Processing studies

Pineapple sample from trial HI06 (Table 2), containing 0.67 mg/kg total propiconazole was peeled, with residues in the pulp at < 0.05 mg/kg and in the skin at 0.35 mg/kg. Residues in pineapple juice made from the pulp were also < 0.05 mg/kg.

APPRAISAL

The triazole fungicide propiconazole was evaluated in the periodic review program by the 2007 JMPR, when an ADI of 0–0.07 mg/kg bw and a ARfD of 0.3 mg/kg bw were established, and by the 2013 JMPR for residue aspects. Propiconazole was listed by the Forty-fifth Session of the CCPR (2013) for the review of additional uses. Residue trial data on bean (dry), bean (lima), and bean (snap), mint, pineapple following post-harvest application, barley, oat and wheat were submitted to current Meeting.

Residue definition for plant and animal commodities is *propiconazole* for compliance with the MRL and *propiconazole plus all metabolites convertible to 2,4-dichlorobenzoic acid, expressed as propiconazole* for the estimation of the dietary intakes.

Methods of analysis

Methods of analysis used in the trials submitted to this Meeting were evaluated by the 2007 JMPR and were considered fit for purpose for the estimations. Methods that used LC-MS/MS analyses propiconazole, and the results are used for the estimation of maximum residue level. The common moiety method measure all residues convertible to 2,4-dichlorobenzoic (2,4-DCBA), reported as total propiconazole, and the results were used for the estimation of STMR and HR. In the residue trials, samples were stored within the period that guarantee the integrity of the residues as shown in the storage stability studies.

Results of supervised residue trials in crops

No estimations were made for lima bean, snap bean, dry beans and mint, as only the total propiconazole residue was reported in pre-harvest treatment trials. Data for these crops will not be discussed further.

Pineapple

The GAP of the USA for propiconazole in pineapple is for one post-harvest dipping treatment in a 0.015 kg ai/hL solution. Three trials were conducted using this rate, giving total residue of 1.1, 1.8 and 3.6 mg/kg of total propiconazole (highest of 4.1 mg/kg in an individual sample). As it is unlikely that propiconazole metabolites are formed between treatment and sample preparation for analysis, the results comply with both the residue definition for MRL and dietary risk assessment.

The Meeting agreed that the number of trials was not sufficient to estimate a maximum residue level for propiconazole in pineapple following post-harvest treatment, and did not change its previous recommendation of 0.02* mg/kg.

Cereals

In the USA, GAP for propiconazole in barley, oats and wheat, is for up to 2 applications at 0.125 kg ai/ha, the second one being at least 14 days following an early season application and should not be performed after full head emergence, which corresponds to BBCH 59.

In one trial conducted in USA in barley, matching GAP, residues of propiconazole were < 0.01 mg/kg and of total propiconazole < 0.05 mg/kg. In eight other trials the second application was made after full head emergence (BBCH 71 to 85).

In one trial conducted in USA in oats according to GAP, residues of propiconazole were < 0.01 mg/kg and of total propiconazole were 0.26 mg/kg. In eleven other trials the second application was made after full head emergence (BBCH 69 to 71).

In one trial conducted in USA in wheat according to GAP residues of propiconazole were < 0.01 mg/kg and of total propiconazole 0.06 mg/kg. In fourteen other trials, the second application was made after full head emergence (BBCH 69 to 75).

The Meeting agreed that there were not enough trials matching US GAP to estimate a maximum residue level for propiconazole in barley, oats and wheat.

The Meeting did not change its previous recommendation of 0.02 mg/kg for propiconazole in wheat, rye and triticale and of 0.2 mg/kg for propiconazole in barley.

Animal feeds

Cereals

In the USA, the GAP for propiconazole in barley, oats and wheat, is for up to 2 applications at 0.125 kg ai/ha, the second at least 14 days following an early season application and should not be performed after full head emergence, corresponding to BBCH 59. No PHI is specified for straw, and the PHI is 7 days for forage and hay.

Forage

Eleven trials were conducted in oat forage in the USA matching US GAP, with total propiconazole residues of 0.50 (2), 0.78, 1.4, 1.5 (2), 1.7, 1.8, 1.9, 2.0 and 2.4 mg/kg (2.5 mg/kg highest of individual samples).

The Meeting estimated a medium and highest residue of 1.5 and 2.5 mg/kg, respectively, for propiconazole in oat forage.

Fifteen trials were conducted in wheat forage, gave total propiconazole residues of 1.2 (2), 1.3, 1.4, 1.6, 1.9, 2.1, 2.2, 2.8, 3.0, 3.4, 3.8, 3.9, 4.8 and 9 mg/kg.

The Meeting estimates a medium and highest residue of 2.2 and 9 mg/kg, respectively, for propiconazole in wheat forage.

Hay

Nine trials were conducted in barley hay with propiconazole residues of 0.19, 0.44, 0.73, 0.78, 0.81, 1.7, 2.2, 3.0 and 4.2 mg/kg. Total propiconazole residues were: 2.1, 2.6, 2.7, 4.0, 4.3, 6.2, 10, 11 and 12 mg/kg (highest 13 mg/kg).

The Meeting estimated a maximum residue level of 8 mg/kg for propiconazole in barley straw and fodder, dry. The Meeting also estimated medium and highest residue of 4.3 and 13 mg/kg, respectively, for propiconazole in barley hay.

In the 11 trials conducted with oat hay, according to US GAP, propiconazole residues were: 0.18, 0.24, 0.35, 1.1, 1.2, 1.4, 2.0, 2.4, 3.6, 4.2 and 4.5 mg/kg. Total propiconazole were: 0.80, 0.90, 1.1, 2.7, 3.2, 3.3, 4.8 (2), 6.2, 7.7 and 8.5 mg/kg.

The Meeting estimated a maximum residue level of 8 mg/kg for propiconazole in oat straw and fodder, dry. The Meeting also estimated a medium and highest residue of 3.3 and 8.5 mg/kg, respectively, for propiconazole in oat hay.

In 15 trials conducted in wheat hay, propiconazole residues were: 0.44, 0.75, 1.1, 1.3, 1.6, 1.9, 2.0 (2), 2.2, 2.8, 3.0, 3.3, 4.2, 5.4 and 9.6 mg/kg. Total propiconazole were: 2.0, 3.2, 3.4, 4.0, 4.1, 4.3, 4.4, 5.3, 6.7, 7.9, 9.3, 10 (2), 12 and 21 mg/kg (highest of 22 mg/kg).

