%, < 0.001 mg/kg)

^f Derives from chromatography of multiple extracts. Includes baseline material and non-discrete areas of ¹⁴C

^g Acetonitrile wash of debris (liver), SDS extraction of debris (kidney), which consists of two extracts (max 6.2% TRR, 0.007 mg/kg)

^h Consists of two extracts, largest represents 7.4% (0.007 mg/kg) in liver and 7.1% (0.008 mg/kg) in kidney

ⁱ Consists of three extracts, largest representing 11.0% TRR (0.012 mg/kg) of the which could not be chromatographed due to the high concentration of acid present. These extracts were considered to chemical distinct in terms of their ionic nature

^j Consists of two extracts, largest represents 6.3% TRR (0.006 mg/kg) liver

^k Consists of two precipitates, largest represents 22.7% (0.023 mg/kg) liver |TRR. This was hydrolysed with 6 N HCl and derivatized with isobutyl chloroformate. The resulting acidic organosoluble fraction consisted of five components, the largest representing 4.0% (0.004 mg/kg)

^l The slight discrepancy is due to rounding of the calculated values.

Tables 5 shows the results of the characterization study of residues in milk collected from the phenyl labelled experiment (Powell & Marples, 1996). Most of the radioactivity was found in the skimmed milk (97.3% TRR), which was deproteinated using acetone. The resultant aqueous acetone fraction (78.2% TRR) showed to contain at least three polar components, not hydrolysed with enzymes but degraded to up to seven components under harsh acid and basic conditions.

Table 5 Summary of the identification and characterisation of radioactive residues of mesotrione in milk [phenyl-U-¹⁴C]-mesotrione

Based on the extraction of the Day 6 (initial) milk sample. Further characterisation of additional samples was carried out following derivatization or acid/base hydrolysis but as this did not lead to the identification of discrete components the data is not reported in the table above

^a Total concentration taken from sum of extractions and combustion analyses

^b Consists of one sample, skim milk removed from the butterfat samples

^c Consists of one sample from the partition of skimmed milk with dichloromethane

^d Consists of two samples obtained from the aqueous wash of the protein fraction

^e Area corresponding to quantifiable radioactivity containing no discrete bands

TRR in milk from the cyclohexanedione experiment (Hand, 1995) was 0.07 mg/kg eq., 90% of which was associated with the skimmed milk fraction. Lactose accounted for 35.1% TRR in whole milk (Table 6), with the remainder of the extracted radioactivity comprised several unknown components, the largest of which was aqueous soluble and represented 14.7% TRR (0.010 mg/kg). Low levels of radioactivity were found to be associated with the proteinaceous solids and the butterfat.

The radioactive residues in subcutaneous fat were 0.012 mg/kg, with 37% extracted with acetonitrile, leaving 63.3% associated with the debris, from which 46.7% was not extracted (Hand, 1995).

Table 6 Summary of the identification and characterisation of radioactive residues of mesotrione in milk [cyclohexane-2-¹⁴C]-mesotrione

Total ^a	0.070 mg/kg

Total	100.0	0.069 ^e

^a Total concentration taken from sum of skimmed milk and butterfat

^b Consists of five unknowns, largest of which represents 14.7% TRR (0.01 mg/kg)

^c Consists of nine unknowns, largest of which represents 5.3% TRR (0.004 mg/kg)

^d Remainder derives from the chromatography of four extracts. No discrete peaks

^e Slight difference due to rounding.

Swine

One female Hampshire swine (30 kg) was dosed orally with [phenyl-U-¹⁴C]-mesotrione for 5 consecutive days at 6 ppm (Brown, 2006; T020371-04). Excreta were collected daily, the animal sacrificed 23 hours after the final dose, and tissues taken for analysis. Tissue samples were extracted twice with acetonitrile/water (80:20), and further extraction with water was performed on the solids

obtained from the kidney and liver sub-samples. Liquid-liquid partitions were carried out with ethyl acetate after adjustment to pH 2 with acetic acid. C₁₈ SPE columns were used to purify the isolated metabolites. Protein was precipitated with either ammonium sulphate or acetone. To extract ionic material and membrane-bound proteins from cell walls, liver PES was extracted with 2% SDS solution, and the solids obtained were submitted to enzymatic hydrolysis. Analytes were separated using 1 and 2-D TLC on silica gel plates. The metabolites were characterised and isolated using HPLC coupled to a UV detector, radioisotope flow monitor and a fraction collector. Additional confirmation and identification was undertaken using tandem mass spectrometry and ¹H-NMR.

The radioactivity detected in the excreta accounted for 89.4% of the administered dose. In tissues, highest residues were found in liver (1.75 mg/kg eq) and kidney (0.12 mg/kg eq); residues in muscle reached 0.01 mg/kg eq. (Table 7). Residues in the tissues were readily extracted with solvents, and showed to be mainly mesotrione (up to 90% TRR in liver; Table 8). Residues AMBA accounted for up to 2% TRR in kidney. MNBA was only found in liver (0.3% TRR). The major identified residue in urine collected on day 5 was AMBA which accounted for approximately 36.5% TRR.

Table 7 Radioactive residues in swine tissues and excreta after oral administration of [phenyl-U-¹⁴C]-mesotrione

^a These calculations include values obtained from HPLC fraction collecting. Components in the HPLC fractograms, as % of the chromatogram, were calculated from the total radioactivity in specific fractions divided by the total radioactivity injected. The total radioactivity recovered from the HPLC fractions ranged from 97–112%, compared to the amount injected. These recoveries were not taken into account in the calculation and thus contributed to the slight losses or gains in the total accountability compared to the initial residues. Small discrepancies between the % and mg/kg values are due to rounding

^b Includes 2% SDS and protease extraction values

^c < Value not included in summation

^d Portions not identified (0.2% TRR AMBA)

^e Solids remaining after protease and 2% SDS extractions of original PES (16.5% TRR. 0.269 mg/kg)

^f Calculated by % TRR total × total residue mg/kg

Poultry

Two metabolism studies were conducted in poultry, one with [phenyl-U-¹⁴C]-mesotrione (Young & Skidmore, 1995; RJ 177778B) and one with [cyclohexane-2-¹⁴C]-mesotrione (Grout, 1996; RJ 12071B). The studies used the same dosing regimen, sampling protocol and analysis. In each study, hens were dosed by gelatine capsule with [¹⁴C]- mesotrione for 10 consecutive days at 11 ppm, assuming a daily dietary intake of 150 g and average body weight of 2 kg. Each experiment used 10 hens (*Gallus gallus domesticus*). Excreta and eggs were collected daily.

Eggs were separated into yolks and whites and stored frozen for analysis. The hens were sacrificed approximately 16 hours after the final dose, and tissues stored frozen until analysis. Once thawed, liver, kidney and peritoneal fat samples were chopped, muscle samples were minced whilst partly frozen using a food processor. The skin and subcutaneous fat samples were ground with solid CO₂.

The amount of radioactivity in excreta, edible tissues and eggs was determined in 2–3 hens and samples from the remaining hens were retained for analysis if required. TRR were determined using LSC/combustion or tissue solubilisation/LSC. Tissue samples and egg yolk were homogenised and sequentially extracted with methylene chloride, acetonitrile and acetonitrile/water. Fat samples from the cyclohexane experiment were first extracted with hexane. Between each extraction, the organic phase was separated from the solids (post extraction solids, PES) by centrifugation and analysed for radioactivity. Liquid phases were concentrated and extracted with either ethyl acetate and water or hexane and acetonitrile. SDS was used to extract ionic material and membrane-bound proteins from cell walls; proteins were precipitated out with acetone. Samples of edible tissues and eggs that contained a radioactive residue greater than 0.01 mg/kg were analysed further for residue characterisation. Components were separated using 2-D normal and reverse phase TLC, HPLC-UV or a radioisotope flow monitor and a fraction collector.

The radioactivity in excreta accounted for 90 to 98.7% of the administered dose in both experiments. TRR in edible tissues and egg samples are summarised in Table 9. Highest residues were found in liver and kidney (0.06–1.2 mg/kg eq.) Residues in muscle were below 0.02 mg/kg eq in eggs, residues were higher in the yolk compared to whites, reaching 0.094 mg/kg eq. in yolk in the cyclohexanedione label experiment.

Table 9 Radioactive residues (mg/kg eq.) in eggs and tissues following oral administration of [¹⁴C]mesotrione to hens for 10 consecutive days at 11 ppm

	[Phenyl-U- ¹⁴ C]-mesotrione	[¹⁴ C-cyclohexanedione]-mesotrione
Matrix	Mean TRR (n=3)	Mean TRR (n=2)
Liver	1.121	1.245
Kidney	0.063	0.068
Thigh muscle	< 0.004	0.011
Breast muscle	0.004	0.012
Skin/subcutaneous fat	0.042	0.048
Peritoneal fat	< 0.003	0.010
Egg white	< 0.004 at all days	0.012 (day 1) to 0.025 (day 4); mean=0.019
Egg yolk	< 0.003 (day 1) to 0.024 (day 10); mean=0.015	0.002 (day 1) to 0.094 (day 9/10), mean=0.056

Summaries of the radioactivity extracted sequentially using a range of solvents in each study are present in Tables 10 and 11. In the phenyl label experiment (Table 10), most of radioactivity was extracted from liver and egg yolk with ACN/water, and about 70% TRR extracted from fat with methylene chloride (Young & Skidmore, 1995). Radioactivity in PES ranged from 0.6 to 4.5% TRR in egg yolk.

Table 10 Radioactivity levels extracted from hen tissues and egg samples after oral administration of [phenyl- ^{14}C]-mesotrione using a range of different solvents

Matrix (TRR, mg/kg eq.)	Extraction solvent (% TRR)					PES (%)
	Methylene chloride	ACN:water (9:1)	ACN:water (1:1)	Water	SDS solution	
Liver (1.234)	–	52.8	22.0	10.3	14.3	0.6
Skin/subc. fat (0.037)	69.2	23.1	1.4	2.7	–	3.6
Egg yolk (0.021)	37.2	53.1	5.3	0	–	4.5

PES Post extraction solids

– Not applicable

In the ^{14}C -cyclohexanedione experiment (Table 11), the majority of the radioactive residue in skin and subcutaneous fat and egg white was extracted with acetonitrile and acetonitrile/water, while peritoneal fat residues were mostly extracted with hexane (Grout, 1996). Half of residues present in muscle were extracted with acetonitrile, with the remaining staying in PES. Residues from egg yolk were mostly extracted with methylene chloride.

Table 11 Radioactivity levels extracted from hen tissues and egg samples after oral administration of [^{14}C -cyclohexanedione]-mesotrione using a range of different solvents

Matrix	Extract (% TRR)						PES (%)

Mesotrione was detected in both experiments, accounting for over 85% TRR (1.1 mg/kg) in liver (Table 12). Mesotrione was not detected in muscle. The lipid fraction present in the combined yolk sample from the [^{14}C -cyclohexanedione] experiment was extracted with acetone which released 51.7% TRR (0.041 mg/kg), and found to contain mesotrione (0.019 mg/kg). The second acetone fraction was saponified, fractionated and showed to contain palmitic/oleic acid (Table 12). Excreta were shown to contain mesotrione (19.7–55%TRR) and AMBA (18% TRR).

Metabolism of AMBA in cow

AMBA is a metabolite found in maize forage and fodder when the plant is treated with mesotrione. A lactating cow was orally administered [phenyl- ^{14}C]-AMBA using gelatine capsule for 7 consecutive days at a rate of 12.2 ppm in the diet, equivalent to 200 mg ai/day (Hand, 1997; RJ

2309B). Milk and excreta were collected daily. The cow was sacrificed approximately 23 hours after the final dose and tissues were taken for analysis.

Samples were sequentially homogenised in the presence of a variety of solvents including hexane, ethyl acetate, acetonitrile/water (1:1) and water. Liquid-liquid partitions were carried out between ethyl acetate and water. Metabolites were separated using normal or reserve phase TLC with visualisation of the radiochromatograms undertaken by phosphor image analysis.

The total recovery was found to be 88.7% of the administered dose, with the majority of the radioactivity recovered in the excreta (Table 13). Highest residues were found in kidney (0.053 mg/kg eq.) and fat (0.018 mg/kg eq.), with no detected residues in muscle or in omental fat. Residues in milk reached a maximum of 0.009 mg/kg eq. (Day 6), decreasing to 0.003 mg/kg eq. on Day 8 after the initial dose.

Table 13 Radioactive residues in lactating cow after oral administration of [^{14}C]AMBA

Matrix	Radioactive residue	
	[^{14}C]AMBA equivalents (mg/kg)	% Total administered
Liver	0.005	
Kidney	0.053	
Fat (perirenal)	0.018

Fat (subcutaneous)	0.003	
Milk (peak daily concentration)	0.009 (day 6)	0.06
Urine		32.0
Faeces		56.7
Total in excreta		88.7

Residues in the kidney and perirenal fat were readily extracted with solvents. AMBA represented 79.0 and 61.6% TRR, equivalent to 0.038 and 0.013 mg/kg in the kidney and perirenal fat respectively. Unknown components did not account for more than 0.001 mg/kg (Table 14).

Based on the metabolism studies conducted with [cyclohexane-2- ^{14}C]-mesotrione, [phenyl- ^{14}C]-mesotrione and [^{14}C]AMBA with poultry, cow and swine, the proposed biotransformation of mesotrione in livestock involves the oxidative cleavage of the parent molecule to yield MNBA and the reduction of the nitro group in MNBA giving AMBA (Figure 1).

Figure 1 Proposed metabolism of mesotrione in livestock

Plant metabolism

Cranberries

[Phenyl- U - ^{14}C]-mesotrione was applied (diluted with aqueous formulation) twice to pollinated cranberry plants (*Vaccinium spp.* var. Howe), 4 to 5 years in age, in the greenhouse, under two dose regimes (Ray 2005). The first application at 0.331 or 0.919 kg ai/ha, and the second application, 14 days later, at 0.242 or 0.642 kg ai/ha. Total application at 1 $\times$ rate was 0.573 kg ai/ha and at 3 $\times$ rate 1.561 kg ai/ha. The radioactive residues in samples of mature cranberry foliage and fruit, harvested 46 days after the second foliar application, were quantified and characterized. A subsample of each commodity type was homogenised in dry ice and the radioactive residue determined by combustion/LSC. Mature fruit samples that were found to have a radioactive residue greater than 0.01 mg/kg were subject to additional analysis. Samples were extracted with acetonitrile/water and fractionated. Further treatment comprised of hydrolysis with dilute acid under reflux conditions. Extracted radioactivity was analysed by 2D TLC and reverse-phase HPLC. Additional confirmation and identification was undertaken using tandem mass spectrometry and ^1H -NMR.

About 100% of the total residues were extracted from cranberry fruits from both treatments, with about 2.2 to 2.5% corresponding to PES. TRR in the mature foliage were 16.8 mg/kg and 31.8 mg/kg, for the 1 $\times$ and 3 $\times$ treatments, respectively. The extracted TRRs in the mature cranberry fruit were 2.64 mg/kg eq. and 4.94 mg/kg eq., respectively. Only the fruits samples were used for the characterisation and identification of metabolites (Table 15). The extracted residues identified in cranberry fruits were mostly mesotrione and AMBA, accounting for 60.2% TRR and 34.8% at the 1 $\times$ rate, respectively, with MBNA accounting for 3.0% TRR.

Table 15 Summary of radioactive residues in mature cranberry fruit samples following treatment with [phenyl-U-¹⁴C]-mesotrione

Mesotrione tolerant (HT) soya beans

HT soya bean seeds (*Glycine max* var. Jack) were grown under greenhouse conditions in containers filled with a sandy loam soil (Dohn & Chu, 2012). [Phenyl-U-¹⁴C]- and [cyclohexane-2-¹⁴C]-mesotrione were applied separately using three separate treatment regimes. The first application was a single pre-emergence treatment at a nominal rate of 0.225 kg ai/ha, the second was a combined pre-emergence treatment at 0.225 kg ai/ha followed by a post-emergence treatment at 0.125 kg ai/ha and the third was a single post-emergence treatment at a nominal 0.225 kg ai/ha. [¹⁴C]Mesotrione was applied to the plots as a suspension concentrate using a plastic hand held sprayer.

The radioactive residues in the soya bean foliage and hay samples were extracted twice with a mixture of acetonitrile and water (1:1). Soya bean seed samples were sequentially extracted with acetone/hexane (1:4), acetonitrile/water (1:1) and acetonitrile. Characterisation of the PES samples with residues $\geq 10\%$ TRR or ≥ 0.05 mg/kg was attempted using with hydrolytic enzymes, 1 N hydrochloric acid at room temperature and/or 60 °C. One and 2D normal phase TLC, reverse-phase HPLC-UV, radioisotope flow monitor and a fraction collector was used for sample analyses. Additional identification was undertaken using LS-MS.

The TRR (extracted plus PES) for soy commodities from each application regime and labels are summarised in the Table 16. In the phenyl label experiment, PES accounted for 41%TRR in pre-emergence forage to 57.7%TRR in post-emergence seed. In the cyclohexane label experiment, the values ranged from 21.9%TRR in pre-/post-emergence hay to 53.3%TRR in post-emergence seed.

^a [Phenyl-U-¹⁴C]-mesotrione: 110 days. [Cyclohexane-2-¹⁴C]-mesotrione: 118 days. DAA=days after application

A summary of radioactive residues from [phenyl-U-¹⁴C]-mesotrione treated soya bean forage extract is detailed in Table 17. MNBA was the most abundant residue present in the single pre-emergence and combined pre- and post-emergence forage samples and 4 or 5-hydroxy-mesotrione the most abundant residues in the post-emergence sample (0.073 mg/kg). Mesotrione residues were in the range of 0.021–0.03 mg/kg eq.). Extraction and acid hydrolysis released about 30% TRR found in pre-emergence forage PES, and lignin extraction released about 50% TRR in post-emergence forage

PES. Results from the [cyclohexane-2-¹⁴C]-mesotrione experiment showed mesotrione and 4 or 5-hydroxy-mesotrione as the major residues in forage (8.5 to 19.2% TRR), while MNBA and AMBA were not detected. Most of the radioactivity found in PES was released by enzyme, acid extraction and lignin extraction.

The metabolites MNBA and 4/5 hydroxy-mesotrione were the major residues found in hay of soya-treated with [phenyl-U-¹⁴C]-mesotrione in the three application regimes ranging from 9 to 20%TRR (Table 18). Mesotrione accounted for 6.2 to 8.8%TRR (up to 0.178 mg/kg eq.). Treatment of PES with enzymes, 1 N HCl and lignin digestion released 15.5%TRR in plants from the pre-emergence trial and 13.2% TRR in post-emergence. 4/5-hydroxyl-mesotrione was the major identified residue in hay of soya treated with [cyclohexane-2-¹⁴C] mesotrione, accounting for 15 to 25% TRR (0.409 mg/kg eq). Mesotrione accounted for 6.6 to 7.3%TRR, and the metabolites AMBA and MNBA were not detected. PES treatment released a total of 16.8% TRR in the pre-and post-emergence plants.

None of the identified residues in soya bean seeds from the experiment with [phenyl-U-¹⁴C]-mesotrione accounted for more than 10% TRR in any treatment or at levels higher than 0.007 mg/kg eq. (Table 19). Mesotrione accounted for up to 9.5% TRR%, or 0.006 mg/kg eq. AMBA was detected only in the pre-and post-emergence regime (1.9%TRR). Enzyme extracts of PES contained multiple components up to ≤ 0.007 mg/kg. Only mesotrione and 4/5-hydroxy-mesotrione were detected in soya bean seeds from the [cyclohexane-2-¹⁴C] mesotrione experiment. The PES Viscozyme extracts from the combined pre- and post-emergence sample mainly contained unknown polar peak components (0.011 mg/kg, 11.8% TRR).

Maize

[Phenyl-U-¹⁴C]-mesotrione was applied to the soil surface after planting the seeds of maize (*Zea mays*) (pre-emergence) at a rate of 0.28 kg ai/ha and post-emergence by application to surfaces of plants and soil 28 days after planting at a rate of 0.164 kg ai/ha (Tarr & van Neste, 1997; RR 96-007B). The radioactive residues in plant samples of forage (55 days after planting) and of grain and straw from mature crops (125 days after post-emergence treatment) were characterised.

Samples were extracted with water and acetonitrile (1:1) and fractionated by partition with ethyl acetate and/or with Amberlite XAD7 resin. Acid hydrolysis (micro-wave or reflux) followed by base hydrolysis or treatment with enzymes (porcine carboxylic acid esterase, papain, pancreatin, pectolyase and driselase) of the extracted residues and PES was attempted for characterisation and further solubilisation of residues. The PES from post-emergence fodder was also treated with a solution of potassium permanganate to solubilise bound residues by oxidation. Residue characterization was performed using normal and reversed-phase TLC and/or reversed-phase HPLC with radio-detector or fraction collecting, and LSC.

Table 20 summarises the TRRs found in maize matrices after pre- or post-emergence application. Total residues were higher in fodder and forage, and similar in both treatments in seed (0.013–0.014 mg/kg eq.). Using acetonitrile/water (1:1 v/v), most of the residues were extracted from forage and seed, but unextracted residues accounted for over 60% TRR in fodder. No additional analysis was conducted in seed due to the low radioactivity found.

DAT: Days after treatment

^a Based on residue values derived from initial combustion

Table 21 shows the characterization of the residues found in forage and fodder from both treatments. Mesotrione was a minor component of the residue, present at a higher level in pre-emergence forage samples (2.2% TRR, 0.008 mg/kg eq.). MNBA was the major identified compound in forage from the pre-emergence treatment (19.7%TRR) and a minor component in post-emergence and in fodder. AMBA was a major compound mostly presented in conjugated form accounting for 12–28%TRR in forage and fodder. The predominant AMBA conjugates isolated were α - and β -anomers of the 2-acylglucosides. Acid or base hydrolysis and enzyme treatment did not release additional AMBA from fodder extracts.

Table 21 Summary of radioactive residues in maize forage and fodder samples following pre- and post-emergence application of ¹⁴C-phenyl labelled mesotrione

In another study conducted in maize, [phenyl-U-¹⁴C]-mesotrione was applied to the bare sandy loam soil surface one day after planting the seeds (pre-emergence) at a rate of 0.302 kg ai/ha and post-emergence (31 days after planting) by application to surfaces of plants at the true eight leaf stage at a rate of 0.179 kg ai/ha (Vispetto & Smith, 1999; RR 99-006B). Samples of forage (78 days after first pre-emergence treatment) and of stover and grain from mature crops, 121 days after pre-emergence treatment were taken for analysis.

Samples were extracted with a mixture of water and acetonitrile (1:1), extracts fractionated by hydrolysis with HCl or partitioned with ethyl acetate. PES which exceeded 10% TRR or 0.05 mg/kg were hydrolysed by microwave extraction with HCl, and the hydrolysates cleaned up by C₁₈ SPE. HPLC radiochromatograms were obtained by fraction collecting and LSC. TLC was conducted using silica plates.

Highest residues were detected in the stover (0.57 mg/kg), with lower residues in the forage (0.27 mg/kg) and grain (0.03 mg/kg) (Table 22). Over 60% of the radioactivity was extracted and contained a large number of components, all at ≤ 0.01 mg/kg and predominantly water soluble. Mesotrione was not detected in any sample. AMBA, MNBA and their conjugates, and 4-hydroxy-mesotrione were the major compounds identified in forage. 4-hydroxy mesotrione was not detected in grain and stover.

Table 22 Total radioactive residues (TRRs) in maize after pre- and post-emergence application of [phenyl- ^{14}C]-mesotrione

In the third study conducted in maize, [cyclohexane-2- ^{14}C]-mesotrione was applied to the soil surface after planting the seeds (pre-emergence) at a rate of 0.307 kg ai/ha and post-emergence 28 days after planting at a rate of 0.161 kg ai/ha (Wei & Dohn, 1997; RR 96-026B). Samples of forage (27 or 28 days after planting) and of grain and straw from mature crops (125 days after post-emergence treatment) were extracted three times with either a mixture of water and acetonitrile (1:1). Acid hydrolysis of the extracted residues and PES from post-emergence fodder samples was attempted for characterization of residues and enzyme digestion was used in pre- and post-emergence forage samples. HPLC radiochromatograms were obtained using a flow through radio-detector or by fraction collecting and LSC. All critical analyses were confirmed by use of at least two TLC and or HPLC methods.

Total radioactive residues in maize were 0.067, 0.001 and 0.015 mg/kg in pre-emergence forage, grain and fodder respectively. Corresponding values for post-emergence treatments were 0.098, 0.011 and 0.330 mg/kg (Table 23). Much of the radioactivity in forage was readily extracted (78–84% TRR). Remaining solids after extraction were not analysed further. About 60% TRR in pre-emergence fodder and post-emergence grain were not extracted with solvents.

Table 23 Total radioactive residues (TRRs) in maize after pre- and post-emergence application of [cyclohexane-2- ^{14}C]-mesotrione

Sample	TRR by initial combustion	Extracted residues		Unextracted residues

Grain	0.011	35.1	0.004	60.7	0.007

^a % TRR's are based on residue values derived from initial combustion

^b The extractions were performed on the leaf sample, but the mg/kg values are corrected for the total (leaves + stalks) sample mass

^c Includes material released by acid hydrolysis and lignin and cellulose fractions

The major identified residue in forage was 4-dihydroxy-mesotrione, accounting for up to 10.4%TRR in pre-emergence samples (0.007 mg/kg) (Table 24). Mesotrione was found at low levels (up to 0.002 mg/kg). In fodder, mesotrione was detected only in trace amounts (< 0.0005 mg/kg) and no other compound was identified (Table 24). The solubilised material from PES accounted for 13.6% TRR (0.045 mg/kg) and showed to contain glucose. Treatment of remaining solids gave evidence for the incorporation of ¹⁴C into lignin and cellulose.

Table 24 Summary of radioactive residues in maize forage and fodder following pre- and post-emergence application of [cyclohexane-2-¹⁴C]-mesotrione

Component	Forage		Fodder (leaves and stalks)
	Pre-emergence mg/kg (% TRR)	Post-emergence ^a % of TRR ^b	post-emergence mg/kg eq.

Rice

Rice plants (*Oryza sativa* spp. *japonica* cv Kirana 397) at the 2–3 leaf stage in a flooded paddy greenhouse system were treated with [phenyl-U-¹⁴C]-mesotrione added directly to the paddy water at either 0.090 kg ai/ha or 0.225 kg ai/ha (Humphries & Evans. 2005; RJ 3738B). The day 14 and 27 days after treatment (DAT) samples were whole tops, the 40 DAT samples were separated into ears and stalks, the 109 DAT samples were separated into grain, husk and straw. The paddy was maintained flooded to a depth of 3–5 cm until 7 days before final harvest, when irrigation was stopped allowing the paddy system to dry. Natural daytime sunlight was supplemented with artificial light with a fixed 13 hour day period. Samples were extracted with acetonitrile/water mixture and water and PES were further extracted with microwave assisted extractions and acid hydrolysis. Liquid partitions were carried out between ethyl acetate/water (1:1). Extracted radioactivity was analysed by normal and reversed-phase TLC and reverse-phase HPLC.

Extracted radioactivity in the whole tops up to 27 DAT accounted for at least 60%TRR (Table 25). Total residues in grain were 0.01 and 0.02 mg/kg eq. at 0.09 and 0.225 kg ai/ha, respectively, with extracted residues accounting for up to 0.003 mg/kg eq., which were not further characterized. Residues in straw were higher (0.032 and 0.066 mg/kg eq.), from which 43–45%TRR was extracted.

Table 25 Total radioactive residues (TRRs) in rice after treatment of paddy water with [phenyl-U-¹⁴C]-mesotrione

^a %TRR's are based on residue values derived initial combustion^b Immature plants harvested by cutting the plant 2 cm above the paddy rice water

Tables 26 shows the residues identified in immature whole tops (14 and 27 DAT) and stalks (40 DAT). All commodities analysed contained parent mesotrione, 5-hydroxy-mesotrione, AMBA and MNBA. At early stage, mesotrione comprised the majority of the residues, accounting for 28% TRR for the 0.225 g ai/ha treatment.

^a Immature plants harvested by cutting the plant 2 cm above the paddy rice water^b 5-Hydroxy-mesotrione was assigned based on TLC data from later samples where reference standards were available^c Not chromatographed

Residues in straw extracts showed the similar pattern as seen in whole tops and stalk samples (Table 27). Baseline polar extract was acidified to 0.1 M with HCl, heated to 80 °C for two hours to released 5-hydroxy-mesotrione (3.2% TRR, 0.001 mg/kg) and MNBA (2.4% TRR, 0.0008 mg/kg), mesotrione (1.5% TRR, 0.0005 mg/kg) and AMBA (1.1% TRR, 0.0004 mg/kg). The 56.9% TRR

(0.0183 mg/kg) in the PES was further extracted showing mesotrione and AMBA present at < 1% TRR (0.0002 mg/kg), MNBA and 5-hydroxy-mesotrione (0.4% TRR).

Peanuts

[Phenyl-U-¹⁴C]-mesotrione was solubilised in acetonitrile, diluted with aqueous blank formulation and applied to peanuts (*Arachis hypogaea* var. NCV 11) planted in silt loam soil in three outdoor subplots (Brown, 2003; Report 1286-01). [¹⁴C]mesotrione was applied to the soil surface after planting the seeds (pre-emergence) at 0.305 and 0.796 kg ai/ha. Peanut foliage was harvested 90 DAT (50% maturity), mature peanuts and peanut hay were harvested 153 DAT.

Samples were extracted four times with water:acetonitrile (8:2) and nutmeat was extracted twice with hexane and twice with acetonitrile:water (8:2). Aliquots of the extracts were partitioned with hexane, dichloromethane or chloroform. Cellulase and amyloglucosidase enzymes were added to sodium acetate buffered subsamples of aqueous and hexane fractions (pH 4.6). Esterase, lipase, and/or pancreatin were added to TRIS-hydrochloric acid buffered subsamples of aqueous and hexane fractions (pH 7.8–8). Samples were incubated for approximately 24 hours at 42 or 47 °C. Aqueous and hexane fractions and PES were hydrolysed with 6 N hydrochloric acid under reflux followed by XAD-7 separation and/or dichloromethane partitioning. Hexane fractions were hydrolysed with 1 N potassium hydroxide in water under reflux for approximately 6 or 24 hours. Aminolysis using diethylamine was attempted. PES was refluxed over night with water to extract various complex sugars. Plant extracts cleaned up with C₁₈ or NH₂ SPE. Components were separated using 2-D normal phase TLC. Reversed-phase HPLC coupled to UV detector, radioisotope flow monitor and a fraction collector was also used. Additional separation was performed by ion exchange chromatography where necessary.

Table 28 shows the residues found in peanut foliage and hay after both treatments. From 30 to 42% TRR was extracted from foliage and hay, with MNBA being the major residue. AMBA residues were released from PES after basic hydrolysis. MBA was found in trace amount only in hay treated at the highest rate.

^e At least four components ranging from 0.2% to 1.4% TRR

In another study conducted with peanuts, [cyclohexane-2-¹⁴C]-mesotrione was applied to the soil surface after planting the seeds (pre-emergence) at rates of 0.327 kg ai/ha and 0.836 kg ai/ha (Brumback, 2003; Report 1287-01). Peanut foliage was harvested 90 DAT (50% maturity), and mature peanuts and peanut hay harvested 154 DAT. Auxiliary in vitro experiments with peanut cell culture and excised peanut shoots were performed to generate metabolites for identification. Peanut cells were dosed at 50 mg/L [cyclohexane-2-¹⁴C]-mesotrione, diluted in dimethyl sulfoxide (DMSO) and harvested 7 and 14 days after dosing. Peanut shoots were dosed at 100 mg/L and harvested after 2 days. Plant samples having radioactive residues ≥ 0.010 mg/kg were extracted with water:acetonitrile (8:2). Nutmeat was sequentially extracted with hexane, hexane/ethyl acetate and acetonitrile:water (8:2). Aliquots of the extracts were partitioned between aqueous and organic phases. An aqueous buffer mixture of 0.1 M sodium acetate buffer and 0.1 M acetic acid (1:1) was added to subsample extracts, following addition of cellulase and amyloglucosidase enzymes and incubation for 16 hours at 37 to 47 °C. Nutmeat extracts were acidified to pH 1 after microwave treatment and partitioning between water and hexane. Components in extracts were separated using 2-D normal phase TLC and/or reversed-phase or anion exchange. The components were detected with HPLC-UV detector; radioisotope flow monitor and a fraction collector were also used. Additional confirmation was undertaken using tandem mass spectrometry and 1H-NMR for the metabolites isolated from the in vitro experiments.

Samples of peanuts treated at 0.327 kg ai/ha resulted in TRR < 0.01 mg/kg eq and no further analysis in the samples was performed. Table 30 shows the radioactive residues found in peanut samples from the higher rate plots. TRR was higher in foliage and nutmeat (0.02 mg/kg eq.), with about 40–50%% being extracted. Characterisation of extracts from foliage, hay and hull samples from the 0.836 mg/kg rate showed only one significant metabolite, identified as 4-hydroxy-mesotrione, which was also generated in vitro. The peanut oil fraction was shown to be composed primarily of ¹⁴C-labelled neutral lipids resulting from metabolism of mesotrione to single carbon units that entered the carbon pool.

Table 30 Summary of radioactive residues in peanut samples following treatment with [cyclohexane-2-¹⁴C]-mesotrione at 0.836 kg ai/ha

Based on the metabolism studies conducted in cranberries, soya bean, maize, rice and peanut with labelled mesotrione, a metabolism pathway of mesotrione in plants is proposed in Figure 2. The process involves hydroxylation, hydrolysis to form MNBA, which is reduced to AMBA followed by de-amination to form MBA.

Figure 2 Proposed metabolism of mesotrione in plants

Environmental Fate in Soil

Two soil photolysis studies and five aerobic and anaerobic degradation studies of mesotrione in soil were conducted, using soils collected in 1994 and 1995 in Richmond, Wisconsin (USA). The soil characteristics are shown in Table 31.

^a Biological activity of soil was monitored by measuring the soil respiration for 11 days soil pre-incubation. The soil was active as indicated by the formation of 0.6 mg of CO₂ per gram of soil during 11 days of incubation.

Soil photolysis

The photolysis of [phenyl-¹⁴C] mesotrione and [cyclohexane-¹⁴C] mesotrione was studied silt loam soil (Table 31) (Van Nest *et al.*, 1996; RR 96-060B). Mesotrione was applied at a nominal rate of 0.30 kg ai/ha, the soil incubated for 31 to 36 days in local sunlight (latitude 37° 56') at 20 to 24 °C. Dark control plates were maintained at 20 to 24 °C. Photolysis of mesotrione was studied under experimental conditions specified by EPA and EEC guidelines. In the EPA protocol, the soil disks were air-dried overnight before the treatment, whereas in the EEC conditions, they were further oven-dried at 35 °C for 7 hours prior to treatment. One day of xenon irradiation corresponded to 2.42 days of irradiation by sunlight in the phenyl EPA study, 2.17 days in the phenyl EEC study and 2.20 days in the cyclohexane study.

The percentage of mesotrione recovered at each sampling interval is shown in Tables 32 and 43. Over 90% AR was recovered immediately after application from the photolysed samples and 88.6% from the control samples. In general, CO₂ was the major photodegradation product from the irradiated samples of [phenyl-¹⁴C]- and [cyclohexane-¹⁴C] mesotrione. The total ¹⁴CO₂ produced after 31–36 sunlight equivalent days of photolysis was approximately 12% AR for the [phenyl-¹⁴C] mesotrione and 32% AR for the [cyclohexane-¹⁴C] mesotrione. MNBA and AMBA residues accounted for less than 12% AR each. The calculated half-lives of [phenyl-¹⁴C] mesotrione (EEC study), [cyclohexane-¹⁴C] mesotrione and [phenyl-¹⁴C] mesotrione (EPA study) were 15, 19 and 21 days, respectively, with a mean of 18.5 ± 3.6 days (equivalent to 20.3 days at 50°N; Eya, 1997).

Aerobic and anaerobic degradation in soil

The metabolism of [phenyl-2-¹⁴C]-mesotrione (Subba-Rao, 1996; RR 95-082B) and [cyclohexane-2-¹⁴C]-mesotrione (Vispetto & Tovshteyn, 1997; RR 95-047B) was investigated in a silt loam soil under aerobic conditions at a rate equivalent to 0.313 and 0.348 kg ai/ha, respectively. The treated soil was incubated in the dark at 25 ± 1 °C and the moisture content was maintained at 20.6% for 58–63 days under conditions which allowed ¹⁴CO₂ and any other volatilised degradates to be trapped. In addition, the metabolism of [phenyl-¹⁴C] mesotrione was further investigated at a rate of 0.233 kg ai/ha in a soil incubated in the dark at 20 ± 2 °C and 23.6% moisture content (Miller, 1997; RR 97-033B). ¹⁴CO₂ was collected in NaOH traps over the course of the study. Polyurethane foam plugs inserted in the sidearm of the flasks were analysed for any other volatile radioactive degradates. Soil was extracted with 0.05 M NH₄OH and acetone or acetonitrile. Unextracted radioactivity was further extracted from soil with 0.5 N NaOH or 0.1 N NaOH and microwave extraction.

Average recoveries ranged from 89.8 to 111% AR in the three studies. The percentages of mesotrione and resultant degradates recovered at each sampling interval are presented in Tables 34–36. Levels of radioactivity bound to the soil (unextracted) in the cyclohexane study ranged from 1.5 to 15.2% AR, with no correlation with incubation time; CO₂ accounted for 75% AR by the end of the study (Table 34). In both phenyl- labelled studies (Table 35 and 36), bound residues in soil (unextracted with 0.5 M NaOH) increased throughout the incubation period, when accounted for 34.1 to 37.0% AR. DT₅₀ and DT₉₀ values for the three studies calculated using first order kinetic ranged from 12 to 14 days and from 45 to 54 days, respectively.

^a The radioactivity not extracted by ammonium hydroxide and acetone was further extracted from soils with 0.5 N NaOH. The alkali extracts humic and fulvic acid components of soil organic matter. This is the overall total for the NaOH fraction before additional clean-up and analysis steps

In the study conducted by Miller (1997; RR 97-033B).MNBA reached a maximum level of 5.8% of the [phenyl- ^{14}C] applied radioactivity after 10 days and declined rapidly to non-detectable levels at 56 days (Table 36). In this study the DT₅₀ of MNBA, calculated using a first order metabolite model was 0.7 day.

^a Radioactivity associated with the flocculate which precipitated after acidification of the 0.05 M NH_4OH extract

In two studies to investigate the degradation of mesotrione under anaerobic conditions, [cyclohexane-2- ^{14}C] (Vispetto & Tovshteyn, 1996; RR 95-048B) and [phenyl- ^{14}C]-mesotrione (Carley, 1996; RR 96-033B) were applied to a silt loam soil at 0.280 and 0.340 kg ai/ha, respectively. The soil was incubated in the dark at $25 \pm 2^\circ\text{C}$ and anaerobic conditions were produced by flooding the soil under nitrogen for 30 days prior to treatment.

Average total recoveries ranged from 86.2 to 105% AR throughout the incubation period, with the exception of day 59 of the phenyl-labelled experiment (Tables 36 and 37). Using the [cyclohexane-2- ^{14}C]-mesotrione, the amount of unextracted radioactivity increased to a maximum of 23.4% AR after 30 days of incubation (Table 36), while it reached 17% AR after 59 days of incubation using [phenyl- ^{14}C]-mesotrione (Table 37). AMBA was found to be the only degradation product (Table 37).

Table 38 summarizes the degradation rates of mesotrione in silt loam soil estimated under aerobic and anaerobic conditions.

Table 38 Mesotrione DT₅₀ and DT₉₀ in silt loam soil under aerobic and anaerobic conditions

Labels (ref)	Conditions	DT ₅₀ (days)	DT ₉₀ (days)
[Cyclohexane- ^{14}C] mesotrione (Vispetto & Tovshteyn, 1995)	Aerobic	14	45
[Phenyl- ^{14}C] mesotrione (Subba-Rao, 1996)	Aerobic	12	54
[Phenyl- ^{14}C] mesotrione (Miller, 1997)	Aerobic	14	47
[Cyclohexane- ^{14}C] mesotrione (Vispetto & Tovshteyn, 1996)	Anaerobic	4.1	14
[Phenyl- ^{14}C] mesotrione (Carley, 1996)	Anaerobic	3.6	12

The rate of aerobic degradation of mesotrione was studied in sandy loam, loam and clay loam soils with the characteristics summarised in Table 39 (Miller & Wilson, 1997; RR 96-090B). with [phenyl- ^{14}C]-mesotrione applied at a nominal rate of 0.165 kg ai/ha and the soils incubated for up to 56 days in the dark at 20 ± 2 °C. Moisture content was 50% of the maximum holding capacity and under conditions which allowed $^{14}\text{CO}_2$ to be trapped.

[Phenyl-U-¹⁴C]-mesotrione was applied at rates ranging from 0.60 to 0.85 mg/kg soil, equivalent to approximately 0.600 to 0.850 kg ai/ha, to 13 soils (characteristics summarised in Table 41) (Tarr, 1997, RR 93-092B). The soils were incubated in the dark, under aerobic conditions at 25 ± 2 °C, maintaining a moisture content of 100% of 1/3 bar moisture capacity and evolved ¹⁴CO₂ was trapped. The soils were incubated for up to 28 days, and samples were extracted with 0.05 M NH₄OH and acetone, acidified and portioned with ethyl acetate.

Average total recoveries immediately after treatment ranged from 86.4 to 92.7% of the applied radioactivity and decreased below 90% for six of the soils after 14 days of incubation (Tarr, 1997). Mesotrione degraded rapidly with DT₅₀ and DT₉₀ values ranging from 8–32 days and 27–105 days, respectively (Table 42). In most soils (10 out of 13), levels of MNBA represented less than 4% AR at any sampling day (DT₅₀ < 2 days).

The aerobic degradation of [phenyl-U-¹⁴C]-mesotrione was studied in subsamples of two soils from Michigan (Table 43) treated at a rate of about 1/10 the rate of application to surface soils, or 0.03 mg/kg (Tarr & Tovshteyn, 1997; RR 97-053B). The soils were incubated for up to 42 days in the dark at 20 ± 1 °C, maintaining moisture contents of 100% to 600% of 1/3 bar moisture capacity (about 5 to 10% of the dry soil weight). The higher percentage moisture content was necessary because the soil was very sandy and appeared too dry at < 100% of 1/3 bar. Mesotrione was degraded in soils collected from all depths, at a slower rate in subsoil collected from 1.8–4.8 m below the surface (Table 43).

Aerobic soil degradation of MNBA

One study was conducted with the purpose to determine the rate of degradation of MNBA in four soils collected from agricultural fields in England and the United States (Lay & Peyton, 2000; RR 99-098B). MNBA was applied to the incubated soil at 0.22 µg/g soil (equivalent to 0.220 kg ai/ha). Immediately after treatment of the soil, eight soil samples were taken for analysis and the remaining soil samples were incubated in the dark under aerobic conditions at 20 °C±2 °C. Samples were collected 0.3, 1, 2, 3, 4, 7, 14, 21, 45 and 60 days after treatment, and extracted with 0.05 N NH₄OH. The MNBA in the extract was chemically reduced to AMBA, which was analysed by a reversed-phase HPLC system using fluorescence detection. DT₅₀s ranged from 0.6 days to 10.6 days (Table 44).

Table 44 DT₅₀ and DT₉₀ values for MNBA in soils under laboratory aerobic conditions

Figure 3 Proposed metabolism of mesotrione in soil

Water sediment study

Mesotrione labelled in either the cyclohexane or phenyl rings was applied to two water sediment systems at a rate equivalent to 0.200 kg ai/ha, evenly distributed throughout a 30 cm deep water body (Cary, 1999; RR 96 033B). The physico-chemical characteristics of the systems are shown in Table 48. The systems were incubated up to 101 days in the dark at 20 °C.

Radioactivity recovered from the water/sediment systems immediately after application ranged from 93% and 102% of the applied dose. The mean recovery from all the samples taken throughout the remainder of the 101 days incubation period was 100% AR. DT₅₀ were 3–6 days (Table 46). The level of mesotrione in the sediment did not exceed 4% AR at any time point, and DT₅₀ and DT₉₀ values in the water-sediment were equivalent to the ones in the water phase.

[Phenyl-¹⁴C] mesotrione was degraded to MNBA and AMBA (Tables 49 and 50). MNBA was only detected in the Virginia Water system. It reached a maximum of 8% AR on Day 3 and was almost entirely present in the water phase. AMBA was distributed in both the water and the sediment and reached up to 18% at Day 28 in the ‘Old Basing’ system and up to 19% in ‘Virginia Water’ system at Day 14.

Degradation in soil-field studies

Six field studies were conducted to evaluate the rate of degradation of mesotrione in soil. A single application of a 0.100 kg ai/L suspension concentrate of mesotrione was applied to bare soil at rates of 0.150 and 0.200 g ai/ha in 1995/96 and 1996/97 seasons, respectively (Table 51). Soil samples were collected up to 30 cm depth, prepared in 10 cm horizons and analysed for mesotrione, MNBA and AMBA. Calculated DT₅₀ and DT₉₀ for mesotrione are also shown in Table 51.

In the 1996-1997 Italian trial, MNBA was detected at up to 0.031 mg/kg in 0–10 cm horizon, six days after application and declined to < 0.005 mg/kg by 89 days after treatment. AMBA was detected only in the 0-10 cm horizon six days after application (0.006 mg/kg). In one 1996–1997 German trial, MNBA reached a maximum of 0.016 mg/kg in the 0–10 cm horizon eight days after application and decreased to <0.005 mg/kg 89 days after treatment. No measurable residues of mesotrione or metabolites were detected in the soil below 10 cm.

Aerobic soil degradation of AMBA

In another study, [phenyl-U-14C]-AMBA was applied at 0.213 kg ai/ha (Marth, 1997; RR 97-032B) or 0.225 kg ai/ha (Lay, 2000; RR 99-096B). Soil characteristics are shown in Table 52. The soils were incubated for up to 60 days in the dark under aerobic conditions at a temperature of 20 ± 2°C,

maintaining a moisture content of 40% of water holding capacity. Average total recoveries ranged from 92.7–98.6% AR at Day 0. AMBA DT₅₀ ranged from 2 to 6 days and no AMBA degradates exceeded 10% AR in any of the three soils (Table 52).

Confined rotational crops

This study was designed to provide information on the uptake and metabolism of [phenyl-U-¹⁴C]-mesotrione in rotational crops following a single application onto the bare surface of a sandy loam soil at a rate of 0.165 kg ai/ha (Gorder *et al.*, 1997; RR 96-084B). At intervals of 120 and 300 days after treatment (DAT), three representative rotational crops (endive, radish and wheat) were sown into the treated soil. Crops planted in the 120 DAT soils were harvested: endive at 78 days after planting (DAP), radish roots and leaves at 56 DAP, wheat forage at 22 DAP, wheat hay at 57 DAP and wheat grain and straw at 134 DAP. The 300 DAT crops were not harvested due to low residues found in 120 DAT crops. Crops with residues ≥ 0.01 mg/kg were extracted with acetonitrile/water and the extracted residues (> 0.01 mg/kg) were analysed by HPLC-radiodetector.

Analysis of soil cores showed that the residue had declined to 34% of the applied radioactivity (AR) after 120 days and to 15% AR after 300 days. In soil, mesotrione accounted for 0.1% AR after 120, MNBA for 8% and AMBA for 2% AR.

Total radioactive residues in crop commodities from the 120 DAT are shown in Table 53. Residue levels were ≤ 0.035 mg/kg for feed commodities and ≤ 0.014 mg/kg eq. for food commodities. Untreated soil and pots contained low levels of radioactivity (≤ 0.004 mg/kg eq.), resulting from mineralisation of [¹⁴C]mesotrione in the soil. Unextracted residues represented ≤ 0.015 mg/kg eq. and were not further analysed.

Commodities with residues > 0.01 mg/kg eq. were extracted with acetonitrile/water. From 46 to 59% TRRs were extracted. The major metabolite in wheat commodities was MNBA accounting for 36%TRR in forage (Table 53). AMBA was present mostly in conjugated form.