Taking into account the trial conditions, the Meeting concluded that the residues measured in hay are applicable for straw and fodder, and recommended a maximum residue level of 15 mg/kg for

propiconazole in wheat straw and fodder, dry, and extend this estimation for rye and straw and fodder, dry. The Meeting also estimates a medium and highest residue of 5.3 and 22 mg/kg, respectively, for propiconazole in wheat hay.

The Meeting withdrew its previous maximum residue level recommendation for barley, rye, triticale and wheat straw of 2 mg/kg.

Residues in animal commodities

One cow and one poultry study were evaluated by the 2007 JMPR, and only the relevant information from these studies are summarized in this appraisal.

Lactating dairy cows

Dairy cows were dosed once daily either in the feed with propiconazole at 15 ppm, 75 ppm and 150 ppm for 14–28 consecutive days. No parent propiconazole was detected in any milk (< 0.01 mg/kg), muscle and kidney samples (< 0.05 mg/kg) at all feeding levels. The maximum level in liver was 0.14 mg/kg at the 15 ppm feeding level and 0.34 mg/kg in the 75 ppm feeding level; in fat it was < 0.05 mg/kg at the 15 ppm and 75 ppm feeding levels.

No total propiconazole (< 0.01 mg eq./kg) was found in milk at 15 ppm; at 75 ppm, the average was 0.044 mg eq./kg (maximum of 0.08 mg eq./kg). In muscle, no total propiconazole (< 0.05 mg/kg) was detected at 15 ppm and the maximum level was 0.11 mg/kg at the 75 ppm (average 0.08 mg/kg). In liver, residues were 0.81 mg/kg at the 15 ppm (average 0.63 mg/kg) and 4.3 mg/kg in the 75 ppm (average 3.7 mg/kg). In kidney, it was 0.63 mg/kg at the 15 ppm (average 0.60 mg/kg) and 4.7 mg/kg in the 75 ppm (average 3.8 mg/kg). In fat it was < 0.05 mg/kg at the 15 ppm and 0.23 mg/kg at the 75 ppm feeding level (average 0.15 mg/kg).

Laying hens

Hens were fed propiconazole at 7.5, 37.5 and 75 ppm in the feed. No propiconazole residues (< 0.05 mg/kg) were found in the eggs or the tissue sample analysed, regardless of feeding level.

At 7.5 ppm, no total propiconazole was detected in eggs, muscle, fat (< 0.05 mg/kg) and liver (< 0.1 mg/kg). At 37.5 ppm, residues can reach 0.18 mg/kg in eggs, 0.16 mg/kg in liver and 0.07 mg/kg in fat, but no residues were detected in muscle.

Farm animal dietary burden

The Meeting estimated the dietary burden of propiconazole (as total propiconazole) in farm animals on the basis of the OECD Animal Feed data published in the 2009 FAO Manual, the STMR, STMR-Ps or highest residue levels estimated at the present and by the 2007 JMPR. Dietary burden calculations are provided in Annex 6.

Commodity	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	3.9	2.1	15.9	4.3	36 ^a	12 ^c	10.1	1.62

Feeding study	7.5	< 0.05	7.5	< 0.05	< 0.05		< 0.05
Dietary burden and highest residue	5.1	< 0.05	4.6	< 0.05	< 0.05		< 0.05
STMR for poultry							
Feeding study	7.5	< 0.05	7.5	< 0.05	< 0.05		< 0.05
Dietary burden	1.88	< 0.05	4.6	< 0.05	< 0.05		< 0.05

The maximum dietary burden for the estimation of maximum residue levels in cattle tissue and milk were 36 and 29 ppm, respectively. The Meeting confirms its previous recommendation of 0.01* mg/kg for propiconazole milks and meat (from mammals other than marine mammals) and estimates a maximum residue level of 0.5 mg/kg for edible offal (mammalian) and of 0.01* mg/kg in mammalian fat (except milk fats).

The Meeting withdraw its previous recommendation of 0.01* mg/kg for propiconazole in edible offal (mammalian).

The maximum dietary burden for the estimation of HR in cattle tissues was 36 ppm. Based on the feeding levels at 15 and 75 ppm, the Meeting estimated a HR of 0.085 mg/kg in meat (from mammals other than marine mammals), of 1.97 mg/kg in edible offal (mammalian) and of 0.115 mg/kg in mammalian fat (except milk fats).

The mean dietary burden for the estimation of STMR levels in cattle tissues and milk was 12 ppm, respectively. Based on the feeding study conducted at 15 ppm, the Meeting estimates a STMR of 0.035 mg/kg in milks, 0.064 mg/kg in meat (from mammals other than marine mammals), 0.504 mg/kg in edible offal and 0.05 mg/kg in mammalian fat.

The highest calculated dietary burden for poultry is 35.1 ppm. In eggs, muscle and fat no propiconazole or total propiconazole residues were detected at the 7.5 ppm feeding level. The Meeting confirms its previous recommendation of a maximum residue level of 0.01* mg/kg for propiconazole in poultry meat and eggs, and a STMRs and HRs of 0.05 mg/kg in eggs, muscle and fat.

DIETARY RISK ASSESSMENT

Long-term intake

The IEDI of propiconazole based on the STMRs estimated by this and previous Meetings for the 17 GEMS/Food regional diets were 1–10% of the maximum ADI of 0.07 mg/kg bw (see Annex 3 of the 2014 Report). The Meeting concluded that the long-term dietary intake of residues of propiconazole is unlikely to present a public health concern.

Short-term intake

An ARfD for propiconazole is 0.3 mg/kg bw. The International Estimated Short-Term Intake (IESTI) of propiconazole for the commodities for which STMR, HR and maximum residue levels were estimated by the current Meeting. The results are shown in Annex 4 of the 2014 Report. The IESTI represented a maximum of 8% of the ARfD. The Meeting concluded that the short-term intake of propiconazole residues from uses considered by the current Meeting was unlikely to present a public health concern.

RECOMMENDATION

Residues: For plant and animal commodities is *propiconazole* for compliance with the MRL and *propiconazole plus all metabolites convertible to 2,4-dichlorobenzoic acid, expressed as propiconazole* for the estimation of the dietary intakes.

The residue if fat soluble

CCN	Commodity name	Recommended maximum residue level (mg/kg)		STMR (P) mg/kg	HR (P) mg/kg
		New	Previous		
AS 0640	Barley straw and fodder, dry	8	2		
MO 0105	Edible offal (mammalian)	0.5	0.01*	0.504	1.97

PROTHIOCONAZOLE (232)

The first draft was prepared by Professor Árpád Ambrus, temporary adviser, Hungary.

EXPLANATION

Prothioconazole is a systemic triazolinthione fungicide that is used for the control of diseases caused by *Ascomycetes*, *Basidiomycetes* and *Deuteromycetes* in a range of crops. It is registered for use in a variety of crops worldwide.