Table 53 Summary of total radioactive residues in rotational crop samples grown in soil treated at 0.165 kg/ai/ha with [phenyl-2-¹⁴C]-mesotrione–120 DAT

Crop	TRR, mg/kg eq.	Extracted, mg/kg (%TRR)	PES, mg/kg (%TRR)	Losses in sample work-up, mg/kg (%TRR)

^a All radioactivity that did not form discrete HPLC peaks

In another study, [phenyl-U-¹⁴C]-mesotrione was applied at 0.308 kg ai/ha and 0.462 kg ai/ha, the lower rate representative of the pre-emergence use and the higher rate being representative of a pre-emergent followed by post-emergent use (Gorder *et al.*, 1996; RR 96-035B). Each application was sprayed onto the bare surface of a sandy loam soil contained in 51 cm diameter pots. The pots were sown with combinations of wheat, soy, endive and radish at intervals of 30, 120 and 300 DAT. Leaf and root crops could not be planted at 30 DAT due to crop sensitivity

Samples having radioactive residues greater than or equal to 0.01 mg/kg were extracted 2–3 times with acetonitrile/water. The 30-DAT wheat grain sample was extracted by refluxing with 2 M HCl. Solids with residues > 0.05 mg/kg (> 10% TRR) were subjected to further extraction with 1 M/10M ammonium hydroxide and 6 M HCl at ambient temperature and/or under reflux. HPLC and TLC were used for the characterisation of residues.

Radioactive residues in soil declined to 27% AR at 300 DAT. Mesotrione levels were < 1% AR between 28 and 300 DAT, forming MNBA and to a lesser extent AMBA present at the 120 and 300 day sowing intervals.

Radioactive residues in wheat feed commodities declined with increasing sowing intervals, being highest in wheat straw (2.58 mg/kg eq. at 30 DAT). In wheat grain, it was 0.038 mg/kg at 30 DAT and < 0.02 mg/kg at all other planting intervals. Soya bean residues were 0.145 mg/kg at DAT with feed commodities containing 0.462 and 0.645 mg/kg for hay and forage respectively. Residues in endive and radish root declined to 0.019 and 0.005 mg/kg respectively after 300 DAT (Table 55). Residues in control did not exceed 0.007 mg/kg eq.

The major identified metabolite in all wheat samples was MNBA, reaching 0.63 mg/kg in 30 DAT wheat forage (Tables 56 and 57). AMBA was mostly present as sulphate conjugate. Wheat grain samples from 30 DAT contained MNBA at 0.003 mg/kg and an unidentified glucose conjugate (0.013 mg/kg). About 70% TRR of grain samples from 120 and 300 DAT were retained in PES, but no further work was conducted in the samples.

^a The aqueous fraction for the wheat grain sample was a hydrolysate

Radioactive residues in soy forage represented 0.645 mg/kg, of which 61% TRR was extracted (Table 58). The PES containing 38% TRR was hydrolysed releasing a further 20% TRR (0.129 mg/kg). MNBA was the major metabolite in soy forage and hay (up to 48% TRR). Over 40%TRR in the soya beans was extracted. The PES containing 54% TRR (0.078 mg/kg) was further extracted with base, acid with hexane, which solubilised a further 24% TRR (0.036 mg/kg). AMBA was the major compound in soya bean (0.024 mg/kg), in addition to a unknown glucose metabolite (0.003 mg/kg). A number of unknown metabolites were observed in all commodities, no one representing > 0.011 mg/kg.

The major residue in endive was MNBA, accounting for up to 38% TRR (0.02 mg/kg) at 120 DAT (Table 59). Traces of AMBA were detected at 300 DAT. A number of minor unknowns were seen, each at ≤ 0.002 mg/kg. Residue levels in radish were low (≤ 0.05 mg/kg), and distributed with slightly more radioactivity in tops than roots, with MNBA accounting for to up to 53%TRR (Table 59).

[Cyclohexane-2-¹⁴C]-mesotrione at a nominal rate of 0.165 kg ai/ha was sprayed once onto the bare surface of a sandy loam soil contained in pots in greenhouse (Spillner *et al.*, 1997; RR 95-042B). Endive, radish and wheat were sown into the treated soil (120 DAT). Soil cores were taken immediately after sowing and at 273 and 300 DAT. Endive was harvested 63 DAP, radish roots and leaves at 56 DAP, forage wheat at 22 DAP, forage hay at 57 DAP and wheat grain and straw at 131 DAP. Total radioactive residues in all samples ranged from < 0.001 mg/kg eq. in endive and radish to 0.004 mg/kg eq. in wheat straw. Residues in control reached 0.002 mg/kg in wheat grain and straw.

Radioactive residues in soil declined to 4% of the applied radioactivity by 120 DAT. No further analysis was conducted since the radioactive residues were < 0.01 mg/kg.

In another rotational study, [cyclohexane-2-¹⁴C]-mesotrione was sprayed once at 0.308 kg ai/ha or 0.462 kg ai/ha to sandy loam soil pots (Spillner *et al.*, 1996; RR 96-005B). Wheat was planted at 30, 120 and 300 DAT, soy at 30 DAT and endive and radish at 120 DAT. Samples with residues ≥ 0.01 mg/kg were extracted with acetonitrile:water. Soya beans were first extracted with hexane to remove the oil. The 30-DAT wheat grain sample was hydrolysed using 2 N hydrochloric acid; the hydrolysate partitioned with ethyl acetate to remove the organosoluble residues, and the aqueous phase was analysed for ¹⁴C-glucose. Reverse-phase HPLC was used for the characterisation mesotrione and its metabolites.

Radioactive residues in the soil declined to 10, 5 and 4% AR after 30, 120 and 300 DAT, respectively. Radioactive residues in wheat commodities declined over time, with the highest residues found in feed (Table 60). Residues in the soy ranged from 0.017 in beans to 0.026 mg/kg in forage at 30 DAT. In root crops at 120 DAT they reached 0.004 mg/kg in radish leaves and were not further investigated.

Table 60 Summary of total radioactive residues in rotational crop samples grown in soil treated with [cyclohexane-2-¹⁴C]-mesotrione

Mesotrione was a major residue in feed wheat commodities, but was not detected in grain, in which the only identified residue was a glucose conjugate (Table 61). Residues in wheat grain was 0.01 mg/kg at 30 DAT. 4-hydroxy mesotrione was the major metabolite identified, accounting for up to 15% TRR in forage (0.008 mg/kg). Over 70% of the residues were extracted from all matrices, and PES was not analysed further.

^a The aqueous fraction for the wheat grain sample was a hydrolysate, not an extract; 4-OH: 4-hydroxy-mesotrione; 4-OGlu: 4-hydroxy-mesotrione glucoside conjugate; 5-OH: 5-hydroxy-mesotrione; XanH4: 6-(methylsulfonyl)-1-oxo-1.2.3.4-tetrahydro-9H-xanthen-9-one

About 70% of radioactivity was extracted from soy forage and hay, and PES was not analysed further. 13% TRR was extracted from soya beans with hexane and 20% TRR with acetonitrile/water mixtures (< 0.01 mg/kg); PES accounted for 64% TRR (0.01 mg/kg). Neither the soya bean extracts nor PES were analysed further. Mesotrione was the major residue in soy forage and hay (up to 11% TRR, 0.003 mg/kg), while 5-hydroxy-mesotrione and 4-hydroxy-mesotrione represented 4 to 6% TRR (Table 62).

The proposed pathways of mesotrione in rotated crops obtained from studies using the mesotrione labelled in phenyl and the cyclohexane are shown in Figure 4.

Figure 4 Proposed metabolic pathway of mesotrione in rotational crops

Analytical Methods

Vegetable crops

In Method RAM 366/01, residues of mesotrione and MNBA were extracted from crop samples with acetonitrile/water containing 10 g/L sodium chloride (50:50), an aliquot diluted with water and formic acid and cleaned up by Oasis[®] HLB SPE. The extract is partitioned into methylene chloride, evaporated to dryness, taken up with acetonitrile/water and analysed by HPLC-MS/MS, in negative ion mode, 290.9 m/z ion for quantification and no confirmation ion included. LOQ was 0.01 mg/kg in all crop matrices. Recovery data for mesotrione in corn (Hill, 2001; Report 2704 and Crook, 2001; RJ3253B), and cranberry (Salzman, 2005; 08903) are summarised in Table 63. The method was also successfully validated for MNBA.

In Methods TMR0643B and TMR0882B, mesotrione and MNBA residues are extracted with acetonitrile/water (1:1). An aliquot is diluted with water, acidified, partitioned with ethyl acetate and subjected to silica SPE clean-up. Further clean-up is done by reversed phase HPLC. The MNBA, isolated in the first fraction, is chemically reduced to AMBA with SnCl_2 in HCl. The mesotrione residue, isolated in the second fraction, is oxidised to MNBA using hydrogen peroxide, which is reduced to AMBA using acidic SnCl_2 . After clean-up by C18 SPE, mesotrione and MNBA fractions are each analysed for the AMBA conversion product by a reversed-phase HPLC-fluorescence detection (ex 227 nm; em 424 nm). Mesotrione and MNBA standards were converted to AMBA concurrent with the samples. The method was validated for corn with a LOQ of 0.01 mg/kg for both mesotrione and MNBA. Independent validation was also provided. The recovery data for mesotrione are shown in Table 65.

Method TMR0643B was radio-validated using incurred radioactive residues in a forage sample treated pre-emergence (Tarr & van Neste, 1997). An aliquot of the forage sample was extracted once with an acetonitrile:water mixture (1:1) using a high speed homogeniser, an aliquot of the supernatant partitioned three times into ethyl acetate, the combined fractions evaporated and reconstituted in acetonitrile. Residues of mesotrione and MNBA were quantified by TLC with storage-phosphor autoradiography. Levels of mesotrione and MNBA in forage were 0.008 and 0.073 mg/kg, respectively. Residues of mesotrione and MNBA obtained by exhaustive extraction within this metabolism study were 0.008 mg/kg and 0.070 mg/kg, respectively.

In Method TMR0689B (Meyers, 1996), mesotrione and MNBA residues are extracted from corn commodities with acetonitrile/water (1:1), an aliquot diluted with a sodium sulphate solution, acidified and partitioned with methylene chloride. The methylene chloride extract is evaporated and the residue heated with Jones Reagent (chromium^{VI} oxide acid solution) to convert mesotrione to MNBA. The total MNBA is extracted with ethyl acetate, evaporated to dryness, the residue dissolved in methyl ethyl ketone and the isopropyl ester of MNBA is formed by heating the mixture with 2-iodopropane and potassium carbonate. The methyl ethyl ketone is evaporated, the residue extracted with acetone, evaporated to dryness and the isopropyl-MNBA residue dissolved in toluene containing 0.05% (w/v) 5-nitrovanillin for analyse by GC-MS (monitoring ion: m/z 246). The method determines the sum of mesotrione and MNBA at a combined LOQ of 0.01 mg/kg (Table 66).

Samples were analysed based on the QuEChERS multi-residue method (Watson, 2013). The method involves extraction with acetonitrile, addition of magnesium sulphate, sodium chloride and buffering citrate salts, centrifugation, an aliquot of the acetonitrile phase transferred to the freezer overnight (oilseed rape seed only) and cleaned up with magnesium sulphate prior to analysis by LC-MS/MS. Primary secondary amine (PSA) used in the original QuEChERS was not included due to low procedural recoveries for mesotrione. The LOQ was 0.01 mg/kg in all matrices. Recovery data in orange, maize and oilseed rape are summarised in Table 67.

Food of animal origin

In method TMR0914B, mesotrione and MNBA residues are extracted from milk and eggs with acetone and from animal tissues with an acetone/water (60:40). An aliquot is diluted with acidified water, partitioned twice into methylene chloride, and residues of mesotrione are converted to MNBA using hydrogen peroxide. After elimination of excess peroxide with catalase enzyme, MNBA is reduced to AMBA by heating with SnCl₂ and HCl and AMBA determined by reversed phase HPLC-fluorescence detection. The LOQ was 0.01 mg/kg in all matrices. Recovery data for mesotrione is summarised in Table 68.

Mesotrione was determined in animal matrices using the modified QuEChERS, excluding PSA (Watson, 2013; Report no. S12-03250). LOQ was 0.01 mg/kg. The same procedure was independently validated (Bernal, 2013; Report no. S12-04608). The results are shown in Table 69.

Storage stability under frozen conditions

Samples of maize grain, maize forage, maize fodder, radish root, and soya bean seed were homogenized and fortified at 0.1 mg/kg with either mesotrione or MNBA (Wiebe & Peyton, 1999). Duplicate samples were stored under frozen conditions ($-18^{\circ}\text{C} \pm 5^{\circ}\text{C}$) and analysed at intervals up to 44 months. Mesotrione and MNBA were quantified as AMBA by HPLC fluorescence detection (Method TMR0643B). The limit of quantification for mesotrione and MNBA in all matrices was 0.01 mg/kg. The results are shown in Table 70.

^a Single value reported; duplicate sample lost during sample clean-up

Samples of blueberry, asparagus, sugarcane and okra were grounded in dry ice and fortified with mesotrione at 1.0 mg/kg (Link, 2007). Duplicate samples were prepared and stored under frozen conditions (-20°C) and analysed at intervals over 13 months for sugarcane and okra and over 22

months for blueberry and asparagus. Mesotrione was quantified by HPLC-MS/MS (LOQ of 0.01 mg/kg). The results shown in Table 71 are not corrected for procedural recovery.

USE PATTERNS

Mesotrione is an herbicide used pre-emergence and post-emergence for selective control of annual broad-leaved weeds, which cease growth soon after application (high or low volume sprayers). Mesotrione is registered in many countries, but only the relevant GAP information for this evaluation is given in Table 72. DAT means days after treatment.

Table 72 Registered uses of mesotrione relevant for the evaluation

Crop	Country	Formulation		Application		No	PHI (days)
		kg ai/L kg	Type	Method	Rate kg ai/ha

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Supervised residue trials conducted with mesotrione on a variety of crops in Europe, Canada and USA were submitted to the Meeting. Studies were conducted according to GLP, and specified concurrent determination of residues in untreated crops gave residues < LOQ, unless specified. Residues of mesotrione arising from use patterns where rate or days after treatment (DAT) $\pm$ 25% of GAP are underlined and considered for estimation of maximum residue levels and STMRs. When residues in samples harvested at a later stage were higher than those found at the critical PHI, they were used for the estimations. In trials conducted in the USA, duplicate or multiple field samples from replicate plots were taken for analysis at each sampling time and the mean was selected for the estimations. In total, 373 supervised trials were submitted and food commodities analysed for residues; in 193 cereal trials, feed commodities were also analysed. The data are summarized in Table 73.

Berries and other small fruits

Twenty five supervised residue trials were conducted on berries in the USA using broadcast application during 2004 and 2005. Five trials were conducted on cranberries and ten trials were conducted on bush and cane berries. The results are shown in Table 74. Samples were stored deep-frozen for a maximum of 16.4 months and analysed for residues of mesotrione using method RAM 366/01 (LC-MS/MS).

^c Trials conducted at the same location, but in different periods.

Okra

Twenty supervised residue trials were conducted on *okra* in the USA (Report T021571-04) during 2005 using either one pre-emergence application or one post-emergence application directed to the weed. A suspension concentrate (SC) formulation containing mesotrione was applied using soil surface spray pre-emergence (SS), post-emergence broadcast application over-the-top of the weed (POT) and or post-emergence directed application (PD). Samples were analysed for mesotrione residues using the method RAM 366. The results are summarized in Table 75.

Sweet corn

Eight post-emergence trials were conducted on sweet corn in France in 2003/2004, and 18 trials in the USA during 2001 and 2008, with either one pre-emergence and one post-emergence application or with two early post-emergence applications. Samples were analysed for mesotrione and MNBA using method RAM 366/1 (LC-MS/MS) or TM0643B (HPLC-FL). The data for mesotrione residue are summarised in Table 76. Residue levels for MNBA were < 0.01 mg/kg in all cases.

Soya bean, dry

Twenty three supervised residue trials were conducted on soya bean in the USA during 2007 (Report T005595-06), with mesotrione applied pre-emergence direct to the soil. The DAT is driven by the normal vegetation period of the crop and is in the range of 113 to 160 days. Samples were analysed for mesotrione and MNBA using RAM 366/1. The results for mesotrione are shown in Table 77. MNBA residues were < 0.01 mg/kg in all samples.

Mesotrione-tolerant soya bean, dry

Forty-nine supervised residue trials were conducted on herbicide-tolerant soya bean in the USA during 2009 and 2012 with either one pre-emergence and one post-emergence application at growth stage R1 (BBCH 60) or with one early post-emergence application at growth stage V2 (BBCH 13). Samples were analysed for mesotrione and MNBA using RAM 366/1. The results for mesotrione are shown in Table 78. MNBA residues were < 0.01 mg/kg in all samples.

(m)—Mature

Asparagus

Twenty four supervised residue trials were conducted on asparagus in the USA (Report T021572-04 2005) during 2005 using either one pre-emergence soil surface spray (PSS), post-emergence over-the-top of the weeds (POT) or a combination of the two applications. Samples were analysed for mesotrione using RAM 366/1. The results are shown in Table 79.

Table 79 Summary of residue data for mesotrione on asparagus (spears) using SC formulation in the USA during 2005

Animal Feed

Cereal trials from the studies reported previously have included the analysis of feed samples. The results are shown in Tables 88 to 92.

Processing studies

A residue trial on soya beans conducted in the USA with one pre-emergence application at a 1.1 kg ai/ha (Table 77; report T005595-06). Soya beans harvested at 113 DAT were processed into meal, hulls and refined oil simulating commercial practices, and samples analysed using method RAM 366/01. Residues of mesotrione were < 0.01 mg/kg in the soy sample, meal, hulls and refined oil, and no processing factors were derived

Two residue trials on mesotrione-tolerant HT soya beans were conducted in the USA using pre- plus post-emergence applications at 1.1 and 0.6 kg ai/ha, respectively (Table 93, Report T000908-07). Soya bean samples were harvested at 76 or 102 DAT, processed according to commercial practices, and samples analysed using method RAM 366/01. The results are show in in Table 93.

Table 93 Processing factors for mesotrione residues in mesotrione-tolerant soya beans

Mesotrione	Soya bean	Meal	Hulls	Crude oil	Refined oil	AGF	Flour	Soya milk	Tofu	Soya sauce	Miso

RESIDUES IN ANIMAL COMMODITIES

No studies were provided

APPRAISAL

Mesotrione is a systemic pre-emergence and post-emergence herbicide for the selective contact and residual control of broadleaf weeds. The compound was scheduled for evaluation by 2014 JMPR as a new compound at the Forty-fifth Session of the CCPR (2013). Metabolism studies on animal and plants, confined rotational crops and environmental fate studies, analytical methods and residue trials on berries, okra, sweet corn, soybean, asparagus, rhubarb maize, millet, oat, rice, sorghum, sugarcane and linseed were submitted for evaluation. The structure of mesotrione and the main metabolites found in livestock, plant tissues and soil are shown below

 [Phenyl-U-¹⁴C] Mesotrione	 [Cyclohexane-2-¹⁴C] Mesotrione
 4-Hydroxy-mesotrione	 5-Hydroxy-mesotrione
 MNBA [4-(methylsulphonyl)-2-nitrobenzoic acid]	 AMBA [(2-amino-4-(methylsulphonyl)-benzoic acid)]
 MBA [4-(methylsulphonyl) benzoic acid]	

Animal metabolism

Rats

The metabolism of mesotrione was evaluated at the present Meeting by the JMPR WHO Panel. The compound is rapidly and extensively absorbed, minimally metabolized and excreted primarily in urine after a single or repeated dose. The majority of the radioactivity was excreted as the parent compound within 12 hours post-dose, accounting for 43–64% of the dose in urine. The metabolites found in the excreta includes 4 and 5-hydroxy mesotrione, MNBA and AMBA.

Livestock animals

Metabolism studies with mesotrione were conducted in lactating cows, swine and poultry. Additionally, the metabolism of AMBA, was investigated in the cow.

In two metabolism studies conducted in lactating cows, the animals were dosed with [phenyl- $U-^{14}C$]-mesotrione or [cyclohexane-2- ^{14}C]-mesotrione for 7 consecutive days at a nominal rate of 10 ppm in the diet, and sacrificed 16 hours after the final dose. Over 90% of the administered dose was found in excreta, mostly in faeces. TRR was higher in liver and kidney (0.07 to 0.11 mg eq./kg), reached 0.007 mg eq./kg in muscle, 0.013 mg/kg eq in fat and 0.08 mg eq./kg in milk (at least 90% TRR in skimmed milk). Mesotrione accounted for 10–18% TRR in liver and kidney (0.01–0.02 mg eq./kg). AMBA was identified in kidney of the phenyl label experiment (0.01 mg eq./kg).

One female swine was dosed orally with [phenyl- $U-^{14}C$]-mesotrione for 5 consecutive days at 6 ppm, and sacrificed 23 hours after the final dose. About 90% of the administered dose was recovered in the excreta, mostly in the faeces. Highest TRRs were found in liver (1.75 mg eq./kg) and kidney (0.12 mg eq./kg), with 0.01 mg eq./kg in muscle and 0.006 mg eq./kg in fat. Mesotrione was the main identified residues (90% TRR in liver, 73% TRR in kidney and 78% TRR in muscle). AMBA accounted for up to 2% TRR in tissues (up to 0.029 mg eq./kg in liver). MNBA was only detected in liver (0.005 mg eq./kg).

Two metabolism studies were conducted in poultry, in which hens were dosed for 10 consecutive days at 11 ppm either with [phenyl- $U-^{14}C$]-mesotrione or [cyclohexane-2- ^{14}C]-mesotrione; the hens were sacrificed 16 hours after the final dose. The radioactivity in excreta accounted for over 90% of the administered dose, and contained mesotrione (up to 55% TRR) and AMBA (18% TRR). TRRs were similar in both experiments for liver (1.1–1.2 mg eq./kg) and kidney (0.06–0.07 mg eq./kg), but were higher in the cyclohexane experiment in muscle (up to 0.012 mg/kg eq), fat (up to 0.048 mg eq./kg), reaching 0.094 mg eq./kg in egg yolk, and 0.025 mg eq./kg in the white. Mesotrione was not detected in muscle in any experiment, and was the only compound identified in tissues and eggs in both experiments, corresponding to at least 70% TRR in the liver and fat. In egg yolk, mesotrione accounted for 81% TRR in the phenyl experiment, and 19.5% TRR in the cyclohexane experiment, in which about 15% TRR was shown to be incorporated into palmitic/oleic acid.

A lactating cow received [phenyl- $U-^{14}C$]-AMBA for 7 days at 12.2 ppm in the diet and was sacrificed 23 hours after the final dose. About 90% of the dose was recovered in the excreta, mostly in the faeces. Highest residues were found in kidney (0.053 mg eq./kg), with AMBA accounting for 79% TRR. Perineal fat contained 0.018 mg eq./kg, 62% identified as AMBA. TRR in liver were 0.005 mg eq./kg, and reached a maximum of 0.009 mg eq./kg in milk (day 6), but were not characterized. No radioactive residues were detected in muscle.

In summary, the biotransformation of mesotrione in livestock involves the oxidative cleavage of the parent molecule to yield MNBA, which is reduced in the nitro group to give AMBA. Highest residues were found in liver and kidney, and the levels in muscle were low, reaching a maximum of 0.012 mg eq./kg Mesotrione accounted for up to 18% TRR in cow liver and kidney, at least 70% TRR in tissues of swine and poultry, and up to 80% TRR in egg yolk. No single compound was detected in muscle. The metabolism of Mesotrione in rats was found to be similar to that described for livestock.

Plant metabolism

Metabolism studies were conducted in cranberries, tolerant soya bean, maize, rice and peanuts. [Phenyl- U - ^{14}C]-mesotrione was applied twice to cranberry plants at $0.331 + 0.242$ kg ai/ha ($1\times$) or $0.919 + 0.642$ kg ai/ha ($3\times$ rate), and samples harvested 46 days after the last treatment (DAT). TRRs in mature foliage were 16.8 mg eq./kg and 31.8 mg eq./kg for $1\times$ and $3\times$, respectively. TRRs in the mature cranberry fruit were 2.6 mg eq./kg and 4.9 mg eq./kg, respectively, mostly as mesotrione (60–67% TRR) and AMBA (24–35% TRR), MNBA accounted for up to 3% TRR.

Mesotrione tolerant soya bean seeds grown in sandy loam soil were treated with either [phenyl- U - ^{14}C]- or [cyclohexane-2- ^{14}C]-mesotrione using three GAP application regimes: one pre-emergence at 0.225 kg ai/ha (T1), a combined pre-emergence at 0.225 kg ai/ha followed by a post-emergence at 0.125 kg ai/ha (T2), or one post-emergence at 0.225 kg ai/ha (T3). Forage was sampled at 22–28 DAT, hay at 40–42 DAT and seeds at 90–123 DAT.

Higher radioactivity was recovered from the phenyl label experiment. In forage, TRR were 0.16 to 0.5 mg eq./kg, mostly as MNBA (13 to 24% TRR; 0.04 to 0.06 mg eq./kg); mesotrione and its 4 and 5-hydroxy metabolite accounted for up to 14.6% TRR each (0.01 to 0.08 mg eq./kg). In hay, TRR ranged from 0.14 mg/kg eq (T1) to 2 mg eq./kg (T2), mostly MNBA (up to 20% TRR) and 4/5-hydroxy-mesotrione (up to 16% TRR); mesotrione accounted for up to 9% TRR. AMBA was only detected in T2 hay (0.055 mg eq./kg; 2.7% TRR). Residues in soya bean seed ranged from 0.052 to 0.104 mg eq./kg, with mesotrione and 4/5-hydroxy-mesotrione the main compounds identified (< 10% TRR). Low levels of MNBA and AMBA were found in the T1 and T2 samples (< 5% TRR, 0.005 mg eq./kg).

Results from the cyclohexane experiment showed mesotrione accounting for up to 18% TRR in forage, 8.2% TRR in hay and 5.1% TRR in seed (0.02 mg eq./kg). 4 and 5-hydroxy-mesotrione accounted for up to 19% TRR in forage and hay, and 7% TRR in seeds.

Three studies were conducted with maize, two with [phenyl- U - ^{14}C]-mesotrione and/or one with [cyclohexane-2- ^{14}C]-mesotrione. In all cases, the compound was applied to the soil surface after planting the seeds at a rate of 0.3 kg ai/ha (pre-emergence; T1) or post-emergence at 0.16–0.18 kg ai/ha, 28 days after planting (T2).

Results from the phenyl label experiments showed higher total residues in fodder/stover (0.8 to 1.1 mg eq./kg) and forage (0.244 to 0.356 mg eq./kg). Over 60% of the residues in fodder were not extracted with ACN/water. In T1 forage, MNBA and AMBA were the major residues (up to 19.7 and 12.2% TRR, respectively). In fodder, AMBA was the major residue (up to 28% TRR in T2). 4-hydroxy-mesotrione was mainly present in forage (up to 8% TRR, about 50% conjugated). Mesotrione was a minor component of the residues in all cases, present at a higher level in T1 forage samples (2.2% TRR, 0.008 mg eq./kg). TRR in grain was 0.01 mg/kg eq, and was not further characterized.

In the cyclohexane experiment, TRR reached 0.1 mg eq./kg in forage and 0.33 mg eq./kg in fodder. In forage, the identified residues were mesotrione (up to 3% TRR) and 4-hydroxy-mesotrione (up to 10% TRR). About 18% TRR was incorporated into lignin and cellulose. Residues in grain were low (up to 0.011 mg eq./kg) and were not be further characterized.

Rice plants were treated at the 2–3 leaf stage with [phenyl- U - ^{14}C]-mesotrione added directly to the paddy water at either 0.09 kg ai/ha ($1\times$) or 0.225 kg ai/ha ($2.5\times$). TRRs were higher in whole tops and straw (0.03 to 0.06 mg eq./kg at $1\times$), with 60–71% extracted by ACN/water. Residues in grain and husk (109 DAT) reached 0.01 mg eq./kg, about 33% being extracted (acid released up to 75.1% TRR in grain). Immature whole tops from $1\times$ rate contained mesotrione and 5-hydroxy-mesotrione at up to 0.01 mg/kg eq. each (11 to 15% TRR), and traces of MNBA and AMBA (< 5% TRR from $1\times$). In $1\times$ stalk and straw, mesotrione and its metabolites represented < 10% TRR each. No characterization was performed in grain. Residues from $2.5\times$ samples were 2–5 times higher (0.02 mg eq./kg in grain).

[Phenyl- ^{14}C] or [cyclohexane-2- ^{14}C]-mesotrione were applied to the soil surface after planting peanut seed (pre-emergence) at 0.3 (T1) or 0.8 kg ai/ha (T2). Peanut foliage was harvested 90 DAT (50% maturity), mature peanuts and peanut hay at 153 DAT. Residues from [phenyl- ^{14}C] treatment were higher in foliage (0.028 and 0.064 mg eq./kg, in T1 and T2, respectively) and approximately 0.01 mg eq./kg in hay, hull and nutmeat. Traces of MNBA, MBA, AMBA and 4-hydroxy-mesotrione were found in hay (< 6% TRR, ≤ 0.002 mg eq./kg), but only AMBA was found in nutmeat (up to 15% TRR, 0.002 mg eq./kg, in T1). TRR from [cyclohexane-2- ^{14}C] treatment were ≤ 0.01 mg eq./kg in T1 samples ranged from 0.01 to 0.02 mg eq./kg in T2. 4-hydroxy-mesotrione was only identified in hulls (7% TRR). The peanut oil fraction was shown to be composed primarily of ^{14}C -labelled neutral lipids.

In summary, the metabolic pathway of mesotrione following pre- and/or post-emergence foliar applications in cranberries, maize, rice, peanut and tolerant soya bean are similar. It proceeds via cleavage of the parent molecule to yield MNBA and reduction to AMBA, which either conjugated or degraded to MBA. Mesotrione is also hydroxylated in the cyclohexane-dione ring to give 4 or 5-hydroxy-mesotrione. Incorporation of radioactive residues into natural products (lignin cellulose sugar or lipid) was seen in all crops, except cranberry fruit. Residues in cranberry fruits were mostly mesotrione and AMBA (over 20% TRR each). Maize, soya and rice feed commodities contained mostly MNBA and AMBA (> 10% TRR in most cases). Residues in grains were low and mesotrione only represented higher than 10% TRR in tolerant soya bean seed.

Environment fate

The photolysis of [phenyl- ^{14}C] mesotrione and [cyclohexane- ^{14}C]-mesotrione was studied in silt loam soil treated at 0.3 kg ai/ha and incubated in local sunlight (latitude 37° 56') at 20 to 24°C. About half of the radioactivity was present as mesotrione at 12–13 DAT. MNBA and AMBA accounted for 2–8% TRR at 5 DAT, increasing up to 8% TRR at 30 DAT.

The metabolism of [phenyl-2- ^{14}C] or [cyclohexane- ^{14}C]-mesotrione applied to various soils at rates ranging from 0.165 to 0.85 kg ai/ha and kept under aerobic conditions in the dark at 25±1°C for 28 to 60 days was investigated. Mesotrione degrades relatively fast, with DT₅₀ values ranging from 4.5 to 32 days. DT₅₀ for MNBA was < 2 days in these studies.

In two water sediment systems experiments conducted with either [phenyl-2- ^{14}C] or [cyclohexane- ^{14}C]-mesotrione at 0.20 kg ai/ha and incubated in the dark for 101 days, showed DT₅₀ were from 3 to 6 days, with mesotrione in the sediment never exceeding 4% AR. MNBA and AMBA were found in both water and sediment, starting at day 3.

The aerobic degradation of [phenyl-2- ^{14}C]-AMBA was studied in soils incubated up to 60 days in the dark, showing DT₅₀ ranging from 2 to 6 days.

Field studies

In six studies conducted with soils collected from different regions of Europe, mesotrione was applied at 0.15–0.2 kg ai/ha. MNBA and AMBA were detected at 6 DAT in 0–10 cm horizon (0.031 and 0.006 mg eq./kg, respectively). No residues of mesotrione or metabolites were detected in the soil below 10 cm. DT₅₀ ranged from 2 to 8 days.

In one study conducted with four soils from England and USA treated with MNBA at 0.22 kg ai/ha, DT₅₀ ranged from 0.6 to 10.6 days.

Confined rotational crops

Endive, radish and wheat were sown 120 days after a sandy loam soil being treated with [phenyl- ^{14}C] or [cyclohexane-2- ^{14}C]-mesotrione at 0.165 kg ai/ha. Endive was harvested at 78–63 days after planting (DAP), radish roots and leaves at 56 DAP, wheat forage at 22 DAP, wheat hay at 57 DAP and wheat grain and straw at 134–131 DAP. In the [phenyl- ^{14}C] experiment, residues in soil declined to 34% of the applied radioactivity (AR) at 120 DAT, with the most abundant metabolites being MNBA (8% AR) and AMBA (2% AR); mesotrione accounted for only 0.1% AR. TRR were

0.02 to 0.04 mg eq./kg in wheat forage, hay and straw, mostly MNBA (0.011 mg eq./kg in forage). Residues were 0.006 mg eq./kg in wheat grain, 0.014 mg eq./kg in endive and 0.004 mg eq./kg in radish root and leaves. TRR in all cyclohexane-2-¹⁴C samples were < 0.005 mg eq./kg in endive, and wheat straw, and were not further characterized.

[Phenyl-U-¹⁴C] or [cyclohexane-2-¹⁴C]-mesotrione was applied at 0.308 kg ai/ha (T1, characteristic of pre-emergence) and 0.462 kg ai/ha (T2, characteristic of pre + post-emergence) onto a sandy loam soil, and wheat, soya, endive or radish planted at 30, 120 and/or 300 DAT. Residues in soil declined to 27% AR at 300 DAT. Residues in wheat commodities from the [phenyl-U-¹⁴C] experiment were higher in straw (2.58 mg eq./kg at 30 DAT, T1). In wheat grain, residues were 0.038 mg eq./kg at 30 DAT (T1) and 0.014–0.015 mg eq./kg at 120 and 300 DAT (T2). At 30 DAT (T1), the major identified metabolite was MNBA, with residues ranging from 0.17 to 0.63 mg eq./kg in wheat forage, hay and straw and 0.003 mg eq./kg in grain. AMBA was mostly present as sulphate conjugate (total of 0.67 mg eq./kg in straw), and mesotrione and its 4-OH metabolite were only detected in forage (0.01 mg eq./kg).

At 30 DAT (T1), residues were 0.145 mg eq./kg in soya bean, and 0.46–0.64 mg eq./kg in soya feed. MNBA was 0.17–0.31 mg eq./kg in forage and hay and 0.014 mg eq./kg in soya bean. AMBA levels were 0.02–0.07 mg eq./kg. Residues in endive and radish ranged from 0.037 to 0.053 mg eq./kg at 120 DAT, declining to 0.005 to 0.019 mg eq./kg at 300 DAT (T2). The major residue was MNBA (0.02 mg eq./kg at 120 DAT, T2, in endive and radish tops).

Highest residues from [cyclohexane-2-¹⁴C] experiment were found at 30 DAT, T1: 0.05 - 0.06 mg eq./kg in wheat feed, 0.01 mg eq./kg in wheat grain, and 0.02–0.03 mg eq./kg in soya bean samples. Residues in endive and radish were < 0.01 mg eq./kg. Mesotrione and 4-hydroxy mesotrione were identified in wheat and soya bean feed (< 0.01 mg eq./kg at 30 DAT, T1).

In summary, mesotrione degrades quickly in soil under aerobic conditions. Although mesotrione is relatively stable to hydrolysis at pH 5–9 (less than 10% degradation after 30 days at 25 °C), it degrades rapidly in flooded systems with a half-life of approximately 4 days. Mesotrione metabolites, mainly MNBA, are expected in wheat and soya bean feed, endive and radish root when the crops are planted up to 120 days after the soil is treated with mesotrione at 0.3 kg ai/ha rate or higher. As currently the compound is used at rates lower than 0.3 kg ai/ha, no residues arriving from the use of mesotrione are expected in rotational crops.

Methods of analysis

Mesotrione residues in vegetable crops may be analysed by LC-MS/MS (negative mode, $m/z=338 \rightarrow 291$) after extraction with acetonitrile/water and cleaned up by SPE. Recovery data for mesotrione in maize commodities and cranberries showed good performance (84–114% recovery, 3–21% RSD, $n=3-6$) at the 0.01 mg/kg (LOQ) to 10 mg/kg range. The method was used in various supervised trials, with recovery data for mesotrione and MNBA within the acceptable levels at the LOQ or higher.

A modified QuEChERS LC-MS/MS multi-residue method (no clean up with primary-secondary amine (PSA) is used) was validated for mesotrione in oranges, maize and oilseed rape, with a LOQ of 0.01 mg/kg.

In a reversed-phase HPLC-fluorescence method, mesotrione and MNBA residues are extracted with acetonitrile:water (1:1) and cleaned up on silica SPE. The extract is submitted to reversed phase HPLC, the mesotrione fraction converted to MNBA with H_2O_2 and reduced to AMBA using acidic $SnCl_2$ and the MNBA fraction reduced to AMBA. Each fraction is cleaned-up by C18 SPE, and the AMBA conversion product quantified by HPLC-fluorescence. The method was validated for corn commodities with a LOQ of 0.01 mg/kg.

In a GC-MS method, mesotrione and MNBA residues are extracted from corn commodities with acetonitrile:water (1:1), acidified, partitioned with methylene chloride, which is evaporated and the residue heated with Jones Reagent (Cr^{VI} oxide acid solution) to oxidize mesotrione to MNBA. The total MNBA is extracted with ethyl acetate, evaporated to dryness, and the residue reacted with 2-

iodopropane and potassium carbonate to form isopropyl ester of MNBA for analyse by GC-MS. The method determines both mesotrione and MNBA at a combined LOQ of 0.01 mg/kg.

The acetonitrile:water (1:1) extraction efficiency was radio-validated using incurred radioactive residues in forage. After extraction using a high speed homogeniser, an aliquot was partitioned three times into ethyl acetate, and residues of mesotrione and MNBA quantified by TLC with storage-phosphor autoradiography. Levels of mesotrione and MNBA in forage were similar to the results obtained after exhaustive extraction within the metabolism study.

Mesotrione and MNBA residues are extracted from milk and eggs with acetone and from animal tissues with an acetone:water, the extract acidified, partitioned into methylene chloride, and residues of mesotrione oxidised to MNBA using H₂O₂. MNBA is reduced with acidic SnCl₂ and AMBA determined by reversed phase HPLC-fluorescence detection. The LOQ was 0.01 mg/kg in all matrices. Mesotrione may also be determined in animal matrices using the modified QuEChERS, excluding PSA, at an LOQ of 0.01 mg/kg.

The analytical methods were considered fit for purpose to determine mesotrione alone or in combination with MNBA in plant and animal commodities at a LOQ of 0.01 mg/kg.

Stability under frozen conditions

Residues of mesotrione and/or MNBA in fortified samples of maize commodities, radish root, and soya bean seed at 0.1 mg/kg were stable under frozen conditions for at least 32 months (at least 80% of the residues remained, quantified as AMBA by HPLC-FL). Samples of blueberry, asparagus, sugarcane and okra fortified with mesotrione at 1.0 mg/kg were shown to be stable for at least 13 months when stored frozen (quantified by HPLC-MS/MS). The residue trials reports also include additional information on storage stability, and the samples were stored within the period that guaranteed the integrity of the residues at the time of analysis.

Definition of the residue

Metabolism studies conducted in cow, swine and poultry fed with ¹⁴C mesotrione at 6 to 11 ppm showed higher residues in liver and kidney, and ranged from 0.01 to 0.08 mg eq./kg in muscle, milk and in eggs. When detected, mesotrione was the main residue found in animal commodities, accounting for up to 18% TRR in cow liver and kidney, at least 70% TRR in tissues of swine and poultry, and up to 80% TRR in egg white. When cow was fed with ¹⁴C AMBA, residues reached a maximum of 0.05 mg eq./kg in kidney and fat, with over 60% as AMBA. Residues in other tissues and in milk were < 0.01 mg eq./kg

The Meeting agreed that the residue definition of mesotrione in animal commodities for enforcement and dietary exposure assessment is mesotrione.

The residues do not concentrate in fat and mesotrione has a log P_{ow} of 0.1, confirming that mesotrione is not fat soluble.

Mesotrione is a herbicide that can be applied to the soil pre and/or post emergence of the plant, with exception of cranberry, for which the use is foliar. The compound is rapidly degraded in soil. Metabolism study showed residues in cranberry fruits mostly as mesotrione (over 60% TRR) and AMBA (over 20% TRR). Metabolism studies conducted in tolerant soya bean, maize, rice and peanut showed higher residues in feed commodities, mostly as mesotrione (up to 28% TRR in rice tops), MNBA (up to 24% TRR in soya bean forage) and AMBA (up to 29% TRR in maize fodder). Total residues in edible commodities were low (≤ 0.03 mg eq./kg) and when characterized, showed mesotrione as the main residue.

The Meeting concluded that MNBA and AMBA appear to be of low toxicological concern. When the information was available, MNBA was not detected in any sample from the residue trials.

The Meeting agreed that mesotrione is an adequate marker for the uses of mesotrione in plants and is suitable for dietary intake assessment

The Meeting agreed in the following residue definition for both plant and animal commodities for enforcement and dietary risk assessment: *Mesotrione*

The residues are not fat soluble.

Residues of supervised residue trials on crops

Cranberry

GAP in USA for cranberries is 2 broadcast foliar applications at 0.28 kg ai/ha, PHI 45 days. In five trials using 2 applications, the first being at 0.388 kg ai/ha, residues were: < 0.01 mg/kg (5), indicating that no residues are expected when the product is applied at the GAP rate.

The Meeting agreed to recommend a maximum residue level of 0.01* mg/kg, and a STMR of 0 mg/kg for mesotrione in cranberries

Bush berries and cane berries

GAP in USA for bush and cane berries is 1 post-direct spray at 0.21 kg ai/ha before bloom, with no PHI specified.

In one trial conducted in blueberry in USA according to GAP (application at BBCH 59), residues were < 0.01 mg/kg (77 DAT). In five other trials where the application was done after bloom residues at 32 to 88 DAT were < 0.01 mg/kg.

In four trials conducted with raspberry at GAP, residues at 32 to 88 DAT were < 0.01 mg/kg (4) at 52 to 83 DAT.

As no residues above the LOQ were found even in the late application trials, the Meeting agreed to estimate a maximum residue level of 0.01* mg/kg and a STMR of 0 mg/kg for bush berries and cane berries

Okra

In USA, mesotrione can be applied either at pre-emergence (0.21 kg ai/ha) or post emergence (0.105 kg ai/ha). PHI in both cases is 28 days. Five post-emergence trials conducted according to GAP gave residues < 0.01 mg/kg (5).

The Meeting agreed to recommend a maximum residue level of 0.01* mg/kg, and a STMR of 0.01 mg/kg for mesotrione in okra.

Sweet corn

Mesotrione is registered in Germany for post-emergence use on sweet-corn (BBCH 12–18) at 0.15 kg ai/ha. In four trials conducted in France at this GAP rate gave residues were: < 0.01 mg/kg (4) in the kernels and in the cob at 38 to 61 DAT.

In USA, mesotrione can be used in sweet corn via three application regimes: 1) one pre-emergence application at 0.27 kg ai/ha, 2) two post emergence applications, with a maximum of 0.21 kg ai/ha; or 3) 1× pre + 1× post emergence, with a maximum of 0.27 kg ai/ha. In all cases, the PHI is 45 days. The second application should be done up to the 8 leaf stage. In one trial, conducted according to regime 2, residues in the ears were: < 0.01 mg/kg (2); other two trials conducted at the same rate residue were the same 28 to 32 DAT. In 12 trials conducted at a higher rate (0.48 to 0.50 kg ai/ha; regimes 1 or 2 residues were: < 0.01 mg/kg from 23 to 36 DAT.

Although only one trial was conducted in USA according to GAP, 14 trials conducted at higher rates and/or lower PHI showed that no residues are expected in the ears of sweet corn after treatment according to GAP.

The Meeting agreed to estimate a maximum residue level of 0.01* mg/kg and a STMR of 0 mg/kg for mesotrione in sweet corn (kernels plus cob without husk).

Soya bean, dry

In USA, GAP for mesotrione in conventional soya is one pre-emergence application at 0.21 kg ai/ha, with no PHI specified. In 20 trials conducted according to GAP, residues at 117 to 174 DAT were < 0.01 mg/kg (20). Three trials conducted at higher rates (0.6–1 kg ai/ha) gave the same results.

GAPs for mesotrione tolerant soya are i) one pre-emergence or ii) early post-emergence (up to BBCH 13) application at 0.225 kg ai/ha, or iii) one pre + one post emergence application (BBCH 14–60) at 0.225 kg ai/ha and 0.125 kg ai/ha, respectively. Forty seven trials were conducted with tolerant soya using application using regimes 2 or 3, residues in the mature seeds were: < 0.01 (44) and 0.02 (3) mg/kg.

Using the data from trials conducted in tolerant crops, the Meeting agreed to estimate a maximum residue level of 0.03 mg/kg and a STMR of 0.01 mg/kg for mesotrione in soya bean, dry.

Asparagus

In the USA, mesotrione can be use in asparagus either as a pre-emergence application on the soil surface at 0.27 kg ai/ha in the spring prior to spear emergence, one application after completion of harvesting directed to the weed at 0.105 kg ai/ha, or both at a maximum of 0.27 kg ai/ha. In eight trials conducted in USA using the pre-emergence GAP, residues at 8 to 18 DAT were < 0.01 mg/kg (8). In 16 other trials the application was done after emergence of the plant.

The Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0.01 mg/kg for mesotrione in asparagus.

Rhubarb

In USA, mesotrione can be use in rhubarb as pre-emergence application on the soil surface prior to any spring green-up at 0.21 kg ai/ha and 21 days PHI. In four trials conducted at GAP rate, residues at 28 to 42 DAT were < 0.01 mg/kg. Four trials were conducted at higher rates and gave the same result.

As the PHI is not relevant to a pre-emergence application, the Meeting agreed to estimate maximum residue level of 0.01* mg/kg and a STMR of 0.01 mg/kg for mesotrione in rhubarb.

Maize

Mesotrione is registered in Germany for post-emergence use on maize (BBCH 12–18) at 0.15 kg ai/ha. In two trials conducted in Germany and UK at this GAP gave results at 112 to 143 DAT of < 0.01 mg/kg (2).

In the USA, mesotrione can be used in maize in three application regimes: 1) one pre-emergence at 0.27 kg ai/ha, 2) two post emergence, with a maximum of 0.21 kg ai/ha; or 3) 1× pre + 1× post emergence, with a maximum of 0.27 kg ai/ha. The second application should be done up to the 8 leaf stage. In all cases, the PHI was 45 days. Eight trials were conducted in Canada and the USA using regime 1 and 32 trials using regime 3 at rates higher than USA GAP. Grain harvested at 68 to 145 DAT gave residues < 0.01 mg/kg.

The results from North American trials conducted at higher rate show that no residues are expected in maize grain after treatment according to GAP.

The Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0 mg/kg for mesotrione in maize grain.

Millet

Mesotrione is registered in the USA as one pre-emergence use at 0.21 kg ai/ha, and no PHI specified. In five trials conducted according to GAP residues were: < 0.01 mg/kg (5) in millet grain (84 to 132 DAT).

With the support from the data from other cereals, the Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0 mg/kg for mesotrione in millet grain.

Oat

Mesotrione is registered in USA either as one pre-emergence use at 0.21 kg ai/ha or as a post-emergence application at 0.105 kg ai/ha. PHI is 50 days. In sixteen post-emergence trials conducted at GAP, residues in oat grain were < 0.01 mg/kg (16). Two trials conducted at up to 5 times the rate gave the same results.

The Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0 mg/kg for mesotrione in oat grain.

Rice

Mesotrione is registered in paddy rice in Republic of Korea as post-planting into the water (5–7 days after transplanting) at 1×0.09 kg ai/ha and no PHI specified. Ten trials were conducted in Republic of Korea and Japan using either a single application at higher rate, two applications at the GAP rate and/or applying latter in the season. In all cases, residues at 45 to 140 DAT were < 0.01 mg/kg. Although the trials were not according to GAP, these results indicate that no mesotrione residues are expected when the product is used according to GAP.

The Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0 mg/kg for mesotrione in rice grain, husked.

Sorghum

The registered use for mesotrione in sorghum in the USA is one pre-emergence application at 0.224 kg ai/ha up to 21 days before planting. In nine trials conducted according to GAP, residues at 78 to 134 DAT were < 0.01 mg/kg (9). Twelve post-emergence trials gave the same results.

The Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0 mg/kg for mesotrione in sorghum.

Sugar cane

The GAP for mesotrione in sugarcane in the USA is either two post-emergence applications at 0.10 kg ai/ha to the base of the sugar cane or a combination of one pre- and one post-emergence application not exceeding a total rate of 0.36 kg ai/ha. PHI is 114 days. In twenty four trials conducted according to either of the GAPs in USA gave residues of < 0.01 mg/kg (24) from 30 to 118 DAT. Two trials conducted at 3 or 5× the rate gave the same results within 114 days PHI.

In South Africa, GAP is a single early post-emergence at 0.15 kg ai/ha, and 181 days PHI. In four trials conducted at higher rate no residues were detected.

The Meeting agreed to estimate a maximum residue level of 0.01*mg/kg and a STMR of 0 mg/kg for mesotrione in sugar cane.

Linseed

Mesotrione is registered in the USA for linseed at one pre or one post-emergence application at 0.21 kg ai/ha, and no PHI specified. Five pre-emergence trials conducted according to GAP gave residues of < 0.01 mg/kg (5). Two post-emergent trials conducted at higher rates gave the same result.

The Meeting agreed to estimate a maximum residue level of 0.01* mg/kg and a STMR of 0.01 mg/kg for mesotrione in linseed.

*Animal feed**Forage*

Mesotrione is registered in Germany for post-emergence use on maize (BBCH 12–18) at 0.15 kg ai/ha, and no PHI specified. In three trials conducted in maize in France, Germany and the UK matching German GAP, residues in stover (remaining plant) at 41–47 DAT were 0.01 mg/kg (3).

In the USA, mesotrione can be used in maize under three application regimes: 1) one pre-emergence at 0.27 kg ai/ha; 2) two post emergence, with a maximum of 0.21 kg ai/ha; or 3) 1× pre + 1× post emergence, with a maximum of 0.27 kg ai/ha. In all cases, PHI was 45 days for forage and stover. The second application should be made up to the 8 leaf stage (or BBCH 19).

In one trial conducted in USA according to GAP, residues in maize forage were 0.12 mg/kg.

Mesotrione is registered in USA in millet as one pre-emergence use at 0.21 kg ai/ha. In five trials conducted at GAP, residues in forage were < 0.01 mg/kg (5).

The Meeting estimated a median residue and a highest residue of 0.01 mg/kg for mesotrione in millet forage

Mesotrione is registered in oats in USA either as one pre-emergence use at 0.21 kg ai/ha or as post-emergence application at 0.105 kg ai/ha. In 16 pre-emergence trials and 16 post-emergence US trials matching GAP, residues in oat forage were < 0.01 mg/kg (32).

The Meeting estimated a median residue and a highest residue of 0.01 mg/kg for mesotrione in oat forage.

The registered use for mesotrione in sorghum in USA is one pre-emergence application at 0.224 kg ai/ha up to 21 days before planting. In 13 trials conducted according to GAP, residues in sorghum forage were < 0.01 mg/kg (13).

The Meeting estimated a median residue and a highest residue of 0.01 mg/kg for mesotrione in sorghum forage.

Hay

In 16 pre-emergence trials and 16 post-emergence trials conducted in oats in USA, matching GAP, residues in oat hay were < 0.01 mg/kg (32). Post-emergence application trials gave the same results.

In five trials conducted in millet at GAP, residues in hay were < 0.01 mg/kg.

The Meeting estimated a median residue of 0.01 mg/kg and a highest residue of 0.01 mg/kg for mesotrione in oat hay and millet hay.

Straw

Mesotrione is registered in paddy rice in Korea as post-planting into the water (5–7 days after transplanting) at 1×0.09 kg ai/ha and no PHI specified. In eight trials conducted in Japan at this GAP gave residues in straw of < 0.002 mg/kg.

The Meeting agreed to estimate a maximum residue level of 0.01* mg/kg for mesotrione in rice straw and fodder, dry

The Meeting estimates a median residue and a highest residue of 0.01 mg/kg for mesotrione in rice straw

Fate of residues during processing

A processing study conducted with soya bean containing 0.04 mg/kg mesotrione showed residues of 0.01 mg/kg in the meal and 0.07 mg/kg in flour, with calculated processing factors of 0.25 and 1.8 mg/kg, respectively. Residues in soya oil, milk, tofu, sauce and miso were < 0.01 mg/kg, with an estimated processing factor of < 0.25. Based on a STMR of 0.01 mg/kg for soya bean, dry, the Meeting estimated a STMR-P of 0.018 mg/kg in soya bean flour, and of 0.002 mg/kg for soya oil, milk, tofu, sauce and miso.

Residue in animal commodities

Farm dietary burden

The Meeting estimated the dietary burden of mesotrione in farm animals on the basis of the OECD Animal Feed data published in the 2009 FAO Manual, and the median and highest residue levels estimated at the present Meeting for oat and sorghum forage, oat hay and rice straw.

The maximum and the mean dietary burden was 0.03 ppm for cattle, 0.01 and 0.001 ppm, for swine, respectively, and 0 ppm for poultry.

Animal commodity maximum residue level

No feeding study on mesotrione was provided to the Meeting. The metabolism study conducted with cattle at 10 ppm, gave residues of mesotrione up to 0.02 mg/kg in tissues and milk. Swine fed with radiolabeled mesotrione at 6 ppm gave residues of 1.5 mg/kg in liver, 0.09 mg/kg in kidney and 0.01 mg/kg in muscle. Interpolation of the residues found in the metabolism studies to what would be expected at the calculated dietary burden indicates that no residue will exceed 0.0025 mg/kg (in swine liver).

The Meeting agreed to estimate a maximum residue level of 0.01* mg/kg for mesotrione in milks, edible offal (mammalian) and meat (from mammals other than marine mammals).

The Meeting also estimated a STMR of 0 for mesotrione in milk and meat (from mammals other than marine mammals), and edible offal (mammalian).

Metabolism study conducted with poultry at 11 ppm showed mesotrione residues of 1.1 mg/kg in liver, 0.03 mg/kg in fat, < 0.01 mg/kg in meat and 0.02 mg/kg in eggs. As the dietary burden for poultry is 0, the Meeting agreed to estimate a maximum residue level of 0.01* mg/kg, and a STMR and a HR of 0 mg/kg for mesotrione poultry meat, poultry offal and eggs.

RECOMMENDATIONS

Definition of the residue (for compliance with the MRL and for estimation of dietary intake for plant and animal commodities): mesotrione.

The residue is not fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The IEDI of mesotrione based on the STMRs estimated by this Meeting for the 17 GEMS/Food regional diets were 0% of the maximum ADI of 0–0.3 mg/kg bw (see Annex 3 of the 2014 Report). The Meeting concluded that the long-term dietary intake of residues of mesotrione is unlikely to present a public health concern.

Short-term intake

The 2014 JMPR decided that an ARfD is unnecessary for mesotrione. The Meeting therefore concluded that the short-term intake of residues of mesotrione is unlikely to present a public health concern.

METRAFENONE (278)

The first draft was prepared by Mr David Lunn, Food Safety Authority, Wellington, New Zealand

EXPLANATION

Metrafenone is a benzophenone fungicide, active mainly against powdery mildews and eyespot, inhibiting mycelium growth, leaf penetration, haustoria formation and sporulation.

Authorisations exist for the use of metrafenone on cereals, grapes, strawberries and fruiting vegetables in over 50 countries in Europe, the Americas, Asia and the Pacific.

Metrafenone was scheduled by the Forty-fifth Session of the CCPR as a new compound for consideration by the 2014 JMPR. Residue and analytical aspects of metrafenone were considered for the first time by the present meeting. The manufacturer submitted studies on metabolism, analytical methods, supervised field trials, processing, freezer storage stability, environmental fate in soil and rotational crop residues.

In this evaluation, the values presented in the tables are as reported in the various studies, but in the accompanying text, they have generally been rounded to two significant digits.

IDENTITY

ISO common name:	Metrafenone
Code number	BASF 560 F
IUPAC name:	3'-bromo-2,3,4,6'-tetramethoxy-2',6-dimethylbenzophenone
Chemical Abstracts name:	(3-bromo-6-methoxy-2-methylphenyl) (2,3,4-trimethoxy-6-methylphenyl)-methanone
CAS number	220899-03-6
CIPAC number	752
Molecular mass:	409.3
Molecular formula	C ₁₉ H ₂₁ O ₅ Br
Structural formula:	

**PHYSICAL AND CHEMICAL PROPERTIES***Pure active ingredient*

A detailed chemical and physical characterisation of the active ingredient, technical grade and selected metabolites are given in Tables 1 and 2.

Formulations

Formulations of metrafenone are available for use as foliar applications, both as solo products or co-formulated with other actives.

Formulation type	Active substance/s and content	Other active ingredients
SC (Soluble Concentrate)	Metrafenone 300 g/L Metrafenone 500 g/L Metrafenone 100 g/L	— — Epoxiconazole 83 g/L
SE (Suspo-emulsion)	Metrafenone 75 g/L	Fenpropimorph 200 g/L + Epoxiconazole 62.5 g/L

METABOLISM

The Meeting received metrafenone metabolism studies on animals (rats, lactating goats and laying hens), plants (grape, cucumber and wheat), soil and rotational crops. Metrafenone radiolabelled on the bromophenyl or the trimethoxyphenyl groups were used in these studies. The label positions are given below:

[Bromophenyl-6-¹⁴C]-metrafenone
(Bromophenyl-label)

* = location of the radiolabel

[Trimethoxyphenyl-U-¹⁴C]-metrafenone
(Trimethoxyphenyl-label)

* = location of the radiolabel

Major metabolites identified in these studies and discussed in this evaluation are listed below.

Table 3 Major metrafenone metabolites identified in plant, animal and soil matrices

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens, following oral dosing with [bromophenyl-6 (¹⁴C)] metrafenone or [trimethoxyphenyl-(U-¹⁴C)] metrafenone. As no cleavage of the molecule was observed in these metabolism studies, the results for both radiolabels are reported together.

Rats

The metabolism of metrafenone in rats was evaluated by the WHO Core Assessment Group of the 2014 JMPR. Absorption of metrafenone is rapid and complete (> 88%) at the low dose of 10 mg/kg bw, limited to 15–20% at the high dose of 1000 mg/kg bw suggesting saturation of the absorption processes. Metrafenone is widely distributed in the body, with highest residue levels mainly found in the gastro-intestinal (GI) tract, liver and fat. There is no evidence of accumulation. The labelled material is relatively rapidly excreted into the GI tract via the bile (85–90%) resulting in extensive excretion via faeces. Excretion via urine is relatively low (5–6% depending on radiolabel position), and even lower at the high dose level (*ca.* 1%). Metrafenone is extensively metabolised, with most of the radioactivity (*ca.* 80%) not identified, consisting of many (11–26) different components and totalling < 0.1 ppm at the low dose and < 1 ppm at the high dose. The identified metabolites, mostly < 1.0 mg eq/kg, included metrafenone and glucuronic acid conjugates in fat, liver and kidney.

Lactating goats

In a study reported by Fung, 2002 [Ref: 2002/7005114], the metabolism and distribution of [¹⁴C]metrafenone were investigated in lactating goats following repeated oral administration of radiolabelled metrafenone in gelatin capsules over five consecutive days at nominal dose levels equivalent to 10 ppm and 70 ppm in the diet (based on an average feed consumption of 2 kg per goat per day). The goat body weights ranged from 46–55 kg prior to treatment and 45–54 kg at sacrifice (21–23 hours after the last dose), and mean feed consumptions ranged from 1.5–2.3 kg.

[Bromophenyl-6-¹⁴C]-metrafenone, enriched with C¹³ (49%) as a mass marker to assist in mass spectrometric analysis of metabolites was administered to two goats at daily doses equivalent to 13 ppm or 87 ppm feed and [trimethoxyphenyl-(U-C¹⁴)] metrafenone enriched with C¹³ (49%) was administered to two goats at doses equivalent to 8 ppm or 87 ppm in the diet.

The majority of the radioactivity (76–86% AR) was excreted, mainly through the faeces. The highest residue levels were found in liver (0.21–0.23 mg eq/kg at the lower dose and 0.72–1.3 mg eq/kg at the higher dose) and kidney (0.05–0.06 mg eq/kg at the low dose and 0.16–0.33 mg eq/kg at the higher dose). Residues were significantly lower in fat (0.015–0.022 mg eq/kg)

and were < 0.01 mg eq/kg in muscle and up to 0.01 mg eq/kg in milk regardless of the dose rate. In milk, a plateau level not higher than 0.01 mg eq/kg was reached within about 3 days.

Table 4 Total radioactive residues in dissected tissues, excreta and milk of lactating goats following five daily oral administrations of [¹⁴C]metrafenone

	Treatment Groups

Milk (Day 5)	< 0.005	< 0.005	0.006	0.01
Sample type	Excretion (% total dose)			
Urine + Faeces	85.7%	84.0%	82.2%	75.7%

Liver and kidney samples from the higher dose groups were sequentially extracted with acetonitrile, acetonitrile:water (80:20), methanol:acetone:water:trimethylamine (24:24:50:2) and methanol:water:trifluoroacetic acid (99:30:1). The post extraction solids were subject to pepsin hydrolysis followed by extraction with hydrochloric acid in methanol. Fat samples were triple-extracted with methanol. Milk samples were extracted with acetone, concentrated, redissolved in acetonitrile and partitioned with hexane, with the aqueous layer retained and the hexane extract partitioned with methanol. The two aqueous layers were then combined for analysis. The sample extracts were analysed by HPLC with a variable wavelength detector and radio detector within 15 days of sampling and the fractions were isolated for LC-MS analysis. A storage stability study indicated that residues of the glucuronide metabolites were stable in frozen storage for up to 3 months in liver, 6 months in kidney and that metrafenone was stable for up to 10 months in fat.

In liver, 95–97% TRR was able to be extracted (0.7–1.2 mg eq/kg) and 98–101% TRR (0.15–0.33 mg eq/kg) was extractable from kidney. The two sequential extractions of milk with acetone accounted for 99.9% TRR (ca 0.01 mg eq/kg).

Metrafenone was the predominant residue in fat (0.01–0.02 mg eq/kg), making up 60–85% TRR but was only found at 2.7–4.4% TRR in liver and kidney (0.025–0.035 mg eq/kg in liver and 0.005–0.014 mg eq/kg in kidney).

In liver and kidney, the predominant residues were two metabolites (CL 1500698 and CL 1023363) which together represented 15–21% of the TRR in liver (max 0.27 mg eq/kg) and 26–28% of the TRR in kidney (max 0.09 mg eq/kg). An additional group of three metabolites (CL 1023361, CL1023362 and CL 1500702) were found at up to 13% of TRR (0.17 mg eq/kg) in liver. While a number of other metabolites were present, these generally made up < 10% TRR.

In milk, residues of parent (24% TRR) and metabolites (up to 10% TRR) were all < 0.005 mg eq/kg and no metabolites were found in fat above 0.005 mg eq/kg (9% TRR).

In summary, when goats were treated orally for five consecutive days with metrafenone, the majority (76–86%) of the dose was excreted, with TRR being highest in liver and 0.01 mg eq/kg or less in milk and muscle. Metrafenone made up about 3–4% of the TRR in liver and kidney and was the main component in fat. Most of the residues in liver and kidney were the glucuronide conjugates of metrafenone (CL 1500698, CL 1023363) which together made up 15–30% TRR, with several other conjugates also found at lower levels.

The proposed metabolic pathway includes hydroxylation and demethylation of the methyl groups and the phase II glucuronidation of the hydroxylated metabolites to various mono-O-glucuronides, qualitatively similar to the metabolic pathway in the rat.

Figure 1 Metabolic pathway in lactating goats

Laying hens

In a study reported by Hoefs, 2008 [Ref: 2005/1026047], the metabolism and distribution of [¹⁴C]metrafenone were investigated in laying hens following repeated oral administration of radiolabelled metrafenone in gelatin capsules over twelve consecutive days at nominal dose levels equivalent to 12 ppm in the diet (based on an average feed consumption of 120 g per hen per day). The actual dose rates for the two groups of eight laying hens were 14.2 mg/kg (trimethoxyphenyl label) and 13.9 mg/kg (bromophenyl label). Average body weights for the two dose groups were 1.55 kg and 1.64 kg prior to treatment and 1.58 kg and 1.66 kg at sacrifice (22 hours after the last dose), and mean feed consumptions ranged from 102–185 g/day.

Overall recoveries of radioactivity were approximately 96 and 86% of the total applied dose for the trimethoxyphenyl and bromophenyl labels, respectively. Radioactivity was rapidly eliminated within 24 hours with 95% (trimethoxyphenyl label) and 86% (bromophenyl label) of the administered dose recovered in the excreta. About 0.25% AR was found in eggs and 0.06–0.09% AR was measured in liver. Radioactivity in skin + fat was < 0.01% AR and muscle contained 0.003% AR. TRRs in eggs reached a plateau about day 9–10.

Table 7 Total radioactive residues in dissected tissues, excreta and eggs of laying hens following 12 daily oral administrations of [^{14}C]metrafenone

Tissue and egg samples were extracted sequentially with three aliquots of methanol and two aliquots of water, with the combined methanol extracts and the combined water extracts being analysed by LSC. Residues in the post extraction solids were determined by LSC after combustion. Eggs were homogenized with an equal weight of water before extraction.

Extraction of pooled eggs (days 9–12) yielded 63% TRR (0.06–0.07 mg eq/kg) in the methanol extract and a further 17% (0.017 to 0.02 mg eq/kg) in water, giving a total of 80% TRR (0.079 to 0.094 mg eq/kg) as extractable residues. Unextractable residues accounted for about 20% TRR.

Low levels of radioactivity (0.01–0.013 mg eq/kg) were found in muscle with about 27–31% TRR extracted with methanol and a further 1–1.8% TRR extracted in water. Unextractable residues accounted for about 68–72% TRR (0.007 to 0.009 mg eq/kg).

About 58–61% TRR in skin + fat was able to be extracted and overall extractability in liver was about 30% TRR.

HPLC analysis of acetone-extracted egg samples and bile extracts stored for more than 19 months showed comparable metabolite patterns to those from samples analysed within 8 days of extraction.

^d Sum of all extracts and post extraction solids

Characterisation of metabolites was performed by LC-MS and LC-MS/MS analysis. Metrafenone was found only in eggs (1.8–2.2% TRR) and in skin + fat (1.9% TRR). A comparison with the retention times and metabolite patterns for the components in the methanol extract of excreta (bromophenol-label), allowed the assignment of the metabolite M560F06 in the skin + fat extracts (at about 6–11% TRR) and tentatively in eggs (unquantifiable). With the exception of one unknown component in eggs (found at about 14% TRR and 0.015 mg eq/kg) all other components were below 10% TRR (< 0.01 mg eq/kg) in all tissues and eggs.

Table 9 Residues of metrafenone and other characterised components in hen matrices following following 12 daily oral administrations of [^{14}C]metrafenone.

ⁱ Includes six peaks, each < 4.5% TRR

^j Includes five unknown peaks, each < 4.1% TRR

In summary, after 12 consecutive daily oral administrations of [¹⁴C]metrafenone to laying hens, there was rapid absorption and almost complete excretion within 24 hours. The total radioactive residues in edible tissues and organs were about 0.11 mg eq/kg in eggs, up to 0.57 mg eq/kg in liver, about 0.012 mg eq/kg in muscle, and up to 0.1 mg eq/kg in skin with adhering fat.

Metrafenone made up about 2% of the TRR in eggs and skin + fat (0.002 mg/kg) and the M560F06 metabolite was tentatively identified in skin + fat and eggs. The proposed metabolic pathway for metrafenone involves:

Hydroxylation at the bromophenyl ring or the attached methyl group to form M560F05, which can be demethylated and conjugated with glucuronic acid in bile to form M560F07

Demethylation at the trimethoxyphenyl ring to form M560F06, with glucuronic acid conjugation in bile to form the metabolites M560F08 and M560F09

Oxidation of the methyl group on the bromomethoxytoluene ring to the carboxylic acid (via the respective isomer of M560F05) to form M560F03.

Figure 2 Metabolic pathway of metrafenone in laying hens

Plant metabolism

The Meeting received plant metabolism studies on grapes, cucumbers and wheat following foliar treatments with with [bromophenyl-6 (^{14}C)] metrafenone or [trimethoxyphenyl-(U- ^{14}C)] metrafenone.

Grape

In a study reported by Class & Schluter, 2001 [Ref: 2001/7000342], the metabolism of metrafenone in outdoor grapevines was investigated following five foliar applications at 10–11 day intervals of about 0.2 kg ai/ha of [^{14}C]metrafenone (trimethoxyphenyl-label or bromophenyl-label, both being diluted with ^{13}C as a mass marker). Grape and leaf samples were taken immediately after each application; nineteen days after the last treatment (61 days after the first application, BBCH 85) and at maturity, 35 days after the last application (77 days after the first application, BBCH 89).

Grapes from the second and third samples were separated into juice and marc, and the marc was sequentially extracted with acetone, methanol:water (4:1) and then water. Leaves were surface washed with acetone and then sequentially extracted with acetone, methanol:water (4:1) and water. The post-extraction solids from the mature leaf and grape samples were further extracted with HCl:methanol and then sequentially treated with pepsin, cellulose, surfactant and refluxed with 6 M HCl. Radioactivity was analysed by LSC or combustion LSC and characterisation of the radioactive residues was conducted by TLC and HPLC-UV and HPLC-MS.

TRRs (calculated from extracted and non-extracted radioactivity) immediately after the last treatment were 0.6–0.77 mg eq/kg in grapes immediately after the last treatment and about 40 mg eq/kg in leaves. At maturity, 35 days after the last treatment, TRRs were 0.28–0.44 mg eq/kg in grapes and 25–38 mg eq/kg in leaves (with about 39–45% TRR present in the leaf surface wash).

NA = not applicable

Characterisation of the residues in juice indicated the presence of several metabolites more polar than parent. One of these, CL197675, made up about 9% TRR (0.006 mg eq/kg), with the others present at lower concentrations. Metrafenone was not found. Low levels of radioactivity precluded further investigation.

In pomace extracts, metrafenone was the major residue, making up about 23–25% TRR (0.06–0.11 mg eq/kg), with other, more polar fractions not exceeding 0.05 mg eq/kg (12–17% TRR). These fractions were not investigated further.

Analysis of leaf samples showed rapid metabolism to several polar compounds. At maturity (35 days after the last treatment), unchanged parent had decreased to about 15% TRR (5.8 mg/kg) and 11% (2.7 mg/kg) for the bromophenyl-label and trimethoxyphenyl-label, respectively. None of the degradation products could be positively identified against the reference standards. However analysis of fragmentation patterns allowed for the proposal of several metabolite structures, identified as CL3000402, CL379395 and CL1500836. As with grapes, no other extracts could be investigated due to low levels of radioactivity.

35 DAT5	5.8	15.2	32.33	84.8	2.7	11.0	22.04	89.1

In summary, after five foliar applications of about 0.2 kg ai/ha of [^{14}C]metrafenone, TRRs in mature grapes, 35 days after the last application were about 0.3–0.4 mg eq/kg, with parent being the major component (0.06 to 0.11 mg/kg) in the marc, but not found in juice. Unidentified polar

metabolites did not exceed 0.05 mg eq/kg (12–17% TRR) in mature grape pomace and in juice, CL197675 made up about 9% TRR (0.006 mg eq/kg).

The proposed metabolic pathway involves oxidation of the methyl groups on the bromophenyl and trimethoxyphenyl rings to yield the corresponding aldehydes. In the case of the bromophenyl ring, the aldehyde can undergo further oxidation to the carboxylic acid, cyclization to form the lactone, and/or dehalogenation to form the des-bromo aldehyde.

Figure 3 Metabolic pathway for metrafenone in grapevines

Cucumber

A metrafenone metabolism study in cucumber was reported by Grosshans & Ockert, 2010 [Ref: 2010/1054630]. Cucumber plants were treated with two foliar applications equivalent to 0.2 kg ai/ha (48 g ai/100L) [¹⁴C]metrafenone (trimethoxyphenyl-label), 17 and 3 days before harvest. Leaf samples were taken immediately after the first application and cucumbers were sampled just before the second application (14 DAT1). At maturity, 3 days after the second application, whole plants (without roots) were sampled to investigate residues in cucumber peel, pulp and the vines.

Samples were sequentially extracted three times with methanol and twice with water and radioactivity was measured by LSC or combustion LSC and characterisation of the radioactive residues was by HPLC. Samples were stored frozen for up to 50 days before extraction and a further 36 days before analysis.

TRRs (calculated from extracted and non-extracted radioactivity) in leaves sampled directly after the first application were 6.4 mg eq/kg. In cucumber fruit sampled at maturity, 3 days after the second application, the TRR in whole fruit was 0.05 mg eq/kg with 0.013 mg eq/kg in pulp and 0.26 mg eq/kg in the peel. The TRR in the vines (rest of the plant) was 8.8 mg eq/kg.

Methanol extraction efficiency ranged from 87.5% to 93% in fruit, 91% in peel and pulp, 98.8% in leaves (0DAT1) and 92.6% in vines (rest of plant) at harvest. Up to an additional 1.6% TRR in cucumbers (whole fruit, peel and pulp) was able to be extracted with water.

Metabolite identification and characterisation in leaves (0DAT1) and fruit (14DAT1) was achieved by HPLC co-chromatography with metrafenone and peak assignment in the other samples was done by comparison of the retention times and the HPLC elution profiles with those of the extracts investigated by co-chromatography.

Metrafenone was the main residue component in leaves immediately after the first application (95% TRR) and represented 80% TRR in vines. In fruit at harvest, metrafenone was also the predominant residue, making up 42% TRR (0.022 mg/kg) in whole fruit, 61% TRR (0.16 mg/kg) in peel. In pulp, metrafenone was found at 0.0009 mg/kg or 6.5% TRR, with the majority of the residue being polar or medium polar components (23 peaks), each below 0.002 mg eq/kg.

^h Vines = Whole plant without roots and fruit

In summary, after two foliar applications 0.2 kg ai/ha [¹⁴C]metrafenone to cucumber plants, TRR in mature fruit, sampled 3 days after the second application were about 0.05 mg/kg (TRR), with 0.013 mg eq/kg present in pulp and 0.26 mg eq/kg in peel. More than 89% TRR was able to be extracted with methanol. Metrafenone was the only identified residue component, making up 42% of

the TRR in mature fruit (0.02 mg/kg), mostly in the peel (61% TRR, 0.16 mg/kg). Numerous polar and medium polar metabolites at low concentrations (each less than 9% TRR) were characterized by their retention time behaviour in HPLC or by extractability with water.

Wheat

The metabolism and distribution of metrafenone in wheat was investigated in a study reported by Zulalian, 2002 [Ref: 2002/7005253]. Spring wheat plants were treated with three foliar applications of [¹⁴C]metrafenone (trimethoxyphenyl-label or bromophenyl-label, both being diluted with ¹³C as a mass marker), at nominal rates of 0.3, 0.3 and 0.2 kg ai/ha, applied at 13–14 day intervals with the last application being 35 days before harvest.

Wheat plants (without roots) were sampled immediately after each application and forage samples were also taken 3 days after the first application. Wheat plants (hay) were cut 14 days after the second application and dried for about 33 hours before being collected as samples. Straw (including chaff) and seed were collected at mature harvest, 35 days after the last application. Analysis for total radioactive residues (TRR) was conducted by combustion and liquid scintillation counting (LSC) and residues were characterized and identified by HPLC and where possible, by mass spectrometry.

Highest radioactive residues were found in the straw (ca 8 to 9 mg eq/kg), with similar levels (5–8 mg eq/kg) in forage and straw, and lower levels of 0.2 to 0.4 mg eq/kg measured in grain. Methanol:water extraction was able to release about 95% TRR in forage, 78% TRR in hay, 61% TRR in straw and 35% TRR in grain. Additional extraction with hexane and acidified methanol was able to release a further 12–14% TRR in grain.

Metrafenone was the main component of the TRR in all matrices, making up 3–7.7% TRR in grain (0.013–0.016 mg/kg), 59–64% TRR in forage (3.1–5.3 mg/kg), 13–26% TRR in hay (1.1–2.0 mg/kg) and 7.7–14% TRR in straw (0.64–1.2 mg/kg). While TRRs in several regions of interest were each found at 10–20% TRR, these were described as metabolites more polar than the parent compound and consisted of up to five unidentified components. All other components in all matrices were present at less than 10% TRR. Significant single metabolites in forage, hay and straw were identified as the CL 3000402, CL 434223 and CL 1500831, each present at less than 7% TRR

(0.6 mg eq/kg) in these matrices. In grain, although no identified metabolites were found above 0.004 mg eq/kg, up to half the TRR was not solvent-extracted and while additional residues were released by alpha-amylase treatment of the post-extraction solids, these were not quantified. However HPLC analysis of the alpha-amylase extract showed that the radioactive residues were made up of multiple minor components.

^a Consisting of at least five minor unknown components

In summary, after three foliar applications of [¹⁴C]metrafenone to wheat (totalling 0.8 kg ai/ha), highest radioactive residues (up to 9 mg eq/kg) were found in hay and straw, with the lowest residues found in the grain (0.2 to 0.4 mg eq/kg). The TRR in forage (3DAT1) amounted to ca. 5 to 8 mg eq/kg. Metrafenone was the major component in all matrices, comprising up to 64% TRR in forage, up to 26% TRR in hay, up to 14% in straw and up to about 8% TRR in grain. In forage, hay and straw, other characterized or identified metabolites represented less than 10% TRR. In grain, no identified metabolites were found above 0.004 mg eq/kg and although only about 50% of the radioactivity was extracted, further investigation showed that the unextracted residue was made up of multiple minor components.

The proposed metabolic pathway involves oxidative demethylation of the parent to form CL 434223, CL 376991, and CL 377160 and subsequently CL 1500835. The lactones CL 3000402 and CL 1500831 are formed by oxidation at each benzylic carbon followed by cyclization. Oxidation of the methyl groups on either of the two phenyl rings gives rise to the aldehyde derivatives, CL 1500833, CL 1500834 and CL 1500837. Aromatic oxidation and oxidative de-methylations can produce CL 1500832. Additionally, CL 1500836 is formed by oxidation at the benzylic carbon of the bromophenyl ring followed by reductive de-bromination. The oxidations are proposed to be either enzymatic and/or chemical (photolysis) in nature. Subsequent glucoside conjugation reactions yield the conjugates CL 1500838 and CL 1500839 from their corresponding aglycones, CL 434223 and CL 376991.

Figure 4 Metabolic pathway for metrafenone in wheat

Environmental fate

The Meeting received information the environmental fate and behaviour of metrafenone, including hydrolytic stability, photolysis in aqueous solutions, aerobic metabolism and rotational crop metabolism studies.

Hydrolysis

The hydrolysis of metrafenone was evaluated in a study reported by An, 1999 [Ref: 1999/7000284]. Sterile buffered solutions of 0.2 mg/L [bromophenyl-6-¹⁴C]-metrafenone at pH 4, 7, and 9 were incubated in the dark under sterile conditions at 50 °C, sampled after 5 days and analysed by reversed phase radio-HPLC.

There was no loss of radioactivity during the course of the incubation at any pH values with metrafenone making up 97–106% of the applied radioactivity after 5 days of incubation.

DAT = Days after treatment

Aerobic soil metabolism

In a study reported by Steinfuehrer, 2000 [Ref: 2000/7000152], a silty loam soil (pH 7.5, 2.03% organic C, CEC 18 meq/100 g soil and MWHC 47.3 g water/100 g dry soil) was treated with the 0.9 mg/kg dry soil [trimethoxy-label]-metrafenone or 0.98 mg/kg dry soil [bromophenyl-label]-metrafenone and incubated at 20 ± 2 °C in the dark for up to 210 days. The soil moisture was maintained at about 50% of maximum water holding capacity (MWHC). The application rates corresponded to 0.675 kg ai/ha and 0.735 kg as/ha respectively, assuming a soil mixing depth of 5 cm and a soil density of 1.5 g/cm³.

Duplicate soil samples were taken at treatment and after incubation for 4, 7, 14, 28, 60, 120, and 210 days and exhaustively extracted using acetone, methanol:water (4:1), water, and/or acetonitrile:0.5 N HCl (1:1). The various soil extracts were concentrated by rotary evaporation and analysed separately by radio-TLC (except most water and acetonitrile/HCl extracts, which were not analysed because of low radioactivity content. HPLC and LC/MS were used for metabolite identification. In addition, the non-extracted (bound) radioactivity in the day 210 soil samples was further characterized by fractionation of the extracted soil between fulvic acids, humic acids and humin. The fulvic acid fraction was partitioned into methylene chloride and analysed by TLC.

Between 92–106% of the applied radioactivity (% AR) was able to be recovered and extractable residues accounted for approximately 100% AR up to 14 days, but thereafter decreased steadily to 61% AR after 210 days for both labels. Accordingly, non-extractable (bound) residues increased to 28 and 29% AR at the end of the study. ¹⁴CO₂ reached 3.3% and 2.9% AR after 210 days, showing that both labels were eventually mineralized.

The levels of metrafenone in the extractable residues decreased to 55–57% AR at the end of the 201-day study and the metabolite fraction (< 0.2% AR) detected with TLC in the 210-day methanol/water and water extracts and was shown by HPLC analysis to consist of the substituted benzoic acids CL 197675 and CL 197676, formed by oxidation of the respective methyl group.

The characterization of bound residues in the day 210 samples showed that approximately two-thirds of the radioactivity (18.5–20% AR) was in the humin fraction, while 2–3% AR was in the humic acid fraction and 4–5% AR was in the fulvic acid fraction. Approximately half of the radioactivity in the fulvic fraction was partitioned into methylene chloride and analysed by TLC, which showed a small amount of metrafenone and a polar fraction.

^a Unidentified radioactivity consists of radioactivity in non-analysed water and acetonitrile/HCl extracts, radioactivity remaining at TLC origin and radioactivity lost during sample work-out.

n.a. = not analysed

n.d. = not detected

In a similar study reported by Steinfuehrer, 2000 [Ref: 2000/7000151], three soils (loamy sand, sandy loam, and clay loam) were treated with [bromophenyl-6-¹⁴C]-metrafenone at a concentration of 1.48 mg/kg dry soil (corresponding to field application rates of 1.11 kg ai/ha) and incubated in the dark at 20 ± 2 °C and 40–50% MWHC. Duplicate soil samples taken at treatment time and after incubation for 3, 7, 14, 28, 58, 90, and 120 days were exhaustively extracted with acetone, methanol:water (4:1), and water using ultrasonication. The acetone and methanol:water extracts were concentrated by rotary evaporation and analysed by radio-TLC.

Total recoveries for the three soils were 94–100% of the applied radioactivity and the levels of extractable radioactivity continuously decreased over the incubation period to 67–78% AR after 120 days. Accordingly, increasing amounts of bound residues were formed in the three soils, accounting for up to 17.4–24.8% AR at the end of the 120-day study period. Mineralization was also observed with evolved ¹⁴CO₂ accounting for 2.7 to 5.3% AR after 120 days of incubation for the three soils.

Metrafenone accounted for approximately 90% AR in the extracts at day 0 and slowly decreased to 56.1–68.7 % AR after 120 days. Only one minor metabolite fraction was observed at various sampling times in the three soils, this accounting for less than 0.9% AR and was not identified.

Table 21 Metrafenone residues (%AR) in soils treated with [bromophenyl-6-¹⁴C]-metrafenone and incubated under aerobic conditions in the dark at 20 °C

In a further study reported by Steinfuehrer, 2000 [Ref: 2000/7000150], a loamy sand soil (pH: 6.3, Organic C: 0.72%, CEC: 8 meq/100 g and MWHC: 34.2 g water/100 g dry soil) was treated with [bromophenyl-6-¹⁴C]-metrafenone at a concentration of 1.52 mg/kg dry soil (corresponding to field application rates of 1.14 kg ai/ha) and incubated in the dark at a lower temperature of 10 ± 2 °C and moisture content was maintained at 40–50% MWHC. Duplicate soil samples taken at treatment time and after incubation for 3, 7, 14, 28, 48, 90, and 120 days were exhaustively extracted with acetone, methanol:water (4:1), and water using ultrasonication. The acetone and methanol:water extracts were concentrated by rotary evaporation and analysed by radio-TLC.

Total recoveries were in the range of 100–102% AR and the levels of extractable radioactivity continuously decreased over the incubation period to about 91% AR after 120 days with bound residues increasing to up to 8.2% AR at the end of the 120-day study. Mineralization was also observed, with evolved ¹⁴CO₂ accounting for 1.4% AR after 120 days.

Metrafenone accounted for 93.4% AR at day 0 and slowly decreased to 82.0% AR after 120 days, with no other defined peaks or metabolite fractions observed in the TLC chromatograms at any sampling time.

Table 22 Recovery and distribution of radioactivity in soil treated with [¹⁴C]metrafenone and incubated under aerobic conditions in the dark at 10 °C

n.a. = Not analysed

In summary, metrafenone degraded slowly in the loamy sand, sandy loam and clay loam soils incubated for up to 210 days under aerobic laboratory conditions at 10 °C and 20 °C. About 66–69% AR was still present as the parent compound at the end of the 20 °C study and about 82% AR remaining as metrafenone at the end of the 10 °C study. Calculated half-lives (1st order kinetics) ranged from 182–365 days.

Figure 5 Proposed pathway of degradation in soil under aerobic laboratory conditions for metrafenone

Residues in rotational crops

Rotational crops metabolism

The Meeting received information on the fate of residues in lettuce, radish and canola grown as rotational crops in metrafenone-treated soil.

In an outdoor confined rotational crop study with ¹⁴C labelled metrafenone reported by Zulalian, 2002 [Ref: 2002/7005187], representative leafy vegetable crop (lettuce), root crop (radish) and oil crop (canola) were planted back at various time intervals (30, 60, 90 and 365 days) after a single application of [trimethoxy-label]-metrafenone or [bromophenyl-label]-metrafenone to bare soil at a rate equivalent to 0.625 kg ai/400 L/ha.

Harvested samples were homogenised with dry ice and the TRR determined by combustion of aliquots to yield ¹⁴CO₂, followed by quantification by liquid scintillation counting (LSC). For characterization and identification, samples were extracted with mixtures of methanol:water or hexane and methanol:HCl. The extracts were then subjected to HPLC and resolved into fractions which were

quantified by LSC. Identification was performed by co-chromatography with known reference standards. The TRR of the post extraction solid (PES) was determined either by LSC or combustion.

In general, the highest total radioactive residues (TRR) were found in plants sampled from the 30-day plant back interval, while the lowest residues (< 0.01 mg eq/kg) were detected in plants from the 365 DAT plant back interval. The canola straw/pod contained the highest residues, while very low residues were detected in canola seed at all sampling intervals. In soil, TRR declined by about 50% after 90 days, mostly found in the top 10 cm of soil samples.

Highest TRRs in the 30-day plant back samples residues were 0.048 mg eq/kg in canola straw/pods, 0.008 mg eq/kg in canola seed, 0.023–0.025 mg eq/kg in radish root and top and 0.006 mg eq/kg in lettuce. In the 365 day plant back samples, highest TRRs were < 0.004 mg eq/kg in canola straw/pods, 0.008 mg eq/kg in canola seed, 0.005–0.007 mg eq/kg in radish root and top and < 0.004 mg eq/kg in lettuce.

NA = Not analysed

Characterisation of the radioactive residue in the rotational crop samples containing more than 0.01 mg eq/kg TRR was conducted using reversed phase HPLC/¹⁴C analysis of the solvent extracts. With the exception of canola seed, extraction with methanol:water and methanolic HCl was able to recover 64–88% TRR. Hexane and methanol:water extraction recovered 42–86% TRR in canola seed.

The HPLC results showed that the residue was comprised of unchanged metrafenone and a group of polar compounds (designated ROI 1 (Region of Interest 1)). These were not investigated further because of the low concentrations of the individual peaks. Metrafenone accounted for < 0.005 mg/kg of the TRR in lettuce and radish roots. The major portion of the extractable residues in most of the crops was shown to contain multiple components, all present at < 0.02 mg eq/kg. All other components of the extractable residues were < 0.01 mg eq/kg. The non-extractable residues were less than 0.01 mg eq/kg for all crops.

ERR–Extractable Radioactive Residues

RRR–Residual Radioactive Residues

NA–Not analysed

ND–Not detected

In summary, translocation of radiolabelled metrafenone from soils to representative rotational crops (lettuce, radish, canola) was low, with TRRs ranging from < 0.004 to 0.048 mg eq/kg (in canola pods), generally highest in the samples from the 30-day plant back interval. In soil, radioactive residues declined by about 50% after 90 days, and were mostly found in the top 10 cm of soil samples.

Total extractable residues ranged from 64.0 to 88% TRR in the majority of the samples (42–86% TRR in canola seed) and comprised mostly of multiple unidentified polar components, all present at < 0.02 mg eq/kg. Metrafenone accounted for 0.004 mg/kg of the TRR in lettuce (90DAT) and radish roots (30DAT) and was not found in canola.

METHODS OF RESIDUE ANALYSIS

Analytical methods

The meeting received analytical method descriptions and validation data for metrafenone in crop and animal commodities and in soil and water. A summary of the analytical methods for plant and animal commodities is provided below.

Data collection methods

RLA 12619.02

This method for measuring residues of metrafenone and major metabolites (CL 3000402, CL 434223 and CL 376911) in cereal matrices and was described and validated by Smalley, 2001 [Ref: 2001/7001048], by Kang, 2001 [Ref: 2001/7001770] and for measuring residues of metrafenone in barley 'processing products' by Pollmann, 2002 [Ref: 2002/1004080]. Residues were extracted with methanol:water (80:20), filtered and reduced by rotary evaporation before partitioning into dichloromethane and final clean up through a strong anion exchange cartridge. Residues were measured using LC/APCI mass spectrometry (LC-MS/MS) calculating results using bracketing standards.

Average recovery rates in samples spiked with 0.01–0.1 mg/kg metrafenone ranged from 88–98% (RSD ≤ 13.3%) and the LOQ was 0.01 mg/kg for grain and barley 'processing products' and 0.1 mg/kg for forage and straw.

MRM DFG S19 (plant matrices)

The German multi-residue method DFG S19 with modified extraction was described and reported by Hausmann & Class, 2000 [Ref: 2000/7000136] as suitable for as a data-collection method to measure residues of metrafenone in wheat and barley grain, grapes and wine, with an LOQ of 0.01 mg/kg.

Residues in barley grain, grapes, and wine were extracted with water:acetone (1:2) and partitioned into acetone/ethyl acetate/cyclohexane. Gel permeation chromatography was used to eliminate fat and macromolecules (as described in DFG clean-up method 6) with further silica gel column clean-up before GC/ECD analysis using a 5% phenyl methyl silicone column (non-polar stationary phase). Confirmatory analysis used a methyl siloxane column (non-polar stationary phase) and the 393 m/z ion was the target ion for quantitation.

Average recovery rates in samples spiked with 0.01–0.2 mg/kg metrafenone ranged from 88–128% (RSD ≤ 13%) and the LOQ was 0.01 mg/kg.

This method was independently validated in a study reported by Steinhauer & Pelz, 2001 [Ref: 2001/7001286] with average recovery rates in samples spiked with 0.02–0.2 mg/kg metrafenone (barley grain, grapes) or 0.01–0.1 mg/kg (wine) ranged from 88–114% (RSD ≤ 17%).

RLA 12612V (grapes)

This GC-MS method was described and validated by Smalley, 2000 [Ref: 2000/7000111] as suitable for the analysis of metrafenone residues in grapes with an LOQ of 0.05 mg/kg.

Residues of metrafenone were extracted from grapes with n-heptane and acetone. Metrafenone was cleaned up further using solid phase extraction using silica cartridges. Measurement of metrafenone was carried out by gas chromatography using an electron capture detector. The specificity of the method was determined using GC-MS.

Average recovery rates in samples spiked with 0.05–1.0 mg/kg metrafenone ranged from 93–96% (RSD ≤ 2.0%) and the LOQ was 0.05 mg/kg and this method was independently validated with average recovery rates in samples spiked with 0.05–1.0 mg/kg metrafenone ranged from 79–91% (RSD ≤ 5%).

	1.0	79	4.2		

QuEChERS (plant matrices)

The QuEChERS method (including Amendment 1) was described and reported by Meyer, 2011 [Ref: 2011/7007816] as suitable for as a data-collection method to measure residues of metrafenone in wheat forage, straw and grain, cucumber, lemon, dry bean seed, oilseed rape seed and dried hop cones, with an LOQ of 0.01 mg/kg.

Homogenised samples were extracted with acetonitrile in frozen conditions. After addition of magnesium sulphate, sodium chloride and citrate salts for buffering to pH 5–5.5, the samples were centrifuged for phase separation and an aliquot of the acetonitrile phase was cleaned-up by a

dispersive SPE on PSA (primary secondary amine sorbent). Analysis was by LC-MS/MS, monitoring two parent daughter ion transitions (MRM). The LOQ of the method was 0.01 mg/kg for each matrix.

A matrix effect was noted in the undiluted dry hop cone extracts and matrix-matched standard calibration solutions were therefore used for the evaluation of the recovery rates of these extracts fortified at 0.01 mg/kg and 0.1 mg/kg. The extracts fortified at 20 mg/kg were diluted by a factor of 100 and therefore determined against solvent standard calibration solutions.

Average recovery rates in samples spiked with 0.01–5.0 mg/kg metrafenone (0.01–20 mg/kg for hop cones) ranged from 86–111% (RSD $\leq$ 5.1%) and the LOQ was 0.01 mg/kg.

This method was independently validated in a study reported by Weber, 2011 [Ref: 2001/7007817] with average recovery rates in samples spiked with 0.01–5.0 mg/kg metrafenone (wheat forage, straw and grain, cucumber, lemon, dry bean seed and oilseed rape seed) or 0.01–20 mg/kg (dried hop cones) ranged from 82–94% (RSD $\leq$ 11%) except in oilseed rape seed where the average recovery rate was 70% (RSD $\leq$ 5.7%). In this study, extracts were shown to be stable for up to 3 days when stored in the dark at about 8 °C and up to 7 days at 3 °C.

In a number of the supervised field trials, method validation was also conducted prior to analysis the field samples, and the recovery rates in these studies are also summarized in the following table.

BASF Method 535/3 (L0076/03)—hops and beer

The BASF Method 535/3 was described and reported by Lehmann, 2010 [Ref: 2010/1089964] as suitable for as a data-collection method to measure residues of metrafenone in hop cones (green and dried) and in beer, with an LOQ of 0.01 mg/kg.

Metrafenone residues are extracted with a mixture of methanol water and hydrochloric acid. An aliquot of the extract is centrifuged and partitioned at alkaline conditions against cyclohexane. The final determination was performed by HPLC-MS/MS and the LOQ of the method was 0.01 mg/kg for each matrix.

Average recovery rates in samples spiked with 0.01 mg/kg and 0.1 mg/kg metrafenone ranged from 88–100% (RSD ≤ 5.2%) and the LOQ was 0.01 mg/kg.

Table 32 Metrafenone analytical recovery rates for BASF method 535/3 (L0076/3)

Matrix	Fortification (mg/kg)	Average recovery (%)	RSD (%)	No of tests

MRM DFG S19 (animal matrices)

The German multi-residue method DFG S19 (extended version) was described and reported by Pelz & Steinhauer, 2001 [Ref: 2001/7000486] as suitable for as a data-collection method to measure residues of metrafenone in milk, meat (muscle) and eggs, with an LOQ of 0.01 mg/kg for milk and 0.05 mg/kg for meat and eggs.

Residues were extracted from the various animal matrices with water:acetone (2:1) as described in module E.1 and partitioned into ethyl acetate:cyclohexane (1:1) and the organic extract was cleaned up using gel permeation chromatography (GPC module). Extracts were analysed for metrafenone using capillary gas chromatography with mass selective detection (module D.4.). The limit of quantitation (LOQ) was 0.01 mg/kg (ppm) for milk and 0.05 mg/kg (ppm) for meat and eggs.

Average recovery rates in samples spiked with 0.01 mg/kg and 0.1 mg/kg metrafenone ranged from 69–89% (RSD ≤ 15%) and the LOQs were 0.01 mg/kg (milk) and 0.05 mg/kg (meat and eggs).

This method was independently validated in a study reported by Class, 2001 [Ref: 2001/7001287] that used matrix-matched calibration standards. Analysis was by GC-MS (module D.4.). Average recovery rates in samples spiked with 0.01 mg/kg and 0.1 mg/kg (milk) or 0.05 mg/kg 0.5 mg/kg (muscle and eggs) ranging from 76–101% (RSD ≤ 14%).

Table 33 Metrafenone analytical recovery rates for analytical method DFG S19

Matrix	Fortification (mg/kg)	Average recovery (%)	RSD (%)	No of tests	Reference

	0.5	97	14	5	

Enforcement methods*Multi-residue method DFG S19*

The German method DFG S19 with GC-ECD or GC-MS analysis is suitable for enforcement of the MRL for metrafenone in plant commodities with a high starch content and high acid content (based on the method validation for wheat and barley grain and in grapes), with an LOQ of 0.01 mg/kg and in muscle, milk and eggs with an LOQ of 0.01 mg/kg for milk and 0.05 mg/kg for meat and eggs.

QuEChERS (plant matrices)

The QuEChERS method (including Amendment 1) is suitable for enforcement of the MRL for metrafenone in plant commodities, based on the method validation for cucumber and wheat forage (representing high water content), lemon (high acid content), wheat grain (high starch content), dry beans (high protein content) and oilseed rape (high oil content).

Analytical (concurrent) recoveries in supervised crop trials

Analytical recovery rates were measured in all the supervised crop field trials, with control samples being fortified with metrafenone at 0.01 mg/kg and at higher levels that generally reflected the range

of expected residues. In the European trials the common analytical method was Method 535/3 and the QuEChERS method was predominantly used in the North American trials. Some of the earlier European cereal trials used method RLA 12619 to measure residues of metrafenone and several metabolites.

For each study, average recoveries per fortification level generally fell within the 70–120% range, with a relative standard deviation of 20% or less. Information on the concurrent recovery rates for individual commodities are summarised in the relevant supervised crop field trial sections.

Stability of residues in stored analytical samples

Plant matrices

The Meeting received information on the stability of residues of metrafenone in various substrates with a high water content (lettuce, tomato, wheat forage and straw), a high starch content (carrot, wheat grain), a high protein content (dry peas), a high oil content (soya beans) and a high acid content (grape) stored at freezer temperatures for 24 months.

In a study by Class, 2001, [Ref: BN-326-010], samples of carrots and lettuce were fortified with 0.5 mg/kg metrafenone and stored in the dark at -18 °C. Samples were taken for extraction (n-heptane:acetone (8:2), partitioning into ethyl acetate and analysis after 0, 3, 8, 12, 18 and 24 months, with the stored control samples being freshly fortified and analysed concurrently to determine the procedural recovery efficiency. The 1-month and 3-month samples were analysed by GC-MS and the remaining samples were cleaned up using gel permeation chromatography before GC-ECD analysis. Mean procedural recovery rates over the study period were $92 \pm 13\%$ in carrots and $92 \pm 4\%$ in lettuce.

After 24 months storage the measured residues of metrafenone in stored lettuce and carrot samples were greater than 80% of the spiked levels.

Table 34 Stability of metrafenone residues in carrot and lettuce samples spiked at 0.5 mg/kg and stored at -18 °C.

Commodity	Storage interval (months)	Residues remaining ^a (mg/kg)	Residues remaining (%)	Procedural recovery ^b (%)

^a Mean of three analyses

^b Mean of two analyses

In a study by Class, 2000, [Ref: 2000/7000144], spiked samples of grapes (fortified with 0.5 mg/kg metrafenone and wine (fortified with 0.1 mg/kg metrafenone) were stored in the dark at -18 °C. Samples were taken for extraction (n-heptane:acetone (8:2), partitioning into ethyl acetate and analysis after 0, 3, 8, 12, 18 and 24 months, with the stored control samples being freshly fortified and analysed concurrently to determine the procedural recovery efficiency. The 1-month, 3-month and 6-month samples were cleaned up and analysed using on line coupled HPLC/GC-MS and the remaining samples were cleaned up using gel permeation chromatography before GC-ECD analysis. Mean procedural recovery rates over the study period were 95% in grapes and 103% in wine.

After 18 months storage the measured residues of metrafenone in stored grape and wine samples were greater than 80% of the spiked levels.

Table 35 Stability of metrafenone residues in grape and wine samples spiked at 0.5 mg/kg and 0.1 mg/kg respectively and stored at –18 °C

^a % fortified level, mean of three analyses

^b Recovery in freshly fortified samples, mean of two analyses

In a study by Class, 2002, [Ref: 2002/7004653], spiked samples of wheat grain and wheat straw fortified with 0.5 mg/kg metrafenone were stored in the dark at –18 °C. Samples were taken for extraction (n-heptane:acetone (8:2), partitioning into ethyl acetate and analysis after 0, 11-12, 18, 24 and 29 months (grain only), with the stored control samples being freshly fortified and analysed concurrently to determine the procedural recovery efficiency. The initial (0-month) samples were cleaned up and analysed using on line coupled HPLC/GC-MS and the remaining samples were cleaned up using gel permeation chromatography before GC-ECD analysis. Mean procedural recovery rates over the study period were 101% in wheat grain and 93% in wheat straw.

After 24 months (grain) and 29 months (straw) storage, the measured residues of metrafenone in frozen samples were greater than 97% of the spike level and in wheat straw were greater than 82% of the spike level.

Table 36 Stability of metrafenone residues in wheat grain and straw samples spiked at 0.5 mg/kg and stored at -18 °C

	24	0.35	70	94

^a % fortified level, mean of three analyses

^b Recovery in freshly fortified samples, mean of two analyses

In a study by Smalley, 2003, [Ref: 2003/1013928], spiked samples of wheat plants, grain and straw fortified with a combined solution of metrafenone and three metabolites (CL 3000402, CL434223 and CL 376991), each at a concentration of 1.0 mg/kg. Spiked samples were stored in the dark at –20 °C. Samples were taken for extraction and analysis using Method RLA 12619V after 1–3, 7, 15, 19, 24 and 31 months, with the stored control samples being freshly fortified and analysed concurrently to determine the procedural recovery efficiency. Metrafenone procedural recovery rates over the study period ranged from 91–107% in wheat plants, 81–97% in wheat straw and 71–90% in wheat grain.

After 31 months the measured residues of metrafenone in samples of wheat plants and straw were greater than 77% of the spike level and in wheat grain were greater than 74% of the spike level.

In a study by Lehmann & Mackenroth, 2011 [Ref: 2011/1043493], spiked samples of wheat plants, grain and straw, grapes, tomatoes, and dry pea and soya bean seed, fortified with 0.1 mg/kg metrafenone were stored in the dark at –20 °C. Samples were taken for extraction and analysis using BAF Method 535/3 after about 1, 6, 12, 15 and 24 months, with additional soya bean seed samples being analysed after about 2 and 3 month storage. Stored control samples were also freshly fortified and analysed concurrently to determine the procedural recovery efficiency. Mean procedural recovery rates over the study period were greater than 85% in all matrices.

After 24 months the measured residues of metrafenone in samples of wheat plants, grain and straw, grapes, tomato, dried peas and soya bean seeds were greater than 80% of the spike level after correction for procedural recovery.

^a % fortified level, mean of two analyses

^b Recovery in freshly fortified samples, mean of three analyses

In summary, metrafenone residues were stable in analytical samples stored frozen, i.e., -18 to -20 °C) for up to 24 months in representative substrates with a high water content (lettuce, tomato), a high starch content (carrot), a high protein content (dry peas), a high oil content (soya bean) and a high acid content (grape, wine) and in wheat grain (high starch), wheat forage and straw (high water content) residues were stable for up to 31 months. In general, residues in the stored samples were greater than 80% of the spiked levels.

USE PATTERNS

Information on GAP in 50 countries in Europe, the Americas, Asia and the Pacific was provided to the Meeting on the use of metrafenone, available as SC formulations, often co-formulated with either epoxiconazole and/or fenpropimorph. Proposed uses were also provided but are not reported.

The following table summarises the representative critical national or regional GAPs for the crops for which supporting residue trials have been provided.

Table 39 Registered uses of metrafenone (300 g ai/L or 500 g ai/L SC formulations)

RESIDUES RESULTING FROM SUPERVISED TRIALS

The Meeting received information on supervised field trials involving foliar treatments of metrafenone to the following crops.

Group	Crop	Countries	Table no
Berries and other small fruits	Grape	USA	40–41
	Strawberry	Europe	42
Fruiting vegetables, Cucurbits	Cucumber	Europe, Nth America	43–45
	Summer squash	Europe, Nth America	46–47
	Melon	Europe, Nth America	48–49
Fruiting vegetables, other than Cucurbits	Mushrooms	Europe	50
	Peppers	Europe, Nth America	51–52
	Tomato	Europe, Nth America	53–55
Cereals	Wheat	Europe	56
	Barley	Europe	57

Group	Crop	Countries	Table no
Cereal forage and fodders	Wheat	Europe	58 and 60
	Barley	Europe	59 and 61

The supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation including procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ. In such cases, the residues found are noted as “c=nn mg/kg” in the Reference and Comments columns. Residue data are recorded unadjusted for recovery.

Results from replicated field plots are presented as individual values. When residues were not detected they are shown as ND. Residues and application rates have been reported as provided in the study reports, although the results from trials used for the estimation of maximum residue levels (underlined> have been rounded to two significant digits (or if close to the LOQ, rounded to one significant digit) in the Appraisal.

In some trials, samples were taken just before the final application and then, again on the same day after the spray had dried. In the data tables the notation for these two sampling times is '-0' and '0' respectively.

When multiple applications were made to a crop, the application rate, spray concentration and spray volume were not always identical from one application to the next. In most trials, the actual treatment rates were within 10% of the listed ‘target’ application rates, but if not, the actual treatment rates are listed.

Berries and other small fruits

Grape

Results from supervised trials from the USA on grapes conducted in 2005 and in 2011 were provided to the Meeting. In the 2011 trials, three foliar airblast applications of metrafenone (0.33 kg ai/ha, SC formulation) with added non-ionic surfactant were applied to 12–24 vine plots, 14–15 days apart, using about 1000–1500 L water/ha. Grape samples (min 1 kg and at least 12 bunches or part bunches) were frozen within 3 hours of sampling and stored frozen for up to 20 months before analysis of berries for metrafenone using the QuEChERS method. Procedural recovery rates in grapes fortified at 0.01 to 1.5 mg/kg ranged from 74 to 104% (mean $91 \pm 10\%$, n=10) and the LOQ was 0.01 mg/kg.

Table 40 Residues in grapes from supervised trials in the USA involving three foliar applications of metrafenone (SC formulation).

In the 2005 trials, six foliar applications of metrafenone (0.33 kg ai/ha, SC formulation) with no added surfactant were applied 12–15 days apart, with dilute (100–1500 L water/ha) and concentrate (500–700 L water/ha) treatments being applied to separate 40–220 square metre plots.

Grape samples (min 1 kg and at least 12 bunches or part bunches) were frozen within 3 hours of sampling, and stored frozen for up to 6 months before analysis of berries for metrafenone using Method 535/3. Average procedural recoveries of metrafenone from grapes fortified with 0.01–20 mg/kg ranged from 82–127% (mean $99 \pm 13\%$, n=26) and the LOQ was 0.01 mg/kg.

Strawberry

Results from supervised trials from Europe on protected strawberries conducted in 2009 were provided to the Meeting. In these trials, two foliar applications of 0.15 kg ai/ha metrafenone (SC formulation) in about 200 L water/ha were applied 7 days apart, using motorized knapsacks or 6-nozzle mini-boom sprayers.

Fruit samples (min 1 kg) were frozen within 12 hours of sampling and stored frozen (−18 °C) for up 15 months before analysis for metrafenone using Method 535/3. Average procedural recoveries of metrafenone from strawberries fortified with 0.01 or 1.0 mg/kg were 101% and 98% respectively and the LOQ was 0.01 mg/kg.

Table 42 Residues in protected strawberries from supervised trials in Europe involving two foliar applications of metrafenone (SC formulation).

Fruiting vegetables, Cucurbits

Results from supervised trials from Europe and the USA on cucumbers, zucchini (summer squash) and melons (cantaloupes) were provided to the Meeting.

Cucumber

In the European outdoor trials, two foliar applications of 0.1 kg ai/ha metrafenone (SC formulation) in about 300–1000 L water/ha were applied 7 days apart, using motorized knapsacks or 4–8 nozzle mini-boom sprayers. Plot sizes were larger than 30 square metres. In the European indoor cucumber trials, two foliar applications of 0.15 kg ai/ha were applied at 7-day intervals using motorized knapsacks or vertical boom sprayers to apply about 1500 L spray mix/ha to plots of at least 18 square metres.

Fruit samples (min 1 kg) fruit (without stems) were frozen within 12 hours of sampling and stored frozen (-18 °C) for up to 16 months before analysis for metrafenone using Method 535/3. Average procedural recoveries of metrafenone from samples fortified with 0.01 mg/kg and 1.0 or 2.0 mg/kg ranged from 90% to 101% and the LOQ was 0.01 mg/kg.

In the North American trials, three foliar applications of 0.34 kg ai/ha metrafenone (SC formulation) with added adjuvant were applied at 6–8 day intervals, using motorized knapsacks or tractor-mounted 4–9 nozzle sprayers to apply about 300–700 L/ha. Plot sizes were larger than 33 square metres.

Duplicate fruit samples (min 2 kg, 12 units) were taken, with the larger cucumber fruit being sub-sampled in the field, frozen within 12 hours of sampling and stored frozen for up to 24 months before analysis for metrafenone using the QuEChERS LC-MS/MS method. The average procedural recovery of metrafenone from samples fortified with 0.01 mg/kg or 1.0 mg/kg was 104% and the LOQ was 0.01 mg/kg.

Summer squash

In the European outdoor trials, two foliar applications of 0.1 kg ai/ha metrafenone (SC formulation) in about 300–1000 L water/ha were applied 7 days apart, using motorized knapsacks or 4–8 nozzle mini-boom sprayers. Plot sizes were larger than 30 square metres.

Fruit samples (min 1 kg) fruit (without stems) were frozen within 12 hours of sampling and stored frozen (-18 °C) for up 14 months before analysis for metrafenone using Method 535/3. The average procedural recovery of metrafenone from samples fortified with 0.01 or 1.0 mg/kg was 96% and the LOQ was 0.01 mg/kg.

In the North American trials, three foliar applications of 0.34 kg ai/ha metrafenone (SC formulation) with added adjuvant were applied at 6–8 day intervals, using motorized knapsacks or

tractor-mounted 4–9 nozzle sprayers to apply about 300–700 L/ha. Plot sizes were larger than 33 square metres.

Duplicate fruit samples (min 2 kg, 12 units) were frozen within 12 hours of sampling and stored frozen for up to 28 months before analysis for metrafenone using the QuEChERS LC-MS/MS method. The average procedural recovery of metrafenone from samples fortified with 0.01 mg/kg or 1.0 mg/kg as 100% and the LOQ was 0.01 mg/kg.

Melons, except Watermelon

In the European outdoor trials, two foliar applications of 0.1 kg ai/ha metrafenone (SC formulation) in about 300–1000 L water/ha were applied 7 days apart, using motorized knapsacks or 4–8 nozzle mini-boom sprayers. Plot sizes were larger than 30 square metres.

Fruit samples (min 2 kg or 12 units) were subsampled in the field (two opposite quarters/fruit) and frozen within 12 hours and stored at or below -18 °C for up 14 months before analysis for metrafenone using Method 535/3. Average procedural recoveries of metrafenone from samples fortified with 0.01 mg/kg and 1.0 mg/kg ranged from 93% to 98% and the LOQ was 0.01 mg/kg.

In the North American trials, three foliar applications of 0.34 kg ai/ha metrafenone (SC formulation) with added adjuvant were applied at 6–8 day intervals, using motorized knapsacks or

tractor-mounted 4–9 nozzle sprayers to apply about 300–700 L/ha. Plot sizes were larger than 33 square metres.

Duplicate fruit samples (min 2 kg, 12 units) were sub-sampled in the field (two opposite quarters, eighths or sixteenths/fruit), frozen within 12 hours and stored frozen for up to 27 months before analysis for metrafenone using the QuEChERS LC-MS/MS method. The average procedural recovery of metrafenone from samples fortified with 0.01 mg/kg or 1.0 mg/kg was 104% and the LOQ was 0.01 mg/kg.

^a Average results from three replicate analyses

Fruiting vegetables, other than Cucurbits

Results from supervised trials from Europe and the USA on peppers and tomatoes and on mushrooms from Europe were provided to the Meeting.

Mushrooms

In a trial conducted in France with mushroom compost sourced from four different suppliers, one drench application equivalent to 0.05 kg ai metrafenone/100 square metres was applied to the mushroom compost in 15–17 litres water, 20 days after inoculation and mushroom samples (min 0.8 kg) were harvested 10 days after treatment and stored frozen for up to 17 months before analysis using the MRM DFG S19 method to measure metrafenone. The LOQ for this method was 0.1 mg/kg and average procedural recovery rates were 86% and 88% in samples spiked with 0.1 mg/kg and 1.0 mg/kg respectively.

Duplicate samples were also analysed at a separate laboratory after a further 9 months frozen storage using Method 535/1 with a lower LOQ of 0.01 mg/kg and with average procedural recovery rates of 101% and 91% in samples spiked with 0.01 mg/kg and 0.2 mg/kg respectively.

One (5 kg) sample was also taken for processing, with the mushrooms being washed 3–4 times in cold running water, stored for 24 hours in sulphured water and blanched for 15 minutes at 98 °C before cooling and placed in cans with added salt, sugar and citric acid. After sealing, the cans were sterilised at 136 °C for 6 minutes.

Results are duplicate analyses by separate laboratories (different analytical methods and LOQs)

Processing factor (residues in processed commodity/residues in RAC) = 0.16

Peppers

In the European trials on indoor sweet peppers, two foliar applications of 0.15 kg ai/ha metrafenone (SC formulation) in about 1000 L water/ha were applied 7 days apart, using motorized knapsack sprayers. Whole fruit samples (min 1 kg) were frozen within 24 hours of sampling and stored frozen (–18 °C) for up to 12 months before analysis for metrafenone using Method 535/3. Average procedural recoveries of metrafenone from samples fortified with 0.01–2.0 mg/kg ranged from 73% to 132% with an overall mean of 96% and the LOQ was 0.01 mg/kg.

In the North American trials on outdoor sweet (bell) peppers and chili (non-bell) peppers, three foliar applications of 0.34 kg ai/ha metrafenone (SC formulation) with added adjuvant were applied at 7 day intervals, using pressurised knapsack sprayers (2–6 nozzles) to apply about 200–300 L/ha. Plot sizes were larger than 28 square metres.

Duplicate whole fruit samples (min 2 kg, 12 large or 24 small fruit) were frozen within 2 hours of sampling and stored frozen (–15 °C) for up to 25 months before analysis for metrafenone using the QuEChERS LC-MS/MS method. Average procedural recoveries of metrafenone from samples fortified with 0.01–0.1 mg/kg ranged from 109% to 114% with an overall mean of 112% and the LOQ was 0.01 mg/kg.

Tomato

In the European trials on outdoor and indoor tomatoes, two foliar applications of 0.225 kg ai/ha metrafenone (SC formulation) in about 1500 L water/ha (0.015 kg ai/hL) were applied 7 days apart, using motorized knapsack (1–2 nozzle) or mini-boom (6-nozzle) sprayers. Whole fruit samples (min 1 kg) were frozen within 24 hours of sampling and stored frozen (–18 °C) for up to 12 months before analysis for metrafenone using Method 535/3. Average procedural recoveries of metrafenone from samples fortified with 0.01–1.0 mg/kg ranged from 78% to 111% with an overall mean of 102% in the outdoor trials and 99% in the indoor trials. The LOQ was 0.01 mg/kg.

In the North American trials on outdoor tomatoes (large and small fruited varieties), three foliar applications of 0.34 kg ai/ha metrafenone (SC formulation) with added adjuvant were applied at 6–8 day intervals, using knapsack or tractor-mounted boom sprayers (3–11 nozzles) to apply about 300–800 L/ha. Plot sizes were larger than 30 square metres.

Duplicate fruit samples (min 2 kg, 12 large or 24 small fruit) were frozen within 3 hours of sampling and stored frozen (–15 °C) for up to 24 months before analysis for metrafenone using the QuEChERS LC-MS/MS method. Average procedural recoveries of metrafenone from samples fortified with 0.01–0.1 mg/kg ranged from 91% to 118% with an overall mean of 105% and the LOQ was 0.01 mg/kg.

Cereal grains

Results from supervised trials from Europe on wheat and barley were provided to the Meeting.

Wheat

In the European trials on winter and spring wheat, two foliar applications of 0.15–0.2 kg ai/ha metrafenone were applied by knapsack or plot sprayers with 4–12 nozzle booms to apply 20–400 Litres spray mix/ha to plots larger than 30 square metres. Generally, applications were made during the stem elongation period (BBCH 30–39) and again 4–8 weeks later (towards the end of flowering or later), up to about 5–6 weeks before harvest. In some trials, different formulations (SC, EC, SE) of metrafenone, alone or in combination with other fungicides were applied to separate plots.

Samples of grain (min 1 kg) were taken at maturity, frozen within 24 hours and stored at or below –18 °C for up to 29 months before analysis. In the trials conducted before 2004, samples were analysed for metrafenone and the metabolites CL 3000402, CL 434223 and CL 376991 using Method RLA 12619 and in the later trials, Method 535/3 was used to measure only the parent compound. Average procedural recoveries of metrafenone from samples fortified with 0.01 and 0.1 mg/kg ranged from 71% to 104% and the LOQ was 0.01 mg/kg.

Barley

In the European trials on winter and spring barley, two foliar applications of 0.15–0.2 kg ai/ha metrafenone were applied by knapsack or plot sprayers with 5–12 nozzle booms to apply 200–400 Litres spray mix/ha to plots larger than 30 square metres. Generally, applications were made 4–8 weeks apart over the flowering and grain development stages (BBCH 61–83). In some trials, different formulations (SC, EC, SE) of metrafenone, alone or in combination with other fungicides were applied to separate plots.

Samples of grain (min 1 kg) were taken at maturity, frozen within 24 hours and stored at or below –18 °C for up to 25 months before analysis. In the trials conducted before 2004, samples were analysed for metrafenone and the metabolites CL 3000402, CL 434223 and CL 376991 using Method RLA 12619 and in the later trials, Method 535/3 was used to measure only the parent compound. Average procedural recoveries of metrafenone from samples fortified with 0.01 and 0.1 mg/kg ranged from 71% to 108% and the LOQ was 0.01 mg/kg.

Table 57 Residues in barley grain from supervised trials in Europe involving 1–3 foliar applications of metrafenone.

Animal feeds

Wheat forage, hay and straw

In some of the above European trials on winter and spring wheat, whole plants (without roots) were sampled 0–14 days after the last application and again 28–35 DALT, with these later samples being separated into ears and the rest-of- the-plant ('foliage'). Samples were frozen within 24 hours and stored at or below -18 °C for up 29 months before analysis. In the trials conducted before 2004, samples were analysed for metrafenone and the metabolites CL 3000402, CL 434223 and CL 376991 using Method RLA 12619 and in the later trials, Method 535/3 was used to measure only the parent compound. Average procedural recoveries of metrafenone from samples fortified with 0.01–20 mg/kg ranged from 71% to 104% and the LOQs were 0.1 mg/kg.

Values in (brackets) are residues of the CL 3000402 metabolite found above LOQ

Foliage = plants without ears. Also described as 'culm' in some studies

^a Samples may have been transposed

Barley forage

In some of the above European trials on winter and spring barley, whole plants (without roots) were sampled just after the last application and again 28–35 DALT, with these later samples being separated into ears and the rest-of- the-plant (‘foliage’). In the trials conducted before 2004, samples were analysed for metrafenone and the metabolites CL 3000402, CL 434223 and CL 376991 using Method RLA 12619 and in the later trials, Method 535/3 was used to measure only the parent compound. All samples were frozen within 24 hours and stored at or below –18 °C for up to 25 months before analysis. Average procedural recoveries of metrafenone from samples fortified with 0.01–20 mg/kg ranged from 71% to 108% and the LOQs were 0.1 mg/kg.

Table 59 Residues in barley forage from supervised trials in Europe involving 1–3 foliar applications of metrafenone

Foliage = plants without ears. Also described as 'culm' in some studies

Wheat hay and straw

In the above European trials on winter and spring wheat, samples of straw (min 0.5 kg) were taken at maturity, and in many cases, whole plants (without roots) were sampled 0–14 days after the last application and again 28–35 DALY, with these later samples being separated into ears and the rest-of-the-plant ('foliage').

Frozen within 24 hours and stored at or below –18 °C for up to 29 months before analysis. In the trials conducted before 2004, samples were analysed for metrafenone and the metabolites CL 3000402, CL 434223 and CL 376991 using Method RLA 12619 and in the later trials, Method 535/3 was used to measure only the parent compound.

Average procedural recoveries of metrafenone from samples fortified with 0.01–20 mg/kg ranged from 71% to 104% and the LOQs were 0.1 mg/kg.

Barley hay and straw

In the above European trials on winter and spring barley, samples of straw (min 0.5 kg) were taken at maturity, frozen within 24 hours and stored at or below –18 °C for up to 25 months before analysis. In the trials conducted before 2004, samples were analysed for metrafenone and the metabolites CL 3000402, CL 434223 and CL 376991 using Method RLA 12619 and in the later trials, Method 535/3 was used to measure only the parent compound. Average procedural recoveries of metrafenone from samples fortified with 0.01–20 mg/kg ranged from 71% to 108% and the LOQs were 0.1 mg/kg.

FATE OF RESIDUES IN STORAGE AND PROCESSING

High temperature hydrolysis

In a study reported by AN, 2000 [Ref: 2000/7000137], the high-temperature hydrolysis of [bromophenyl-6-¹⁴C]-metrafenone in buffered solutions of pH 4, 5, and 6 was investigated to simulate representative processing conditions: pasteurization at 90 °C for 20 minutes in pH 4 solution; baking, brewing, or boiling at 100 °C for 60 minutes in pH 5 solution; and sterilization at 120 °C for 20 minutes in pH 6 solution.

Solutions of buffered [bromophenyl-6-¹⁴C]-metrafenone were incubated in the dark at 90, 100, and 120 °C at pH 4, 5, and 6, respectively, and samples were analysed after 20 min. (pH 4 and 6) and 1 h (pH 5) by LSC and HPLC. Examination of the radio-chromatograms showed only one major peak in all samples, identified as the parent compound.

Recoveries of radioactivity at 0-time were 91–92% of the applied radioactivity and after incubation were 96–102% of applied dose. Metrafenone made up about 91% of the radioactivity at 0-time and 95–101% of the applied dose after incubation. The relatively low pre-incubation recovery was attributed to retention on the glass tubes. The results indicate that metrafenone is hydrolytically stable under the simulated processing conditions of pasteurization, baking, brewing, boiling and sterilization.

Table 62 Distribution of radioactivity for [bromophenyl-6-¹⁴C]-metrafenone in buffer solutions—high temperature hydrolysis (% radioactivity)

Processing

Apples

An apple processing study was reported by Carringer, 2013 [Ref 2012/7004393]. In two field trials in USA, involving three foliar applications of 1.68 kg ai/ha metrafenone (SC formulation), applied at 6–7 day intervals in 750–1000 L water/ha, with added surfactant, bulk samples (36 kg) were taken 6–7 days after the last application and cool-stored for up to 4 days before processing using simulated commercial practices into juice, wet pomace, apple sauce, canned apples, and dried apples).

The bulk apples for processing were quartered, sliced and a portion of these apple slices were set aside for raw juice generation. The remaining portion was ground in a food strainer/sauce maker, producing puree and wet pomace. Apple sauce was prepared by evaporating the puree at 82–93 °C in a kettle. Apple slices for juice were processed through a juice processor to produce juice and the resulting wet pomace was combined with the wet pomace generated during puree production. Canned apples were prepared from whole apples by peeling, slicing and coring, with the sliced fruit heated with water to about 70 °F for approximately 45 minutes and stirred to produce slices in syrup. For dried fruit production, whole apples were peeled, cut into 0.3 cm slices, cored and placed one layer deep on dehydrator trays and dried at 65–70 °C for about 24 hours to achieve a moisture content of approximately 10%.

Figure 6 Processing flowchart for apple sauce, juice, and wet pomace

Figure 7 Processing flowchart for canned and dried apple

Representative samples of whole apples (≥ 2 kg), dried apples (approximately 0.5 kg), juice (2 litres) and other processed fractions (≥ 1 kg) were stored at ≤ -16 °C for up to 22 months before analysis for metrafenone using the LC-MS/MS QuEChERS method. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 92–106% in samples spiked with 0.01 to 10.0 mg/kg.

Table 63 Residues in fresh and processed apples from supervised trials in North America involving three foliar applications of metrafenone (SC formulation)

APPLE Study ID	Commodity	Metrafenone (mg/kg)	Processing Factor ^a
R080753 Alton, NY, 2010 3 × 1.7 kg ai/ha PHI: 7 days	Whole Fresh Fruit	1.46	—
	Juice (raw)	0.28	0.189
	Wet Pomace	1.88	1.29
	Apple Sauce	7.01	4.80
	Canned Apples	0.2	0.140
	Dried Apples	1.1	0.719
R080754 Weiser, ID, 2010 3 × 1.7 kg ai/ha PHI: 6 days	Whole Fresh Fruit	2.17	—
	Juice (raw)	0.489	0.225
	Wet Pomace	2.37	1.09
	Apple Sauce	8.94	4.12
	Canned Apples	0.226	0.104
	Dried Apples	0.851	0.392

^a The processing factor was calculated by dividing the residue in the apple processed commodity by the residue in the apple RAC sample.

Grapes

One grape processing study conducted in USA was reported by Jordan & Kasiri, 2006 [Ref: 2006/7007012]. In one field trial in the USA, involving six foliar applications of 0.34 kg ai/ha metrafenone (SC formulation) in 1280 Litres water/ha, applied at 12–15 day intervals from BBCH 75 (berries pea-sized), bulk grape samples (170 kg) were taken immediately after the last application and either cool-stored for up to 3 days before processing into juice, red wine, white wine or sun-dried in the field for 28 days before washing.

Grapes were processed into grape juice by crushing and after removing the stems, the pulp was heated to 52–57 °C for 10 minutes and then to 60–66 °C for a further 10 minutes before pressing to separate the juice and pulp. The collected juice was filtered through a U.S. #40 screen to remove course solids and samples were then frozen for analysis.

For wine, the grapes were de-stemmed and crushed, the juice/pulp was heated to approximately 60 °C then cooled to approximately 21 °C (red wine only), and allowed to stand for about an hour after the addition of potassium metabisulfite and pectic enzyme before pressing. The must was allowed to rest overnight and after addition of yeast, primary fermentation was continued at room temperature until the specific gravity reached approximately 1.03. The wine was then racked and stored at approximately 13 °C for 1–2 weeks before the sediment was removed. This ‘young wine’ was then treated with gelatine as a fining agent and stored for about 3 months before the lees were removed and the finished wine was vacuum filtered over diatomaceous earth.

Representative samples of grapes and processed fractions were stored at ≤ -17 °C for up to 4 months (6 months for grapes) before analysis for metrafenone using the HPLC-MS/MS Method 535/3. The reported LOQ in all matrices was 0.01 mg/kg and average concurrent recoveries were 80–127% in samples spiked with 0.01 to 20.0 mg/kg.

In a series of studies conducted in Europe and reported by Smalley, 2002 [Refs: 2002/7004451, 2002/7004455, 2002/7004459, 2002/7004460], grapes from field trials involving eight applications of 0.01–0.033 kg ai/hL metrafenone (0.09–0.13 kg ai/ha), applied at either 7 or 14 day intervals, were taken 27–29 days after the last application and processed into red or white wine or sun-dried to produce raisins.

The wine processing steps were generally as described above, with potassium metabisulphite added as a fermentation inhibitor and gelatin used as a fining agent. For the sparkling wine, sugar and yeasts were added to wine prior to bottling and the bottles stored at 5–10 °C for about 9 months (turned regularly during the last month) before uncapping, disgorging and recapping and frozen for subsequent analysis.

Representative samples of grapes and processed fractions were stored at about –20 °C for up to 6 months before analysis for metrafenone using Method RLA 12612V. The reported LOQ in all matrices was 0.05 mg/kg and average concurrent recoveries were 77–102% in samples spiked with 0.05–0.5 mg/kg.

Strawberries

In a study reported by Plier, 2011 [Ref: 2011/1041883], bulk samples (min 10 kg) of strawberries were taken from four field trials conducted in Germany (2 × 0.45 kg ai/200 Litres/ha metrafenone, 7 days apart) 3–4 days after the last application and chilled to about 5–8 °C for up to 3 days before processing into jam, preserved fruit and syrup.

Fruit (without stems and crowns) were washed and processed into jam by cooking with sugar and glucose syrup until a dry matter content of about 64% was achieved and after the addition of citric acid and pectin, heated further until a dry matter content reached about 62%. The jam (pH 2.7–3.3) was then cooled and samples frozen for up to 8 months before analysis.

Washed fruit were also preserved by heating with ascorbic acid, citric acid, sugar and water until boiling and immediately pouring the mixture into jars which were topped up with boiled syrup, sealed and pasteurized for one minute at 90–95 °C. Cooled samples (pH 3–4) were then frozen for up to 8 months before analysis.

The analytical method 535/1 was used to measure residues of metrafenone, with an LOQ of 0.01 mg/kg and concurrent recoveries from samples spiked with 0.01, 0.1 or 1.0 mg/kg ranged from 82–94%, with an average recovery of 89%.

Tomatoes

In a study reported by Plier, 2011 [Ref: 2011/1041884], tomatoes were taken for processing from four field trials conducted in Germany. In these field trials, two applications of 0.6–0.7 kg ai/ha were applied 6–8 days apart using 450–550 Litres spray mix/ha. Bulk samples of 13–21 kg ripe tomatoes were taken 3–4 days after the last application and chilled to about 5–8 °C for 1–12 days before processing into preserve, juice, paste, ketchup and puree.

Tomatoes (without stems) were washed, blanched (1 minute at 75–85 °C), cooled and peeled manually. The peeled tomatoes were placed in jars, topped up with water, sealed and autoclave sterilised (5–12 minutes at 118–125 °C) before cooling and sampling for subsequent analysis.

For juice, puree and ketchup, washed tomatoes were crushed and heated for 30 minutes at 80–87 °C, then pressed and sieved to separate the juice and pomace. Samples of the raw juice were concentrated to achieve a dry matter content of 7–14% (for paste) and 18–24% (for puree). Ketchup was prepared by adding vinegar (0.4%), sugar (42%) and salt (15%) to the paste. The paste, ketchup and puree were pasteurised at 90–95 °C for 1–20 minutes, cooled and samples were stored frozen for up to 6 months before analysis for metrafenone using Method 535/1, with a limit of quantification of 0.01 mg/kg. Concurrent recoveries from samples spiked with 0.01–5.0 mg/kg ranged from 80–109%, with an average recovery of 93%.

Barley

In a study reported by Pollmann, 2002 [Ref: 2002/1004080], samples of summer barley grain were taken for processing from four field trials conducted in Germany. In these field trials, two applications of about 0.5 kg ai/ha were applied 10–15 days apart using about 300 Litres spray mix/ha. Bulk samples of at least 25 kg grain were taken 35 days after the last application and stored at ambient temperature for 2–3 months before processing into pearl barley and beer.

Pearl barley was prepared by mechanical de-awning and cleaning (< 2.5 mm slotted screen) to separate husks and other impurities, conditioning to 14% moisture content and decortications to achieve an abrasion rate of 20–30%. Samples were frozen within 4 hours for subsequent analysis

The malting and brewing process involved steeping the barley (2 × 3 hours at 14 °C), sprouting over 7 days at about 12 °C and kilning (7 hours at 55 °C and 1.5 hours at 85 °C) before the sprouts were separated over a wire mesh and the malt was conditioned for 8–21 days at 12–15 °C before being ground for brewing. Mash was produced using the infusion method and wort was removed during the lautering process. Hops were added to the wort during the 1 hour boiling period and after cooling, yeast was added to initiate fermentation. Primary fermentation proceeded for 7–8 days at 8–14 °C and after bottling, secondary fermentation continued for 21–32 days (8–14 °C) when samples were frozen for subsequent analysis.

Samples were stored frozen (about -18 °C) for up to 7 months before analysis for metrafenone using Method RLA 12619.03V (993/0), with a limit of quantification of 0.01 mg/kg. Concurrent recoveries from samples spiked with 0.01–0.1 mg/kg ranged from 73–93% (except malt sprouts, where the recovery was 47%), with an average recovery of 85%.

Wheat

In a study reported by Pollmann, 2002 [Ref: 2002/1006302], samples of summer wheat grain were taken for processing from four field trials conducted in Germany. In these field trials, two applications of about 1.5 kg ai/ha were applied 27 or 38 days apart using about 300 Litres spray mix/ha. Bulk samples of at least 7 kg grain were taken 35 days after the last application and stored frozen for up to 2 months before processing into flour, bran and bread.

After cleaning to remove dust and plant fragments, 6–10 kg samples of wheat grain were conditioned to a moisture content of about 17% and milled by passing through a series of corrugated and smooth rollers (0.5 mm down to 0.01 mm apertures) to obtain flour and bran + adhesive flour, the latter being centrifuged to separate the coarse bran, fine bran and the bran flour. Samples were frozen within 9 hours for subsequent analysis.

A sample of the whole meal flour was kneaded with water, ascorbic acid, yeast, salt, sugar and peanut fat to produce dough, which was allowed to ferment at about 27 °C for 30 minutes before being formed into a loaf and given a further 60 minute fermentation period (32 °C) before baking at 210 °C for 50 minutes. The loaves were then cooled and samples were immediately frozen for subsequent analysis.

Samples were stored frozen (about –18 °C) for up to 7 months before analysis for metrafenone using Method RLA 12619.03V (993/0), with a limit of quantification of 0.01 mg/kg. Concurrent recoveries from samples spiked with 0.01–0.1 mg/kg ranged from 76–104% with an average recovery of 89%.

Hops

In two studies reported by Braun, 2011 [Ref: 2011/1041879] and Plier, 2011 [Ref: 2011/1041886], hops from field trials conducted in Germany were taken for drying or processing into beer. In these field trials, two applications of about 0.33–0.35 kg ai/ha were applied 6–8 days apart using about 3300 Litres spray mix/ha.

Samples of green cones were taken 3–4 days after the last application and kiln-dried for about 7–8 hours at approximately 58 °C to produce dried cones. The green and dried cone samples were frozen within 12 hours and stored below –18 °C for subsequent analysis (up to 8 months after sampling). In addition, bulk dried cone samples (min 1.8 kg) were stored at ambient temperatures for about 1 month prior to processing.

Dried cones were milled and added to the separated wort and after boiling for about 90 minutes, the flocs (hops draff) were separated in a whirlpool and after cooling, yeast was added to initiate fermentation. Primary fermentation proceeded for 9–11 days at about 9 °C and secondary (cask) fermentation continued for a further 2 days at 20 °C and under pressure for a further 24 days at 2 °C before being filtered and sampled for subsequent analysis.

Dried cones were also processed into Extracted Hops by dissolving with ethanol using a soxhlet extractor for 3–4 hours, with the miscella being filtered and concentrated twice using a vacuum evaporator (above 50 °C and 0.5–1.0 bar) before cooling and sampling for subsequent analysis.

Samples were stored frozen (about -18 °C) for up to 4 months before analysis for metrafenone using Method 535/3, with a limit of quantification of 0.01 mg/kg. Concurrent recoveries from samples spiked with 0.01–1.0 mg/kg (and 10 mg/kg in extracted hops and 50–100 mg/kg in dried cones) ranged from 73–111% (except in extracted hops, where recovery rates were 65–68%) with an average recovery of 87%.

^a Each value represents a separate study where residues were above the LOQ in the RAC. The factor is the ratio of metrafenone residues in the processed item divided by the residue of metrafenone in the RAC.

^b See Table 50

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

No livestock feeding studies were provided.

NATIONAL RESIDUE DEFINITIONS

Table 72 Metrafenone: National residue definitions for MRL-compliance and dietary intake estimation

Country	MRL-compliance	Dietary intake estimation
Australia	metrafenone	metrafenone
Canada	metrafenone	metrafenone
Europe	metrafenone	metrafenone
Korea	metrafenone	metrafenone
New Zealand	metrafenone	metrafenone
USA	metrafenone	metrafenone

APPRAISAL

Metrafenone is a benzophenone fungicide, active mainly against powdery mildews and eyespot, inhibiting mycelium growth, leaf penetration, haustoria formation and sporulation.

It was scheduled by the Forty-fifth Session of the CCPR as a new compound for consideration by the 2014 JMPR. The manufacturer submitted studies on metabolism, analytical methods, supervised field trials, processing, freezer storage stability, environmental fate in soil and rotational crop residues.

Authorisations exist for the use of metrafenone on cereals, grapes, strawberries and fruiting vegetables in over 50 countries in Europe, the Americas, Asia and the Pacific.

Metrafenone
(MW 409.3)

The following abbreviations are used for the major metabolites discussed below:

Major metrafenone metabolites identified in plant, animal and soil matrices

Code	Structure	Chemical Name	Occurrence
CL 1023363		3-(3-bromo-6-methoxy-2-methylbenzoyl)-6-hydroxy-2-methoxy-4-methylphenyl β-D-glucopyranosiduronic acid Mono-O-glucuronide of Methanone, (3-bromo-6-hydroxy-2-methylphenyl)(3,4-dihydroxy-2-methoxy-6-methylphenyl-	goat

Code	Structure	Chemical Name	Occurrence
CL 1500698		3-(3-bromo-6-methoxy-2-methylbenzoyl)-2,6-dimethoxy-4-methylphenyl β-D-glucopyranosiduronic acid Methanone, (3-bromo-6-methoxy-2-methylphenyl)[3-beta-D-glucopyranuronosyloxy]-2,4-dimethoxy-6-methylphenyl-	rat, goat
CL 1500836		3-methoxy-2-(2,3,4-trimethoxy-6-methylbenzoyl)benzaldehyde	wheat grape
CL 197675		Methanone, (3-bromo-6-methoxy-2-carboxyl)(2,3,4-trimethoxy-6-methylphenyl)-	grape
CL 3000402		7-bromo-4-methoxy-3-(2,3,4-trimethoxy-6-methylphenyl)-2-benzofuran-1(3H)-one	rat wheat grape
CL 376991		Methanone, (3-bromo-6-methoxy-2-methylphenyl)(2,3,4-trimethoxy-6-methylphenyl)-	rat wheat
CL 379395		2-(3-bromo-6-methoxy-2-methylbenzoyl)-3,4,5-trimethoxybenzaldehyde	grape
CL 434223		Methanone, (3-bromo-6-methoxy-2-methylphenyl)(4-hydroxy-2,3-dimethoxy-6-methylphenyl)-	rat wheat
M560F06	R = H, R' and R'' = CH₃ or R' = H, R and R'' = CH₃ or R'' = H, R and R' = CH₃	Methanone, (3-bromo-6-methoxy-2-methylphenyl)(2-hydroxy-3,4-dimethoxy-6-methylphenyl)- or Methanone, (3-bromo-6-methoxy-2-methylphenyl)(3-hydroxy-2,4-dimethoxy-6-methylphenyl)- or Methanone, (3-bromo-6-methoxy-2-methylphenyl)(4-hydroxy-2,3-dimethoxy-6-methylphenyl)-	hen

Animal metabolism

The Meeting received information on the metabolism of ¹⁴C-metrafenone, separately labelled at the bromophenyl and the trimethoxyphenyl groups, in rats, lactating goats and laying hens. As no cleavage of the molecule was observed in these metabolism studies, the results for both radiolabels are reported together.

The metabolism of metrafenone in rats was evaluated by the WHO Core Assessment Group of the 2014 JMPR. Absorption of metrafenone is rapid and complete (> 88%) at the low dose of 10 mg/kg bw, limited to 15–20% at the high dose of 1000 mg/kg bw suggesting saturation of the

absorption processes. Metrafenone is widely distributed in the body, with highest residue levels mainly found in the gastro-intestinal (GI) tract, liver and fat. There is no evidence of accumulation. The labelled material is relatively rapidly excreted into the GI tract via the bile (85–90%) resulting in extensive excretion via faeces. Excretion via urine is relatively low (5–6% depending on radiolabel position), and even lower at the high dose level (*ca.* 1%). Metrafenone is extensively metabolised, with most of the radioactivity (approximately 80%) not identified, consisting of many (11–26) different components and totalling < 0.1 ppm at the low dose and < 1 ppm at the high dose. The identified metabolites, mostly < 1.0 mg eq./kg, included metrafenone and glucuronic acid conjugates in fat, liver and kidney.

Lactating goats

Lactating goats were orally dosed with ^{14}C -metrafenone at doses equivalent to about 10 ppm (8–13 ppm) and 70 ppm (60–87 ppm) in the feed for 5 consecutive days and sacrificed 23 hours after the last dose.

The majority of the radioactivity (76–86% AR) was excreted, mainly through the faeces. The highest residue levels were found in liver (0.21–0.23 mg eq./kg at the lower dose and 0.72–1.3 mg eq./kg at the higher dose) and kidney (0.05–0.06 mg eq./kg at the low dose and 0.16–0.33 mg eq./kg at the higher dose). Residues were significantly lower in fat (0.015–0.022 mg eq./kg at the high dose rate) and were ≤ 0.01 mg eq./kg in muscle and milk regardless of the dose rate. Residues reached a plateau in milk (0.01 mg eq./kg) within 3 days.

Residue characterization and identification was conducted on samples from the high dose groups with more than 95% TRR could be extracted from liver, kidney, milk and fat. Muscle samples were not investigated further because of the low TRR levels (< 0.01 mg eq./kg).

In fat, the predominant residue was metrafenone (0.01–0.02 mg/kg), making up 60–85% TRR and no other residues above 0.005 mg eq./kg (9% TRR) were found.

In liver and kidney, metrafenone made up about 3–4% TRR. The predominant residues were the glucuronide metabolites CL 1500698 and CL 1023363, not measured individually but together represented up to 15–21% TRR (0.27 mg eq./kg) in liver and up to 26–28% TRR (max 0.09 mg eq./kg) in kidney. An additional radiolabel fraction that included the glucuronide metabolites CL 1023361, CL1023362 and CL 1500702 totalled about 9–14% of TRR (max 0.17 mg eq./kg in liver and 0.03 mg/kg in kidney). About half the TRR was made up of a number of other unidentified metabolites, each present at < 5% TRR.

In milk, residues of metrafenone (24% TRR) and numerous metabolites, including one radiolabel fraction containing CL 1500698 and CL 1023363 (11% TRR), were all < 0.005 mg eq./kg.

Laying hens

In a poultry study laying hens were orally dosed with ^{14}C -metrafenone at doses equivalent to about 14 ppm in the feed for 12 consecutive days and sacrificed 22 hours after the last dose.

The majority (86–95%) of the administered dose was excreted, with about 0.25% AR (0.1 mg eq./kg) remaining in eggs, up to 0.09% AR (0.3–0.5 mg eq./kg) found in liver, < 0.01 % AR (0.06–0.08 mg eq./kg) present skin+fat and 0.003% AR (0.01 mg eq./kg) in muscle. Residues reached a plateau in eggs after 9 days.

Extraction was able to retrieve about 80% TRR from eggs, 60% TRR from skin+fat and about 30% TRR in liver and muscle. Characterisation and identification of residues in solvent-extracted samples indicated the presence of numerous polar and non-polar components. The one identified metabolite M560F06 was found in poultry skin+fat (6–11% TRR, < 0.01 mg eq./kg) and was identified but not quantified in eggs.

Metrafenone was found only in eggs and skin+fat, making up about 2% TRR (0.001–0.002 mg/kg) and the metabolite M560F06 was also measured in skin+fat (6–11% TRR) and

identified in eggs. With the exception of one unknown component in eggs (about 14% TRR, 0.015 mg eq./kg) all other metabolites were < 10% TRR (< 0.01 mg eq./kg) in all tissues and eggs.

In summary, residues were rapidly eliminated in the excreta (76–95% of the dose) with up to 0.5% of the total administered dose remaining in liver, 0.25% remaining in eggs, and TRRs were up to 0.02 mg eq./kg in fat and ≤ 0.01 mg eq./kg in muscle, poultry skin+fat and in milk.

The proposed metabolic pathways include hydroxylation and demethylation of the methyl groups and the phase II glucuronidation of the hydroxylated metabolites to various mono-O-glucuronides, qualitatively similar to the metabolic pathway in the rat.