Prothioconazole was evaluated for the first time by the 2008 JMPR, which established an ADI of 0–0.05 mg/kg bw and an ARfD of 0.8 mg/kg bw for woman of child bearing age for the parent prothioconazole, and an ADI of 0–0.01 mg/kg bw and an ARfD of 0.01 mg/kg bw for woman of child bearing age and 1 mg/kg bw for general population for prothioconazole-desthio. In addition, the Meeting recommended limits for a number of plant commodities and for mammalian meat and fats, edible offal and milks, based on a residue definition of ‘prothioconazole-desthio’.

The 2008 JMPR meeting concluded that the residue definition for plant commodities for enforcement and dietary risk assessment was prothioconazole-desthio. The residue definition for animal commodities for enforcement was prothioconazole-desthio and for dietary risk assessment the sum of prothioconazole-desthio, prothioconazole-desthio-3-hydroxy, prothioconazole-desthio-4-hydroxy and their conjugates, expressed as prothioconazole-desthio. The residue was considered to be not fat-soluble for the purposes of residue definition.

The 2009 JMPR evaluated residue data on additional commodities.

For the 2014 Meeting data were provided on blueberry, corn, cranberry, cucurbits, potato, sweet corn peanut and soya bean together with current use recommendations.

METHODS OF RESIDUE ANALYSIS

A number of validated analytical methods for the determination of residues in plant, animal tissue, milk and soils were evaluated by the 2007 and 2008 JMPR Meetings.

Detailed descriptions of additional analytical methods for crops that had been used in the residue trials evaluated by this Meeting are described below. References to report numbers are in parenthesis. Recovery data obtained during validation of the methods for plant and animal matrices are summarized in Table 1.

*Analytical methods for plant matrices**Method RPA JA/03/01*

Corn/sweet corn (Krolski & Harbin, 2008. RAJAP004; Krolski & Harbin, 2008. RAJAP001), soya beans (RAJAY026 and RAJAY027 in 2008/2009 JMPR)

Analyte:	Prothioconazole Prothioconazole-desthio Prothioconazole-sulfonic acid	HPLC/MS/MS	Method RPA JA/03/01
LOQ:	0.02 mg/kg		
Description:	Method RPA JA/03/01 was previously evaluated by JMPR in 2008. It has been used for the corn/sweet corn trials evaluated by this Meeting.		

Method JA-001-P04-02

Blueberry (Murphy & Dallstream, 2012, RAJAP022), cranberry (Murphy & Dallstream, 2012, RAJAP023), cucurbits (Murphy & Harbin, 2012, RAJAP024).

Analyte:	Prothioconazole	HPLC/MS/MS	Method JA-001-P04-02
	Prothioconazole-desthio		
	Prothioconazole-sulfonic acid		in report JA-001-P04-02

LOQ: 0.02 mg/kg

Description This is a modification of method RPA JA/03/01 and includes information about potential alternative analytical conditions.

The crop matrices are extracted with a mixture of methanol (MeOH), 30% hydrogen peroxide (H₂O₂), and aqueous sodium bicarbonate (NaHCO₃) at about 64°C for 2 hours. This extraction procedure converts prothioconazole to a mixture of prothioconazole sulfonic acid and desthio- prothioconazole. Residues of prothioconazole-desthio are extracted without change. Following the addition of a mixture of isotopically labelled prothioconazole sulfonic acid and prothioconazole-desthio internal standards, the sample extracts are purified by octadecyl solid phase extraction (C-18 SPE). The purified analytes are analysed by high performance liquid chromatography-electrospray/tandem mass spectrometry (LC-MS/MS).

Method 01013

Soya beans (Resende, 2013, F12-012 and Resende, 2013, F13-008), corn (Freitag & Reineke, 2009, 08-2035; Freitag & Reineke, 2009, 08-2036; Freitag, 2008, RA-2675/07; Bomke & Teubner, 2013, 11-2109; Bomke, 2012, 11-2110; Santiago, 2012, F11-034 and Resende, 2013, F12-011), potato (Bomke & Bauer, 2011, 10-2085) and oilseed rape (Freitag, Reineke & Krusell, 2010, 08-2112; Freitag & Hoffmann, 2010, 08-3112)

Analyte:	Prothioconazole	HPLC/MS/MS	Method 01013
	Prothioconazole-desthio		
			in reports MR-06/138, VM11-003 and VM12-006.

LOQ: 0.01 mg/kg

Description: Bayer method no. 01013 is suitable for the determination of the relevant residues of bixafen (BYF00587), prothioconazole, tebuconazole, trifloxystrobin and the metabolites BYF00587-desmethyl, prothioconazole-desthio (SXX0665) and CGA321113 in plant materials.

All analytes are extracted from plant materials using a mixture of acetonitrile/water (4/1; v/v, containing cysteine hydrochloride, by high-speed blending. After filtration of the extract, the stable isotopically labelled analytes are added. The solution is made up to volume, diluted and subjected to reversed phase HPLC-MS/MS without a further clean-up step. Residues are quantified using internal stable labelled standards.

Prothioconazole-desthio is detected using electrospray ionization in the positive ion mode (ESI+). The following transition ions are used for prothioconazole-desthio:

for quantification $m/z = 312 \rightarrow m/z = 70$

for confirmation $m/z = 312 \rightarrow m/z = 125$

Prothioconazole is detected using electrospray ionization in the negative ion mode (ESI-). The following transition ions are used for prothioconazole:

for quantification $m/z = 342 \rightarrow m/z = 100$
 for confirmation $m/z = 342 \rightarrow m/z = 125$

Method 01013 was developed for the determination of residues of prothioconazole and prothioconazole-desthio in/on plant materials, and validated in citrus fruit, pea seed, wheat grain, rape seed and corn green material (MR-06/138). The method has additionally been validated for prothioconazole and prothioconazole-desthio in soya bean seed and wheat grain (Resende, 2013, VM12-006) and also in bean seed, soya bean seed, oat grain, citrus fruit and sugar cane (Santiago, 2012, VM11-003) using the chromatographic conditions described in method 00765 (Sur, 2003, MR-231/02).

Method 00598/M001

Potato (Freitag & Wolters, 2007, RA-2569/05; Freitag & Wolters, 2007, RA-2604/05; Freitag & Wolters, 2007, RA-2570/05 and Freitag & Wolters, 2007, RA-2603/05)

Analyte: Prothioconazole HPLC/MS/MS Method 00598/M001
 Prothioconazole-desthio in report MR-689/99

LOQ: Wheat and barley grain, canola seed: 0.01 mg/kg
 Wheat and barley forage and straw: 0.05 mg/kg
 Potato tubers: 0.01 mg/kg

Description: Method 00598/M001 is a modification of method 00598 previously evaluated by JMPR in 2008. Method 00598/M001 was designed to measure prothioconazole and its main metabolite prothioconazole-desthio in cereal and canola matrices. It has been used in potato trials included in this evaluation.

Prothioconazole and prothioconazole-desthio are extracted from the samples with an acetonitrile/water mixture by high-speed blending after addition of cysteine-hydrochloride solution. After filtration the extract is cleaned up by liquid-liquid partition using n-hexane (saturated with acetonitrile) and dichloromethane. The analytes are chromatographed by reversed-phase HPLC on a silica-based C18-column using isocratic acetonitrile/water eluent containing acidic acid. The analytes are determined by HPLC-MS/MS in the MRM mode. Calibration is performed against internal labelled bracketing standards.

Prothioconazole-desthio is detected using electrospray ionization in the positive ion mode (ESI+) using the following transition ions for quantification: $m/z = 312 \rightarrow m/z = 70$.

Prothioconazole is detected using electrospray ionization in the negative ion mode (ESI-), using the following transition ions for quantification: $m/z = 342 \rightarrow m/z = 100$.

Method 00598/M001 was validated in wheat and barley grain, green material and straw, and canola seed, green material, straw and pod (Heinemann, 2000, MR-689/99).

Method ATM-0053

Peanut (Ellis, 2012, BCS-0232 and Ellis, 2012, BCS-0383)

Analyte: Prothioconazole HPLC/MS/MS Method ATM-0053
 Prothioconazole-desthio in report BCS-0232

- LOQ: Peanut Seeds, peanut shells: 0.01 mg/kg
Peanut forage: 0.05 mg/kg
- Description: Method ATM-0053 was used to analyse residues of prothioconazole and prothioconazole-desthio in plant material. It has been used for the peanut trials included in this evaluation.
- Residues are extracted with 20:80 water/acetonitrile after the addition of 12.5 g/L L-cysteine. The extract is filtered using a 0.45 µm filter. The analytes are determined by HPLC-MS/MS in the MRM mode. Quantitation is achieved using matrix matched analytical standards and a stable labelled internal standard for prothioconazole.
- Detection is by turbospray ionization in the positive ion mode using the following transition ions for quantification:
- Prothioconazole-desthio: $m/z = 312 \rightarrow m/z = 70$.
- Prothioconazole: $m/z = 344 \rightarrow m/z = 154$.
- Method ATM-0053 was developed for the determination of residues of prothioconazole and prothioconazole-desthio in/on cereal grain, straw and forage, canola seed and almond hull and shell. Additional recoveries in peanut matrices are provided in reports Ellis, 2012, BCS-0232 and Ellis, 2012, BCS-0383.

Analytical methods for animal matrices

Method 01009

Bovine milk, muscle, liver, kidney and fat, poultry egg (Billian & Wolters, 2006, MR-06/120 and Schulte & Oel, 2013, amendment 1 to MR-06/120)

Analyte:	JAU 6476-desthio	HPLC/MS/MS	Method: 01009
	JAU 6476-3-hydroxy-desthio		in reports MR-06/120 and
	JAU 6476-4-hydroxy-desthio		P 111G
	JAU 6476-3,4-dihydroxy-desthio		
	JAU 6476-4,5-dihydroxy-desthio		

LOQ: 0.01 mg/kg

Description: Method 01009 is for the determination of relevant residues of prothioconazole (JAU 6476-desthio, JAU 6476-3-hydroxy-desthio, JAU 6476-4-hydroxy-desthio, JAU 6476-3,4-dihydroxy-desthio, and JAU 6476-4,5-dihydroxy-desthio) in/on matrices of animal origin. This method has been independently validated (P 1111 G).

Residues are extracted from cattle (milk, muscle, kidney, liver, fat) and poultry (egg) matrices with acetonitrile / water (4/1, v/v) using a high-speed blender. Subsequently, the solutions are refluxed for 2 hours with 5 N HCl. This hydrolysis step cleaves conjugates to agylcones and converts the metabolites with diene structure back to aromatic compounds. Residues of all analytes are determined using HPLC-MS/MS. Residues are quantified against matrix-matched standards.

The following MRM transitions for quantitation and confirmation are used:

JAU 6476-desthio: m/z 312→70 or 312→125

JAU 6476-3-hydroxy-desthio: m/z 328→70 or 328→141

JAU 6476-4-hydroxy-desthio: m/z 328→70 or 328→141

JAU 6476-3,4-hydroxy-desthio: m/z 344→70 or 344→157

JAU 6476-4,5-hydroxy-desthio: m/z 344→70 or 344→157

Bovine meat, milk and egg (Bacher, 2006, P 1111 G)

Analyte: JAU 6476-desthio HPLC/MS/MS Method: 01009

JAU 6476-3-hydroxy-desthio

JAU 6476-4-hydroxy-desthio

JAU 6476-3,4-dihydroxy-desthio

JAU 6476-4,5-dihydroxy-desthio

LOQ: 0.01 mg/kg

Description: This is the independent laboratory validation (ILV) for method 01009, as described above.

Recovery data obtained during the validation of the methods described above are summarized in Table 1. In addition to these data, concurrent recoveries were also determined together with the analysis of field trial samples. Mean recoveries from both method validation and concurrent recoveries were within the acceptable range of 70%-120% with % RSD < 20%.

Multi-residue Methods

A GG/MS multi-residue method has been validated for the analysis of prothioconazole-desthio, and this method was evaluated at the 2008 JMPR Meeting.

A summary of recovery data with the methods used for plant commodities in this submission are presented in the table 1.

Table 1 Summary of recovery data obtained during method validation

^a Prothioconazole recovery is the sum of prothioconazole-desthio and prothioconazole-sulfonic acid values from recovery samples fortified with prothioconazole only.

Storage Stability under Frozen Conditions

Plant commodities

Information relating to storage stability of residues in wheat, canola (seed, pod, straw), spinach (leaves), sugar beet (root, leaf with root collar), tomato (fruit) and field pea (dried) was evaluated at the 2008 JMPR Meeting. This showed that residues of prothioconazole-desthio were stable over a frozen storage period of up to 36 months in wheat and at least 24 months for the other crops. Residues

of prothioconazole and prothioconazole-desthio were stable in wheat hay and straw, canola seeds, mustard greens, turnip root and tomato fruit over a frozen storage period of 36-42 months.