Metrafenone made up about 2–4% of the TRR in liver, kidney, eggs and poultry skin+fat, was the main component in fat and was about 24% TRR in milk, but at very low levels (< 0.005 mg eq./kg). Most of the residues in liver and kidney were the glucuronide conjugates of metrafenone (CL 1500698, CL 1023363) which together made up 15–30% TRR, and numerous unidentified components, each present at < 10% TRR.

Plant metabolism

The Meeting received information on the metabolism of ^{14}C -metrafenone, separately labelled at the bromophenyl and the trimethoxyphenyl groups, in grapes, cucumber and wheat.

Grape

In outdoor grapevines treated with five foliar applications of ^{14}C -metrafenone at a rate equivalent to 0.2 kg ai/ha, 10–11 days apart, TRRs in grapes immediately after the last application were 0.6–0.77 mg eq./kg, reducing to 0.28–0.44 mg eq./kg at maturity, 35 days later. In leaves sampled immediately after the last application, TRRs were 40–42 mg eq./kg, reducing to 25–38 mg eq./kg after 35 days.

In grape juice, pomace and in leaves, 77–100% TRR was able to be sequentially extracted with acetone, methanol:water and water, with about 39–45% of the TRR in leaves being present in the acetone surface wash. Whole grapes were not analysed.

Metrafenone was not found in juice, but was the major residue in pomace (23–25% TRR, 0.06–0.11 mg/kg), and made up about 11–15% TRR in mature leave (35 days after the last application).

Characterisation of the residues in grape juice and pomace indicated the presence of several chromatographic fractions more polar than the parent, not exceeding 0.05 mg eq./kg and not more than 17% TRR. These were not identified further except for CL197675, found in juice at about 9% TRR (0.006 mg eq./kg).

Cucumber

In cucumber plants (confined) treated with two foliar applications of ^{14}C -metrafenone, applied 17 and 3 days before harvest, at a rate equivalent to 0.2 kg ai/ha, TRR in mature fruit, sampled 3 days after the second application were about 0.05 mg eq./kg (TRR), with 0.013 mg eq./kg present in pulp and 0.26 mg eq./kg in peel. More than 89% TRR was able to be extracted with methanol.

Metrafenone was the only identified residue component, making up 42% of the TRR in the mature fruit (0.02 mg/kg), and mostly in the peel (61% TRR, 0.16 mg/kg). Metrafenone also made up about 80% TRR in vines (without roots and fruit) at harvest.

Numerous polar and medium polar metabolites, characterized by their HPLC retention times and elution profiles, were present in fruit and vines at low concentrations (each less than 9% TRR).

Wheat

In outdoor wheat plants treated with 3 foliar applications of ^{14}C -metrafenone at rates equivalent to 0.3, 0.3 and 0.2 kg ai/ha, applied at 13–14 day intervals and with the last application being 35 days before

harvest, highest radioactive residues (up to 9 mg eq./kg) were found in hay and straw, with the lowest residues found in the grain (0.2–0.4 mg eq./kg). The TRR in foliage, 3 days after the first application were 5–8 mg eq./kg. Methanol:water extraction was able to release about 95% TRR in foliage, 78% TRR in hay, 61% TRR in straw and 35% TRR in grain. Additional extraction with hexane and acidified methanol was able to release a further 12–14% TRR in grain.

Metrafenone was the major component in all matrices, about 59–64% TRR in foliage, 13–26% TRR in hay, 8–14% in straw and 3–8% TRR in grain.

Other characterized or identified metabolites in foliage, hay and straw each represented less than 10% TRR. In grain, no identified metabolites were found above 0.004 mg eq./kg and although only about 50% of the radioactivity was extracted, further investigation showed that residues in the PES were made up of multiple minor components.

The proposed metabolic pathway involves oxidation of the methyl groups on the bromophenyl and trimethoxyphenyl rings to yield the corresponding aldehydes. In the case of the bromophenyl ring, the aldehyde can undergo further oxidation to the carboxylic acid, cyclization to form the lactone, and/or dehalogenation to form the des-bromo aldehyde.

In summary, metrafenone is the predominant residue in crops, with numerous minor metabolites or fractions present at low concentrations and generally more polar than the parent. While these were not all identified or quantified, individual peaks were < 10% TRR or < 0.01 mg eq./kg.

Environmental fate

The Meeting received information the environmental fate and behaviour of metrafenone, including hydrolytic stability, photolysis in aqueous solutions, aerobic metabolism and rotational crop metabolism studies.

Metrafenone was stable in sterile buffered solutions at pH 4, 7, and 9 but rapidly degraded in aqueous pH 7 solutions by photolysis (DT₅₀ values of 2.6–3.1 days) with the formation of multiple degradation products, all found at < 10% of the applied radioactivity. DT₉₀ values were 8.5 days (natural water) and 10.2 days (sterile water).

Aerobic soil metabolism

Metrafenone degraded slowly in loamy sand, sandy loam and clay loam soils treated with the equivalent of about 0.1 kg ai/ha [bromophenyl-label]-metrafenone or [trimethoxy-label]-metrafenone and incubated for up to 210 days under aerobic laboratory conditions. Metrafenone made up about 82% AR after 120-days and 66–69% AR after 210 days. Calculated half-lives (1st order kinetics) ranged from 182–365 days.

Residues in succeeding crops

In one outdoor rotational crop metabolism study, a leafy vegetable crop (lettuce), root crop (radish) and oil crop (canola) were planted back at various time intervals (30, 60, 90 and 365 days) after a single application of [trimethoxy-label]-metrafenone or [bromophenyl-label]-metrafenone to bare soil at a rate equivalent to 0.625 kg ai/ha.

The uptake of residues in these representative rotational crops (lettuce, radish, canola) was low, with TRRs at all plant-back intervals ranging from < 0.004 to 0.048 mg eq./kg (in canola pods), generally highest in the samples from the 30-day plant back interval. In soil, radioactive residues declined by about 50% after 90 days, and were mostly found in the top 10 cm of soil samples.

Total extractable residues ranged from 64% to 88% TRR in the majority of the samples (42–86% TRR in canola seed) and comprised mostly of multiple unidentified polar components, all present at < 0.02 mg eq./kg. Metrafenone accounted for 0.004 mg/kg of the TRR in lettuce (90 DAT) and radish roots (30 DAT) and was not found in canola or radish tops.

In summary, metrafenone is stable to hydrolysis, rapidly degraded by photolysis, slowly degraded in soil under aerobic conditions (remaining mostly in the top 10 cm) and not found at

significant levels in rotational crops. The Meeting concluded that residues are not expected in rotational crops following treatments according to the GAPs under consideration.

Analytical methods

Several analytical methods have been reported and validated for the analysis of metrafenone in plant and animal commodities. One method has also been validated for measuring residues of the CL 300402, CL 434223 and CL 376991 metabolites. The basic approach employs extraction with methanol/water, aqueous acetone or n-heptane/acetone, SPE or GPC clean-up and analysis by GC-ECD, GC-MS, or LC-MS/MS. In some methods, an additional partition step is included, using dichloromethane, cyclohexane, acetone, ethyl acetate, singly or sequentially.

For plant and processed plant commodities, the DFG S19 (GC-ECD or GC-MS) or the QuEChERS (LC-MS/MS) methods were used in most of the supervised residue field trials, with the RLA 12619 (LC-MS/MS) method used to measure parent and metabolites in some cereal trials. These methods were validated in a range of matrices (wheat, barley, grapes, cucumber, summer squash, melon, tomato, pepper, lemon, dry bean, oilseed rape and hops). The LOQ is 0.1 mg/kg for mushrooms and cereal forage and straws and 0.01 mg/kg for all other matrices.

For animal commodities, the DFG S19 (GC-MS) method was validated for the analysis of metrafenone in muscle, milk and eggs. After extraction with aqueous acetone, extracts are partitioned into ethyl acetate/cyclohexane before SPE clean-up and analysis. The LOQ is 0.01 mg/kg for milk and 0.05 mg/kg for muscle and eggs.

Stability of pesticide residues in stored analytical samples

Metrafenone residues were stable in analytical samples stored frozen (-18 to -20 °C) for up to 24 months in representative substrates with a high water content (lettuce, tomato), a high starch content (carrot, wheat grain), a high protein content (dry peas), a high oil content (soya bean) (grape, wine) and in , wheat forage and straw residues were stable for at least 31 months. In general, residues in the stored samples were greater than 80% of the spiked levels.

Definition of the residue

In animal commodities, metrafenone was the main identified component in goat fat (60–85% TRR) and poultry eggs and skin+fat (2% TRR) but made up about only 3–4% of the TRR in goat liver and kidney. Most of the identified residues in goat liver and kidney were in the radiolabel fraction that included CL 1500698 and CL 1023363 (totalling 15-30% TRR), with numerous unidentified minor fractions found at lower levels, each generally < 5% TRR. In muscle, TRRs were not found above 0.01 mg eq./kg in the highest dose groups of 65–87 ppm (goat) and 14 ppm (hen) and the TRR in milk was also < 0.01 mg eq./kg.

Based on the metabolism studies, a residue definition for animal commodities that includes metrafenone and the CL 1500698 and the CL 1023363 glucuronides could be considered. However the Meeting noted that these metabolites were not found in hens and only present in goats at low levels (totalling up to 0.27 mg eq./kg in liver and 0.09 mg eq./kg in kidney) following dosing at levels more than 7 times higher than the anticipated maximum livestock dietary burdens. CL 1023363 is structurally similar to rat metabolites and CL 1500698 was found in the rat metabolism study. Both metabolites are accommodated in the ADI. The Meeting therefore concluded that they need not be included in the residue definitions.

Based on the anticipated dietary exposure, the Meeting concluded that significant residues of the CL 1500698 and CL 1023363 metabolites are not expected in animal commodities and as a multi-residue method existed to measure the parent compound in animal commodities, a suitable residue definition for MRL-compliance and dietary intake estimation was metrafenone. Based on the Log P_{ow} of 4.3 and since residues of metrafenone were only found in fat and milk, the Meeting concluded that metrafenone is fat-soluble.

In plant commodities from treated crops, the metabolism studies indicated that metrafenone was the major residue in grape (up to 25% TRR in grape pomace), cucumber (up to 42% TRR) and wheat matrices (up to 8% TRR in grain and 14-64% TRR in foliage and straw), with numerous minor metabolites or radiolabel fractions present at low concentrations and generally more polar than the parent. While these were not all identified or quantified, individual peaks were <10% TRR or <0.01 mg eq./kg.

Metabolite CL 3000402 was occasionally found in grain at levels up to about 10% of the parent concentration but were <0.02 mg/kg. Metabolites CL 3000402, CL 434223 and CL 376991, found in the wheat metabolism study at up to 7% TRR in foliage and straw, were also measured in the foliage, straw and hay from a number of wheat and barley field trials, generally at levels less than 10% of the parent residue. These three metabolites were also found in the rat metabolism study and are accommodated in the ADI.

The Meeting noted that multiresidue methods exist to measure parent residues and agreed that for MRL-compliance and dietary intake estimation, the residue definition for plant commodities should be metrafenone.

Proposed definition of the residue (for compliance with the MRL and estimation of dietary intake for plant commodities): *metrafenone*.

Proposed definition of the residue (for compliance with the MRL and estimation of dietary intake for animal commodities): *metrafenone*.

Metrafenone is fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised trial data for foliar applications of metrafenone on a range of berries and other small fruits, fruiting vegetables, cereals and hops. These trials were conducted mainly in Europe and/or North America.

Where residues have been reported as ND (<LOD) the values have been considered as <LOQ (<0.01 mg/kg) for the purposes of MRL setting. If a higher residue level was observed at a longer PHI than the GAP, the higher value has been used in MRL setting.

The Meeting noted that GAP has been authorised for the use of metrafenone in more than 50 countries in Europe, the Americas, Asia and the Pacific and that product labels were available from many of these countries. Supervised trial data were also provided for pome fruit, stone fruit and hops, but no GAP information was available to support maximum residue level estimations for these commodities.

Berries and small fruit

Results from supervised trials on grapes conducted in USA and strawberries conducted in Europe were provided to the Meeting.

Grape

The critical GAP for metrafenone on grapes is in Canada, up to 6 foliar applications of 0.225 kg ai/ha applied at least 14–21 days apart with a PHI of 14 days and with a total of 1.35 kg ai/ha/season. In trials from USA conducted at about 1.5 times higher rate than the Canadian GAP, metrafenone residues in grapes were: 0.11, 0.17, 0.18, 0.27, 0.32, 0.62, 2.1, 2.3, 2.4, 3.0, and 3.2 mg/kg. When proportionally adjusted to the Canadian GAP (scaling factors (S_f) of 0.64–0.68), metrafenone residues in these trials are: 0.08, 0.11, 0.12, 0.17, 0.22, 0.42, 1.1, 1.4, 1.5, 1.6, 2.0 and 2.2 mg/kg (n=12).

The Meeting estimated an STMR of 0.74 mg/kg and a maximum residue level of 5 mg/kg for metrafenone on grapes.

Strawberry

The critical GAP for metrafenone on strawberries is on protected crops in the Netherlands, up to 2 foliar applications of 0.15 kg ai/ha, applied at least 7 days apart with a PHI of 3 days. In trials on protected strawberries matching this GAP in Netherlands, metrafenone residues in fruit were: 0.05, 0.06, 0.08, 0.1, 0.16, 0.23, 0.28 and 0.34 mg/kg (n=8).

The Meeting estimated an STMR of 0.13 mg/kg and a maximum residue level of 0.6 mg/kg for metrafenone on strawberries.

Fruiting vegetables, Cucurbits

Results from supervised trials on cucumbers, summer squash (zucchini) and melons (cantaloupes) conducted in Europe and North America were provided to the Meeting. However no GAP information was available from North America

Cucumber

The critical GAP for metrafenone on cucumbers is in France, up to 2 foliar applications of 0.1 kg ai/ha, applied at least 7–10 days apart with a PHI of 3 days. This GAP applies to both outdoor and protected crops.

In trials on outdoor cucumbers in Europe matching this GAP in France, metrafenone residues in cucumbers were: 0.01, 0.02, 0.02, 0.02, 0.02, 0.02, 0.03 and 0.04 mg/kg (n=8).

In trials on protected cucumbers matching this GAP in France, metrafenone residues in cucumbers were: 0.02, 0.04, 0.04, 0.05, 0.05, 0.06, 0.06, 0.07 and 0.09 mg/kg (n=9).

Based on the data set for protected cucumbers, the Meeting estimated an STMR of 0.05 mg/kg and a maximum residue level of 0.2 mg/kg for metrafenone on cucumber.

The Meeting also agreed to extrapolate these estimations to gherkins.

Summer squash

The critical GAP for metrafenone on summer squash is in France, up to 2 foliar applications of 0.1 kg ai/ha, applied at least 7–10 days apart with a PHI of 3 days. In trials on summer squash in Europe matching this GAP in France, metrafenone residues in summer squash were: 0.01, 0.01, 0.01, 0.01, 0.02, 0.02, 0.02 and 0.04 mg/kg (n=8).

The Meeting estimated an STMR of 0.015 mg/kg and a maximum residue level of 0.06 mg/kg for metrafenone on summer squash.

Melons (except watermelon)

The critical GAP for metrafenone on melons is in France, up to 2 foliar applications of 0.1 kg ai/ha, applied at least 7–10 days apart with a PHI of 3 days. In trials on melons in Europe matching this GAP in France, metrafenone residues in melons were: < 0.01, 0.01, 0.01, 0.02, 0.02, 0.02, 0.02, 0.02, 0.02, 0.03, 0.05, 0.06 and 0.07 mg/kg (n=13).

However the Meeting noted that in these trials, the melons had been quartered in the field and although the subsamples had been frozen within 12 hours after sampling, no information was available on residue stability in chopped or sliced samples.

The Meeting was unable to estimate a maximum residue level for metrafenone on melons.

Fruiting vegetables, other than Cucurbits

Results from supervised trials on tomatoes and peppers (sweet, bell and non-bell) conducted in Europe and North America and from trials on mushrooms in Europe were provided to the Meeting.

Mushrooms

The critical GAP for metrafenone on mushrooms is in France, one broadcast treatment of 0.05 kg ai/15 litres water/100 square metres of compost, applied up to 10 days before harvest. In trials on mushrooms in Europe matching this GAP in France, metrafenone residues in mushrooms were: 0.1, 0.1, 0.11 and 0.19 mg/kg (n=4)

The Meeting estimated an STMR of 0.105 mg/kg and a maximum residue level of 0.5 mg/kg for metrafenone on mushrooms.

The Meeting noted that the OECD MRL-calculator proposed a maximum residue level of 0.4 mg/kg, but agreed that a higher value on 0.5 mg/kg was more appropriate due to the small data set and because the relatively close spread of results may not reflect the residue variability arising from different composts used in mushroom production.

Pepper, Sweet

The critical GAP for metrafenone on peppers is in France for protected crops, up to 2 foliar applications of 0.15 kg ai/ha, applied at least 7–10 days apart with a PHI of 3 days. In trials on protected sweet peppers matching this GAP in France, metrafenone residues in peppers were: 0.07, 0.08, 0.1, 0.11, 0.12, 0.2, 0.21 and 1.3 mg/kg (n=8).

The Meeting estimated an STMR of 0.115 mg/kg and a maximum residue level of 2.0 mg/kg for metrafenone on peppers, sweet and agreed to extrapolate these estimations to chili pepper.

For dried chili peppers, applying the default processing factor of 10 to the STMR and the maximum residue level estimated for peppers, the Meeting estimated an STMR-P of 1.15 mg/kg and a maximum residue level of 20 mg/kg for metrafenone on dried chili peppers.

Tomato

The critical GAP for metrafenone on tomatoes is in Spain, up to 2 foliar applications of 0.015 kg ai/hL with a PHI of 3 days. This GAP applies to both outdoor and protected crops.

In trials on outdoor tomatoes in Europe matching this GAP in Spain, metrafenone residues in tomatoes were: 0.02, 0.05, 0.05, 0.06, 0.06, 0.07, 0.08 and 0.15 mg/kg (n=8).

In trials on protected tomatoes matching this GAP in Spain, metrafenone residues in tomatoes were: 0.06, 0.09, 0.09, 0.1, 0.1, 0.1, 0.16 and 0.17 mg/kg (n=8).

Based on the data set for protected tomatoes, the Meeting estimated an STMR of 0.1 mg/kg and a maximum residue level of 0.4 mg/kg for metrafenone on tomato.

Cereal grains

Results from supervised trials on wheat and barley conducted in Europe were provided to the Meeting.

Wheat

The critical GAP for metrafenone on wheat is in Poland, up to 2 foliar applications of 0.15 kg ai/ha with a PHI of 35 days. In trials in Europe matching this GAP in Poland, metrafenone residues in wheat grain were: < 0.01 (9), 0.01 (4), 0.02, 0.03, 0.03, 0.04 and 0.04 mg/kg (n=18).

The Meeting estimated an STMR of 0.01 mg/kg and a maximum residue level of 0.06 mg/kg for metrafenone on wheat.

The Meeting also agreed to extrapolate these estimations to rye and triticale.

Barley

The critical GAP for metrafenone on barley is in Poland, up to 2 foliar applications of 0.15 kg ai/ha with a PHI of 35 days. In trials in Europe matching this GAP in Poland, metrafenone residues in

barley grain were: < 0.01, 0.02 (3), 0.03, 0.04, 0.05 (3), 0.06, 0.06, 0.07, 0.08, 0.09, 0.11, 0.13, 0.15, 0.16, 0.23 and 0.4 mg/kg (n=20).

The Meeting estimated an STMR of 0.06 mg/kg and a maximum residue level of 0.5 mg/kg for metrafenone on barley.

The Meeting also agreed to extrapolate these estimations to oats.

Animal feeds

Cereal forages

Wheat and barley plant or foliage samples were collected in many of the European trials matching the GAP in Hungary/Poland (up to 2 foliar applications of 0.15 kg ai/ha).

Wheat forage

In wheat trials matching the GAP in Poland, metrafenone residues in plant (forage) samples taken 0-days after the last application were: 1.8, 2.0, 2.0, 2.6, 2.6, 2.6, 2.8, 3.3, 3.7, 3.8, 4.3 and 4.8 mg/kg (fresh weight).

The Meeting estimated a median residue of 2.7 mg/kg (fresh weight) and a highest residue of 4.8 mg/kg (fresh weight) for wheat forage and agreed to extrapolate these estimations to rye and triticale.

Barley forage

In barley trials matching the GAP in Poland, metrafenone residues in plant (forage) samples taken 0-days after the last application were: 1.8, 2.3, 2.5, 2.5, 3.1, 3.4, 3.7, 3.8, 4.6, 5.0, 5.8 and 5.9 mg/kg (fresh weight).

The Meeting estimated a median residue of 3.75 mg/kg (fresh weight) and a highest residue of 5.9 mg/kg (fresh weight) for barley forage and agreed to extrapolate these estimations to oats.

Cereal and grass straws and hays

Wheat and barley straw samples were collected in many of the European trials matching the GAP in Poland (up to 2 foliar applications of 0.15 kg ai/ha).

Wheat straw

In trials in Europe matching this GAP in Poland, metrafenone residues in wheat straw (fresh weight) were: 0.67, 0.67, 0.98, 1.1, 1.3, 1.4, 1.6, 1.7, 1.8, 2.0, 2.1, 2.3, 3.1, 3.1, 3.5, 3.6, 3.6 and 6.7 mg/kg (n=18). After correction for an average 88% dry matter content, residues (dry weight) were: 0.76, 0.76, 1.1, 1.3, 1.5, 1.6, 1.8, 1.9, 2.1, 2.3, 2.4, 2.6, 3.5, 3.5, 4.0, 4.1, 4.1 and 7.6 mg/kg.

The Meeting estimated a median residue of 1.9 mg/kg (fresh weight), a highest residue of 6.7 mg/kg (fresh weight) and a maximum residue level of 10 mg/kg (dry weight) for metrafenone in wheat straw.

The Meeting also agreed to extrapolate these estimations to rye and triticale.

Barley straw

In trials in Europe matching the GAP in Poland, metrafenone residues in barley straw (fresh weight) were: < 0.01, 0.24, 0.41, 0.95, 1.0, 1.1, 1.1, 1.1, 1.2, 1.3, 1.3, 1.5, 1.7, 1.8, 1.9, 1.9, 2.0, 2.1, 3.6 and 3.9 mg/kg (n=20). After correction for an average 89% dry matter content, residues (dry weight) were: < 0.01, 0.29, 0.46, 1.1, 1.1, 1.2, 1.2, 1.24, 1.4, 1.5, 1.5, 1.5, 1.9, 2.0, 2.1, 2.1, 2.3, 2.4, 4.0 and 4.4 mg/kg.

The Meeting estimated a median residue of 1.3 mg/kg (fresh weight), a highest residue of 3.9 mg/kg (fresh weight) and a maximum residue level of 6 mg/kg (dry weight) for metrafenone in barley straw.

The Meeting also agreed to extrapolate these estimations to oats.

Fate of residues during processing

The effect of processing on the nature of residues was investigated using radiolabelled metrafenone in buffer solutions incubated under conditions simulating pasteurisation (in pH 4 buffer at 90 °C for 20 minutes); baking, brewing, or boiling (in pH 5 buffer at 100 °C for 60 minutes); and sterilization (in pH 6 buffer at 120 °C for 20 minutes). Metrafenone was stable under these processing conditions with no significant changes in the radio-chromatograms.

The fate of metrafenone residues has been examined in a number of studies simulating household and commercial processing of apples, grapes, strawberries, tomatoes, barley, wheat and hops. Estimated processing factors and STMR-Ps for the commodities considered at this Meeting are summarised below.

Summary of selected processing factors and STMR-P values for metrafenone

RAC	Matrix	Metrafenone ^a	PF best estimate	STMR (mg/kg)	STMR-P (mg/kg)
		Calculated processing factors			
Grape	grapes			0.76	
	must (red wine)	0.03, 0.15, < 0.18, 0.26, 0.57, 0.77, 0.78, 0.81, 1.17, 1.29	0.67		0.51
	wet pomace	2.8, 3.6	3.2		2.4

	whole grain bread	0.6, 0.64, 0.71, 1.0	0.675		0.007

^a Each PF value represents a separate study where residues were above the LOQ in the RAC and is the ratio of the metrafenone residues in the processed item divided by the residues in the RAC.

The Meeting noted that in the studies available, metrafenone residues did not concentrate in food commodities during processing, except in dehydrated commodities such as raisins, bran and flour. Residues also increased in wet pomace (grape and tomato), tomato peel and barley abrasion fractions.

The Meeting estimated a maximum residue level for dried grapes of 20 mg/kg based on the maximum residue level estimated for grapes (5.0 mg/kg) and the median processing factor (3.75) from the USA processing studies.

The Meeting estimated a maximum residue level for wheat bran (processed) of 0.25 mg/kg based on the maximum residue level estimated for wheat (0.06 mg/kg) and a median processing factor of 4.2.

The Meeting estimated a maximum residue level for wheat wholemeal of 0.08 mg/kg based on the maximum residue level estimated for wheat (0.06 mg/kg) and a median processing factor of 1.4.

Residues in animal commodities

Farm animal dietary burden

The Meeting estimated the dietary burden of metrafenone in farm animals on the basis of the diets listed in Appendix IX of the 2009 edition of the JMPR Manual. Noting that fresh forage commodities are not significant in international trade, the Meeting only included the burden contributions from the cereal forages in the European dietary burden calculation, as metrafenone is not authorised for use on cereals in US-Canada, Australia or Japan.

Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6 of the 2014 Report and are summarized below:

Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden, metrafenone, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.8	0.26	5.9	3.8	9.3 ^a	4.9 ^c	0.07	0.07
Dairy cattle	0.8	0.25	5.9	3.8	9.2 ^b	4.9 ^d	0.42	0.14
Poultry – broiler	0.05	0.05	0.05	0.05	0.02	0.02	0.007	0.007
Poultry – layer	0.05	0.05	2.0 ^{e g}	1.3 ^{f h}	0.015	0.015	0.008	0.008

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues

^b Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

^c Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues.

^f Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues.

^g Highest maximum poultry dietary burden suitable for MRL estimates for poultry eggs.

^h Highest mean poultry dietary burden suitable for STMR estimates for poultry eggs.

For beef and dairy cattle, the calculated maximum dietary burden is 9.3 ppm dry weight of feed and for poultry, noting that in some countries, laying hens may also be consumed, the calculated maximum dietary burden suitable is 2.0 ppm dry weight of feed.

Farm animal feeding studies

No livestock feeding studies were provided.

Animal commodity maximum residue levels

The Meeting noted that in the goat metabolism study, up to 0.014 mg/kg metrafenone was found in the kidney from the high (87 ppm) dose group animals and by extrapolation, this would equate to a maximum level of 0.0015 mg/kg in kidney from animals exposed to the calculated maximum dietary burden of 9.3 ppm.

In liver, metrafenone residues were up to 0.025 mg/kg in the high (60 ppm) dose group animals and by extrapolation, this would equate to a maximum level of 0.004 mg/kg in liver from animals exposed to the calculated maximum dietary burden of 9.3 ppm.

In animals dosed with 10 ppm in the diet (approximating the maximum calculated dietary burden for beef and dairy cattle, radiolabel residues were < 0.005 mg eq/kg in muscle, milk and fat.

The Meeting estimated maximum residue levels of 0.01* mg/kg for metrafenone in meat (from mammals other than marine mammals), 0.01 mg/kg for edible offal (mammalian), 0.01* mg/kg for mammalian fat and 0.01* mg/kg for milks. Estimated STMRS for dietary intake estimation are 0 mg/kg for meat, 0.01 mg/kg for edible offal, 0 mg/kg for fat and 0 mg/kg for milk.

In the hen metabolism study, residues of metrafenone were up to 0.002 mg/kg in eggs and up to 0.001 mg/kg in skin+fat in hens dosed with 14 ppm in the diet (about 7-fold higher than the maximum calculated dietary burden for poultry). In muscle and liver, metrafenone residues were not detected.

The Meeting estimated maximum residue levels of 0.01* mg/kg for metrafenone in poultry meat, 0.01* mg/kg for poultry offal, 0.01* mg/kg for poultry fat and 0.01* mg/kg for eggs. Estimated STMRS for dietary intake estimation are 0 mg/kg for poultry fat, 0 mg/kg for poultry meat, 0 mg/kg for poultry offal and 0 mg/kg for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for MRL-compliance and estimation of dietary intake, plant commodities): *metrafenone*.

Definition of the residue (for MRL-compliance and estimation of dietary intake, animal commodities): *metrafenone*.

The residue is fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intake (IEDI) for metrafenone was calculated for the food commodities for which STMRs or HRs were estimated and for which consumption data were available. The results are shown in Annex 3.

The International Estimated Daily Intakes of metrafenone for the 17 GEMS/Food cluster diets, based on estimated STMRs were 0% of the maximum ADI of 0.3 mg/kg bw (Annex 3). The Meeting concluded that the long-term intake of residues of metrafenone from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The 2014 JMPR decided that an ARfD was unnecessary. The Meeting therefore concluded that the short-term intake of metrafenone residues is unlikely to present a public health concern.

MYCLOBUTANIL (181)*First draft prepared by Dr. Yibing He,**Department of Science and Education, Ministry of Agriculture, China***EXPLANATION**

Myclobutanil was originally evaluated by the JMPR in 1992 and re-evaluated for residues several times up to 1998. It was reviewed as part of the periodic re-evaluation programme of CCPR on residue and toxicity in 2014 JMPR. Myclobutanil is a systemic protectant fungicide used to control brown rot, powdery mildew and leaf spot in stone fruit crops, and belongs to the sterol demethylation inhibitor (DMI) class of fungicides.

At the Forty-fifth Session of the CCPR (REP13/PR, Appendix XIV), myclobutanil was scheduled for periodic residue review by the 2014 JMPR. The Meeting received information on physical and chemical properties, metabolism, environmental fate, analytical methods and freezer storage stability, national registered use patterns, as well as supervised trials, processing studies and livestock feeding studies.

IDENTITY

ISO Common name	myclobutanil
Chemical name	
IUPAC name	(R,S)-2-(4-chlorophenyl)-2-(1H-1,2,4-triazole-1-ylmethyl)hexanenitrile
CAS name	α -n-butyl- α -(4-chlorophenyl)-1H-1,2,4-triazole-1-propanenitrile
CAS Registry Number	88671-89-0
CIPAC Number	442
Synonyms and trade names	
Manufacturer's codes	RH-53,866
Structural formula	

Molecular formula	C ₁₅ H ₁₇ Cl N ₄
Molecular weight	288.8 g/mol
Minimum content of ai	

PHYSICAL AND CHEMICAL PROPERTIES

Pure active ingredient		Ref
Appearance (purity 98.75%) (purity 95.4%)	White crystal Colourless to white crystal	134760 134761
Odour (purity 98.75%) (purity 95.4%)	Odourless Faint aldehyde	134760 134761
Vapour pressure (purity 99.9%):	1.98×10^{-4} Pa at 20 °C	94926
Henry's law constant	4.33×10^{-4} kPa m ³ /mol	94865
Boiling point (purity 98.75%)	390.8 °C at 97.6 kPa	94922
Melting point (purity 98.75%)	70.9 °C	111087
Octanol-water partition coefficient at 22 °C: (purity 99.9%)	log P _{OW} = 2.556 There is no pH effect as the molecule is neither acidic nor basic. It does not dissociate.	138549
Solubility in water at 20 °C (purity 99.9%):	pH 3-5: 124 g/L pH 7: 132 g/L pH 9-11: 115 g/L	94924
Relative density (purity 98/75%)	1.243 g/cm ³ 20.4 °C	95055
Dissociation constant in water (purity 99.6%)	The pure ingredient does not have acidic hydrogen and is expected to be a very weak base. Attempts to measure pK _a by titration failed to detect any inflection curve indicating no dissociation	
Hydrolysis rate at pH 4, 7 and 9 under sterile and dark conditions	At 25 °C myclobutanil is hydrolytically stable more than 1 year at pH 4, 7 and 9.	94798
Direct phototransformation in sterile water using artificial light		
Surface tension, 24 °C (purity 99.8%)	46.8 mN/m for 90% saturated aqueous solution at 24 °C.	95055
Quantum yield efficiency (purity 97.3%)		
Solubility in organic solvents at 20 °C:	Acetone > 250 g/L Dichloromethane > 250 g/L Ethyl acetate > 250 g/L n-Heptane 1.02 g/L Methanol > 250 g/L Xylene 270 g/L	134458

Formulations

Myclobutanil is available in various formulations such as the following formulations:

Formulation	Products
Suspension concentrate	45 g/L SC, 60 g/L SC
Wettable Powder	2.25% WP, 40% WP, 35% WP, 10% WP, 10.8% WP, 1% WP, 2.25% WP, 8 g/kg WP, 2.0% WP, 3.8% WP

Emulsion Concentrate	240 g/L EC, 125 g/L EC, 32.4 g/L EC, 75 g/L EC, 25.8% EC, 45 g/L EC, 23.4%EC, 30% EC
Emulsion Oil in Water	200 g/L EW, 45 g/L EW, 25 g/L EW

METABOLISM AND ENVIRONMENTAL FATE

The Meeting received information on animal metabolism, plant metabolism and environmental fate studies using [^{14}C]-myclobutanil (phenyl and triazole ring labelled) and unlabelled myclobutanil.

a ^{14}C -Phenyl myclobutanil

b ^{14}C -Triazole myclobutanil

Unlabelled myclobutanil

Structures, names and codes for myclobutanil and its metabolites in metabolism and environmental fate studies are summarized below.

Code Name	Chemical Name	Metabolite Identity	Matrix where found
Myclobutanil Parent	α -butyl- α -(4-chlorophenyl)-1H-1,2,4-triazole-1-propanenitrile		Grapes Apples Wheat Sugar beet Laying hens Ruminants
(RH-9089)	(2RS)-2-(4-chlorophenyl)-5-oxo-2-(1H-1,2,4-triazol-1-ylmethyl)hexanenitrile		Grapes Apples Sugar beet Ruminants
(RH-9090)	α -(4-chlorophenyl)- α -(3-hydroxybutyl)-1H-1,2,4-triazole-1-propanenitrile		Grapes Apples Wheat Sugar beet Ruminants
MW 318 Acid (butyl carboxylic acid of myclobutanil)	5-(4-chlorophenyl)-5-cyano-6-(1H-1,2,4-triazol-1-yl)hexanoic acid		Groundwater Soil Ruminants

Code Name	Chemical Name	Metabolite Identity	Matrix where found
N-Glucuronic Acid Conjugate of Myclobutanil	1-[2-(4-chlorophenyl)-2-cyanoethyl]-4-hexopyranuronosyl-1H-1,2,4-triazol-4-ium		Ruminants
Hydroxy-lactone	3-(4-chlorophenyl)-5-(1-hydroxyethyl)-3-(1H-1,2,4-triazol-1-ylmethyl)dihydrofuran-2(3H)-one		Ruminants
RH-9090 Glucuronic Acid Conjugate	5-(4-chlorophenyl)-5-cyano-6-(1H-1,2,4-triazol-1-yl)hexan-2-yl hexopyranosiduronic acid		Grapes Apples Wheat Sugar beet Ruminants
RH-9090 Sulfate Conjugate	5-(4-chlorophenyl)-5-cyano-6-(1H-1,2,4-triazol-1-yl)hexan-2-yl hydrogen sulfate		Laying hens Ruminants
MW 334 Acid	5-(4-chlorophenyl)-5-cyano-2-hydroxy-6-(1H-1,2,4-triazol-1-yl)hexanoic acid		Ruminants
RH-294 (Diol)	α -(4-chlorophenyl)- α -(3,4-hydroxy-butyl)-1H-1,2,4-triazole-1-propane-nitrile		Laying hens Ruminants
RH-294 Sulfate Conjugate	5-(4-chlorophenyl)-5-cyano-1-hydroxy-6-(1H-1,2,4-triazol-1-yl)hexan-2-yl hydrogen sulfate		Ruminants
TA (Triazolyl Alanine)	(2 <i>RS</i>)-2-amino-3-(1H-1,2,4-triazol-1-yl)propanoic acid		Rotational wheat

Code Name	Chemical Name	Metabolite Identity	Matrix where found
TAA (Triazolyl Acetic Acid)	1H-1,2,4-triazol-1-ylacetic acid		Rotational wheat

Animal Metabolism

The Meeting received animal metabolism studies with myclobutanil in lactating goats and laying hens.

Lactating goats

Myclobutanil was orally given to lactating goats (Alpine dairy goats) for five days. Individual goats were dosed separately with myclobutanil radiolabelled in either the triazole (TZ) portion or the phenyl ring (PH) at the rate of 24 ppm and 14 ppm (Rotondaro, S. L. *et al.*, 2010, 2006417) in dry feed of the diet per day, respectively. Milk, urine and faeces were collected daily. The animals were sacrificed 6–7 hours after the final dose and the following tissues were collected: liver, muscle (flank and loin), fat (subcutaneous, omental, and renal), and kidney. Samples were stored at -10 °C or below until analysis. Levels of total radioactive residues (TRR) in urine and milk samples were determined by direct liquid scintillation counting (LSC). TRR levels in the liver, kidney, muscle and faecal samples were determined by oxidative combustion followed by LSC. TRR levels in fat were determined by the heated solubilisation followed by direct LSC of the liquefied samples. The amount of the milk, fat, excreta and edible tissues, and after extraction with acetone, hexane and acetonitrile/water (80/20) and liquid-liquid partition they were analysed by HPLC. Myclobutanil and metabolites in urine, liver and kidney were identified by MS. The results were summarized in Table 1 and Table 4.

^b Reported residues for RH-9089 in liver and kidney may be artificially high as the radioactivity eluting in the RH-9089 zone in the HPLC system used was often very broad in nature. Reanalysis of these extracts in another system or by LC-MS often showed only very low levels of RH-9089. Much of the radioactivity during reanalysis appeared to be additional RH-9090 or conjugates of RH-9090.

The unchanged parent compound was only observed in liver. The metabolite RH-9090 and its sulphate and glucuronic acid conjugates were the primary residue in liver, in kidney, in muscle, in fat and in milk. The hydroxyl-lactone was the only other metabolite present in liver more than 10% of the TRR. The only other two metabolites representing 10% or more of the TRR were RH-294 and the MW 318 carboxylic acid in milk and no parent compound was detected in milk.

Figure 1 Proposed metabolic profile for myclobutanil in ruminants

Laying hens

[¹⁴C]-Myclobutanil or a mixture of RH9090/9089 (82:18) were each administered orally by gelatine capsule to separate groups of three laying hens (Leghorn) once daily for 7 consecutive days at the nominal equivalent of 110 ppm in the diet (Jacobson, 1986, 94610; Martin, 1986, 94169). The test substances were uniformly labelled in the phenyl ring (myclobutanil: 110 ppm) and in the triazole ring (82 ppm RH9090: 18 ppm RH9089). Ten hens were used as a control group. All chickens in these groups were sacrificed 24 hours after final dose. All eggs were separated into yolks and whites on study days 1 and 6. All samples were frozen pending analysis. Radioactivity was measured by liquid scintillation counting (LSC). Whole eggs and muscle were extracted with ethyl acetate, and then extracted with methanol. Fat and edible offal were extracted with n-hexane and methanol. The nature of radioactivity in all tissues was investigated further. The nature of radioactivity in eggs and tissues was investigated further. The results were summarized in Tables 5 to 7.

Table 5 Myclobutanil residue equivalents (expressed as mg myclobutanil equivalents/kg) in tissues from hens dosed orally at rates equivalent to 110 ppm in the diet

Residues in tissues were extremely low at the exaggerated dose level of 110 ppm. Highest levels were observed in the liver and kidney. Residues in fat were extremely low and there was no evidence of accumulation of residues in fatty tissues. The major components of the residue were attributed to the RH-9090, RH-9089, RH-294 (diol), RH-9090-sulphate and the 4-hydroxy-lactone, which were all detected at very low levels, and would be anticipated to be not-detectable or barely detectable at a normal dose rate.

Figure 2 Proposed metabolic pathway of myclobutanil in laying hens

Plant metabolism

The Meeting received plant metabolism studies with myclobutanil in grapes, apples, wheat, and sugar beets.

Grapes

Experiments on grape seedlings (*Vitis*, variety De Chaunac) were conducted in nutrient solution with either 68.5 μg (4.6 mg/L) of ^{14}C -phenyl myclobutanil (specific activity 10.28 mCi/g, radiochemical purity 99%) or 52.4 μg (3.5 mg/L) of ^{14}C -triazole myclobutanil (specific activity 10.98 mCi/g, radiochemical purity 99%). The plants were placed in the greenhouse. Additional nutrient solution was added as needed. The study was terminated after either 7 or 16 days uptake (Nelson, SS, 1984, 94279). The roots were washed in 20 mL of water to remove any radiolabelled material on the root surface. Plants were stored frozen prior to analysis. Radioactivity was measured by liquid scintillation counting (LSC). The plants were extracted with methanol followed by successive partitioning with chloroform and 1-butanol for the 7 day uptake plants and with hexane and chloroform for the 16 day uptake plants. The effect of enzymatic hydrolysis using α - and β -glucosidase enzymes on the chromatographic behaviour of conjugates was investigated. The natures of radioactivity in the selected samples were investigated further with TLC. The results were summarized in Tables 8 and Table 9.

Grape vines (variety not stated) received five weekly sprays of myclobutanil, labelled with ^{14}C in the phenyl ring or the triazole ring each at a rate equivalent to 0.05 kg ai/ha (Nelson, SS, 1998, 98373) during August 1984. Samples of grapes and foliage were taken after each treatment. Final harvest was 7 days after the final treatment. Two bunches of grapes (from upper and lower branches) were taken at each harvest except for the final harvest when all remaining fruit were removed from the vines. Grapes and foliage taken after each of the treatments were ground with dry ice. The radioactivity in all samples was determined by combustion of samples and analysed by liquid scintillation counting (LSC). The residues in juice were partitioned successively against chloroform and 1-butanol. Wet pomace and foliage were soxhlet extracted with methanol and subsequently partitioned against hexane. The nature of radioactivity in the selected samples were investigated further with TLC and confirmed by GC-ECD. The results were summarized in Tables 10 to Table 12.

Apples

Apple trees (semi-dwarf MacIntosh variety) received ten approximately weekly sprays of myclobutanil, labelled with ^{14}C in the phenyl ring or the Triazole ring in 1984 (Nelson, SS and Streelman, DR, 1984, 94618). One apple tree received phenyl labelled myclobutanil whilst the other received triazole labelled material. The apples from both trees were separately harvested fourteen days after the final application. Applications were begun in mid-June until end August. The application rate was equivalent to 240 g ai/ha. Harvested apples were quartered and separated into juice and pomace. Wet pomace obtained in this way was frozen and ground to a fine consistency with dry ice. Both juice and pomace were stored frozen until analysis. The radioactivity in pomace samples was determined by combustion of samples and analysed by liquid scintillation counting (LSC). Juice samples were assayed directly by LSC. The residues in juice were extracted successively with chloroform and 1-butanol. Pomace was soxhlet extracted with methanol and subsequently partitioned against chloroform. The natures of radioactivity in the selected samples were investigated further with TLC. The results were summarized in Tables 13 and Table 14.

Wheat

Approximately 30 wheat (*Triticum aestivum*, variety Wanser) seedlings were placed in a foil covered jars containing 65 mL of 1/3 strength Hoaglands nutrient solution and either 2700 μg (42 ppm) of ^{14}C -phenyl myclobutanil (specific activity 10.28 mCi/g, radiochemical purity 99%) or 4170 μg (64 ppm) of ^{14}C -triazole myclobutanil (specific activity 10.98 mCi/g, radiochemical purity 99%). The plants were placed in the greenhouse (Nelson, SS, 1984, 94218). After 11 days, the plants' roots were placed in 90 mL of water to wash off any myclobutanil remaining on the root surface. Wheat seedlings,

excised wheat shoots, and excised wheat heads were stored frozen prior to analysis. Radioactivity was measured by liquid scintillation counting (LSC). The different plant parts were homogenized with methanol followed by liquid/liquid partitioning against hexane. The nature of radioactivity in samples was investigated further with TLC or GLC. The results were summarized in Table 15.

The metabolism of myclobutanil, radiolabelled in either the phenyl (Ph) or triazole (Tz) ring, was studied in wheat under field conditions at a rate equivalent to 0.28 kg ai/ha (Streelman, DR, 1984, 94246). The Tz labelled wheat received 2× 0.28 kg ai/ha treatments and the Ph treated wheat 1× 0.28 kg ai/ha treatment. The first application was in April 1983 (BBCH 30) and the second in early May (BBCH 32) with Tz labelled myclobutanil. A single application of phenyl labelled myclobutanil was BBCH 45. In a second experiment, wheat grown in the greenhouse was treated with 2× 0.28 kg ai/ha of Ph-labelled myclobutanil. The first application was made to plants as BBCH 31 and the second at BBCH 45. Plants were harvested on the day of application and at 41 days for PH label under field, 68 days for TZ label under field and 43 days for PH label under greenhouse after last treatment (DALT) then separated into straw, chaff and grain by threshing. Samples of all plant fractions were combusted to $^{14}\text{CO}_2$ which was determined by liquid scintillation counting (LSC). Straw and grain samples were extracted with methanol and followed by liquid/liquid partitioning between water and chloroform. The nature of radioactivity in the selected samples were investigated further with TLC and/or further analysed by GC-MS or MS. The results are summarized in Tables 16 to 20.

Sugar beet

The metabolism of myclobutanil, radiolabelled in either the phenyl (specific activity 4.00 mCi/mmol, radiochemical purity 98%) or triazole ring (specific activity 6.10 mCi/mmol, radiochemical purity 98%), was studied in sugar beets (*Beta vulgaris* cv. Wildcat) at approximately twice the maximum commercial use rate (150 g ai/kg) and approximately 20 times the maximum use rate (1500 g ai/ha) 30 days prior to maturity (MacDonald, AMG, Gray, J, Coyle, D, 2004, 207048). Plants were harvested from each plot on the day of application (when the spray had dried), and at 15 and 30 days after treatment (DAT). All samples were stored frozen (−20 °C). Radioactivity was measured by liquid scintillation counting (LSC). Samples were extracted with acetonitrile, aqueous acetonitrile and where necessary by acid and base hydrolysis. The natures of radioactivity in the selected samples were investigated further with HPLC or by LC-MS. The results are summarized in Tables 18 to 20.

In summary, the metabolism of myclobutanil in crops is qualitatively consistent and considered comparable except in wheat treatment with TZ label. The conversion of myclobutanil to RH-9090 followed by conjugation with glucose is the major metabolic pathway. Minor amounts of RH-9089 are probably a result of oxidation of RH-9090. The presence of RH-3968 and RH-4098 in wheat treated with TZ label indicates that the phenethyl triazole linkage in parent was metabolically cleaved.

Figure 3 Proposed metabolic pathway of myclobutanil in crops

Environmental fate in soil

The Meeting received information on the environmental fate of myclobutanil in soil, including studies on soil metabolism, and crop rotational studies.

Soil metabolism (aerobic degradation)

The aerobic soil metabolism of myclobutanil was investigated in a silt loam (pH 5.3, 0.7% OC) freshly collected from the farm field and sieved through a 3.45 mm screen before use (Ackermann, IB, 1984, 94786; Ackermann, IB, 1986, 94822). The soil was treated with either ^{14}C -phenyl-myclobutanil (uniformly labelled in the chlorophenyl ring, 22616 DPM/ug, radiochemical purity 99%) or ^{14}C -triazole-myclobutanil (uniformly labelled in the triazole ring, 24380 DPM/ug, radiochemical purity 97%) at a nominal rate of 1 mg per kg dry soil. Soil aliquots of 200 g (dry weight basis) in the flasks were maintained aerobically for one year. The total CO_2 evolved by myclobutanil was measured with the trap solutions. On selected dates, soil samples were removed from the flasks to radioassay the ^{14}C content.

Soil samples were added acetonitrile/1 N acetic acid and placed on a mixer for thirty minutes. The suspension was centrifuged and transferred to a graduate cylinder. This procedure was performed twice. The suspension was vacuum filtered and two 1 mL aliquots were radioassayed. The filtrate was quantitatively transferred to a separatory funnel and water was added. Then it was partitioned three times with methylene chloride. The methylene chloride extract was evaporated for TLC analysis. Triplicate 0.5 gram samples of the air dried soil were radioassayed.