Subsequently, a freezer storage stability study for residues of prothioconazole and prothioconazole-desthio (JAU6476-desthio) in wheat (forage, straw, grain, bran and flour), canola (seed and oil), mustard greens, tomato (fruit and paste) and turnip roots was performed over a 36-month period (Gould and Timberlake, 2008; Report RAJAY016), and the final results are summarized below.

Wheat, canola, mustard greens, tomato, turnip

Untreated control samples were fortified individually with prothioconazole or its metabolite prothioconazole-desthio at a concentration of 0.25 mg/kg and then frozen at < -10°C. Samples were analysed with method RPA JA/03/01 immediately after fortification (0 day) and after storage intervals up to 36 months. At the day 0, three fortified samples for each compound and one control were analysed. At subsequent analysis intervals, two stored samples and two freshly fortified samples for each compound and one control were analysed.

Prothioconazole is measured indirectly as the sum of the two oxidation products (prothioconazole-sulfonic acid and prothioconazole-desthio). Prothioconazole-desthio is measured directly. The limits of quantification (LOQ) were 0.01 mg/kg for prothioconazole-sulfonic acid and prothioconazole-desthio.

The stability of residues expressed as the mean of two replicate analyses in the stored samples is summarized in Table 2.

USE PATTERN

Prothioconazole is a broad spectrum systemic triazolinthione fungicide that is used for the control of diseases caused by *Ascomycetes*, *Basidiomycetes* and *Deuteromycetes* in a range of crops. It has protective, curative and eradicated activity and can be used as both a seed treatment and a foliar treatment. Its mode of action is interference with the synthesis of ergosterol in the target fungi by inhibition of CYP51, which catalyses demethylation at C14 of lanosterol or 24-methylene dihydrolanosterol, leading to morphological and functional changes in the fungal cell membrane.

Prothioconazole is registered for use in a variety of crops worldwide. In this evaluation the national registered uses are summarised where supervised trials have been conducted or in countries with similar GAPs to where the supervised trials were carried out. Table 3 represents a summary of these relevant GAPs.

Table 3 Registered uses of prothioconazole

The bush berry subgroup includes: Aronia berry; blueberry (highbush and lowbush); Chilean guava; highbush cranberry; currant (black, buffalo, and red); elderberry; European barberry; gooseberry; edible honeysuckle; huckleberry; jostaberry; juneberry (Saskatoon berry); lingonberry; native currant; salal; sea buckthorn; and cultivars, varieties, and/or hybrids of these.

Low growing berry subgroup, except strawberry, includes: Bearberry; bilberry; cloudberry; cranberry; muntries; partridgeberry; and cultivars, varieties, and/or hybrids of these.

RESIDUES RESULTING FROM SUPERVISED TRIALS

Supervised trials were conducted to support MRLs for the following crops or groups of crops: blueberry, cranberry, cucurbits (cucumber, summer squash and melon), sweet corn, soya bean, potato, maize (field corn, popcorn) and peanuts. The results of these supervised trials are summarized in the following tables.

Crop Group	Commodity	Country, year of trials	Table No.
Berries and other small fruits	Blueberry	USA and Canada, 2010	4
	Cranberry	USA, 2010	5

In addition to the description and details of the field trials and analytical methods, each report includes procedural recoveries and in some cases a summary of the method validation.

The residue definition for monitoring and risk assessment is prothioconazole-desthio only. However for consistency with previous JMPR evaluations, for trials conducted in the USA, Canada and Brazil, the tables show residues of prothioconazole sulfonic acid (JAU 6476 sulfonic acid), prothioconazole-desthio (JAU 6476 desthio) and total prothioconazole (JAU 6476). For trials conducted in Australia, the tables show residues of prothioconazole (JAU 6476), prothioconazole-desthio (JAU 6476 desthio) and total prothioconazole (JAU 6476). Unless otherwise indicated: the prothioconazole (JAU 6478), JAU 6476 sulfonic acid and total prothioconazole (JAU6478 total) residues are expressed as mg prothioconazole equivalents/kg. The prothioconazole-desthio (JAU 6476 desthio) residue is expressed as mg prothioconazole-desthio/kg.

Only the residues of prothioconazole-desthio have been used for calculation of MRL, HR and STMR values.

The prothioconazole recovery was calculated as the sum of prothioconazole-desthio and prothioconazole-sulfonic acid from recovery samples fortified with prothioconazole only.

In a number of studies, residues of triazole-derived metabolites (TDMs) and hydroxylated metabolites were determined in addition to residues of prothioconazole, prothioconazole desthio and prothioconazole sulfonic acid. The results of these analyses are not summarised here as these analytes are not included in the residue definition for monitoring or risk assessment.

The maximum periods between sampling and analyses were within the tested storage stability period of 3 years for prothioconazole-desthio.

In the trials where multiple analyses were conducted on a single sample, the mean value is reported. Where multiple samples were taken from a single plot, the mean residue value is reported. Where results from separate plots with distinguishing characteristics such as different formulations, varieties or treatment schedules were reported, results are listed for each plot.

The performance parameters of the methods used in the trials are summarised in section on Methods of residue analysis. Results have not been corrected for concurrent method recoveries. Residues and application rates have generally been rounded to two significant figures or, for residues near the LOQ, to one significant figure. Residue values from the trials conducted according to the maximum GAP were used for the estimation of maximum residue levels. Those results included in the tables are underlined.

Berries and Other Small Fruit

Bushberries - Blueberry

Supervised trials in USA and Canada: Eleven supervised trials on blueberry were conducted in 2010 in the major blueberry-producing states in the USA and Canada (Murphy & Dallstream, 2012, RAJAP022). The trials were carried out according to the GAP in the USA/Canada. Two applications of an SC formulation containing 480 g/L prothioconazole were made at 6–7 day intervals and samples of blueberries were taken from each plot at 5–7 days after last application (DALA). In the two decline trials, additional samples were collected at 0, 3, 13 or 14, and 21 days after the last application.

The blueberries were frozen after collection and stored frozen (< -20 °C) until extraction and analysis, with the exception of the bulk ‘washing’ sample from trial JA007-10DA, which was shipped unfrozen. A sub-sample of blueberry RAC was taken from the bulk ‘washing’ sample and frozen after collection. A second sub-sample was washed with water, drained and then frozen.

Residues of prothioconazole on blueberries were determined by the method, JA-001-P04-02. Procedural recoveries at fortification levels of 0.02–1.5 mg/kg were within 70–120% for prothioconazole-desthio, prothioconazole-sulfonic acid and prothioconazole, with the exception of one recovery for prothioconazole at 0.02 mg/kg which was 65. The results of the trials are summarized in Table 4.