Thirty-five mL of 0.5 N NaOH was added to samples of aged aerobic soil and mixed for seven hours. The suspension was centrifuged and transferred to a graduate cylinder. Duplicate 0.5 mL aliquots were taken for radioassay. Thirty-five mL of 1.0 N NaOH were added to the remaining soil. Then it was mixed overnight (fifteen hours) with a mixer. The suspension was centrifuged and the supernatant was transferred to a graduate cylinder. The extracted soil was washed with 1.0 N NaOH and distilled water, respectively. The supernatant was added to the graduate. Duplicate 1 mL aliquots were taken for radioassay. The soil was dried and then pulverized. Triplicate 0.5 g samples were taken for radioassay. Results are presented in Tables 21 to 23.

The majority of radioactivity in the extracts was always the unchanged compound. None of metabolites exceeded 10% TAR. The half-lives were calculated to be 61 to 71 days for degradation of parent compound. Mineralization to ¹⁴CO₂ reached a total of 4.0% to 30% TAR. No other volatile compounds were detected.

Figure 4 Proposed metabolic pathway of myclobutanil in aerobic soil

Soil Photolysis

The photodegradation of [¹⁴C]-myclobutanil (labelled uniformly in the phenyl ring, 10.28 mCi/g, radiochemical purity 98.0%; labelled in the 3,5 position of the triazole ring, 10.98 mCi/g, radiochemical purity 100%) were studied on a silt loam soil (1.20% OM, pH 5.3) under black lamps and fluorescent sun lamps (Nelson, SS, 1985, 94821; Nelson, SS, 1985, 222060). Either [¹⁴C]-phenyl-myclobutanil or [¹⁴C]-triazole-myclobutanil was fortified on the surface of the dry soil in flasks at the nominal concentration of 5 mg/kg dry soil. The incubation conditions were irradiation from an array of three fluorescent blacklights and three fluorescent sunlamps at 34 °C for 30 days. Samples were taken 0, 3, 7, 16 and 30 days after treatment. Dark control samples were analysed at the same sampling days. Volatiles were measured in appropriate trapping solutions. Soil samples were extracted with 70:30 acetonitrile/1 M acetic acid and the extracts analysed by liquid scintillation

counting (LSC) and GC-ECD or NPD. Bound residues were quantified by combustion and subsequent LSC measuring.

The light source in this study had a range of about 290–480 nm. The intensities of the wavelength emitted from the light source in the 290–480 nm range were greater than that found in natural sunlight. Myclobutanil did not photodegrade to any appreciable extent, even under the greater intensities of the shorter wavelengths. This study was done at 34 °C, somehow higher than the desired range of 20–30 °C. In this experiment the dark controls, which were maintained at the same temperature, were very stable. Comparison of the extracts from day 0 to day 30 dark controls does not indicate any substantial change in the amount of myclobutanil. The extracts from day 30 irradiated samples contained only 88.8% of phenyl ring labelled myclobutanil and 87.7% of triazole ring labelled myclobutanil. Thermal degradation of myclobutanil was slight or non-existent at this higher temperature. Comparison of studies from soil photolysis and metabolism, it is concluded that photolysis will not be a route of degradation of myclobutanil in the soil as soil metabolism will occur more rapidly. The results are shown in Tables 24 to 26.

^a Average from two different solvent systems.

Myclobutanil was very stable, even using these conditions which are more severe than those encountered in real sunlight. The above studies indicate that the major route of degradation of myclobutanil in the soil will be by soil metabolism and not photolysis.

Crop rotation studies

Information on the fate of myclobutanil in follow-on crop studies was made available to the Meeting.

A confined rotational crop study was conducted with [^{14}C]triazole-labelled myclobutanil (Graper, LK *et al.*, 2012, 090061). The active substance was soil-applied to confined plots of sandy loam soil at a rate of $1 \times 360 \text{ g ai/ha}$. The nature and the level of radioactive residues were investigated in lettuce (Variety: *butter crunch*), radish (Variety: *cherry belle*) and wheat (Variety: *hard red VNS*) after plant back intervals of 30, 120 and 365 days. Plant samples were harvested at maturity, and additional immature lettuce samples as well as wheat forage samples (in part dried to hay) were taken 30 days, 120 days and 365 days after planting or sowing, respectively. Soil (0.5% OM; pH 7.6) samples were taken after ploughing and after harvest of the mature crops for each plant back interval. The sampled material was stored in a freezer. All plant samples were homogenised and the radioactive residues in these samples and in the soil samples were determined by combustion analysis. Lettuce, radish and wheat samples were extracted with an accelerated solvent extractor using 80/20 acetonitrile/water. Extracts were measured with LSC and cleaned up using solid phase extraction (SPE) for HPLC analysis. The remaining tissue after ASE extraction was analysed by oxidative combustion to determine the amount of non-extractable radioactive residue.

Lettuce, radish and wheat were planted at rotational intervals of 30, 120 and 365 days after treatment and total radioactive residues ranging from 0.07 to 2.69 mg eq/kg were found in harvested crops. Residues in immature and mature lettuce and radish roots declined over time, while residues in radish tops increased. Residues in wheat hay, straw and grain did not show consistent increase or decline. All samples at all plant-back time points were subjected to extraction and characterization. For all samples, 62.9 to 104.0% of the TRR was extracted into neutral organic solvent which was analysed by SPE to give load & wash (polar) and eluate (non-polar) fractions requiring HPLC analysis. When the load & wash and eluate fractions were considered together, 63.0 to 105.8% of the sample TRR was analysed by HPLC. The three most abundant non-polar metabolites were myclobutanil at 0.43 mg eq/kg (55.2% TRR) in 30 DAT mature lettuce and MW 309 di-acid at 0.381 mg eq/kg (14.2% TRR) and RH-9090 at 0.47 mg eq/kg (17.3% TRR), both in 30 DAT wheat straw. The largest unidentified non-polar peak was 0.09 mg eq/kg (3.4% TRR) in 30 DAT wheat straw. The two most abundant polar metabolites were the triazole alanine at 0.45 mg eq/kg (30.1% TRR) and triazole acetic acid at 0.43 mg eq/kg (28.8% TRR), both in 120 DAT wheat grain. The highest concentration of the largest polar unidentified peak was 0.21 mg eq/kg (12.8% TRR) in 365 DAT wheat straw. Bound residues exceeded both 10% of the TRR and 0.05 mg eq/kg only in wheat hay, straw and grain at all plant-backs. For wheat grain, the bound residues ranged from 26.0 to 38.8% TRR and from 0.21 to 0.57 mg eq/kg.

^a As received, the ground and frozen 365 day plant-back wheat hay sample was comprised of 31.2% moisture. At this moisture, the sample residue level was calculated to be 1.168 mg eq/kg. Because OECD guidelines indicate that wheat hay should be dried to a moisture content of 10 to 20 percent, the mg eq/kg value in the table above was arithmetically adjusted as if the moisture was 15%, and the value used for the study was as shown above in the table.

– = No detection.

The parent compound, RH-9090 and its conjugates were found in most part of the four crops. The other two most abundant metabolites were MW 309 di-acid and butyric acid, which were not identified in the metabolism studies of crops.

Figure 5 Proposed degradation pathway in ^{14}C -TZ labelled myclobutanil in the confined rotational crop study

RESIDUE ANALYSIS

Analytical methods

The Meeting received descriptions and validation data for analytical methods for residues of myclobutanil and RH-9090 (its alcohol metabolite) in plant and residues of myclobutanil in meat. Myclobutanil residues can be measured in most matrices to an LOQ of 0.01 to 0.05 mg/kg. No stereoselective methods were submitted for two myclobutanil enantiomers.

Analytical Method for the Measure of RH-3866 and RH-9090 Residues in Various Crops, Soil, Meat, Milk and Eggs. (Stavinski, SS *et al.*, 1988, 94356)

Analyte:	myclobutanil, RH-9090	GC/ECD or NPD
LOQ:	0.01–0.1 mg/kg	
Description	Samples are extracted by blending with methanol. However, wheat straw is extracted by soxhlet extraction with methanol and fat is extracted by refluxing in heptane. Water is added and the resulting solution is partitioned with hexane. The hexane is discarded and additional water is added to give a 50/50, v/v, water to methanol ratio. This solution is partitioned with methylene chloride. The aqueous phase is discarded and the methylene chloride is evaporated to dryness under diminished pressure. The residue is dissolved in toluene for Florisil column chromatography. After column chromatography, the eluent is evaporated to dryness and the residue is dissolved in 3% methanol/toluene for quantitation by GC-ECD. Wheat straw samples were quantitated with GC-NPD.	

Validation of the Residue Analytical Method for Myclobutanil (RH-3866) in Animal Tissues (Hen Muscle and Bovine Fat). (Wais, A, 2000, 94182)

Analyte:	myclobutanil	GC-ECD
LOQ:	0.01 mg/kg.	
Description	Step 1 (fat): The samples were extracted with n-heptane under heat reflux about 1 h. After cooling to room temperature the mixture was transferred into the separatory funnel and added methanol and sodium chloride solution. After shaking the n-heptane phase was discarded. The sample proceeded to step 2. Step 1 (muscle): The samples were extracted with methanol using high speed homogenizer. The mixture was filtered through a glass filter frit covered with Celite. The bottle and the filter cake were washed using methanol. The sample proceeded to step 2. Step 2. The sample solution was transferred into separatory funnel with addition of hexane and sodium chloride solution. The suspension was shaken for about 1 min. After shake and separation the lower aqueous layer was transferred into separatory funnel. The hexane layer was discarded. The sample was shaken with addition of sodium chloride solution and dichloromethane. The dichloromethane layer was filtered over sodium sulphate into a flask. The solution was evaporated to complete dryness. Step 3. The extraction residue was redissolved in toluene. The sample solution was transferred onto the Florisil column and repeated this procedure. Myclobutanil was eluted using a methanol/toluene mixture. The solution was evaporated to complete dryness. The residue was dissolved using a methanol/toluene mixture for determination by GC-ECD.	

Determination of Residues of Myclobutanil and Its Alcohol Metabolite (RH-9090) in Apples, Tomatoes, Grapes, Soybeans, Wheat and Radishes by Liquid Chromatography with Tandem Mass Spectrometry. (Shackelford, DD, *et al.*, 2003, 137270).

Analyte:	myclobutanil, RH-9090	LC-MS/MS	GRM 03.01
LOQ:	0.01 mg/kg.		
Description	Residues of myclobutanil and its alcohol metabolite (RH-9090) are extracted from the crop samples by homogenizing and shaking overnight with methanol. An aliquot is hydrolysed to release conjugated RH-9090 by adding concentrated hydrochloric acid and heating for 2 hours. The sample is then evaporated to dryness, and the residues reconstituted in an 80% water/20% methanol solution. The sample is applied to a SPE column. The column is washed with a 70% water/30% methanol solution, and the analytes are eluted from the column with a 80% methanol 20% water solution. The eluate is then evaporated to dryness, and the residues are reconstituted in a 97% methyl-t-butyl ether/2% methanol/1% acetic acid solution and applied to an NH ₂ SPE column. The eluate is collected and evaporated to dryness, and the residues reconstituted in a 70% water/ 30% methanol mobile phase containing 5 mM ammonium acetate and analysed with LC/MS/MS (APCI mode).		

Validation Report for Method GRM 03.01–Determination of Residues of Myclobutanil and its Alcohol Metabolite (RH-9090) in Apples, Tomatoes, Grapes, Soybeans, Wheat and Radishes by Liquid Chromatography with Tandem Mass Spectrometry. (Shackelford, DD, 2003, 137270)

Analyte:	Myclobutanil and RH-9090	HPLC/MS/MS	GRM 03.01
LOQ:	0.01 mg/kg.		

Description	The method mentioned above is applicable for the quantitative determination of residues of myclobutanil and its alcohol metabolite (RH-9090) in whole apples, whole tomatoes, whole grapes, radishes (roots and tops), wheat forage and soybean forage, which are representative of 'wet' crops. The method is also applicable for the quantitative determination of residues of myclobutanil and its alcohol metabolite (RH-9090) in soybeans (seed), a representative 'oily' crop, and in wheat grain, wheat hay and wheat straw, which are representative of 'dry' crops. The method was validated over the concentration range of 0.010–0.50 µg/g.		
Independent Laboratory Validation of Method GRM 03.01—Determination of Residues of Myclobutanil and its Alcohol Metabolite (RH-9090) in Apples, Tomatoes, Grapes, Soybeans, Wheat and Radishes by Liquid Chromatography with Tandem Mass Spectrometry. (Reed, RL, 2003, 137271)			
Analyte:	Myclobutanil and RH-9090	HPLC/MS/MS	GRM 03.01
LOQ:	0.01 mg/kg.		
Description	The method mentioned above is applicable for the quantitative determination of residues of myclobutanil and its alcohol metabolite (RH-9090) in whole tomatoes and wheat grain.		
Independent Laboratory Validation of the Multi-Residue Method-1 (MRM-1) for the Determination of Myclobutanil in Crops. (Mollica, J and West, S, 2003, 135042)			
Analyte:	myclobutanil	LC-MS/MS	The Netherland's MRM-1
LOQ:	0.2 mg/kg.		
Description	A sample of the plant material was homogenized with acetone. Dichloromethane and petroleum ether were added and the mixture was homogenized again. The sample was centrifuged and the organic extract was decanted through sodium sulphate to remove any remaining water. The extract was transferred to a volumetric flask and brought to volume with the acetone/dichloromethane/petroleum ether solution. For the apple extracts an OPC clean-up procedure was employed. Cyclohexane/ethyl acetate was used as mobile phase. Fractions were collected and then rotary evaporated to dryness under a gentle stream of nitrogen. Final extracts were reconstituted and analysed by GC/MS.		
Assessment and Validation of the Multi-Residue Enforcement Method DFG S19 for the Determination of Myclobutanil and its 1,2,4-Triazole Metabolite in Soil and the RH-9090 Metabolite in Animal Tissue. (Teasdale, R, 2003, 34429)			
Analyte:	Myclobutanil, 1,2,4-triazole metabolite and RH-9090 metabolite	LC-MS/MS	DSG S19
LOQ:	0.01 mg/kg.		
Description	Milk, meat, liver and kidney: Water was added to the sample which washomogenized followed by the addition of acetone and further homogenization. Sodium chloride and ethyl acetate/cyclohexane were added and the sample homogenized again. An aliquot of the upper organic phase was filtered through glass wool covered with sodium sulphate. The filter and the measuring cylinder were rinsed four times with portions of ethyl acetate/cyclohexane. The filtrate was evaporated. Ethyl acetate was added to the concentrated residue which was then ultrasonicated. Sodium sulphate/sodium chloride was added and the flask was swirled. Cyclohexane was added and the flask was swirled vigorously again. The extract was filtered for storage until GPC clean-up. Fat and whole egg: The sample of homogenised matrix was extracted with acetone and acetonitrile and macerated. The homogenate was then suction-filtered through filter paper in a Buchner funnel under a gentle vacuum to minimize filtrate evaporation. The filtrate was then filtered into a graduated cylinder. An aliquot of the filtrate was measured and transferred with acetone rinsings into a round bottom flask. Tri-methyl pentane was added and the solution was concentrated using rotary evaporation with a water bath. The last traces of solvent were removed using a gentle stream of air at room temperature. The residue was dissolved in ethyl acetate/cyclohexane. Once all substrates were cleaned up by GPC they were adjusted to a final volume and quantitated by GC-ECD.		
Validation of Method GRM 05.07.R1-Determination of Residues of Myclobutanil and its RH-9090 Alcohol Metabolite in Soybean Commodities using Online Solid Phase Extraction Coupled to High Performance Liquid Chromatography with Tandem Mass Spectrometry. (Shackelford, DD and Olberding, EL, 2013, 208707)			
Analyte:	Myclobutanil and RH-9090	LC-MS/MS	GRM: 05.07.R1
LOQ:	0.01 mg/kg.		

Description Residues of myclobutanil and its alcohol metabolite (RH-9090) are extracted from the sample matrix sample by homogenizing and shaking overnight with methanol. An aliquot is hydrolyzed to release conjugated RH-9090 by adding concentrated hydrochloric acid and heating for 2 hours at approximately 70 °C. The pH is adjusted to near neutral using 0.5 M aqueous Tris base. The sample is filtered, and the final solution is analysed using online solid phase extraction coupled to LC/MS/MS (APCI mode).

Method Validation Report for Method GRM 07.06—Determination of Residues of Myclobutanil and Its RH-9090 Alcohol Metabolite in Agricultural Commodities using On-line Solid Phase Extraction Coupled to Liquid Chromatography with Tandem Mass Spectrometry. (Shackelford, DD, 2008, 260120)

Analyte: Myclobutanil and RH-9090 LC-MS/MS GRM 07.06

LOQ: 0.01 mg/kg.

Description Residues of myclobutanil and its alcohol metabolite (RH-9090) are extracted from the crop samples by homogenizing and shaking overnight with methanol. An aliquot is hydrolyzed to release conjugated RH-9090 by adding concentrated hydrochloric acid and heating for 2 hours at approximately 70 °C. The pH is adjusted to near neutral using a 0.5 M aqueous Tris base solution. The sample is filtered, and the final solution is analysed using on-line solid phase extraction coupled to LC/MS/MS (APCI mode).

Summaries of analytical methods and procedural recoveries are presented in Table 34 to Table 43.

Table 34 Recoveries of myclobutanil and RH-9090 added to sample substrate (Stavinski, S and Brackett, C, 1988, 94356)

Matrix	Analyte	LOQ	Fortification Range	n =	Recovery Range	Mean

Stability of residues in stored analytical samples

The Meeting received information on the stability of residues of myclobutanil and its alcohol metabolite (RH-9090) in all four types of crops (wet, dry, oily and acidic). Frozen storage stability data is presented here for apples, radish root, soybean, wheat forage, wheat grain, wheat hay, wheat straw, blueberry, cucurbits and snap beans.

Homogenized 5 gram control samples were spiked with 0.1 mg/kg of myclobutanil and RH-9090 (in separate samples) and stored frozen at approximately -20 °C until analysed. Triplicate samples were analysed at 0, 42, 206, 385 and 588 days by analytical method GRM 03.01. A control sample and two fresh fortifications were run concurrently at each sampling interval to validate the analytical procedure (Dial, G., 2006, 240828). The storage stability data are summarized in Table 44.

Homogenized 5-gram control samples (blueberry, cucumber, snapbeans, almond meat and hulls) were spiked with 0.1–2.0 mg/kg of myclobutanil and RH-9090 (in separate samples) and stored frozen at approximately -20°C or -10°C until analysed. Triplicate samples were analysed at different sampling intervals with analytical method GRM 03.01 or TR 34S-88-10 (Malegus, R, 2011, 2017296; Batra, R, 1995, 94240; Thompson, DC, 1996, 263134; Batra, R, 1994, 94237). A control sample and one or two fresh fortification(s) were run concurrently at each sampling interval to validate the analytical procedure. The storage stability data are summarized in Table 45.

Liver and muscle samples were fortified at 1.0 mg/kg with myclobutanil or RH-9090 and stored frozen. At specified analysis intervals, the samples were analysed by the residue analytical method TR 31S-88-21 for myclobutanil and TR 34S-88-22 for RH-9090 ((Desai, R and Garstka, TA, 1997, 94239)). Control samples and fresh fortifications were concurrently run at each analysis interval to validate the analytical procedure. The data show no decline in frozen stored samples with time (up to three months) for both myclobutanil and RH-9090 in liver and muscle. The storage stability data are summarized in Tables 46.

USE PATTERN

Labels and English translations were available for all the uses. Myclobutanil is a systemic fungicide of the triazole class, providing protectant curative and eradicant activity. Mode of action of myclobutanil is inhibiting sterol biosynthesis which disrupts membrane function. A summary of the current approved label rates are provided in Table 47.

Table 47 Summary of registered uses of myclobutanil

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials for myclobutanil uses on the following crops.

Table 48 Crops and crop groups of supervised trials

Crop Group	Commodity	Country	Table No.
Citrus fruits	Orange	ESP	Table 49
	Mandarin	ESP	Table 50
Pome fruits	Apple	AUT, BRA, CAN, FRA, ESP, ITA, GRC, CHL, GER, UK, USA	Table 51
	Pear	BEL, CAN, CHL, FRA, ITA, ESP, USA	Table 52
Stone fruits	Peach	CAN, FRA, GRC, ITA, ESP, USA	Table 53
	Cherry	AUT, BEL, CAN, FRA, GER, HUN, UK, USA	Table 54
	Apricot	FRA, ITA, ESP, USA	Table 55
	Plum	AUT, CAN, C, FRA, GER, HUN, ITA, ESP, USA	Table 56

Crop Group	Commodity	Country	Table No.
Berries and other fruits	Currant	FRA, ITA, UK, USA	Table 57
	Grapes	BRA, FRA, GER, GRC, ITA, PRT, ESP, USA	Table 58
	Strawberry	FRA, ITA, GBR, ESP, USA	Table 59
Fruiting vegetable, Cucurbits	Banana	CRI, USA	Table 60, 61
	Cucumber	FRA, ITA, ESP, USA	Table 62
	Melon	FRA, GRC, ITA, ESP, USA	Table 63
	Squash	ESP, USA	Table 64
	Watermelon	ITA, USA	Table 65
	Pepper	FRA, ITA, ESP, USA	Table 66
Fruiting vegetables, Other than cucurbits	Tomato	FRA, ITA, MAR, ESP, USA	Table 67
	Snap beans	USA	Table 68
	Soybeans	ARG, BRA, USA	Table 69
Dried herbs	Hops	GER, UK, USA	Table 70
Legume animal feed	Soybean forage and hay	USA	Table 71

In addition to the description and details of the field trials, each report includes a summary of the analytical method(s) used, together with the corresponding procedural recoveries. In the field trials where multiple analyses are conducted on a single sample or where multiple samples were taken from a single plot, the average residue value is reported. Where results from separate plots with distinguishing characteristics, such as different formulations, varieties or treatment schedules were reported, results are listed for each plot.

Results have not been corrected for concurrent method recoveries unless indicated. Residues and application rates have generally been rounded to 2 or 3 significant figures or, for residues near the LOQ, to one significant figure. Residue values from the trials conducted according to the maximum GAP have been used for the estimation of maximum residue levels. For purposes of MRL estimation and risk assessment in this report, ND values in the reports were considered as < LOQ.

Citrus fruits

Oranges

A total of 15 post-harvest studies on orange were conducted in Spain 1994 and 1995. Results of orange fruits are summarized in Table 49.

Pome fruits

Apples

A total of 144 trials on apple were conducted in different representative growing areas in Austria, Brazil, Canada, Chile, France, Germany, Italy, Spain, UK and USA during 1984 through 2011 growing seasons. Results of apple fruits are summarized in Table 51.

Cherries

A total of 65 trials on cherry were conducted in different representative growing areas in Austria, Belgium, Canada, France, Germany, Hungary, UK and USA during 1984 through 2011 growing seasons. Results of cherry fruits are summarized in Table 54.

Table 54 Supervised trials on cherry in various countries

Apricot

A total of 21 trials on apricot were conducted in different representative growing areas in France, Italy, Spain and USA during 1986 through 2011 growing seasons. Results of apricot fruits are summarized in Table 55.

Table 55 Supervised trials on apricot in various countries

Plums

A total of 71 trials on plum were conducted in different representative growing areas in Austria, Canada, Czech Republic, France, Germany, Hungary, Italy, Spain and USA during 1987 through 2011 growing seasons. Results of plum fruits are summarized in Table 56.

Table 56 Supervised trials on plum in various countries

Grapes

A total of 70 trials on grapes were conducted in different representative growing areas in Brazil, France, Germany, Greece, Italy, Portugal, Spain and USA during 1987 through 2004 growing seasons. Results of grape fruits are summarized in Table 58.

Table 58 Supervised trials on grapes in various countries

Strawberry

A total of 47 trials on strawberry were conducted in different representative growing areas in France, Italy, Spain, UK and USA during 1988 through 2007 growing seasons. Results of strawberry fruits are summarized in Table 59.

Table 59 Supervised trials on strawberry in various countries

*Assorted tropical fruits, inedible peel**Banana*

A total of 11 trials on banana were conducted in USA and Costa Rica according to treatment of myclobutanil at banana packing stations in Costa Rica in 1991 through 1993. All treatments consisted of one application of myclobutanil, and banana hands were sprayed or dipped at various concentrations. Results of bananas are summarized in Table 60. The total residues were calculated on the basis of peel and pulp and summarized Table 61.

Table 60 Supervised trials on banana in Costa Rica and USA

^a Weight factor = Weight of pulp/ Weight of whole banana This was only available for 1992 and 1993 studies.

^b total residues were calculated from the residues measured in peel and pulp based on weight factor

Fruiting vegetables cucurbits

Cucumber

A total of 31 trials on cucumber were conducted in different representative growing areas in France, Italy, Spain and USA during 1986 through 2007 growing seasons. Results of cucumber fruits are summarized in Table 62.

Table 62 Supervised trials on cucumber in various countries

FATE OF RESIDUES IN STORAGE AND PROCESSING

Information and Data from Residues in Processed Commodities

The Meeting received information on the fate of myclobutanil residues during aqueous hydrolysis and also received the processing studies on apples, grapes, tomatoes, soybeans and hops.

The hydrolytic stability of myclobutanil was investigated in aqueous buffer solutions at pH 4, 7 and 9 at 50 °C over a 5 day period (94798). No degradation of myclobutanil was observed under these conditions.

The two supervised trials on apple (var. Golden delicious) were conducted in Germany to provide bulk samples for processing studies. Apple trees were treated with 12 foliar applications of a formulation of myclobutanil (containing 60 g ai/kg). The first two applications were made at the rate of 0.006 kg as/hL (0.036–0.054 kg ai/ha) when trees were near or at-flowering growth stage. The last ten applications were made at 0.018 kg as/hL (0.072–0.090 kg ai/ha) per application with the last application made at fruit maturity. Bulk samples of treated apples for the processing studies were harvested at 14 days after the last application and processed into juice and wet pomace. The analytical results are listed in Table 72.

Apple trees (Granny Smith variety) were treated with four foliar applications of a formulation of myclobutanil (EW, containing 200 g ai/L) at either 1× or 5× recommended rate. The 5× treatment rate was included in order to improve the ability to quantify residue levels in certain processed fractions of apples, such as apple juice. In the 1× treatment myclobutanil was applied at the rate of 0.006 kg ai/hL (0.094–0.097 kg ai/ha) per application, while in the 5× treatment myclobutanil was applied at the rate of 0.030 kg ai/hL (0.447–0.478 kg ai/ha) per application. The first of the four treatment applications began near the end of fruit enlargement (BBCH 78) with subsequent applications continuing on approximately 10 day intervals through ripe fruit (BBCH 85). Bulk samples of treated apples (both 1× and 5× application rates) were harvested at 14 days after the last application for processing into processed apple products (pasteurized apple juice, wet pomace and apple puree). The analytical results are listed in Table 73.

Two supervised trials on wine grapes (white and red varieties) were conducted in Northern France. Grape vines were treated with eight foliar applications of a formulation of myclobutanil (EW, 200 g ai/L) at the rate of 0.003 kg ai/hL (0.01–0.05 kg ai/ha) per application. The first application was made at pre-bloom and continued on a 10 to 14-day interval until the grapes were harvested. Bulk samples of treated grapes for the processing studies were harvested at 14 days after the last application and transported to a processing facility in Germany. Samples of whole grapes, grape must (juice), young and mature wine were analysed for myclobutanil using an analytical method with limits of quantitation and detection of 0.01 mg/kg and 0.0025 mg/kg, respectively. Summary of data is shown in Table 74.

Two supervised trials on wine grapes (white and red varieties) were conducted in Germany to provide bulk samples for processing studies. Grapevines were treated with eight foliar applications of a formulation of myclobutanil (EW, 200 g ai/L). White grape was treated at the rate of 0.009 kg ai/hL (0.028–0.048 kg ai/ha) per application while red grapes was treated at 0.003 kg ai/hL (0.012–0.048 kg ai/ha) per application. The first application was made at pre-bloom and continued on a 10

to 14-day interval until the grapes were harvested. Bulk samples of control and treated grapes for the processing studies were harvested 14 days after the last application and transported to a processing facility in Germany. Samples of whole grapes, grape must (juice), young wine (8–10 weeks aging) and mature wine (5–6 months aging) were analysed for myclobutanil using an analytical method with limits of quantitation and detection of 0.01 mg/kg and 0.0025 mg/kg, respectively. Summary of data is shown in Table 75.

Grapes grown at Napa, CA, and Reedley, CA, were treated with myclobutanil five times at 0.11 kg ai/ha. Samples were harvested at 14 days. The fruit was processed at California State University at Fresno to yield juice, dry pomace, wet pomace, wine, and stems. In addition, filtered wine, A&B raisins, C raisins, midget raisins, waste raisins, and wine lees were produced. Summary of data is shown in Table 76.

Supervised trials on tomatoes were conducted at two sites in France to provide bulk samples for processing studies. Tomatoes were treated with six foliar applications of a formulation of myclobutanil (EW, 200 g ai/L). The first application was made approximately 11 weeks pre-mid-commercial harvest and at 10–14 days thereafter for the next five applications. Bulk samples of tomatoes were taken at 3 days after the last application and processed into juice and preserves and puree. Samples of whole fruit, juice, preserves and puree were analysed for myclobutanil using a method with a limit of quantitation of 0.01 mg/kg. Summary of data is shown in Table 77.

A supervised trial on tomatoes was conducted at a field location in California, USA to provide bulk samples for processing studies. Tomatoes were treated with four foliar applications of a formulated product (WP, 40% W/W). The four applications were made at 10–15 day intervals in approximately 74 L/ha spray volumes. Bulk samples of tomatoes for the processing studies were taken at 5 days after the last application and processed into canned, wet pomace, dry pomace, juice, puree, paste, and catsup. Samples of whole fruit and tomato processed fraction were analysed for myclobutanil using a method with a limit of quantitation of 0.01 mg/kg. Summary of data is shown in Table 79.

Supervised trials on soybeans were conducted at a site in USA to provide bulk samples for processing studies. Soybeans were treated with two foliar broadcast applications of EW fungicide (208 g ai/L). The first application was made at BBCH 15 and the second application was made 14 days later at growth stage BBCH 63. Bulk samples of soybeans for the processing studies were taken at 14 days after the last application and processed into hulls, meal and oil. Aspirated grain fractions (dust) were also collected during the processing. Samples of seed, dust, hulls, meal and oil were

analysed for myclobutanil using a method with a limit of quantitation of 0.01 mg/kg. Summary of data is shown in Table 80.

A supervised trial on hops was conducted at a site in Germany to provide bulk samples for processing studies. Hops were treated with four foliar applications of EW fungicide (200 g ai/L). Applications were made at a 1.5× rate of 9 g ai/hL applying a maximum spray volume of approximately 3400 L/ha. The first application was made at approximately 8 weeks prior to mid-commercial harvest and the second, third and fourth applications were made at 10–14 day intervals thereafter. Bulk samples of green hops for the processing studies were taken at 14 days after the last application (14 DAT), dried in the field then sent to be processed into spent hops, trub, yeast, and beer. Samples of green hops, dried hops, spent hops, trub, yeast, and beer were analysed for myclobutanil using a method with a limit of quantitation of 0.50 for dried hops, 0.02 mg/kg for green hops, spent hops, trub and yeast and 0.01 mg/kg for beer. Summary of data is shown in Table 81.

Residues in animal commodities

Farm animal feeding studies

The Meeting received a lactating cow and laying hens feeding study, which provided information on likely residues resulting in animal tissues and milk from residues in the animal diet.

Lactating cows

A cow feeding study was conducted to determine the extent to which residues of myclobutanil in livestock feedstuffs transfer to edible tissues and milk. Lactating Holstein cows ranging in age from approximately 3 to 5 years and in weight from 434 to 675 kilograms were used as the test animals in this study. Sixteen cows were randomly assigned to four treatment groups based on concentration of myclobutanil in the diet. Each of the four treatment groups consisted of four cows. Each cow was tagged with a neck chain which contained a unique identification number that matched the number on a card affixed to the individual stall. The dosing levels of myclobutanil in the four feeding groups were as follows: a control group (0 ppm), low dose level (1.3× feeding level, equivalent to 1.6 ppm in feed), medium dose level (3.9× feeding level, equivalent to 4.8 ppm in feed) and a high dose level (13× feeding level, equivalent to 16.0 ppm in feed). The dose preparations were based on the highest feed consumption through day 14 of the quarantine period. The cows were orally dosed using gelatin capsules containing the test substance. The test substance was administered to the cows once daily for 28 consecutive days. Gelatin capsules containing no test substance were administered to the group of control cows during the 28 day dosing period.

The cows were weighed weekly throughout the study. Feed consumption was determined daily. Observations were made twice daily for mortality, morbidity, and pharmacotoxic signs. Milk was collected and measured gravimetrically twice daily. Milk samples were collected for analysis on test days -1, 1, 4, 7, 10, 14, 17, 21, 24, 28 and 31. A milk sample (divided into two containers each with 125 mL of milk) for each cow on each of the sample collection days was obtained by pooling the milk collected from that cow for the a.m. and p.m. milkings in proportion to the cow's total daily production. On test day 28 three cows from each of the four treatment groups were humanely sacrificed. The one remaining cow from each of the four treatment groups was placed on a three-day withdrawal period and then sacrificed on test day 31 to evaluate depuration of residues in tissues. For each cow, a representative sample of liver, kidney, peritoneal fat, and pectoral muscle tissue was taken at the scheduled sacrifices and frozen immediately.

Myclobutanil as well as the metabolite RH-9090 were quantitated in all matrices (milk, fat, muscle, kidney and liver). Additionally, the metabolite RH-0294 was quantitated in milk. Analytical methods used are listed below by matrix and analyte. The limit of quantitation (LOQ) and limit of detection (LOD) for all analytes (myclobutanil, RH-9090, and RH-0294) in the analytical methods listed below is 0.01 ppm and 0.003 ppm, respectively. The results are shown in Table 82 and Table 84.

Laying Hens

A poultry feeding study was conducted to determine the extent to which residues of myclobutanil in poultry feedstuffs transfer to edible tissues and eggs.

Eighty white leghorn laying hens in top laying condition (38 weeks old) were used in this study and acclimated to the testing facility for (7) days. Ten hens were randomly assigned to each of (5) groups. Groups 6 and 7 were not utilized for residue analysis. Each hen received the radiocarbon

dose in a gelatin capsule for 28 days followed by < 24 hr, 7, and 14 day withdrawal periods (groups 1–5).

Eggs were collected each day (AM) from each hen for egg production records. All eggs for a group were kept on days -1,1,2,4,7,10,14,21,28,29,30,31,32,35 and 42, deshelled and stored frozen. Necropsy was performed for dose groups 1–5 on days 28, 35, and 42 (3–4 hens per group). At necropsy, the following tissues and whole organs were collected after exsanguinations, and immediately frozen: Breast muscle, thigh muscle, liver, kidneys, gizzard (washed, w/o contents), heart, fat. On each sacrifice day, the control hens were necropsied first, followed by the low dose group, working finally to the higher dose group hens last. Terminal body weights were taken for hens in groups 1–5.

All egg samples were homogenized by blending, aliquoted and combusted in duplicate. Tissue samples were blended with dry ice to a fine consistency and aliquoted for combustion. Combusted samples were quantitated for radiocarbon content using a liquid scintillation spectrometer in the external standardization mode. The results are shown in Table 85.

Kidney	28	ND	0.003	ND	0.021
	35	ND	ND	ND	ND
	42	ND	ND	ND	ND

The results presented in each group are the average of 10 hens. Actual feed concentrations were 1.05, 3.57, 10.2, and 28.3 ppm. Results reported as RH-3866 equivalents.

^a ND = no detectable residue. The minimum quantifiable limit for tissue except fat was 0.002 ppm for groups 1 to 3, 0.006 ppm for group 4, and 0.018 ppm for group 5. The minimum quantifiable limit for fat was 0.005 ppm for groups 1 to 3, 0.015 ppm for group 4, and 0.045 ppm for group 5.

RESIDUES IN FOOD IN COMMERCE OR AT CONSUMPTION

There are no data on market-basket monitoring studies available for myclobutanil.

NATIONAL RESIDUE DEFINITIONS

Information wasn't provided on national residue definitions for myclobutanil.

APPRAISAL

Myclobutanil was originally evaluated by the JMPR in 1992 and re-evaluated for residues several times up to 1998. Myclobutanil is a systemic protectant fungicide used to control brown rot, powdery mildew and leaf spot in stone fruit crops, and belongs to the sterol demethylation inhibitor (DMI) class of fungicides.

At the Forty-fifth Session of the CCPR (REP13/PR, Appendix XIV), myclobutanil was scheduled for periodic residue review by the 2014 JMPR. The Meeting received information on physical and chemical properties, metabolism, environmental fate, analytical methods and freezer storage stability, national registered use patterns, as well as supervised trials, processing studies and livestock feeding studies.

Myclobutanil is (R, S)-2-(4-chlorophenyl)-2-(1H-1, 2, 4-triazol-1-ylmethyl) hexanenitrile and exists as a racemate.

The following compound codes are used for the metabolites discussed below:

RH-9089	(2RS) -2-(4-chlorophenyl) -5-oxo-2-(1H-1,2,4-triazol-1-ylmethyl)hexanenitrile	
RH-9090	α -(4-chlorophenyl)- α -(3-hydroxybutyl)-1H-1,2,4-triazole-1-propanenitrile	
MW 318 Acid (butyl carboxylic acid of myclobutanil)	5-(4-chlorophenyl)-5-cyano-6-(1H-1,2,4-triazol-1-yl)hexanoic acid	
N-Glucuronic Acid Conjugate of Myclobutanil	1-[2-(4-chlorophenyl)-2-cyanoethyl]-4-hexopyranuronosyl-1H-1,2,4-triazol-4-ium	

Hydroxy-lactone	3-(4-chlorophenyl)-5-(1-hydroxyethyl)-3-(1H-1,2,4-triazol-1-ylmethyl)dihydrofuran-2(3H)-one	
RH-9090 Glucuronic Acid Conjugate	5-(4-chlorophenyl)-5-cyano-6-(1H-1,2,4-triazol-1-yl)hexan-2-yl hexopyranosiduronic acid	
RH-9090 Sulfate Conjugate	5-(4-chlorophenyl)-5-cyano-6-(1H-1,2,4-triazol-1-yl)hexan-2-yl hydrogen sulfate	
MW 334 Acid	5-(4-chlorophenyl)-5-cyano-2-hydroxy-6-(1H-1,2,4-triazol-1-yl)hexanoic acid	
RH-294 (Diol)	α -(4-chlorophenyl)- α -(3,4-dihydroxybutyl)-1H-1,2,4-triazole-1-propane-nitrile	
RH-294 Sulfate Conjugate	5-(4-chlorophenyl)-5-cyano-1-hydroxy-6-(1H-1,2,4-triazol-1-yl)hexan-2-yl hydrogen sulfate	
RH-3968 (Triazolyl Alanine, TA)	(2R)-2-amino-3-(1H-1,2,4-triazol-1-yl)propanoic acid	
RH-4098 (Triazolyl Acetic Acid, TAA)	1H-1,2,4-triazol-1-ylacetic acid	

Animal metabolism

Information was available on metabolism of myclobutanil in rats, lactating goats and laying hens.

Laboratory animals: Myclobutanil was mainly and rapidly absorbed (> 89%), extensively metabolised and rapidly and completely excreted after oral administration in rats. Peak plasma and tissue radiolabelled myclobutanil were achieved within 1 hr after oral administration and plasma elimination was biphasic. No significant tissue accumulation was observed 96 hr post-dosing. Metabolism appears to have occurred mainly through a variety of oxygenation reactions of the butyl group. The major metabolic processes involved oxygenation to the butyl group and among the

metabolites formed are the RH9090 and RH9089, the major unconjugated phenethyl triazole-containing metabolites found in plants.

Lactating goats: Myclobutanil was orally dosed to lactating goats for 5 days. Individual goats were dosed separately with myclobutanil radiolabelled in either the triazole (TZ) portion or the phenyl ring (PH) at the rate of 24 ppm and 14 ppm in the diet per day, respectively. Approximately 71% and 79% of TAR was recovered in the faeces and urine for the TZ-label and PH-label dosed animal. Most of administered dose was rapidly absorbed, metabolised and rapidly eliminated via the urine (49–58% TAR) and faeces (22% TAR). TRR levels in tissues ranged from 0.016 mg eq/kg in omental fat to 0.49 mg eq/kg in liver for the low dosed goat (PH label) and from 0.027 mg eq/kg in omental fat to 0.92 mg eq/kg in liver for the high dosed goat (TZ label). Residue levels were highest in liver and kidney and significantly lower in muscle and fat.

Milk and edible tissues were extracted with acetone, hexane and acetonitrile/water (80/20) and 78–101% radioactive residues were recovered. Unchanged parent compound was only observed in liver (2.1–6.0% TRR, 0.019–0.029 mg/kg). The metabolite RH-9090 and its sulphate and glucuronic acid conjugates were the primary residue in liver (total 59–60% TRR, 0.29–0.54 mg eq/kg), in kidney (total 58–61% TRR, 0.13–0.30 mg eq/kg), in muscle (total 47–80% TRR, 0.02–0.03 mg eq/kg) and in fat (total 44–46% TRR, 0.01–0.02 mg eq/kg). The hydroxy-lactone was the only other metabolite present in liver at levels in excess of 10% of the TRR (12–16% TRR, 0.08–0.11 mg eq/kg).

For both labels in milk, the residue levels reached a plateau within 4 days after the initiation of dosing at a level of approximately 0.033–0.079 mg eq/kg. The primary residue was RH-9090 which constituted about 28–58% of the TRR, while the only other two metabolites representing 10% or more of the TRR were RH-294 and the MW 318 carboxylic acid. No parent compound was detected in milk.

Laying hens: [^{14}C]-Myclobutanil was administered orally to groups of three laying hens once daily for 7 consecutive days at the nominal equivalent of 110 ppm in a diet. Over 95% of the dosed radioactivity was recovered in the excreta. Whole eggs and muscle were extracted with ethyl acetate, and then extracted with methanol. Fat and edible offal were extracted with n-hexane and methanol. The extracted radioactive residues accounted for 69% TRR in whole eggs, 79% TRR in fat, 83% TRR in thigh muscle, 97% TRR in breast muscle, 156% TRR in kidney (118% TRR as uncharacterized) and 72% TRR in liver (61% TRR as uncharacterized), respectively.

Total radioactive residues were observed in the liver (0.52 mg eq/kg) and the kidney (0.32 mg eq/kg), while lower residues were found in muscle (0.06 mg eq/kg) and fat (0.02 mg eq/kg). Parent myclobutanil was a main residue in fat (67% TRR) in kidney (12% TRR) in liver (4.8% TRR), and in muscle (up to 4% TRR). A band that co-chromatographed with RH-9090/RH9089 and lactone accounted for 15% TRR in kidney. The major component of the residue in muscle was RH-9089 (61–72% TRR). The major component of the residue in eggs was RH-9090 accounting for 36% TRR. No parent compound was observed in eggs.

In summary, the metabolism found in livestock was qualitatively comparable with that observed in laboratory animals. Characterization of the residues show myclobutanil together with RH-9090 and its conjugates are the major residues in the animal tissues, milk and eggs except RH-9089 as a major component in the muscle of laying hens.

Plant metabolism

The Meeting received plant metabolism studies with myclobutanil on grapes, apples, wheat, and sugar beets.

Grape seedlings in the greenhouse were placed in nutrient solution containing either ^{14}C -phenyl myclobutanil or ^{14}C -triazole myclobutanil. An average of 37% TRR remained as the parent compound. RH-9090 accounted for 6% TRR, with 11% TRR present as the RH-9090 glucoside and 14% TRR as an unknown polar component. In the 16-day uptake samples, parent compound accounted for an average of 53% TRR, RH-9090 8% TRR and RH-9090 glucoside 12% TRR.

Grape vines were sprayed five times weekly with myclobutanil, labelled with ^{14}C in the phenyl ring or the triazole ring each at a rate equivalent to 0.05 kg ai/ha. The overall recovery of identified radioactive residues ranged from 79% to 82%. TRR in whole grapes at harvest were 0.32 and 0.24 mg eq/kg for PH and TZ grapes, respectively. The major component of residue was the parent compound accounting for 66% TRR, RH-9090 for 7–9% TRR, RH-9090 glucoside for 5–6% and RH-9089 for 1%, respectively.

Apple trees received ten approximately weekly sprays of myclobutanil, labelled with ^{14}C in the phenyl ring or the triazole ring, at 0.24 kg ai/ha. After extraction with chloroform or methanol, the overall recoveries of identified radioactive residues ranged from 84% to 86% TRR. TRR in whole grapes at harvest were 0.48 and 0.32 mg eq/kg for PH and TZ grapes, respectively. The major component of the terminal residue remained parent compound accounting for 49% of TRR. Conjugated RH-9090 accounted for 21–24% TRR. Free RH-9090 accounted for 12% TRR. A minor component was RH-9089 present at 1.9% TRR. There were no differences in the metabolic profile between the two radiolabelled experiments.

Wheat seedlings were exposed to ^{14}C -myclobutanil at either 42 mg/kg (PH label) or 64 mg/kg (TZ label) in nutrient solutions for an 11 day period placed in the greenhouse. After extraction with methanol, the overall recovery including the unextracted residue ranged from 90% to 96%. In the wheat seedlings, most of the radioactivity (62–71% TRR) remained as parent compound. The total conjugates constituted the complement of the total residues (accounting for 21–30% TRR). In the excised wheat shoots, more than 72% of TRR maintained as unchanged parent compound. In the excised heads of 13-day uptake samples, parent compound accounted for up to 75% TRR, free RH-9090 for 5% TRR, RH-9090 glucoside for up to 18% TRR for both labelling forms.

The metabolism of myclobutanil, using either PH or TZ labels, was studied in wheat under field conditions and greenhouse at a rate equivalent to 0.28 kg ai/ha. After extraction with methanol, the overall recovery of identified radioactive residues ranged between 77% and 102%. TRRs in wheat grain ranged from 0.07 to 3.6 mg eq/kg, and those in wheat straw were from 2.8–69 mg eq/kg. The main components of the residue in wheat straw were parent myclobutanil (under field: 29–47% TRR), RH-9090 and its conjugates (under field: 23–41% TRR). The main components of the residue in wheat grains were RH-9090 and its conjugates (35% TRR) and parent myclobutanil (11% TRR) treated with PH label under field conditions. However, the main components of the residue in wheat grains were RH-3968 (51% TRR) and RH-4098 (25% TRR), and RH-9090 and its conjugates (8.9% TRR) treated with TZ label under field conditions while unchanged myclobutanil was a minor component of residue treated with TZ label accounting for 0.4% TRR.

Foliar applications were made to sugar beet at application rates equivalent to 0.15 kg ai/ha and 1.50 kg ai/ha using two radiolabelled forms ([^{14}C]-phenyl-myclobutanil and [^{14}C]-triazole-myclobutanil) 30 days prior to maturity. After extracted with acetonitrile, the overall recovery ranged between 91% and 105%. The main components of the residue in roots were parent myclobutanil (27–33% TRR, 0.01–0.03 mg eq/kg), conjugated RH-9090 and free RH-9090 (total 8–14% TRR, 0.006–0.007 mg eq/kg). The main components of the residue in leaves at maturity were RH-9090 (50–62% TRR, 0.26–0.43 mg eq/kg) and parent myclobutanil (16–34% TRR, 0.11–0.18 mg/kg), respectively.

In summary, the metabolism of myclobutanil in crops is qualitatively consistent and considered comparable except in wheat treatment with TZ label. The conversion of myclobutanil to RH-9090 followed by conjugation with glucose is the major metabolic pathway. Minor amounts of RH-9089 are probably a result of oxidation of RH-9090. The presence of RH-3968 and RH-4098 in wheat treated with TZ label indicates that the phenethyl triazole linkage in parent was metabolically cleaved.

Environmental fate in soil

The Meeting received information on the environment fate of myclobutanil in confined and field crop rotational studies. A study on degradation of myclobutanil in aerobic soil showed that half-life values reached up to 574 days. Myclobutanil could be a persistent compound in some soils.

Confined rotational crop

The metabolism of ^{14}C -triazole-myclobutanil in succeeding crops was investigated in wheat, radish and lettuce cultivated at three different plant back intervals for all crops (30, 120 and 365 days) at $1 \times 0.36 \text{ kg ai/ha}$. Lettuce, radish and wheat were planted at rotational intervals of 30, 120 and 365 days after soil treatment, TRRs ranged from 0.07 to 2.7 mg eq/kg were found in harvested crops. Radioactive residues in immature and mature lettuce and radish tops declined over time, while residues in radish roots increased. Residues in wheat hay, straw and grain did not show consistent increase or decline. The three most abundant non-polar components in crops planted 30 days after soil application were myclobutanil at 0.43 mg/kg (55% TRR) in mature lettuce, MW 309 di-acid at 0.38 mg eq/kg (14% TRR) and RH-9090 at 0.47 mg eq/kg (17% TRR), both in wheat straw. The two most abundant polar metabolites were the triazole alanine at 0.45 mg eq/kg (30% TRR) and triazole acetic acid at 0.43 mg eq/kg (29% TRR), both in 120 DAT wheat grain. Unextracted residues exceeded both 10% of the TRR and 0.05 mg eq/kg only in wheat hay, straw and grain at all plant-backs. In wheat hay and straw, the unextracted residues ranged from 11 to 23% TRR and from 0.17 to 0.53 mg eq/kg. For wheat grain, the unextracted residues ranged from 26 to 39% TRR and from 0.21 to 0.57 mg eq/kg.

The unchanged parent molecule was found as main component in samples of immature, mature lettuce (30-day PBI), radish roots (30, 120, 365-day PBI) and wheat forage (30 day PBI). Myclobutanil was detected as minor component in other samples. Metabolites were generally detected in lower concentrations. The parent compound, RH-9090 and its conjugates were found in most parts of the four crops. The other two most abundant metabolites were MW 309 di-acid (0.4–28% TRR) and butyric acid (0.9–15% TRR), were not identified in the metabolism studies of crops. This study indicates a potential uptake of residues for myclobutanil into plant commodities.

Field succeeding crop

Myclobutanil was applied at $6 \times 0.14 \text{ kg ai/ha}$ to zucchini in the USA (California and Georgia) approximating the estimated plateau level in soil after subsequent annual application. Within 2 days after the last application, zucchini fruit were harvested and removed from the plots. The remaining plant parts were incorporated into the soil 7–10 days after harvest and then rotational crops (soya bean, radish and wheat) were planted 30 days after the last application to the target zucchini crop. Rotational crops were sampled ranging between 71 and 258 days after final treatment. The plants were Soxhlet extracted with methanol and analysed for the parent compound and RH-9090. Residues of myclobutanil and RH-9090 occurred up to 0.36 and 0.15 mg/kg in soya bean forage, 0.093 and 0.19 mg/kg in soya bean hay, 0.052 and $< 0.01 \text{ mg/kg}$ in radish root, 0.044 and 0.12 mg/kg in radish tops, 0.071 and 0.11 mg/kg in wheat forage, 0.18 and 0.63 mg/kg in wheat straw, respectively. Myclobutanil and RH-9090 residues were higher in vegetative matrices (forage, hay and straw) than the respective seed or grain crop matrix. Residue values for soya bean seeds and wheat grains were all below LOQ (0.01 mg/kg).

Methods of analysis

The Meeting received descriptions and validation data for analytical methods for residues of myclobutanil and RH-9090 in plant and meat. Myclobutanil residues can be measured in most matrices to the LOQ range of 0.01 to 0.05 mg/kg. No stereo-selective methods were submitted for two myclobutanil enantiomers.

The crop and animal methods typically use an initial extraction with methanol or acetone or acetonitrile, and clean-up with partition and/or column steps. The final solution was analysed by GC-ECD, GC-MS or LC/MS/MS. If RH-9090 and its conjugates are determined, hydrolysis with concentrated acid and heating is applied after extraction. Myclobutanil residues can be measured in most matrices to an LOQ of 0.01 mg/kg. All methods are considered sufficiently validated. Multi-residue enforcement method DFG S19 and MRM-1 were provided and validated. The DFG S19 was valid for RH-9090 in animal tissues except fat and MRM-1 was valid for myclobutanil in crops with the LOQ of 0.2 mg/kg. Analytical methods in the feeding studies were valid for determination of

myclobutanil and total RH-9090 in milk, myclobutanil and free RH-9090 in muscle, fat, liver and kidney.

Stability of residues in stored analytical samples

The Meeting received information on the freezer storage stability of residues of myclobutanil in plant and animal commodities.

Storage stability studies were conducted on apples, radish root, soya bean, wheat forage, wheat grain, wheat hay, wheat straw, blueberry, cucurbits and snap beans. Analytical results demonstrated that myclobutanil and RH-9090 were stable in the different plant matrices for at least one year, the duration of the test period.

Storage stability studies on liver and muscle were carried out. Analytical results demonstrated that myclobutanil and its metabolite RH-9090 were stable for at least 80 days, the duration of the study.

Definition of the residue

The composition of the residue in the metabolism studies, the available residue data in the supervised trials, the toxicological significance of metabolites, the capabilities of enforcement analytical methods and the national residue definitions already operating all influence the decision on residue definition.

The metabolism studies of lactating goats showed that the unchanged parent compound was only observed in liver. RH-9090 and its conjugates were the primary residues in liver, kidney, muscle and fat. The primary residue was RH-9090, constituted about 28–58% of the TRR in milk and no parent compound was observed.

In laying hens studies, the highest ^{14}C levels were observed in liver and kidney, while fewer residues were found in muscle and fat. Parent was one of the main components detected in liver and in kidney. RH-9090-sulphate was another main residue detected in liver. A band that co-chromatographed with RH-9090/RH9089 and hydroxy-lactone accounted for 15% TRR in kidney. The major component of the residue in muscle extracts was RH-9089. The major component of residue in fat was parent compound. RH-9090 was the major component of the residue in eggs. No parent compound was observed in eggs.

RH-9090 and its conjugates are the main residues in the animal tissues, milk and eggs. Parent compound is also identified in most of tissues and as a major component in fat and kidney. Although RH-9090 and RH-9089 are found in tissues of animal metabolism study, no residues of parent compound and metabolites were expected above LOQ on the basis of dietary burden calculation and animal feeding studies. The Meeting recommended that, parent myclobutanil is the appropriate residues of concern for MRL enforcement and dietary risk assessment in animal commodities.

The octanol-water partition coefficient of myclobutanil ($\log K_{\text{OW}} = 2.56$) suggested that myclobutanil is not fat-soluble. Noting that myclobutanil residues in animal fat were less than those in muscle, the Meeting agreed that myclobutanil residue is not fat-soluble.

Metabolism studies on plants, and confined rotational crop showed that the main residues in food or feed of plant origin were myclobutanil and/or conjugated RH-9090 and free RH-9090. The Meeting decided that for plant commodities, parent myclobutanil is the appropriate residue of concern for MRL enforcement, and myclobutanil and RH-9090 and its conjugates for dietary risk assessment.

Definition of the residue (for compliance with the MRL) for plant and animal commodities: *myclobutanil*.

Definition of the residue (for estimation of dietary intake) for animal commodities: *myclobutanil*.

Definition of the residue (for estimation of dietary intake) for plant commodities: *sum of myclobutanil, α -(4-chlorophenyl)- α -(3-hydroxybutyl)-1H-1,2,4-triazole-1-propanenitrile (RH-9090) and its conjugates, expressed as myclobutanil.*

The residue is considered as not fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised trials data for myclobutanil formulations for apple, pear, peach, cherry, apricot, plum, currant, grapes, strawberry, banana, hops, tomato, squash, pepper, cucumber, melon, watermelon, snap beans and soya beans.

The method for calculation of the total residues is illustrated as follows (similar molecular weight, suggest to sum up residue of myclobutanil and RH-9090 as total residue).

RH-9090 less than LOQ (0.01 mg/kg) and more than LOD (0.0025 mg/kg)

Myclobutanil, mg/kg	RH-9090, mg/kg	Total, mg/kg
< 0.01	< 0.01	< 0.02
0.08	< 0.01	0.09

RH-9090 less LOD (0.0025 mg/kg)

Myclobutanil, mg/kg	RH-9090, mg/kg	Total, mg/kg
< 0.01	< 0.0025	< 0.01
0.08	< 0.0025	0.08

RH-9090 equal to or more than LOQ (0.01 mg/kg)

Myclobutanil, mg/kg	RH-9090, mg/kg	Total, mg/kg
0.21	0.03	0.24

Pome fruits

The critical GAP for myclobutanil on pome fruits is in Czech Republic, 3×0.09 kg ai/ha, 14-day PHI. Seven trials were available from Europe on apple against Czech GAP with myclobutanil residue of 0.03(2), 0.05, 0.07, 0.11, 0.20 and 0.34 mg/kg, with total residue of 0.03, 0.04, 0.05, 0.08, 0.12, 0.22 and 0.35 mg/kg.

Eight trials were available from Europe on pear against Czech GAP with myclobutanil residue of 0.03(2), 0.04, 0.05, 0.06, 0.10, 0.28 and 0.32 mg/kg, and with total residue of 0.05(3), 0.06, 0.07, 0.11, 0.29 and 0.35 mg/kg.

Noting the similar data population from apple and pear and medians of the datasets differed less than 5-fold, The Meeting agree to combined residues expressed in terms of myclobutanil of 0.03(4), 0.04, 0.05(2), 0.06, 0.07, 0.10, 0.11, 0.20, 0.28, 0.32 and 0.34 mg/kg. The residues expressed in terms of total residues were: 0.03, 0.04, 0.05(4), 0.06, 0.07, 0.08, 0.11, 0.12, 0.22, 0.29 and 0.35(2) mg/kg. On the basis of myclobutanil residues, the Meeting estimated a maximum residue level of 0.6 mg/kg pome fruits to replace the previous recommendation of 0.5 mg/kg. The Meeting also agreed to combine two datasets to estimate an HR of 0.35 mg/kg, an STMR of 0.07 mg/kg based on the total residue.

Stone fruits

The critical GAP for myclobutanil on peach, nectarine and cherry is in the USA, 8×0.18 kg ai/ha with PHI of 0 day. Nine trials were conducted with application number from 7 to 11 within $\pm 25\%$ GAP rate in the USA. No significant contribution should be expected from the treatments more than 3 half-lives to the final residue. Myclobutanil residues with 0 day PHI on peach were: 0.34, 0.38, 0.62, 0.66, 0.75, 0.84, 0.85 and 1.23 mg/kg and the total residues were: 0.37, 0.55, 0.76, 0.82, 0.91, 1.06, 1.12 and 1.54 mg/kg.

Eight trials were available from the USA on cherry with myclobutanil residue 0.20, 0.28, 0.75, 0.85, 0.92, 1.04, 1.12 and 1.44 mg/kg, and with total residue 0.22, 0.32, 0.82, 1.05, 1.07, 1.52, 1.61 and 2.05 mg/kg.

The Meeting estimated an HR of 2.05 mg/kg, an STMR 1.06 mg/kg, and maximum residue level of 3 mg/kg for cherry.

The critical GAP for myclobutanil on apricot, plum and prune is in the USA, 7×0.18 kg ai/ha with PHI of 0 day. Seven trials were available from the USA and Europe on apricot against US GAP with myclobutanil residue 0.11, 0.12, 0.17, 0.18, 0.23, 0.34 and 0.62 mg/kg, and with total residue 0.13, 0.14, 0.21, 0.25, 0.29, 0.38 and 0.70 mg/kg.

Eight trials were available from the USA on plum against US GAP with myclobutanil residue 0.09, 0.13, 0.20, 0.25, 0.28, 0.59, 0.97 and 1.12 mg/kg, and with total residue 0.11, 0.36, 0.40, 0.73 and 1.45 mg/kg.

The Meeting estimated an HR of 1.45 mg/kg, an STMR 0.40 mg/kg, and maximum residue level of 2 mg/kg and agreed to replace the previous recommendation of 0.2 mg/kg for plums.

Considering the higher residues came from peach, the Meeting decided not to combine datasets of peach and apricot, and estimated an HR of 1.54 mg/kg, STMR 0.865 mg/kg, and maximum residue level of 3 mg/kg for peach, nectarine and apricot on the basis of residues of peach. The Meeting agreed to withdraw the previous recommendation of 2 mg/kg for stone fruits (except plums) and 0.5 mg/kg for prunes.

Currants

The critical GAP for myclobutanil on currants is in the UK, 6×0.09 kg ai/ha with PHI of 14 days. Twelve trials were available from the UK on black currants against GAP with myclobutanil residue 0.19, 0.24(2), 0.26(2), 0.29, 0.30(2), 0.31, 0.35, 0.42 and 0.43 mg/kg, and with total residue 0.21, 0.28(2), 0.31(2), 0.34(2), 0.35, 0.37, 0.39, 0.46 and 0.47 mg/kg.

The Meeting agreed to estimate an HR 0.47 mg/kg, an STMR 0.34 mg/kg, and maximum residue level of 0.9 mg/kg for currants to replace the previous recommendation of 0.5 mg/kg on currants, black.

Grapes

The critical GAP for myclobutanil on grapes is in the USA, 5×0.15 kg ai/ha with PHI of 14 days. Nine trials were available from the USA on grapes against US GAP with myclobutanil residue in grape 0.13, 0.14(2), 0.25, 0.31, 0.32(2), 0.48 and 0.53 mg/kg, and with total residue in grape 0.17, 0.19(2), 0.29, 0.34, 0.40(2), 0.58 and 0.60 mg/kg.

The Meeting estimated an HR of 0.60 mg/kg, an STMR 0.34 mg/kg, and maximum residue level of 0.9 mg/kg for to replace the previous recommendation of 1 mg/kg for grapes.

Strawberry

The critical GAP for myclobutanil on strawberry is in the USA, 6×0.14 kg ai/ha with PHI of 0 day. Seven outdoor trials from the USA against US GAP gave residues 0.03, 0.04, 0.10, 0.15, 0.20, 0.23 and 0.31 mg/kg.

The critical GAP for myclobutanil on strawberry is in the UK, 6×0.09 kg ai/ha with PHI of 3 day. In 19 outdoor trials from Europe at UK GAP, myclobutanil residues were 0.08, 0.10, 0.14, 0.15, 0.17, 0.18(2), 0.19(4), 0.20(2), 0.22, 0.24, 0.30, 0.48, 0.50 and 0.69 mg/kg, and total residues were 0.09, 0.10, 0.15(2), 0.17, 0.18(2), 0.19(4), 0.20(2), 0.22, 0.24, 0.31, 0.48, 0.50 and 0.69 mg/kg. Eight indoor trials were available from Europe on strawberry against UK GAP with myclobutanil residue of 0.13, 0.16, 0.18, 0.19, 0.20, 0.24, 0.37 and 0.46 mg/kg, and with total residue of 0.14, 0.17, 0.19, 0.20, 0.21, 0.25, 0.38 and 0.47 mg/kg.

Considering the higher residues came from Europe, residue populations from indoor and outdoor European trials were similar, the Meeting decided to combine the two datasets. The residues in 27 trials were 0.08, 0.10, 0.13, 0.14, 0.15, 0.16, 0.17, 0.18(3), 0.19(5), 0.20(3), 0.22, 0.24(2), 0.30, 0.37, 0.46, 0.48, 0.50 and 0.69 mg/kg for myclobutanil and 0.09, 0.10, 0.14, 0.15(2), 0.17(2), 0.18(2), 0.19(5), 0.20(3), 0.21, 0.22, 0.24, 0.25, 0.31, 0.38, 0.47, 0.48, 0.50 and 0.69 mg/kg for myclobutanil and RH-9090 and its conjugates. The Meeting estimated a maximum residue level of 0.8 mg/kg on the basis of parent residues for strawberry to replace the previous recommendation of 1 mg/kg on strawberry. The Meeting also estimated an HR of 0.69 mg/kg and an STMR of 0.19 mg/kg on the basis of total residues.

Banana

Myclobutanil is registered in Costa Rica for use as a post-harvest run-off or dip application at 84.8 g ai/hL, application before packaging fruits. Three trials from Costa Rica on banana against GAP gave myclobutanil residues in whole fruits of 0.028(2) and 0.29 mg/kg. Total residues in banana pulp were 0.06, 0.07 and 0.09 mg/kg.

The Meeting agreed that there is not sufficient evidence that the proportionality principal is applicable to post-harvest treatment. Three trials on banana were not enough for estimation of an MRL, an STMR and an HR for banana. The Meeting agreed to withdraw the previous recommendation of 2 mg/kg for banana.

Fruiting vegetables, other than Cucurbits

Tomatoes

The critical GAP for myclobutanil on tomatoes is in the USA, 4× 0.11 kg ai/ha with PHI 0 day. Seventeen outdoor trials were available from the USA on tomatoes against US GAP with myclobutanil residue 0.02, 0.03(2), 0.04(2), 0.06, 0.07(5), 0.08(2), 0.09, 0.10, 0.11 and 0.22 mg/kg, and with total residue 0.02, 0.03, 0.04(2), 0.05, 0.06, 0.07(4), 0.08, 0.09, 0.10(2), 0.11, 0.12 and 0.25 mg/kg.

The Meeting decided to estimate an HR of 0.25 mg/kg, an STMR of 0.07 mg/kg based on total residues, and a maximum residue level of 0.3 mg/kg based on myclobutanil residues for tomatoes to confirm the previous recommendation.

Peppers

The critical GAP for myclobutanil on peppers is in the USA, 4× 0.14 kg ai/ha with PHI of 0 day. Two outdoor trials were available from the USA on sweet pepper against US GAP with myclobutanil residue 0.03 and 0.47 mg/kg, and with total residue 0.05 and 0.64 mg/kg. Four outdoor trials were available from the USA on chilli pepper against US GAP with myclobutanil residue 0.09, 0.18, 1.19 and 2.03 mg/kg, and with total residue 0.12, 0.23, 1.39, 2.40 mg/kg.

Considering residues from sweet and chilli peppers were similar, the Meeting decided to combine two datasets. The residues in six trials were 0.03, 0.09, 0.18, 0.47, 1.19 and 2.03 mg/kg for myclobutanil and 0.05, 0.12, 0.23, 0.64, 1.39, 2.40 mg/kg for myclobutanil and RH-9090 and its conjugates. The Meeting estimated an HR 2.40 mg/kg, an STMR 0.435 mg/kg based on total residues, and maximum residue level of 3 mg/kg based on myclobutanil residues for peppers.

On the basis of residues in peppers and dehydration factor of 7, the Meeting estimated an HR of 16.8 mg/kg, an STMR of 2.45 mg/kg and recommended a maximum residue level of 40 mg/kg for myclobutanil on peppers chilli, dried.

Fruiting vegetables, Cucurbits

The critical GAP for myclobutanil on cucurbits is in the USA, 5 applications at 0.14 kg ai/ha with a PHI of 0 days.

Summer Squash

Nine outdoor trials were available from the USA on summer squash matching US GAP. Myclobutanil residues in squash were: 0.01(2), 0.02(2), 0.04, 0.05, 0.06, 0.10 and 0.16 mg/kg, and with total residue 0.01, 0.02, 0.03(2), 0.04, 0.05, 0.07, 0.11 and 0.16 mg/kg.

Cucumber

Seven outdoor trials were available from the USA on cucumbers matching US GAP. Myclobutanil residues were: 0.02, 0.03(2), 0.04(2) and 0.07 mg/kg, and with total residue of 0.03(2), 0.04 (3) and 0.07 mg/kg.

Melons

Four outdoor trials were available from the USA on melons matching US GAP with myclobutanil residue of 0.02, 0.05, 0.07 and 0.08 mg/kg, and with total residue of 0.02, 0.05, 0.07 and 0.08 mg/kg. Two outdoor trials were available from Southern Europe on melon matching US GAP with myclobutanil residues of 0.09 and 0.10 mg/kg, and total residue of 0.10 and 0.11 mg/kg.

The US GAP is the same for cucumbers, melons and squash. The Meeting considered that the residues from trials with the foliar application on cucumber, melon and squash were similar. The Meeting agreed to propose a group maximum residue level for fruiting vegetables, cucurbits. The residues expressed in terms of myclobutanil were: 0.01(2), 0.02(4), 0.03(2), 0.04(3), 0.05(2), 0.06, 0.07(2), 0.08, 0.09, 0.10(2) and 0.16 mg/kg. The residues expressed in terms of myclobutanil and RH-9090 and its conjugates were: 0.01, 0.02(2), 0.03(4), 0.04(4), 0.05(2), 0.07(3), 0.08, 0.10, 0.11(2) and 0.16 mg/kg.

Based on the trials for cucumbers, melons and squash in the USA and Southern Europe, the Meeting estimated an HR of 0.16 mg/kg, an STMR of 0.04 mg/kg and a maximum residue level of 0.2 mg/kg for fruiting vegetables, cucurbits respectively.

*Legume vegetables**Common bean*

The critical GAP for myclobutanil on snap beans is from the USA, i.e., 4×0.14 kg ai/ha with a PHI of 0 days. Nine trials were available from the USA on snap beans matching US GAP. Myclobutanil residues found were: 0.04, 0.09, 0.14, 0.19, 0.20, 0.22, 0.30, 0.37 and 0.47 mg/kg, and with total residues of 0.06, 0.11, 0.16, 0.21, 0.22, 0.24, 0.32, 0.39 and 0.49 mg/kg.

On the basis of the trials on snap beans, the Meeting estimated an HR of 0.49 mg/kg, an STMR 0.22 mg/kg based on the total residues dataset, and a maximum residue level of 0.8 mg/kg for beans, except broad bean and soya bean (green pods and immature seeds), respectively.

Soya bean (dry)

The critical GAP for myclobutanil on soya beans is from Brazil, 2×0.125 kg ai/ha with a PHI of 24 days. Nine trials were available from Brazil on soya bean matching Brazilian GAP with parent residues of < 0.01(5), < 0.02(2), 0.02 and 0.03 mg/kg.

Noting that total residues were not available from the Brazilian trials, the Meeting decided to not estimate a maximum residue level for soya bean.

Hops

The critical GAP for myclobutanil on hops is from the USA, 4×0.28 kg ai/ha with a PHI of 14 days. Ten trials were available from Germany on hops matching US GAP, myclobutanil residues in dried hops were: < 0.50, 0.53, 0.63, 0.73, 1.02, 1.06, 1.14, 1.54, 1.80 and 3.50 mg/kg, and with total residues of 0.53, < 1.00, 1.13, 1.23, 1.52, 1.56, 2.04, 3.20 and 5.60 mg/kg.

The Meeting estimated an HR of 5.60 mg/kg, an STMR 1.52 mg/kg based on the total residue dataset, and a maximum residue level of 5 mg/kg for dry hops based on myclobutanil residues to replace the previous recommendation of 2 mg/kg on dry hops.

Animal feedstuffs

The critical GAP for myclobutanil on soya bean is in the USA, 2× 0.14 kg ai/ha with PHI of 28 days.

Soya bean forage

Two trials were available from the USA on soya bean forage against US GAP with residue 0.67 and 1.01 mg/kg.

Two trials on soya bean forage were not sufficient for estimation of a median and highest residue.

soya bean hay (dry)

Noting no trials on soya bean hay were available from the USA against US GAP, the Meeting decided not to make recommendations for soya bean hay.

Rotational crops

The Meeting noted that myclobutanil may accumulate in soil and be taken up by follow-crops in significant amounts. Residues were reported in field rotational crop studies following application to zucchini at rates of 6× 0.14 kg ai/ha. Since the foliage of the crop was incorporated into soil after harvest of the fruits, this application rate can be assumed to approximate the estimated soil plateau level following annual treatment according to the GAPs considered by the Meeting.

Residues for parent myclobutanil in respective field studies were < 0.003 mg/kg for soya bean seeds, 0.03 mg/kg to 0.36 mg/kg for soya bean forage and 0.017 mg/kg to 0.093 mg/kg for soya bean straw. The Meeting concluded that for pulses no significant transfer into seeds is expected. Median and highest residues were estimated at levels of 0.195 mg/kg and 0.36 mg/kg for legume forages and of 0.055 and 0.093 mg/kg for legume fodders.

Based on the average dry-matter content of 85% for soya bean hay, the Meeting estimated a maximum residue level of 0.2 mg/kg (DM) for legume animal feeds.

In leaves of radish grown as rotational crops myclobutanil residues were 0.015 mg/kg to 0.044 mg/kg. Extrapolating the residues found in radish leaves to all Brassica vegetables and leafy vegetables (including leafy Brassica vegetables), the Meeting estimated maximum residue levels of 0.05 mg/kg and HR and STMR values of 0.044 mg/kg and 0.030 mg/kg for Brassica vegetables and leafy vegetables (including leafy Brassica vegetables), respectively.

The roots of radish grown as a rotational crop contained myclobutanil residues of 0.026 mg/kg to 0.052 mg/kg. The Meeting decided to extrapolate the results to all bulb vegetables and all root and tuberous vegetables. The Meeting estimated a maximum residue level of 0.06 mg/kg and HR and STMR values of 0.039 mg/kg and 0.052 mg/kg for bulb vegetables and root and tuber vegetables, respectively.

Residues in wheat matrices obtained from field rotational crop studies contained myclobutanil residues < 0.003 mg/kg in the grain, 0.023 mg/kg to 0.071 mg/kg in forage and 0.015 mg/kg to 0.18 mg/kg in hay and straw. The Meeting concluded that for cereal grains no significant transfer of residues into seeds is expected. Median and highest residues were estimated at levels of 0.047 mg/kg and 0.071 mg/kg for cereal forages and of 0.098 and 0.18 mg/kg for cereal straw and fodder.

Based on the average dry-matter content of 88% for wheat straw, the Meeting estimated a maximum residue level of 0.3 mg/kg (DM) for straw and fodder (dry) of cereal grains.

The Meeting also concluded that the contribution of residues by uptake of myclobutanil from soil is insignificant compared to direct treatment for the uses evaluated.

Fate of residues during processing

The Meeting received information on the hydrolysis of myclobutanil as well as processing studies during the food processing of apples, grapes, tomatoes, soya beans and hops.

No degradation of myclobutanil was observed in a hydrolysis study at pH 4, 7 and 9 held at 50 °C, over a 5 day period.

In the following table all processing factors based on parent residues relevant for recommendation of maximum residue levels and estimation of animal dietary burden for processed commodities are summarized.

Portion Analysed	Median Processing Factor	Median residues	
		Raw commodities	Processed commodities
Apple		0.06	
Wet pomace	1.61		0.097
Dry pomace	12.1		0.726
Grapes		0.295	
Wet pomace	0.90		0.266
Dry pomace	3.94		1.16
Raisin	6.31		1.86
Tomato		0.07	
Dry pomace	20.05		1.40
Wet pomace	4.54		0.318
soya bean		0	
Hulls	1.14		0
Meal	0.43		0
Oil, refined	2.14		0
Hops		1.04	
Beer	0.0145		0.015

Based on the median processing factor of 6.31, the Meeting estimated a maximum residue level of 6 mg/kg for raisin.

In the following table all processing factors based on total residues relevant for the estimation of the dietary intake for processed commodities are summarized.

Raw and processed commodity	Median Processing Factor	STMR (mg/kg)	STMR-P (mg/kg)	HR (mg/kg)	HR-P (mg/kg)
Apple		0.07			
Juice	0.17		0.012		
Puree	0.30		0.021		
Grapes		0.34		0.60	
Juice	0.20		0.068		
Wine after half year	0.17		0.058		
Wine at bottling	0.14		0.048		
Raisin	6.29		2.14		3.77
Tomato		0.07			
Juice	0.50		0.031		
Puree	1.33		0.093		
Preserve	0.29		0.020		
Paste	3.92		0.27		
Hops Beer	0.015	1.52	0.023		

Residues in animal commodities

Estimated maximum and mean dietary burdens of farm animals

Dietary burden calculations for beef cattle, dairy cattle, broilers and layers are provided in Annex 6 to the 2014 Report. The calculations were made according to the animal diets from US-Canada, EU, Australia and Japan in the OECD Feed Table 2009.

The calculations are then summarised and the highest dietary burdens are selected for MRL and STMR estimates on animal commodities.

	Animal dietary burden, myclobutanil, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.046	0.26	1.22	0.83	1.47 ^a	0.96 ^b	0.096	0.055
Dairy cattle	0.63	0.45	0.86	0.58	1.31 ^c	0.88 ^d	0.18	0.10
Poultry-broiler	0	0	0.035	0.026	0	0	0.051	0.028
Poultry-layer	0	0	0.22 ^e	0.13 ^f	0	0	0	0

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian meat.

^b Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat.

^c Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for mammalian milk.

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs.

^f Highest mean poultry dietary burden suitable for STMR estimates for meat and eggs.

Lactating cows were orally administered myclobutanil equivalent to 0 ppm, 1.6 ppm, 4.8 ppm and 16 ppm in the feed, respectively. Residues of myclobutanil and RH-9090 in whole milk and tissues of the cows in all groups were < 0.01 mg/kg.

Dietary burden calculations showed the highest dietary burdens were less than the lowest feeding level. The Meeting decided to estimate maximum residue levels of 0.01*, and STMRs and HRs of 0 mg/kg for all milk, eggs and animal tissues. Confirming the previous recommendations of 0.01* mg/kg for cattle meat, milk and edible offal, and eggs, poultry meat and edible offal of the 1992 JMPR.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue concentrations listed below are suitable for establishing MRLs and for assessing IEDIs and/or IESTIs.

Definition of the residue (for compliance with the MRL for plant and animal commodities and for estimation of dietary intake for animal commodities): *myclobutanil*.

Definition of the residue (for estimation of dietary intake for plant commodities): *sum of myclobutanil, α -(4-chlorophenyl)- α -(3-hydroxybutyl)-1H-1,2,4-triazole-1-propanenitrile (RH-9090) and its conjugates, expressed as myclobutanil*.

DIETARY RISK ASSESSMENT

Long term intake

The evaluation of myclobutanil resulted in recommendations for MRLs and STMR values for raw and processed commodities. Data on consumption were available for 33 food commodities and were used to calculate dietary intake. The results are shown in Annex 3 to the 2014 Report.

The International Estimated Daily Intakes (IEDIs) of myclobutanil, based on the STMRs estimated, represented 1–6% of the upper bound of the maximum ADI of 0.03 mg/kg bw for the 17 GEMS/Food cluster diets. The Meeting concluded that the long-term intake of residues of myclobutanil resulting from its uses that have been considered by JMPR was unlikely present a public health concern.

Short-term intake

The 2014 Meeting established an ARfD of 0.3 mg/kg bw for women of childbearing age only; ARfD was unnecessary for the general population.

The International Estimated Short Term Intake (IESTI) for myclobutanil was calculated for the food commodities for which STMRs, HRs and maximum residue levels were estimated by the current Meeting and for which consumption data were available. The results are shown in Annex 4 to the 2014 Report. The IESTI represented up to 10% (peach) for women of childbearing age only. The Meeting concluded that the short-term intake of residues of myclobutanil resulting from uses considered by the current Meeting was unlikely to present a public health concern.

PHOSMET (103)

The first draft was prepared by Dr Guibiao Ye, Institute for the Control of Agrochemicals, Ministry of Agriculture, Beijing, China

EXPLANATION

Phosmet is a broad-spectrum organo-phosphorus insecticide used to control a variety of insect and mite pests which attack berries, pome, stone and citrus fruit. It is also used on field, pasture and forage crops. Phosmet is non-systemic and acts by contact and ingestion as a cholinesterase inhibitor. It is registered in a number of countries, mainly for protecting fruits and vegetables.

Phosmet was evaluated for residues several times by the JMPR from 1976 to 2007, and was evaluated under the periodic review in 1994 for toxicity and in 1997 for residue. The ADI of 0-0.01 mg/kg bw was established in 1994. The ARfD of 0.2 mg/kg bw was established in 2003. Codex MRLs for cotton seed, grapes, apricots/peaches/nectarines, potatoes, tree nuts were established in 2002, and Codex MRLs for apricot, blueberries, citrus fruits, nectarine and pome fruits were established in 2007.

GAP and supervised trials data were submitted to the 2014 JMPR for cranberry.

USE PATTERN

Information on registered uses was reported to the Meeting and is shown in Table 1.

Table 1 Registered uses for phosmet on cranberries

Crop	Country	Form.	Application					PHI days
			Method	Rate kg ai/ha	Spray conc. kg ai/hL	Water L/ha	No.	
Cranberries	USA	70 WSB	Foliar spraying	1.1-3.1	1.68-16.8		4	14

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received new information on supervised field trials on cranberries. Residue data are reported in Tables 2. Five supervised trials were conducted on cranberries in the USA in 1996 (Ref: R04625, DOC. NO.: 632-4301). A wettable powder formulation containing phosmet at 70% w/w was applied to cranberries at a nominal rate of 3.36 kg ai/ha. Four applications were made at intervals of approximately 10 days beginning after bloom with the last to mature fruits, 14 days before harvest. Duplicate samples of berries were collected 14 days after the last application. Mean residues of the duplicate samples are calculated.

The study report also includes residues of phosmet-oxon in addition to residues of phosmet. The results for phosmet-oxon are presented (all are below the LOQ) but not used further.

Results have not been corrected for concurrent method recoveries. Residues and application rates have generally been rounded to two significant figures. Although trials included control plots, residues of all controls are below LOQ.

The samples were frozen immediately after collection and stored at approximately -20 °C until extraction and analysis. The maximum storage period was 88 days (3 months). Residues of phosmet and phosmet-oxon were determined by GC-FPD using Stauffer Chemical company method WRC 73-43 (modified as Morse Laboratories Method Meth-14, Revision 3.). The LOQ of the method was 0.05 mg/kg. Mean procedural recoveries for phosmet at fortification levels of 0.05–10 mg/kg were within the acceptable range of 70–120%, RSD < 20%. The stability of phosmet in cranberry was confirmed by laboratory fortified samples (3× 1.0 mg/kg) that were stored in parallel with field samples. The average stability of phosmet after this period of 88 days was found to be 93%.

Because of the low phosmet oxon residues detected (<10% of parent), the 1997 JMPR decided that the definition of the residue for compliance with the MRL and for the estimation of dietary intake is phosmet.

Table 2 Phosmet residues in cranberries from supervised trials in USA

^a Residues in [] were mean of results from two duplicate sample.

^b Higher residue from two dependent trials was considered and used.

APPRAISAL

Phosmet is a broad-spectrum organo-phosphorus insecticide used to control a variety of insect and mite pests which attack berries, pome, stone and citrus fruit. It is also used on field, pasture and forage crops. Phosmet is non-systemic and acts by contact and ingestion as a cholinesterase inhibitor. It is registered in a number of countries, mainly for protecting fruits and vegetables.

Phosmet was evaluated for residues several times by the JMPR from 1976 to 2007, and was evaluated under the periodic review in 1994 for toxicity and in 1997 for residue. The ADI of 0–0.01 mg/kg bw was established in 1994. The ARfD of 0.2 mg/kg bw was established in 2003. Existing residue definitions for phosmet were set at the 1997 JMPR Meeting. For plant and animal commodities, the residue definition for enforcement and dietary risk assessment is phosmet.

Results of supervised residue trials on crops

Cranberry

GAP and supervised trials data on cranberry were received and evaluated by the current Meeting. Phosmet is registered in the USA for use on cranberry at 1.1–3.1 kg ai/ha with a PHI of 14 days. Five supervised trials were conducted on cranberries in the USA in 1996. The residues of phosmet from four independent trials were: 0.13, 0.84, 0.85, 0.88 mg/kg, with the highest residue of 0.91 mg/kg from a replicate sample in one trial.

The Meeting estimated a maximum residue level of 3 mg/kg, a HR of 0.91 mg/kg, and an STMR of 0.845 mg/kg for cranberries.

RECOMMENDATIONS

On the basis of the data from independent supervised trials, the Meeting concluded that the residue concentrations listed below are suitable for establishing MRLs and for assessing IEDIs and IESTIs.

Definition of the residue:

For compliance with MRLs and for estimation of dietary intake: Phosmet.

Commodity		MRL, mg/kg	STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
CCN	Name			
FB 0265	Cranberry	3	0.845	0.91

DIETARY RISK ASSESSMENT

Long-term intake

The estimates of long-term dietary intake for phosmet (ADI 0–0.01 mg/kg bw) were calculated by the current meeting for the 17 regional diets on the basis of the STMRs estimated by the JMPR in 2002, in 2007 and in 2014. The results are shown in Annex 3 of the 2014 Report.

The International Estimated Daily Intakes (IEDI) of phosmet, based on estimated STMRs from the uses were 3–90% (rounded) of the maximum ADI (0.01 mg/kg bw). The Meeting concluded that the long-term intake of residues of phosmet from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short Term Intake (IESTI) of phosmet was calculated for cranberry. The results are shown in Annex 4 to the 2014 Report.

The IESTI of phosmet calculated on the basis of the recommendations made by current meeting represented 0–3% of the ARfD (0.2 mg/kg bw) for children, 0–2% for the general population. The Meeting concluded that the short-term intake of residues of phosmet resulting from uses in cranberry that have been considered by the JMPR is unlikely to present a public health concern.

PROPAMOCARB (148)

The first draft was prepared by Dr Guibiao Ye, Institute for the Control of Agrochemicals, Ministry of Agriculture, Beijing, China

Propamocarb hydrochloride is a systemic carbamate fungicide with specific activity against Oomycete species that cause seed, seedling, root, foot and stem rots and foliar diseases in a number of edible crops. The compound was firstly evaluated by the JMPR in 1984, and was then reviewed by JMPR in 1986, 1987 and 2005, an ADI of 0–0.4 mg/kg bw and an ARfD of 2 mg/kg bw were established in 2005. Propamocarb was evaluated by the 2006 JMPR for residue and analytical aspect within the periodic review programme. The residue definition in plant for both enforcement and dietary intake purpose is propamocarb (free base), and the residue definition in animal products for both enforcement and dietary intake purpose is propamocarb, and propamocarb is not fat soluble.

The residue data in/on onion, broccoli, cauliflower, Brussels sprouts, head cabbage, kale, leek and lima bean was submitted to JMPR, and were evaluated by current Meeting. In addition, new analytical methods as well as new studies on animal metabolism and feeding, rotational crops and processed commodities are received and evaluated.

ANIMAL METABOLISM

Laying hen

The metabolism and distribution of propamocarb in laying hens were studied using [^{14}C]-propamocarb hydrochloride by Beedle and Miller (2010, MEPRX029, M-366633-01-1). The structural formula and the position of the ^{14}C label are shown below.

Twelve laying hens were dosed orally, via capsule, with [^{14}C] propamocarb hydrochloride at a rate of 1.02 mg/kg body weight (approximately 19 ppm in the feed) once daily for fourteen consecutive days. Eggs were collected once daily during the treatment period. Approximately 6 to 8 hours after the last dose, the hens were sacrificed, and edible tissues (liver, leg muscle, breast muscle, omental fat, subcutaneous fat, and renal fat) were collected. Tissue and egg samples were frozen immediately after collection and all of the samples were analysed within 6 months.

The total radioactive residue (TRR) in the egg and tissues was determined by oxidative combustion followed by liquid scintillation counter (LSC) or by direct LSC. Identification and quantitation of the residues in the egg and tissue extracts were accomplished by using reverse phase high performance liquid chromatography (HPLC) and liquid chromatography-mass spectrometry/mass spectrometry (LC-MS/MS).

Eggs, liver and muscle samples were extracted with acetonitrile/water (4:1) containing 1% acetic acid, blended, centrifuged and decanted from the solids. The extraction and centrifugation were repeated five times. The combined acetonitrile/water/acetic acid extract was radioassayed. The acetonitrile/water extracted solids were refluxed overnight in acetonitrile/water (4:1) containing 1% acetic acid. After cooling, centrifugation and decantation, the acetonitrile/water/acetic acid reflux extract was radioassayed. If un-extracted radioactivity remained in the solids (eggs), the solids were refluxed with extraction solvent followed by a dilute base (2 N KOH). Un-extracted residues in solids of the liver were enzymatically released by agitation with protease at 37 °C and pH 7.4 overnight. All

the extracts were combined and concentrated via rotary evaporator. The sample was radioassayed, and an aliquot was analysed by HPLC.

Fat samples were extracted with hexane, blended, centrifuged and decanted from the solids. The extraction and centrifugation were repeated once. The hexane extracts were combined and radioassayed. The combined hexane extract was partitioned three times with acetonitrile. The combined acetonitrile layers were radioassayed. After that, water was added to the hexane extract two times for a partition. The combined water layers and the hexane extract were radioassayed. The hexane-extracted solids were homogenized with acetonitrile/water (4:1) containing 1% acetic acid, blended, centrifuged and decanted from the solids. The extraction and centrifugation were repeated three times. The acetonitrile/water extracts were combined, radioassayed, and concentrated to an aliquot which was analysed by HPLC. The acetonitrile/water extracted solids were air-dried overnight at room temperature and aliquots were radioassayed. The hexane extract was concentrated to an oily residue via rotary evaporator. An aliquot of 2N potassium hydroxide (KOH) in ethanol was added to the concentrated sample. The sample was refluxed, cooled to room temperature and water was added to the sample which was partitioned two times with hexane. The combined hexane layers were back-extracted with water. The hexane fraction and the water fraction were radioassayed.

The TRR in eggs increased from day-1 through day-7 and reached a plateau at day-8. The TRR (expressed in Propamocarb hydrochloride equivalents) in the egg samples ranged from 0.015 mg/kg in the day-1 eggs to 0.254 mg/kg in the day-11 eggs, at maximum.

The TRR in the tissue samples from the hens dosed with Propamocarb hydrochloride for fourteen consecutive days was 0.492 mg/kg in liver, 0.135 mg/kg in leg muscle, 0.117 mg/kg in breast muscle, 0.042 mg/kg in omental fat, 0.042 mg/kg in subcutaneous fat and 0.065 mg/kg in renal fat.

The majority of the residues (92% to 99% of the TRR) in the egg and tissues were extractable and only 1% to 8% of the TRR (0.001 to 0.038 mg/kg) of the residues in egg and tissues were unextractable. The major residues in the egg and tissues were parent propamocarb (2% to 12% of the TRR; < 0.001 to 0.046 mg/kg) and desmethyl propamocarb (6% to 45% of the TRR; 0.003 to 0.113 mg/kg). The minor residues found in the egg and tissues were bis-desmethyl-propamocarb (< 1% to 7% of the TRR; < 0.001 to 0.029 mg/kg) and propamocarb-N-oxide (< 1% of the TRR; 0.003 mg/kg). The results of these analyses are presented in Table 1.

Metabolic Pathway in hen

Metabolic degradation of propamocarb is rapid and extensive, with between 2% and 12% of the TRR being observed in the egg and tissues as unmetabolized parent propamocarb. Demethylation products including desmethyl-propamocarb and bis-desmethyl-propamocarb were identified as major metabolites in egg and tissue samples, indicating that demethylation is the main route of metabolism for the parent compound. A minor route of metabolism involves oxidation of the tertiary nitrogen to form propamocarb-N-oxide. The proposed metabolic pathway for the metabolism of propamocarb in hens is shown in Figure 1 below

Figure 1 Proposed metabolic pathway of Propamocarb in Hens

Field crop rotational studies

Studies were conducted in Germany and France (Klein, 2004, M-226597-01-1) during 2002 and 2003, with four trials to investigate the residue level of propamocarb hydrochloride in secondary crops (Lamb's lettuce with a PBI of 52–59 days and wheat with a PBI of 81–102 days) after application to cabbages as the primary crop. No residues of propamocarb were found in any sample taken from the rotational crops, i.e., lettuce, wheat grain, wheat (green material) and wheat forage.

Cabbage plants were treated twice by drench applications to seedbeds. The first application was carried out at an application rate of 72.2 kg/ha of propamocarb hydrochloride at BBCH 00–11, directly after sowing and the second drench application 14 days after the first at an application rate of 36.1 kg/ha of propamocarb hydrochloride at BBCH 10–13. After transplanting of the young cabbage plants into the field, two additional foliar treatments were carried out at BBCH 15–45. Both spray treatments were applied at 3.61 kg/ha of propamocarb hydrochloride, the first immediately after transplanting and the second 39 to 66 days later at BBCH 41–45 (20 to 50% of the expected head size reached). Samples of cabbage were taken at day 0, 7, 14, 21 and 27–29 after the last application. After the harvest of the primary crop, the following (rotational) crops wheat and lamb's lettuce were sown in the plots.

Samples of lamb's lettuce were taken at day 111–267 (BBCH 46) and day 217–273 (BBCH 49) after the last treatment. In trial 02R460-4 in France, lamb's lettuce was abandoned due to poor germination and poor plant growth. Samples of wheat (green material) were taken at day 308–348 (BBCH 71) after the last application, wheat grain and wheat straw at day 362–369 (BBCH 89). Samples of soil were taken directly after the last application, at the time of lettuce sowing (day 52–59), at the time of wheat sowing (day 81–102), at the time of lamb's lettuce harvest (day 217–273) and at the time of wheat harvest (day 362–369).

Samples of cabbage, lamb's lettuce, wheat grain, wheat (green material) and wheat straw were analysed for residues of Propamocarb (free base) according to method 00880 by LC-MS/MS (Mende P., 2001; M-200511-02-1 or C015449) and soil samples were analysed for residues of Propamocarb (free base) according to method 20001397/01-RVS by LC-MS/MS (Mende P., 2002; M-215230-01-1 or C023560). The limit of quantification (LOQ) for Propamocarb hydrochloride was established and validated at 0.01 mg/kg in/on cabbage (head), lamb's lettuce (whole plant with root) and wheat grain, at 0.02 mg/kg for soil and 0.05 mg/kg for wheat green material and wheat straw.

* Recovery samples for Propamocarb determination were prepared by fortification of untreated samples with Propamocarb free base reference substance and calculated as Propamocarb hydrochloride.

Four rotational crop studies in The Netherlands, France, Spain and Italy (Melrose and Portet, 2010, M-349882-02-1, M-349137-02-1, M-361470-01-1, and M-349147-02-1) were conducted in/on lettuce as primary crop, followed by lettuce, carrots and winter wheat or winter barley as following rotational crops, with an intended plant black interval (PBI) of 30 days during the years 2008 to 2010.

Propamocarb was applied on lettuce as the primary crop with three spray applications at 2.5 L/ha corresponding to 1.325 kg propamocarb/ha per application. The applications were carried out with 7–13 days interval. The first treatment on lettuce (primary crop) was conducted at BBCH 14–42, whilst the last application was carried out at BBCH 19–48, 5–7 days before the anticipated commercial harvest. Lettuce (primary crop) was harvested at normal harvest stage, 32–69 days after planting. No lettuce samples were taken for analysis. Harvested primary crop lettuce was destructed and the remaining plant parts were incorporated by a mulling machine or a little rotary machine. At the 27–38 day plant back interval for carrots, 26–46 day plant back interval for lettuce and 30–38 day plant back interval for cereals the plots were prepared for crop planting/sowing (rotational crops) following normal agronomic practices for each crop type in the regions. The carrots were harvested at BBCH 46–49, the lettuce was harvested at BBCH 45–49, and the cereals were harvested at BBCH 29–89.

Lettuce, carrot and cereal samples were analysed for residues of propamocarb according to method 00880/M002 by LC-MS/MS with a LOQ of 0.01 mg/kg for carrot (root and leaf), lettuce

(head), winter wheat and winter barley (grain) and with a LOQ of 0.05 mg/kg for winter wheat and winter barley (green material and straw). Residues were determined and expressed as propamocarb.

No residues of Propamocarb could be detected (below LOQ: 0.01 mg/kg for carrots, lettuce and cereals grain, 0.05 mg/kg for cereals straw) in rotational crops at a mean plant black interval (PBI) of 31 days (from 27 to 38 days) in carrots (root and leaf), at a mean PBI of 33 days (from 26 to 46 days) in lettuce (head and leaf) and at a mean PBI of 33 days (from 30 to 38 days) in cereals (grain and straw).

RESIDUE ANALYTICAL METHODS

Analytical methods for the determination of residues of propamocarb in plant and animal matrices have been evaluated by the 2006 JMPR. The QuEChERS Method (BCS method ID 01205) for the determination of residues of Propamocarb in meat (cattle), liver (cattle), kidney (cattle), fat (cattle), milk (cattle) and egg (chicken) was developed and validated (Konrad and Neuland, 2010, M-398135-01-1 and M-387185-01-1).

The Multi Method L 00.00-115 “QuEChERS” of the Official Collection of Test Methods was performed according to § 64 LFGB with:

- extraction with water/acetonitrile (5 g homogenised specimens and 5 mL of water (7 mL for fat samples) and 10 mL of acetonitrile);
- addition of magnesium sulphate, sodium chloride and sodium citrate, liquid/liquid partition and subsequent centrifugation;
- clean up by Primary Secondary Amine (PSA) and/or by freezing-out;
- detection with liquid chromatography tandem mass spectrometry LC-MS/MS using two mass transitions.