Low growing berry subgroup, except strawberry

Cranberry

Six supervised trials were conducted according to the GAP for cranberries in the USA/Canada in the major cranberry-producing states in the USA (Murphy & Dallstream, 2012, RAJAP023) in 2010. Two applications of an SC formulation containing 480 g/L prothioconazole were made at 7–8 day intervals and samples of cranberries were taken from each plot at 43–46 DALA. In the decline trial, additional samples were collected at 35, 40, 50, and 55 days after the last application. The cranberries were frozen after collection and stored frozen (< -20 °C) until extraction and analysis, with the exception of the bulk ‘washing’ sample from trial JA015-10DA, which was shipped unfrozen. A sub-sample of

cranberry RAC was taken from the bulk 'washing' sample and frozen after collection. A second sub-sample was washed with water, drained and then frozen.

Residues of prothioconazole on cranberries were determined with method, JA-001-P04-02. Procedural recoveries at fortification levels of 0.02–1.5 mg/kg were within 70–120% for prothioconazole-desthio, prothioconazole-sulfonic acid and prothioconazole. The results of the trials are summarized in Table 5.

Fruiting Vegetables, Cucurbits

Cucumber, melon and summer squash

In 2010, eight supervised trials were conducted on cucumber, eight trials on musk melon and eight trials on summer squash according to the GAP for cucurbits in the USA/Canada in the USA (Murphy & Harbin, 2012, RAJAP024). One application was made by drip irrigation and two foliar applications

were made using an SC formulation containing 480 g/L prothioconazole, with a 5-8 days interval between the two foliar applications.

Samples of cucumbers, melon or summer squash were taken from each plot prior to the 3rd application (shown as -0 days in the table below), at 2-3 days and at 5-8 DALA. In the decline trials, additional samples were collected at 0, 13-14 and 19-21 days after the last application. The samples were frozen after collection and stored frozen (< -20°C) until extraction and analysis, with the exception of the bulk samples from trials JA032-10HA and JA033-10HA (melon) and JA039-10DA (summer squash), which were shipped unfrozen. Sub-samples of melon and summer squash RAC were taken from the bulk samples and frozen after collection. Second sub-samples of melon were peeled and the pulp frozen. A second sub-sample of summer squash was washed with water and cooked, and samples of washed and cooked summer squash were stored frozen.

Residues of prothioconazole on cucurbits were determined with the method JA-001-P04-02. Procedural recoveries at fortification levels of 0.02-1.5 mg/kg were within 70-120% for prothioconazole-desthio, prothioconazole-sulfonic acid and prothioconazole in each matrix. The results of the trials are summarized in Table 6.

Fruiting Vegetables, Other Than Cucurbits

Sweet corn

Supervised trials in the USA: Twelve supervised trials were conducted in 2006 on sweet corn in the USA (Krolski & Harbin, 2008, RAJAP004). The trials were carried out with 4×200 g ai/ha. The currently supported GAP in the USA is 4×100 g ai/ha. Four foliar applications were made to each treated plot of an SC formulation containing 480 g/L prothioconazole with a 2–11-day intervals between the each application. Each spray included a non-ionic surfactant.

In the sweet corn trials, ears, including seeds plus cob with husk removed, were harvested at 0 and 5–7 DALA (BBCH 73–79). In the decline trial, ears samples were collected at 0, 3, 6, 10 and 14 days. The samples were frozen after collection and stored frozen (< -20 °C) until extraction and analysis. Residues of prothioconazole were determined with method RPA JA/03/01. Procedural recoveries at fortification levels of 0.02–20 mg/kg were within 70–120% for prothioconazole-desthio, prothioconazole-sulfonic acid and prothioconazole in each matrix. The results of the trials are summarized in Table 7.

Pulses

Soya beans

Supervised trials in the USA: Residue data on soya beans from 19 trials conducted in the USA were previously evaluated by the 2008 JMPR and 2009 JMPR. The current USA GAP is 3×88 –175 g ai/ha, PHI 21 days.

Three foliar spray applications of an SC formulation were made using ground-based equipment to

soya beans at 145 to 188 g ai/ha. Intervals between applications were from 7 to 11 days (Duah, F. K.; Harbin, A. M, 2006, Report No.: RAJAY026). A non-ionic surfactant was added as a spray adjuvant at the lowest labelled rate. Duplicate treated samples of seed were collected at PHIs ranging from 19 to 23 days. Residues of prothioconazole, prothioconazole-desthio and prothioconazole sulfonic acid were analysed using Method RPA JA/03/01 with LOQ of 0.05 mg/kg.

GS = growth stage at last application

Supervised trials in Brazil: Ten supervised trials have been conducted in 2012–2013 on soya bean in Brazil (Resende, 2013, F12-012 and Resende, 2013, F13-008). The trials were carried out according to the GAP for soya bean in Brazil (4 x 87.5 g ai/ha, PHI 30 days). Eight of the trials were decline trials and two were at harvest trials. Four foliar applications were made to each treated plot with an SC formulation containing 175 g/L prothioconazole + 150 g/L trifloxystrobin + 125 g/L bixafen at 87.5 g prothioconazole/ha with a 14 day interval between applications. The applications were made at growth stages BBCH 51-79.

The samples were frozen after collection and stored frozen (< -20°C) until extraction and analysis. The maximum period of storage was 213 days (7 months). Residues of prothioconazole-desthio and prothioconazole were determined by HPLC/MS/MS method 01013. The LOQ was 0.01 mg/kg for each analyte.

Root and tuber vegetables

Potato

Supervised trials in Europe (Belgium, UK, Netherlands, Germany, France, Spain and Italy): A total of twenty supervised trials were conducted in 2005 and 2010 on potato (Ref: Bomke & Bauer, 2011, 10-2085; Freitag & Wolters, 2007, RA-2569/05; Freitag & Wolters, 2007, RA-2604/05; Freitag & Wolters, 2007, RA-2570/05 and Freitag & Wolters, 2007, RA-2603/05). All trials were harvest trials.

In the study of Bomke & Bauer, (10-2085), an FS formulation containing 18 g/L prothioconazole and 100 g/L penflufen was applied as a seed treatment to potato tubers at 0.72 g prothioconazole/100 kg seed (equivalent to 36 g prothioconazole/ha). This is a higher application rate than the GAP in the EU (up to 0.64 g ai/100 kg seed, equivalent to 16 g ai/ha), but the trials demonstrate that residues in tubers at harvest are <LOQ, even at the higher application rate. Treated tubers for planting were collected after treatment (shown as 0 or -1 day DAT in the table below, where a 0 day corresponds to the day of planting treated tubers), and then tubers collected at maturity (90 day DAT). Residues of prothioconazole and prothioconazole-desthio were determined by HPLC/MS/MS using method 01013. The LOQ was 0.01 mg/kg for each analyte.

In the studies of Freitag & Wolters, (RA-2569/05) and Freitag & Wolters, (RA-2604/05) an FS formulation containing 8 g/L prothioconazole and 248 g/L penflufen was applied as a seed piece treatment using a roller table prior to planting at 0.60 g prothioconazole/100 kg seed pieces. Treated tubers for planting were collected after treatment (0 day), and then tubers collected at BBCH 43–48 (90–91 DAT) and at maturity/BBCH 49 (110–148 DAT). Residues of prothioconazole and prothioconazole-desthio were determined by HPLC/MS/MS using method 00598/M001. The LOQ was 0.01 mg/kg for each analyte

In the studies of Freitag & Wolters, (RA-2570/05) and Freitag & Wolters (RA-2603/05), an FS formulation containing 8 g/L prothioconazole and 248 g/L penflufen was applied to potato tubers at planting using an in-furrow method at 30.1–32.0 g prothioconazole/ha. Treated tubers were collected after treatment (0 day), then at BBCH 43–48 (90–91 DAT) and at maturity/BBCH 49 (110–148 DAT). Residues of prothioconazole and prothioconazole-desthio were determined by HPLC/MS/MS using method 00598/M001. The LOQ was 0.01 mg/kg for each analyte.

The samples were frozen after collection and stored frozen (< -20 °C) until extraction and analysis. The maximum period of storage was 318 days (10.6 months).

^a 118 g/L FS formulation containing 18 g/L prothioconazole + 100 g/L penflufen.

^b 258 g/L SE formulation containing 8 g/L prothioconazole + 248 g/L pencycuron.

Cereal grains

Maize (field corn) and popcorn

Supervised trials in the USA: Twenty supervised trials were conducted in 2006 on field corn and three trials on popcorn in the USA (Krolski & Harbin, 2008, RAJAP004). The trials were carried out according to the GAP for corn in the USA. Four foliar applications were made to each treated plot with an SC formulation containing 480 g/L prothioconazole with 2–11-day intervals between the application. Each spray included a non-ionic surfactant.

In the field corn trials, grain was harvested at 14 days (BBCH 89) after last application. In the decline trials, grain samples were collected at PHIs of 0, 7, 13–14, 20–21 and 27–28 days.

In the popcorn trials, grain was sampled at harvest at 14 DAT (BBCH 89).

The samples were frozen after collection and stored frozen (< -20 °C) until extraction and analysis. The maximum period of storage was 365 days (12 months). Residues were determined by high performance liquid chromatography – triple stage quadrupole mass spectrometry (LC/MS/MS) with LOQ of 0.02 mg/kg equivalent to 0.0018 mg/kg prothioconazole desthio.

Supervised trials in Brazil: Ten supervised trials were conducted in 2011-2012 on corn in Brazil matching the GAP for corn in Brazil.

In the study of Santiago (F11-034) two foliar applications were made to each treated plot with an SC formulation containing 175 g/L prothioconazole + 150 g/L trifloxystrobin at 87.5 g prothioconazole/ha with a 15-day interval between applications. The applications were made at growth stages BBCH 55–67 and BBCH 60–71.

In the study of Resende (F12-011) two foliar applications were made to each treated plot with an SC formulation containing 175 g/L prothioconazole + 125 g/L bixafen + 150 g/L trifloxystrobin at 87.5 g prothioconazole/ha with a 14-day interval between applications. The applications were made at growth stages BBCH 55-61 and BBCH 65-71.

In the decline trials, seeds were harvested at 10, 14–15 and 19–20 days (BBCH 73–79, 75–79 and 75–79) after last treatment. In the at harvest trials, seeds were harvested at 14–15 days DAT (BBCH 75–79). The samples were frozen after collection and stored frozen (< -20 °C) until extraction and analysis. The maximum period of storage was 88 days (3 months).

Residues of prothioconazole-desthio and prothioconazole were determined by HPLC/MS/MS using method 01013 with the chromatographic conditions described in method 00765. The LOQ was 0.01 mg/kg for each analyte. Procedural recoveries at fortification levels of 0.01–1.0 mg/kg were within the acceptable range of 70–120%, RSD <20%, for prothioconazole and prothioconazole-desthio.

Supervised trials in Europe (Belgium, UK, Netherlands, Germany, France, Spain, Italy, Portugal and Greece): A total of twenty supervised trials were conducted in 2007, 2008 and 2011 on maize/corn in Europe. All trials were decline trials.

In the first set of studies (Freitag & Reineke, 2009, 08-2035 and Freitag & Reineke, 2009, 08-2036) an EC formulation containing 125 g/L prothioconazole and 125 g/L tebuconazole was applied twice to maize at 125 g prothioconazole/ha, with an interval of 23–54 days between applications. The applications were made at growth stages BBCH 33–34 and BBCH 69. Immature (milk ripe) seeds were collected at BBCH 75–79 (8–26 DAT), ear without husk was collected at BBCH 85 (28–56 day PHI) and mature seeds at BBCH 89 (PHI 52–83 DAT). Residues of prothioconazole-desthio were determined by HPLC/MS/MS using method 01013. The LOQ was 0.01 mg/kg. Procedural recoveries at fortification levels of 0.01–3.0 mg/kg were within the acceptable range of 70–120%, RSD < 20%, for prothioconazole-desthio in each matrix.

In the second study (Freitag, 2008, RA-2675/07), an EC formulation containing 250 g/L prothioconazole was applied twice to maize at 200 g prothioconazole/ha, with an interval of 23–43 days between applications. The applications were made at growth stages BBCH 33 and BBCH 69. Ear without husk was collected at BBCH 85 (23–46 DAT) and mature seeds at BBCH 89 (56–69 DAT). Residues of prothioconazole-desthio were determined by HPLC/MS/MS using method 01013 (LOQ was 0.01 mg/kg). Procedural recoveries at fortification levels of 0.01–2.0 mg/kg were within the acceptable range of 70–120%, RSD < 20%, for prothioconazole-desthio in each matrix.

In the other studies (Bomke & Teubner, 2013, 11-2109 and Bomke, 2012, 11-2110) an EC formulation containing 125 g/L prothioconazole and 125 g/L fluopyram was applied twice to maize at 130 g prothioconazole/ha, with an interval of 13–16 days between applications. The applications were made at growth stages BBCH 51–65 and BBCH 67–71. Immature (milk ripe) seeds were collected at BBCH 79 (14–31 DAT), ear without husk was collected at BBCH 79 (14–31 DAT) and BBCH 85 (28–56 DAT) and mature seeds and rest of plant at BBCH 89 (48–82 DAT). Residues of prothioconazole-desthio were determined by HPLC/MS/MS using method 01013. The LOQ was 0.01 mg/kg. Procedural recoveries at fortification levels of 0.01–1.0 mg/kg were in the range of 70–120%, RSD < 20%, for prothioconazole-desthio in each matrix.