The quantification was done by an external calibration using matrix matched standards prepared in solvents. The respective followed mass transitions are presented in Table 3 below.

Table 5 Quantification and confirmatory mass transitions

	Mass transition used for quantification (1 st MRM)	Mass transition used for confirmation (2 nd MRM)
Propamocarb	189 → 102 m/z	189 → 74 m/z

For validation of the method, recovery experiments were performed by fortifying control specimens of the matrices meat, liver, kidney, fat, milk and egg at levels of 0.01 mg/kg (LOQ) up to 0.10 mg/kg.

Matrix effects for propamocarb in meat, liver, kidney, fat, milk and egg were investigated in a preliminary test. For this purpose a calibration solution of 50 ng/mL propamocarb hydrochloride was diluted with acetonitrile / 0.05% acetic acid (1/4, v/v). The same dilution was prepared using control extracts of all matrices. The final concentrations obtained were 5 ng/mL in control matrices or in acetonitrile / 0.05% acetic acid (1/4, v/v). The results are summarized in Table 6 below.

Table 6 Results of the matrix effects assessment

Matrix	Signal of the matrix matched standard relative to the solvent standard in [%]	
	189 → 102 m/z	189 → 74 m/z
Liver	96	93
Meat	78	75
Kidney	95	100
Egg	97	98
Fat	94	90
Milk	99	98

The tests for meat showed a signal depression of up to 25%. Only slight effects were observed for liver, kidney, egg, fat and milk.

The limit of quantification (LOQ) was set at 0.01 mg/kg for propamocarb (expressed as propamocarb) in all the sample materials (meat, liver, kidney, fat, milk and egg).

The limit of determination (LOD) was 0.003 mg/kg (30% of LOQ) for propamocarb (expressed as propamocarb) in all the sample materials (meat, liver, kidney, fat, milk and egg). The chromatographic peaks of propamocarb were greater than the signal equivalent to three times the background noise.

The linearity was demonstrated by injecting standards of propamocarb hydrochloride at concentrations between 0.100 and 20.0 ng/mL. Linearity test was performed by injecting eight standard solutions. Regression coefficients R were higher than 0.999.

The mean recoveries for each fortification level should be in the range of 70–110%. Although single recoveries below 60% (e.g. for egg and fat) were noted, mean values were between 70–110% with a relative standard deviation ≤ 20%. The overall relative standard deviation and the standard deviation for each fortification level were ≤ 20%.

An independent lab validation (ILV) was reported by Weber, 2010 (reference M-387185-1). For this ILV of the analytical method of propamocarb in muscle (cattle), liver (cattle), kidney (cattle), fat (cattle), milk (cattle) and whole egg (chicken), recovery experiments were performed at fortification levels of 0.01 mg/kg (LOQ) and 0.10 mg/kg in all matrices.

The mean recovery at each fortification level should be in the range of 70–110%. Although single recoveries above 110% (e.g. for kidney) were noted, mean values were between 70–110% with a relative standard deviation $\leq 20\%$. The overall relative standard deviation for each fortification level was $\leq 20\%$. The method was therefore considered to be valid for the determination of propamocarb residues in muscle, kidney and liver.

With slightly changed conditions in the sample preparation procedure compared to original BCS method 01205 (extraction by shaking vigorously for five minutes instead of one, no freeze out) the mean recoveries were between 70–110 % for whole milk, fat and whole egg for both levels (LOQ and ten times LOQ), and the overall relative standard deviation for each fortification level was $\leq 20\%$.

The data presented demonstrate that the QuEChERS method (BCS method 01205) is suitable and validated for the determination of residues of propamocarb in animal tissues (meat, liver, kidney, fat, milk and egg) with a LOQ of 0.01 mg/kg. Satisfactory specificity, linearity, accuracy, precision, repeatability and reproducibility have been obtained and therefore have proven its applicability as enforcement method.

Stability of residues in stored analytical samples

JMPR in 2006 has reviewed the storage stability of propamocarb (free base) and propamocarb hydrochloride in plant materials and animal tissues and products. The conclusion of the review shows that the compounds are stable in frozen storage in the tested plant commodities for 14 to 26 months and in animal commodities for at least 6 months. No evidence of residue degradation was seen in any of the studies.

A study of storage stability in commodities with high water content has been performed in cabbages (Everitt and Charter, 2000, M-198306-01-1), and was submitted to the Meeting. Cabbage samples (10 g) were fortified with Propamocarb hydrochloride at a concentration equivalent to 0.5 mg/kg propamocarb (free base) and stored in a deep-freezer at about -18 °C. Samples were removed at intervals of up to 39 months (day 0 and after 3, 7, 18, 25 and 39 months) with three replicates per interval for immediate residue analysis. A range of 80 to 116% of the added residues remained after the storage period. This indicates that residues of propamocarb hydrochloride in cabbage leaves are stable for a period of at least 39 months when stored deep frozen (-18 °C).

Table 9 Storage stability of Propamocarb hydrochloride in cabbage

Storage interval [months]	Fortification level [mg/kg] ^a	Recovered residues in stored samples							Reference
		%Residues remaining				Procedural recovery			
		Single recoveries uncorrected [%]			Mean recovery uncorrected [%]	Single recoveries [%]	Mean recovery [%]

USE PATTERN

Formulations containing propamocarb hydrochloride, alone or co-formulated with other active ingredients, are registered for use on a wide variety of crops in many countries. Registrations cover foliar treatment of vegetable crops and potatoes, soil drench, application via drip irrigation to vegetables and ornamentals and as seed treatments. Registered uses of propamocarb and propamocarb hydrochloride in crops and countries which were relevant to this evaluation are shown in Tables 10 to 17. Representative labels covering the critical GAP were provided to the Meeting.

RESIDUE FROM SUPERVISED TRIALS ON CROPS

New residue trials in broccoli, cauliflower, Brussels sprouts, head cabbage, kale, onions, leeks and Lima bean were submitted to the meeting to support establishment of new MRLs. The formulation used in trials was suspension concentrate (SC).

Onion

A total of twenty one residue trials were performed in/on onion with the propamocarb hydrochloride under field conditions in Europe in 2006 and 2007. The results are shown in Table 18.

Lima Beans

Five field trials were conducted with the Propamocarb hydrochloride on Lima Beans (seed and forage) in United States from 2005 to 2006. The results are shown in Table 25.

FATE OF RESIDUES DURING PROCESSING

Processing studies in tomato, spinach and lettuce have been conducted and submitted to the Meeting. These studies are described below. An overview of the processing factors obtained for the different processed commodities and the processing by-products is given in Table 30.

Tomatoes

Seven studies on the processing of tomatoes into juice, preserve and purée were conducted to determine the transfer of propamocarb from tomato fruits into juice, preserve and puree.

Four studies (Billian, 2008, M-307290-01-1) were conducted in Italy, Spain, Greece and Portugal with 3 sprays of propamocarb (SC formulation) at rate of 4.74 kg ai/ha with interval of 7 days and 1day PHI. Samples of tomato (fruit) to be processed were sampled at 1 day after last treatment.

The processing of tomato samples into fruit, washed; washings; raw juice; juice; fruit, peeled; peel; peeling water; preserves; strain rest, wet; raw puree and puree was performed in the Food Processing Laboratory of BCS-D-ROCS in Monheim am Rhein. The washing and peeling of tomatoes was done using household practice. The preparation of juice, preserves and puree simulated the industrial practice at a laboratory scale.

The tomatoes were washed in lukewarm standing water. The washed tomatoes were cut with a knife into small pieces and were heated after addition of water to 80–100 °C for 40 min in order to prevent enzymatic reactions. After this blanching process, the tomato pulp was passed through a strainer to separate raw juice and strain rest. Sodium chloride (0.5–0.7% (w/w)) was added to the raw juice. An aliquot of the laboratory sample of raw juice was taken. One part of the remaining raw juice was used for the processing into preserves (see below). Another portion of the remaining raw juice was filled into preserving cans and pasteurised. After pasteurisation an aliquot of the laboratory sample juice was taken.

For the processing of tomato into preserves, another portion of the deep-frozen tomatoes were washed in warm standing water. After a few minutes the peel could be taken off with a kitchen knife, but in contrast to other processing procedures the peeling was very difficult and a lot of pulp remained with the peel. The peeling water containing small pots of peel was sieved. Aliquots of the laboratory samples peel, peeling water and fruit, peeled were taken. After addition of raw juice a part of the remaining peeled tomatoes (ratio fruit/juice = 1/0.86) was filled into preserving cans and pasteurised. After pasteurisation, the tomato preserves were minced with a hand mixer. An aliquot of the obtained laboratory sample of tomato preserve was taken.

For the processing of tomato fruits into puree, tomatoes samples were washed in lukewarm standing water. The washed tomatoes were cut with a knife into small pieces and were heated after addition of water to 98–100 °C for 40 min in order to prevent enzymatic reactions. After this blanching process, the tomato pulp was passed through a strainer to separate raw juice and strain rest. The obtained tomato raw juice was mixed up with sodium chloride. An aliquot of the raw juice was concentrated (100–200 mbar, 75 °C) while stirring to obtain tomato raw puree (dry weight: 16%).

After taking an aliquot of the sample raw puree, the remaining raw puree was filled into preserving cans and pasteurised. After pasteurisation, the tomato puree was sampled.

Tomato samples and processed fractions were analysed for residues of propamocarb hydrochloride according to methods 00880/M001 (study RA-3639/07) and 00880/M002 (study 09-3235) by LC-MS/MS with an LOQ of 0.01 mg/kg. The molecular weights of propamocarb hydrochloride and Propamocarb were taken into consideration to determine and express the results as Propamocarb.

Table 27 Recovery data for propamocarb in tomato fruits and processed commodities

FL = Fortification Level,

Fortified with Propamocarb-hydrochloride, determined as Propamocarb and calculated as Propamocarb

^a Tomato fruit, washed; tomato peel; preserve and tomato fruit, peeled are covered by tomato fruit.

^b Tomato washings; tomato raw juice and tomato peeling water are covered by tomato juice.

^c Tomato raw puree and tomato strain rest are covered by tomato puree.

^d The recoveries of the RAC tomato (fruit) were performed during the conduct of study 09-2235

^e Tomato, washings and tomato, peeling water are covered by tomato juice.

^f Tomato, peel and tomato, preserve are covered by tomato fruit, peeled.

^g Tomato, strain rest is covered by tomato, puree

Residues of propamocarb in tomato fruits ranged from 2.8 to 5.9 mg/kg. Residues processed fractions were between 1.2 and 3.1 mg/kg in juice, between 0.88 and 2.0 mg/kg in preserve and between 1.8 and 4.9 mg/kg in puree.

Table 28 Residues of Propamocarb in tomato fruits (RAC) and processed tomato commodities in Italy, Spain, Greece and Portugal

Sample material	Residues of Propamocarb (mg/kg)			
	Italy	Spain	Greece	Portugal
Fruit (RAC)	2.8	5.9	3.4	5.2

Preserve	0.88	2.0	1.7	1.4
Strain rest, wet	1.5	2.6	2.3	2.0
Raw puree	1.8	4.4	2.5	3.9
Puree	1.8	4.9	2.2	3.7

Three studies on tomato (Schulte and Bauer, 2011, M-406443-02-1) were conducted in Northern and Southern Europe (The Netherlands, Italy, and Germany). Propamocarb (SC formulation) was sprayed three times on tomato plants with a nominal product rate of 0.62kg ai/ha and a water rate of 1000 L/ha per application. The applications were carried out with interval of 7 days and 3 days PHI. Samples of tomato (fruit) to be processed were taken at 3 days after last treatment. Residues of propamocarb in tomato fruits ranged from 0.22 to 0.59 mg/kg. Residues in processed fractions were between 0.16 and 0.40 mg/kg in juice, between 0.13 and 0.24 mg/kg in preserve and between 0.10 and 0.19 mg/kg in puree.

Table 29: Residues of Propamocarb in tomato fruits (RAC) and processed tomato commodities in Netherland, Italy, Germany

Sample material	Residues of Propamocarb (mg/kg)		
	The Netherlands	Italy	Germany
Fruit (RAC)	0.22 ^a	0.59	0.35
Raw juice	0.21 ^b	0.39	0.17

Spinach

Four field trials (Billian and Krussel, 2010, M-397716-01-1) were performed with spinach in Belgium, France, Germany and the Netherlands during 2009. Propamocarb was sprayed four times at rate of 3.7-3.98 kg as/ha per application and with interval of 9–11 days.

Spinach samples (leaves) to be processed were harvested at 14–15 days after the last application. The processing of the spinach leaves samples into washed leaf, washings, cooking water and cooked leaf according to household practice. The spinach leaves were washed in lukewarm standing water for about 2–5 min while moving the leaves around slowly. After washing, the leaves were centrifuged in a lettuce drainer. The collected water in the drainer was added to the rest of the washing water. Samples of washed leaves and washings were taken. The remaining washed leaves were cooked in a sieve in water steam (2 kg water/kg leaves) for about 8–10 min. After cooking, samples of cooked leaves and cooking water were taken.

Spinach samples (leaves) and processed fractions were analysed for residues of Propamocarb according to method 00880/M002 by LC-MS/MS with a LOQ of 0.01 mg/kg or 0.01 mg/L. Residues were determined and expressed as Propamocarb.

Table 31 Recovery data for Propamocarb in spinach leaves (RAC) and processed spinach commodities

Portion analysed	Active substance	Fortification level (mg/kg)	Recovery (%)			
			Single values	n	Mean	RSD
Leaf and washed leaf ^c	Propamocarb	0.01 ^a	115	1	115	-
		0.10 ^a	117	2	107	-

		200 ^a	97	1	97	-
		350 ^b	87	1	87	-
Overall Recovery				7	103	11

FL = Fortification Level,

^a Recoveries were determined for washed leaf.

^b Recoveries were determined for leaf.

^c These recoveries cover also washings, cooked leaf and cooking water.

Residues of propamocarb in raw leaves were between 15 and 76 mg/kg at the recommended PHI of 14-15 days. After washing, residues of propamocarb between 21 - 70 mg/kg were found in the washed leaves. The residues of propamocarb found in the washings were between 0.19 and 0.89 mg/L. The residues of propamocarb in cooked leaves were found to decrease slightly to values between 14 and 67 mg/kg. The residues of propamocarb in cooking water were found to be between 5.3 and 26 mg/L.

Table 32 Residues of propamocarb in spinach leaves (RAC) and processed spinach commodities

Lettuce

Two studies (Billian and Reineke, 2009, M-348419-01-1) were performed in the Netherlands and Germany on lettuce under greenhouse conditions in 2008. Propamocarb(SC formulation) was sprayed four times on lettuce plants at rate of 1.325 kg as/ha, with interval of 10 days.

Four studies (Billian and Reineke, 2010, M-397890-01-1) were performed on lettuce in the greenhouse in Belgium, France, Germany and Netherland in 2009. Propamocarb (SC formulation) was sprayed four times on lettuce at rate of 3.98 kg as/ha, with interval of 9–11 days.

Lettuce samples (head) to be processed were harvested at 13 and at 14–15 days after the last application in the 2008 and the 2009 trials, respectively. The processing of the lettuce samples (head) into the processed fractions: outer leaf, head without outer leaves, leaves without stalk, and washed inner leaves simulated household practice.

Outer leaves were removed (leaf, outer), and the remaining heads separated into leaves and stalk. The separated leaves were washed in warm water and drained. Theses fractions were analysed using the method 00880/M002 by LC-MS/MS with a LOQ of 0.01 mg/kg or 0.01 mg/L.

Livestock feeding studies

Dairy cow feeding study

A study on the transfer of propamocarb residues from feed to tissues and milk of dairy cows was provided to the meeting (Tew, 2003, M-240879-02-1; Tauber, 2004, M-243564-01-1).

In 3 dose groups of 3 cows, animals were dosed orally with propamocarb at nominal dose rates corresponding to 0.8ppm (1×), 2.4ppm (3×) or 8.0ppm (10×) in feed.

Animals were dosed each morning after milking and test animals were milked each morning and evening. Samples from each animal's evening and morning milk from study Days 0 (the day before the start of dosing), 1, 4, 8, 11, 15, 18, 22, 25, and 27 were pooled. The two aliquots of milk (evening and morning) were combined in volumes proportional to the total evening and morning volumes collected. Milk from one 10× cow and the control cow collected on study Day 27 was separated into milk fat and skim milk and analysed.

All test animals were sacrificed at the end of the 28-day dose period. Muscle, liver, kidney, and fat tissue samples were analysed for propamocarb (AE B039744) and its metabolites propamocarb-N-oxide (AE F155306), oxazolidine-2-one propamocarb (AE F132679), 2-hydroxy-propamocarb (AE F132675) and propamocarb glucuronide. Samples were initially analysed for all analytes except for propamocarb glucuronide. Samples were analysed for propamocarb glucuronide at a later date based on results from the method radio-validation study (conducted after the feeding study). The method used incorporates extraction with acetonitrile (propamocarb, propamocarb-N-oxide, oxazolidine-2-one-propamocarb and 2 hydroxy-propamocarb) or acidic methanol (propamocarb glucuronide) and detection and quantification by LC/MS/MS (Netzband D.J.; 2003; Document No.: M-240905-01-1). The LOQ and LOD in milk, milk fat and skim milk were 0.01 mg/kg and 0.003 mg/kg, respectively, for all matrices. The LOQ and LOD in beef tissues were 0.05 mg/kg and 0.017 mg/kg, respectively, for all matrices.

Milk samples from study days 11 through 27 were analysed. The only measurable residues found in milk were from cows dosed at the 10× level and these residues consisted entirely of metabolite 2-hydroxy-propamocarb. The average residues of 2-hydroxy-propamocarb in whole milk from 10× cows ranged from 0.012 to 0.014 mg/kg with a maximum of 0.019 mg/kg at day 22. 2-hydroxy-propamocarb residues were detectable, but not quantifiable at the 3× dose level. Residues of propamocarb-N-oxide were detectable, but not quantifiable at the 10× dose level. Residues of propamocarb and oxazolidine-2-one propamocarb were not detectable in milk at the 10× level. No detectable residues of the parent or either metabolite were found at the 1× dose level. No detectable residues of any compound were found in any control sample.

Milk from one of the 10× cows (cow #13) was collected on study Day 27 and separated into milk fat and skim milk. Residues in milk fat and skim milk were 0.013 mg/kg and 0.014 mg/kg, respectively. The residue of 2 hydroxy-propamocarb, found in the corresponding whole milk sample, was 0.014 mg/kg. These data indicate that 2 hydroxy-propamocarb does not concentrate in milk fat.

Beef tissue samples were analysed for propamocarb, 2-hydroxy-propamocarb, propamocarb-N-oxide, oxazolidine-2-one propamocarb and propamocarb glucuronide. No detectable residues of parent or metabolite were found in any control tissue. No detectable residues of parent or metabolite were found in any muscle sample. In liver, residues consisted entirely of the conjugated metabolite propamocarb glucuronide. The maximum propamocarb glucuronide residues in liver were 0.218 mg/kg (10×), 0.099 (3×) and <0.05 mg/kg (1×). In kidney, residues of propamocarb glucuronide were detected, but were below the LOQ in all 10× cows. The parent compound was detected in kidney from one 10× cow. A detectable, but not quantifiable, residue of oxazolidine-2-one propamocarb was also found in kidney from one 10× cow. In fat, the parent compound was found at levels <LOQ in two 10× cows.

Laying hen feed study

The remaining three of the six subgroups of the 10× dose group hens entered into the depuration phase of the study, where eggs and tissues were analysed throughout a three week period following the administration of the last dose. On day 42, egg and tissue samples from six hens (two control and four 10× dose group hens) in the depuration phase were analysed. On study day 49, egg and tissue samples from another six hens (two control and four 10× dose group hens) in the depuration phase were analysed. On study day 56, egg and tissue samples from the remaining six hens (two control and four 10× dose group hens) in the depuration phase were collected and analysed.

Tissue and egg samples were analysed for total propamocarb residue (propamocarb and N-desmethyl propamocarb) by high performance liquid chromatography-electrospray ionization / tandem mass spectrometry (LC-MS/MS) using matrix matched standards. The limit of quantitation (LOQ) was 0.01 mg/kg for each analyte in eggs and poultry tissues. The LOD for Propamocarb were 0.0024 mg/kg in eggs, 0.0013 mg/kg in liver, 0.0010 mg/kg in muscle, and 0.0014 mg/kg in fat. The LOD for N-desmethyl propamocarb were 0.0033 mg/kg in eggs, 0.0011 mg/kg in liver, 0.0011 mg/kg in muscle, and 0.0028 mg/kg in fat.

Propamocarb residues in the eggs were below LOD (0.0024 mg/kg) at Day 42, 49 and 56. N-desmethyl propamocarb residues in the eggs were 0.0136 at Day 42 and less than LOD (0.0033 mg/kg) at Day 49 and 56, respectively.

Propamocarb and N-desmethyl propamocarb residues in fat, liver, and muscle in the depuration phase were below the corresponding LODs.

The highest mean propamocarb residues were found in the 35 days eggs, 10× dose group. In eggs of the 35th days, the average propamocarb residue was 0.056 mg/kg in the 10× dose group, 0.016 mg/kg in the 3× dose group, 0.005 mg/kg in the 1× dose group and 0.0012 mg/kg in the 0.3× dose group. Maximum residues in anyone hen were 0.062 mg/kg in the 10× dose group, 0.016 mg/kg in the 3× dose group, 0.005 mg/kg in the 1× dose group and 0.0013 mg/kg in the 0.3× dose group. Values are presented in Table 40.

The LOD in eggs was 0.0024 mg/kg for propamocarb, 0.0033 mg/kg for N-desmethyl propamocarb and 0.0058 mg/kg for total propamocarb.

In the 35 day fat tissue, the highest mean propamocarb residues were 0.0097 mg/kg in the 10× dose group, 0.0021 mg/kg in the 3× dose group and below 0.0014 mg/kg (LOD) in the 1× and 0.3× dose groups. Maximum residues in anyone hen were 0.028 mg/kg in the 10× dose group, 0.0036 mg/kg in the 3× dose group, <LOD in the 1× and 0.3× dose group.

In the 35 day fat tissue, the highest mean N-desmethyl propamocarb residues were 0.0492 mg/kg in the 10× dose group, 0.0062 mg/kg in the 3× dose group, 0.0039 mg/kg in the 1× dose group and 0.0028 mg/kg in the 0.3× dose group. Values are presented in Table 41.

Table 48 Residues of propamocarb and its metabolite N-desmethyl propamocarb in fat

The LOD in liver was 0.0013 mg/kg for propamocarb, 0.0011 mg/kg for N-desmethyl Propamocarb and 0.0024 mg/kg for total Propamocarb.

In the 35 day muscle tissue, the highest mean propamocarb residues were 0.0104 mg/kg in the 10× dose group, 0.0050 mg/kg in the 3× dose group, 0.0022 mg/kg in the 1× dose group and 0.0010 mg/kg in the 0.3× dose group. Maximum residues in anyone hen were 0.013 mg/kg in the 10× dose group, 0.0086 mg/kg in the 3× dose group, 0.0028 mg/kg in the 1× dose group and 0.0010 mg/kg in the 0.3× dose group.

In the 35 day muscle tissue, the highest mean N-desmethyl propamocarb residues were 0.1017 mg/kg in the 10× dose group, 0.0250 mg/kg in the 3× dose group, 0.0149 mg/kg in the 1× dose group and 0.0053 mg/kg in the 0.3× dose group. Values are presented in Table 43.

Table 50 Residues of propamocarb and its metabolite N-desmethyl propamocarb in muscle

Day	Dose group	Residues (mg/kg)						
		Propamocarb			N-desmethyl propamocarb			Total Propamocarb
		Min	Max	Mean	Min	Max	Mean	Mean
35	0.3×	<LOD	0.0010	0.0010	0.0040	0.0065	0.0053	0.0063
	1×	0.0018	0.0028	0.0022	0.0120	0.0202	0.0149	0.0171
	3×	0.0028	0.0086	0.0050	0.0197	0.0321	0.0250	0.0300
	10×	0.0084	0.0129	0.0104	0.0940	0.1033	0.1017	0.1120
42	10×	<LOD	<LOD	<LOD	<LOD	<LOD	<LOD	<LOD
49	10×	<LOD	<LOD	<LOD	<LOD	<LOD	<LOD	<LOD
56	10×	<LOD	<LOD	<LOD	<LOD	<LOD	<LOD	<LOD

The LOD in muscle was 0.0010 mg/kg for propamocarb, 0.0011 mg/kg for N-desmethyl Propamocarb and 0.0021 mg/kg for total Propamocarb.

Conclusion

Feed consumption, body weights, and egg production were not adversely affected by daily oral administration of propamocarb to laying hens for 35 consecutive days at the average dose rate of 1.2 mg/kg feed (0.3×), 4.1 mg/kg feed (1×), 12.3 mg/kg feed (3×), and 41.1 mg/kg feed (10×).

The mean maximum propamocarb residues in the egg samples from the 10×, 3×, 1×, and 0.3× feeding levels were at day 35: 0.056 mg/kg, 0.016 mg/kg, 0.0047 mg/kg, and 0.0012 mg/kg respectively.

In the fat, the mean maximum propamocarb residues at day 35 was 0.0097 mg/kg in the 10× dose group, 0.0021 mg/kg in the 3× dose group, <LOD in the 1× and 0.3× dose group.

In the liver, the mean maximum propamocarb residues at day 35 was 0.016 mg/kg in the 10× dose group, 0.0082 mg/kg in the 3× dose group, 0.0037 mg/kg in the 1× dose group, and 0.0019 mg/kg in the 0.3× dose group.

In the muscle tissue, the mean maximum propamocarb residues at day 35 was 0.010 mg/kg in the 10× dose group, 0.005 mg/kg in the 3× dose group, 0.0022 mg/kg in the 1× dose group, and 0.001 mg/kg in the 0.3× dose group.

Depuration of residue (mean total Propamocarb residues) was observed from the eggs from day 35 to day 42; 0.402 mg/kg to 0.016 mg/kg respectively. No propamocarb and N-desmethyl propamocarb residue from eggs were observed at subsequent time points, <LOQ (0.01 mg/kg). In fat, liver, and muscle depuration residues were <LOQ (0.01 mg/kg) at Day 42 (and subsequent time points) indicating that propamocarb and N-desmethyl propamocarb residues were rapidly eliminated from the animals.

APPRAISAL

Propamocarb is a systemic carbamate fungicide with specific activity against Oomycete species that cause seed, seedling, root, foot and stem rots and foliar diseases in a number of edible crops. The compound was first evaluated by the JMPR in 1984, and was then reviewed by JMPR in 1986, 1987 and 2005, an ADI of 0–0.4 mg/kg bw and an ARfD of 2 mg/kg bw were established in 2005. Propamocarb was evaluated within the periodic review programme for residue and analytical aspects by JMPR in 2006.

The residue definition in plant and animal products for both enforcement and dietary intake purposes is propamocarb (free base. Propamocarb is not considered fat soluble.

The meeting received information on GAP and supervised residue trials in/on onion, leek, broccoli, cauliflower, Brussels sprouts, head cabbage, kale and lima bean. A new analytical method was provided for propamocarb in animal matrices, as well as new studies in laying hen metabolism, feeding studies on lactating cow and laying hens, rotational crops and processed commodities.

Animal metabolism

Laying hen

A metabolism study with propamocarb in laying hens was received by the Meeting. Laying hens were orally dosed via capsule with [¹⁴C] propamocarb hydrochloride at a rate of approximately 19 ppm in the feed (1.0 mg/kg body weight) once daily for fourteen consecutive days. The majority of the residues (92% to 99% of the TRR) in the egg and tissues could be extracted.

The TRR in eggs increased from day-1 through too day-7 and reached a plateau, at day-8, of about 0.25 mg eq/kg. The TRR in the tissue samples were highest in liver (0.492 mg/kg) with 0.14 mg/kg in leg muscle, 0.12 mg/kg in breast muscle and 0.042 mg/kg in fat (0.065 mg/kg in renal fat).

The major residues in the eggs and tissues were parent propamocarb (2% in fat, 5% in muscle, 9% in liver and 12% in eggs) and desmethyl propamocarb (6% in fat, 22% in liver, 29% in muscle, and 45% in eggs). The minor residues found in the eggs and tissues were bis-desmethyl-propamocarb (< 1% to 7%) and propamocarb-N-oxide (< 1%).

In summary, the metabolic degradation of propamocarb is rapid and extensive in laying hens with desmethyl-propamocarb and propamocarb being the major residues in all tissues (mostly in liver, eggs and muscle). Demethylation is the main route of metabolism for the parent compound. A minor route of metabolism involves oxidation of the tertiary nitrogen to form propamocarb-N-oxide. The pathway and metabolism profile found in laying hen is consistent to that of the lactating cow metabolism study evaluated by 2006 JMPR.

Field crop rotational studies

Rotational crop studies were conducted in Germany and France during 2002/2003. Four applications of 72.2, 36.1, 3.61 and 3.61 kg ai/ha propamocarb were applied to cabbage as the primary crop, and Lamb's lettuce and wheat were grown as rotational crops with a plant-back interval (PBI) of 52–102 days. No residues of Propamocarb were found above LOQ in Lamb's lettuce, wheat grain, wheat (green material) and wheat straw.

Four rotational crop studies were conducted in the Netherlands, France, Spain and Italy from 2008 to 2010. Three spray applications of 1.325 kg ai/ha. propamocarb with 7–13days interval were applied to lettuce as primary crop, and carrots, lettuce and wheat or barley were grown as rotational crops, with plant-back intervals (PBI) of 26–46 days. No residues of propamocarb were found above LOQ in any of these rotational crops.

In rotational field studies with wheat, sugar beet, table beet, dry bean and soya beans conducted in USA in 1997 (four applications at rates of 1.68 kg ai/ha.), which was evaluated by 2006 JMPR, there was no residues detected in wheat grain and straw, soya bean seed, beetroot and beet

tops and dry bean from a 30 day PBI, and residues were in the range of 0.229 to 0.51 mg/kg only in wheat hay and forage from a 30 day PBI.

The meeting noted that the GAP of propamocarb (3–4 applications of 1 kg ai/ha.) approximates the application rate in the new studies and was lower than in the 1997 studies. The Meeting agreed that no residue in food and feed commodities are expected from rotational crops following the registered uses.

Methods of analysis

The meeting received the information on multiresidue QuEChERS Method (BCS method ID 01205) for analysis of residues of propamocarb in meat (cattle), liver (cattle), kidney (cattle), fat (cattle), milk (cattle) and egg (chicken) (mass transitions at m/z 102 and 74). The limit of quantification (LOQ) was at 0.01 mg/kg in meat, liver, kidney, fat, milk and egg. The method was confirmed by results of an independent laboratory validation which repeated mean recovery rates of 80–88% in all matrices.

Stability of residues in stored analytical samples

The meeting received information on storage stability of propamocarb in frozen cabbage samples. Propamocarb hydrochloride was stable for a period of at least 39 months.

Results of supervised residue trials on crops

The meeting received supervised residue trial data for propamocarb in/on bulb onion, leek, broccoli, cauliflower, Brussels sprouts, head cabbage, kale and lima bean.

Bulb vegetables

Bulb onion

In 21 trials conducted in Europe according to GAP in Italy (three foliar applications of 1.0 kg ai/ha, 7days PHI), residues were < 0.01(2), 0.01, 0.02(4), 0.03, 0.04, 0.05(5), 0.07, 0.21, 0.41, 0.52, 0.86, 1.3 and 1.4 mg/kg. The Meeting estimated a maximum residue level of 2 mg/kg, a STMR of 0.05 mg/kg and a HR of 1.4 mg/kg for propamocarb in onion bulb.

Leek

In 12 trials conducted in Europe according to GAP in Albania (four foliar applications at 1.0 kg ai/ha, 14days PHI), residues were 0.24, 0.74, 0.9, 1.1(2), 2.4, 2.6, 4.0, 4.4, 5.5, 11 and 15 mg/kg. The meeting estimated a maximum residue level of 30 mg/kg, a STMR of 2.5 mg/kg and a HR of 15 mg/kg for propamocarb in leek.

Brassica vegetables

Broccoli

In ten trials conducted in Europe according to GAP in Spain (three foliar applications of 1.0 kg ai/ha, 14 days PHI), residues were 0.01, 0.16, 0.17, 0.21, 0.29(2), 0.32, 0.63, 0.97 and 1.7 mg/kg. The meeting estimated a maximum residue level of 3 mg/kg, a STMR of 0.29 mg/kg and a HR of 1.7 mg/kg for propamocarb in broccoli.

Cauliflower

In ten trials conducted in Europe according to GAP in Greece (three foliar applications of 1.0 kg ai/ha, 14 days PHI), residues were < 0.01, 0.01, 0.02(2), 0.03, 0.04, 0.06, 0.08, 0.20 and 0.82 mg/kg. The meeting estimated a maximum residue level of 2 mg/kg, a STMR of 0.035 mg/kg and a HR of 0.82 mg/kg for propamocarb in cauliflower to replace the previous recommendation of 0.2 mg/kg.

Brussels sprouts

In eight trials conducted in Europe matching the GAP of Belgium (three foliar applications of 1.0 kg ai/ha, 14 days PHI), residues were 0.20, 0.25, 0.24, 0.46, 0.48, 0.49, 0.64 and 1.3 mg/kg. The meeting estimated a maximum residue level of 2 mg/kg, a STMR of 0.47 mg/kg and a HR of 1.3 mg/kg for propamocarb in Brussels sprouts.

Head cabbage

In 12 trials conducted in Europe matching the GAP of Spain (three foliar applications at 1.0 kg ai/ha, 14 days PHI), residue were 0.02, 0.03, 0.06, 0.08, 0.13, 0.18, 0.21, 0.23, 0.24, 0.28, 0.32 and 0.36 mg/kg. The meeting estimated a maximum residue level of 1 mg/kg, a STMR of 0.195 mg/kg and a HR of 0.36 mg/kg for propamocarb in head cabbage.

*Leafy Vegetables**Kale*

In nine trials conducted in Europe matching the GAP of Belgium (three foliar applications of 1.0 kg ai/ha, 14 days PHI), residues were 0.33, 0.39, 0.46, 3.9, 4.0, 4.0, 5.2, 10.7 and 11.8 mg/kg. The meeting estimated a maximum residue level of 20 mg/kg, a STMR of 4.0 mg/kg and a HR of 11.8 mg/kg for propamocarb in kale.

*Legume vegetables**Lima Beans*

In three trials conducted in the United States according to US GAP (four foliar applications at 1.0 kg ai/ha, 0 days PHI), residues in seed without pods were 0.26, 0.42 and 0.43 mg/kg, residues in forage were 40.6, 83.6 and 47.4 mg/kg. As only three trials were conducted according to GAP the meeting could not recommend a maximum residue level for propamocarb in lima bean seed without pods.

FATE OF RESIDUES DURING PROCESSING

The Meeting received information on the fate of propamocarb residues during the processing of tomatoes, spinach and lettuce, and a study on the nature of residues in processed commodities. Propamocarb hydrochloride was stable under all conditions of processing tested (pasteurisation, baking, brewing, boiling and sterilisation). Processing factors based on the residue of propamocarb are listed in table below. Using the STMR_{RAC} obtained from propamocarb use, the Meeting estimated STMR-P values for processed commodities to be used in dietary intake calculations and/or livestock dietary burden calculations.

Summary of the processing studies in tomato, spinach and lettuce

Commodity	Processed commodity	Processing factors Residue: PCB	Processing factor(PF) (Mean or best estimate)	STMR-P= STMR _{RAC} X PF(mg/kg)
Tomato 0.515 mg/kg ^a	Juice	0.43, 0.44, 0.46, 0.53, 0.59, 0.68, 0.86	0.53	0.27
	Preserve	0.27, 0.31, 0.34, 0.40, 0.41, 0.50, 0.59	0.40	0.21
	Puree	0.32, 0.40, 0.64, 0.65, 0.71, 0.83, 1.1 ^a , 1.4 ^a , 1.4 ^a , 2.6	0.77	0.40
	Paste a	3.0, 3.2, 3.0	3.1	1.54
Spinach 11.2 mg/kg ^a	Leaf, cooked	0.86, 0.87, 0.88, 0.93	0.88	9.9

^a Data from 2006 JMPR evaluation

Farm animal feeding studies

The meeting received information on feeding studies with lactating cows and laying hens.

Dairy cow feeding study

No measurable residues of propamocarb or its metabolites 2-hydroxy-propamocarb, propamocarb-N-oxide, and oxazolidine-2-one propamocarb were detected in milk or edible tissues of cattle exposed to propamocarb at levels of 0.8, 2.4 or 8 ppm administered daily for 28 days, except for milk, where levels of up to 0.019 mg/kg of 2-hydroxy-propamocarb were found in the highest dose group (8 ppm). These residues were equally distributed between the milk fat and the skim milk. LOQs were 0.01 mg/kg (milk) and 0.05 mg/kg (tissues).

Laying hen feed study

A residue transfer study of propamocarb was conducted in laying hens. Hens were dosed orally for 35 consecutive days at the rates of 1.2 ppm (0.3×), 4.1 ppm (1×), 12.3 ppm (3×), and 41.1 ppm (10×) in the feed.

The mean (maximum) propamocarb residues in the egg samples from 1× and 0.3× feeding levels were: 0.0047 mg/kg (0.005 mg/kg) and 0.012 mg/kg (0.013 mg/kg) at Day 35.

In fat, the mean (maximum) propamocarb residues at Day 35 were < LOD (0.0014 mg/kg) in 1× and 0.3× dose groups.

In liver, the mean (maximum) propamocarb residues at Day 35 were 0.0037 mg/kg (0.0055 mg/kg) in the 1× dose group, and 0.0019 mg/kg (0.0021 mg/kg) in the 0.3× dose group.

In muscle, the mean (maximum) propamocarb residues at Day 35 were 0.0022 mg/kg (0.0028 mg/kg) in the 1× dose group, and 0.001 mg/kg (0.001 mg/kg) in the 0.3× dose group.

Animal commodity maximum residues levels

The dietary burdens were estimated using the OECD diets listed in Appendix IX of the 2009 Edition of FAO Manual. Potential cattle feed items include: cabbage, kale and potatoes (including by-products). Dietary burden calculations for beef cattle and dairy cattle and poultry are provided below.

Summary of livestock dietary burden (ppm of dry matter diet)

	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.38	0.20	16.16	5.58	0.11	0.05	0.00	0.00
Dairy cattle	0.13	0.07	16.11	5.53	31.55a, b	10.70c, d	0.00	0.00
Poultry-broiler	0.00	0.00	0.10	0.04	0.00	0.00	0.00	0.00
Poultry-layer	0.00	0.00	4.03e	1.37f	0.00	0.00	0.00	0.00

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian meat

^b Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

^c Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for mammalian milk

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs

^f Highest mean poultry dietary burden suitable for STMR estimates for poultry meat and eggs

The propamocarb dietary burden for animal commodity MRL and STMR estimation (residue levels in animal feed expressed on dry weight) are 31.55 and 10.7 ppm for mammalian products (based primarily on the new use on kale), and the maximum and mean dietary burdens are 4.03 and 1.37 ppm for poultry products.

Mammalian products

The Meeting noted that the maximum cattle dietary burden was about 3–4 times higher than the dose level (8 ppm) in the feeding study and the metabolism study of lactating cow (11.5 ppm), and could not estimate maximum residue levels for mammalian commodities. The Meeting agreed to withdraw the previous MRLs of 0.01* mg/kg for milk, meat from mammals other than marine mammals, and edible offal, mammals.

Poultry products

The MRLs for poultry products were estimated using the maximum dietary burden and the highest residues obtained from the laying hen feeding study. For the estimation of the STMRs, the mean dietary burden and mean residues on poultry products from the feeding study were used.

The maximum dietary burden of 4.03 ppm DM matches the 1× dose level of the laying hen feeding study. Therefore, the residue levels reported in the feeding study were used as a direct estimate of the residue levels in poultry muscle, fat, liver and eggs resulting from the dietary burden. Similarly, the STMR of 1.37 ppm approximates the lowest dose level of the feeding study (1.2 ppm). Therefore, as an estimate for the STMR in the poultry products, the mean residue levels from the feeding study at this level were used. The estimated MRLs and STMRs are summarized in following table.

	Feed level	Residues	Feed level	Residues (mg/kg) in		
	(ppm) for egg residues	(mg/kg) in egg	(ppm) for tissue residues	Muscle	Liver	Fat
MRL poultry						
Feeding study ^a	4.1	0.005	4.1	0.0028	0.0055	< LOD ^c
Dietary burden and high residue	4.03	0.005	4.03	0.0028	0.0055	< LOD ^c
STMR poultry						
Feeding study ^b	1.2	0.0012	1.2	0.0010	0.0019	< LOD ^c
Dietary burden and residue estimate	1.37	0.0012	1.37	0.0010	0.0019	< LOD ^c

^a Highest residues for tissues and highest residues for eggs

^b Mean residues for tissues and mean residues for eggs

^c LOD in fat was 0.0014 for propamocarb

The meeting estimated the following STMR values: eggs 0.001 mg/kg, muscle 0.001 mg/kg, liver 0.002 mg/kg and fat 0.001 mg/kg. The following HR values are also estimated: eggs of 0.005 mg/kg, muscles of 0.003 mg/kg, liver of 0.006 mg/kg and fat of 0.001 mg/kg.

The meeting recommended the maximum residue levels of 0.01* mg/kg for poultry fat, and confirmed its previous recommendation for maximum residue levels of 0.01* mg/kg for eggs, poultry meat, and poultry, edible offal of.

RECOMMENDATIONS

Summary of the recommendations for the MRL, STMR and HR for propamocarb:

Commodity		Recommended MRL (mg/kg)		STMR (mg/kg)	HR (mg/kg)
CCN	Name	New	Previous		
VA0385	Onion	2		0.050	1.4
VB0400	Broccoli	3		0.290	1.7
VB0404	Cauliflower	2	0.2	0.035	0.82
VB0402	Brussels sprouts	2		0.47	1.3
VB0041	Cabbage, Head	1		0.195	0.36
VL0480	Kale	20		4.00	11.8
VA0384	Leek	30		2.50	15.0
PF0111	Poultry fat	0.01*		0.001	0.001
PM0110	Poultry meat	0.01*	0.01*	0.001	0.003
PO0111	Poultry, edible offal of	0.01*	0.01*	0.002	0.006
PE0112	Eggs	0.01*	0.01*	0.001	0.005

Commodity		Recommended MRL (mg/kg)		STMR (mg/kg)	HR (mg/kg)
CCN	Name	New	Previous		
ML0106	Milk	W	0.01*		
MM0095	Meat from mammals other than marine mammals	W	0.01*		
MO0515	Edible offal, mammals	W	0.01*		

DIETARY RISK ASSESSMENT

Long-term intake

The long-term dietary intake for propamocarb (ADI 0–0.4 mg/kg bw) was calculated for the 17 regional diets on the basis of the STMRs estimated by the JMPR in 2006 and the current meeting. The results are shown in Annex 3 of the 2014 Report.

The International Estimated Daily Intakes (IEDI) of propamocarb were 0–1% of the maximum ADI (0.4 mg/kg bw). The Meeting concluded that the long-term intake of residues of propamocarb from uses that have been considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The ARfD for propamocarb is 2 mg/kg bw. The International Estimated Short Term Intake (IESTI) of propamocarb was calculated for the commodities for the commodities for which residue levels were estimated. The results are shown in Annex 4 of the 2014 Report.

The IESTI of propamocarb calculated were up to 20% of the ARfD (2 mg/kg bw) for children and general population. The Meeting concluded that the short-term intake of residues of propamocarb resulting from uses that have been considered by current meeting is unlikely to present a public health concern.

PROPICONAZOLE (160)

The first draft was prepared by Professor Eloisa Dutra Caldas, University of Brasilia, Brazil

EXPLANATION

The triazole fungicide propiconazole was last evaluated by the JMPR in 2013 for residue aspects. Residue trial data on bean (dry), bean (lima), and bean (snap), mint, pineapple following post-harvest application, barley, oat and wheat were submitted to current Meeting.

Residue definition for plant and animal commodities is *propiconazole* for compliance with the MRL and *propiconazole plus all metabolites convertible to 2,4-dichlorobenzoic acid, expressed as propiconazole* for the estimation of the dietary intakes.

METHODS OF ANALYSIS

Methods where only propiconazole is analysed involves mostly LC-MS/MS detection, with LOQ of 0.01 mg/kg. The common moiety method measure all residues convertible to 2,4-dichlorobenzoic (2,4-DCBA) and are performed using mostly GC-MSD or GC-ECD (after derivatisation of 2,4-DCBA to its methyl ester) with an LOQ of 0.05 mg/kg. These methods have been previously submitted to the JMPR for evaluation, and recovery data was also included in the study reports submitted to the present Meeting.

Samples were analysed within a storage period that was shown not to impact the residue levels, according to storage stability studies evaluated previously by the JMPR, or according to stability studies included in the reports. One exception was

USE PATTERNS

All the supervised trials submitted were conducted in the United States or in Canada. Table 1 shows the registered uses of propiconazole in USA for the crops relevant to this submission.

Table 1 Use patterns of propiconazole in USA

Crop	Formulation	Application				
		Method	Maximum rate (per application)	Number	Interval (days)	DAT (days)
Barley	SE	Foliar	0.125 kg ai/ha	2	14*	7**
Beans, dry and succulent, including lima bean and bean	SE	Foliar	0.126 kg ai/ha	3/year	7-14	7
Mint	SE	Foliar	0.126 kg ai/ha	3	14	7
Oats	SE	Foliar	0.125 kg ai/ha	2	14*	7**
Pineapple	EC	Post harvest dip	0.015 kg ai/100 L water	1	-	Na
Wheat	SE	Foliar	0.125 kg ai/ha	2	14*	7**

* second application following early application can be applied up to full head emergence (BBCH 59).

** Minimum PHI for forage and hay

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Supervised residue trials conducted with propiconazole in Canada and USA were submitted to the Meeting. Studies were conducted according to GLP, and concurrent determination of residues in untreated crops gave residues < LOQ, unless specified otherwise. Residues of propiconazole arising from use patterns where rate or PHI are $\pm 25\%$ of GAP are underlined and considered for estimation of maximum residue levels and STMRs. In each trial, two samples were analysed and the mean value used for the estimation.

Samples were analyzed for total propiconazole, as 2,4-dichlorobenzoic methyl ester, or for propiconazole only.

Pineapple

Three supervised residue trials were conducted in Hawaii in 1997 (Report: IR-4 PR No. 06585). Samples were analyzed for residues of propiconazole and its 2,4-DCBA-containing metabolites using a GC/ECD method, and expressed as total propiconazole. The results from analysis of treated samples are summarized in Table 2.

Table 2 Residues resulting from propiconazole application to pineapple in Hawaii, USA

Crop (Var)	Application			Total propiconazole, mg/kg	Trial
	No.	kg ai/100 L Water	DAT		
Pineapple (Cayenne)	1	0.015	-	<u>3.6</u> (4.1, 3.0)	HI06
	1	0.015 +Fruit Wax	-	0.50, 0.45	
	1	0.015 +Fruit Oil	-	0.56, 0.37	
Pineapple (Cayenne)	1	0.015	-	<u>1.1</u> (1.3, 0.88)	HI07
	1	0.015 +Fruit Wax	-	0.39, 0.34

	1	0.015 +Fruit Wax	-	0.42, 0.34	
	1	0.015 +Fruit Oil	-	0.82, 0.50	

Lima Bean (seeds)

Six supervised residue trials were conducted in USA in 2005 (Report: IR-4 PR No. 09437). Samples were analyzed for residues of propiconazole and its 2,4-DCBA-containing metabolites using a GC/ECD method, and expressed as total propiconazole. The results from analysis of treated samples are summarized in Table 3.

Dry bean

Twelve supervised residue trials were conducted in USA in 2008 (Report: IR-4 PR No. 02008). Samples were analyzed for residues of propiconazole and its 2,4-DCBA-containing metabolites using a GC/ECD method, and expressed as total propiconazole. The results from analysis of treated samples are summarized in Table 5.

Mint

Five supervised residue trials with mint were conducted in USA in 2005 (Report: IR-4 PR No. 09419). Samples were analyzed for total propiconazole as 2,4-dichlorobenzoic methyl ester, using GC/ECD. The results are summarized in Table 9.