The samples were frozen after collection and stored frozen (< -20 °C) until extraction and analysis. The maximum period of storage was 406 days (13.3 months).

^b 250 g/L SE formulation containing 125 g/L prothioconazole + 125 g/L AE C656948 (fluopyram)

Oilseeds

Peanuts

Eight supervised trials were conducted in 2011–2012 on peanut in Australia (Ellis, 2012, BCS-0232 and Ellis, 2012, BCS-0383). Four trials included plots which were treated according to the GAP for peanut in Australia (4 times 120–192 g ai/ha at 10–14 days apart, 28-day PHI), and four trials included plots which were treated at total application rates within 25% of the GAP rate, but shorter PHI (up to 21 days). These trials are submitted in support of the use on peanuts as they show that residues in peanut seeds are <LOQ at all sampling intervals. All of the trials were decline trials.

In study of Ellis, (BCS-0232), 3, 3 or 5 foliar applications were made to each treated plot with an SC formulation containing 480 g/L prothioconazole at nominally 180 or 120 g ai/ha with a 10 day interval between applications. Seeds were harvested immediately before the last application and after 0, 7, 14–15 and 20–21 days. For the plot treated at 5 × 120 g ai/ha samples of seeds were collected after field drying following pulling at 7 DAT.

In another study of Ellis, (BSC-0383), each trial consisted of up to 7 treated plots. Plots were treated with an SC formulation containing 480 g/L prothioconazole. One plot received an in-furrow treatment at 192 g ai/ha at planting, and the plants lifted 117–167 DAT. The remaining plots received 3 or 4 foliar applications at 192 or 288 g ai/ha, or an in-furrow application followed by 3 or 4 foliar applications at 192 or 288 g ai/ha, and the plants lifted at 14–15, 21–22 and 27–29 DAT. In furrow applications were made at growth stage BBCH 00, and foliar applications were made at growth stages BBCH 59–89. For all plots, plants were left to dry for 7–13 days before samples of seeds were collected.

Residues of prothioconazole-desthio and prothioconazole were determined by HPLC/MS/MS using method ATM-0053. The LOQ was 0.01 mg/kg for each analyte and matrix in study BCS-0232, and 0.01 mg/kg for each analyte in seeds and shells and 0.05 mg/kg for each analyte in forage in study

BCD-0383. Procedural recoveries at fortification levels of 0.01 (or 0.05)–1.0 mg/kg were within the acceptable range of 70–120%, RSD < 20%, for prothioconazole and prothioconazole-desthio.

The samples were frozen after collection and stored frozen (< -20 °C) until extraction and analysis. The maximum period of storage was 612 days (20 months), which falls within the confirmed stability period of 3 years.

In peanut seeds, residue levels of prothioconazole-desthio were < 0.01 mg/kg, residues of prothioconazole were < 0.01 mg/kg and residues of total prothioconazole (sum of prothioconazole-desthio and prothioconazole, expressed as prothioconazole) were < 0.02 mg/kg at all sampling intervals in all trials.

The results of the trials relevant to the Australian GAP are summarized in Table 15.

Soya bean forage and hay

Supervised trials in the USA: Residue data on soya beans from 19 trials conducted in the USA were previously evaluated by the 2008 JMPR and 2009 JMPR. In these trials the time between last application and sampling was too short (7 days) and therefore cannot be used to estimate residue levels.

Peanut fodder

Eight supervised trials were conducted on peanut in Australia. Peanut fodder was analysed in four trials at 28 DAT. The residue values are summarised in Table 20. Residues in hay are not reported because the use instructions indicate: 'Do not feed hay or threshings or allow livestock to graze in treated areas.'

Table 20 Prothioconazole residues in peanut resulting from supervised trials in Australia

FATE OF RESIDUES IN STORAGE AND IN PROCESSING

Information and Data from Residues in Processed Commodities

Processing studies on corn, peanut and oilseed rape are summarized in this section.

Processing Corn into Corn Flour, Starch, Grits, Oil, Aspirated Grain Fractions and Bran

A corn processing study (Krolski & Harbin, 2008, RAJAP001) has been conducted in which field corn was treated with an SC formulation containing 480 g/L prothioconazole at an exaggerated total application rate of 4.0 kg ai/ha, equivalent to 5× the maximum total seasonal rate for prothioconazole on corn. Bulk samples of corn grain were collected at maturity (BBCH 89) at 13 DAT, and frozen prior to analysis/processing. Subsamples of corn grain were removed for analysis, aspirated grain fractions were generated, and the remaining grain was used to generate the required processed commodities of starch, oil (wet and dry milled, refined, bleached, and deodorized), grits, flour, meal and bran. Processing was performed using procedures that simulated commercial processing practices.

Grain samples were dried in an oven until the moisture content was 10–13%. The corn grain was then aspirated and the material that passed through the 2360 micron sieve was recombined to produce an aspirated grain fraction. After generation of aspirated grain fractions, whole corn was cleaned by aspiration and screening. A subsample of cleaned corn grain was dry milled to form large grits and grits, meal, flour and bran.

The germ material was conditioned and flaked and then extracted with hexane to give crude oil and solvent extracted germ flakes. The crude oil was neutralised with 16 degree Baumé sodium hydroxide to give alkali refined oil and soapstock. The soapstock was discarded. The refined oil was bleached using activated bleaching earth and deodorised using 0.5% citric acid solution to give deodorized oil (dry milled) and distillates.

A second subsample of dried cleaned corn grain was wet milled to form hull, germ, starch and gluten fractions. The germ material was conditioned, flaked and pressed to form crude oil and presscake. The presscake was extracted with hexane to form solvent extracted presscake and crude oil. The combined crude oil was refined using 16 degree Baumé sodium hydroxide to give refined oil and soapstock. The soapstock was discarded. The refined oil was bleached and deodorised as described above to give deodorized oil (wet milled) and distillates.

The samples were frozen after collection and stored frozen ($< -12^{\circ}\text{C}$) until extraction and analysis. The maximum period of storage was 429 days (14 months) for grain and 85 days (3 months) for aspirated grain fractions and processed commodities, which falls within the stability period of 3 years as confirmed by previous studies.

Residues of prothioconazole were determined by high performance liquid chromatography – triple stage quadrupole mass spectrometry (LC/MS/MS). The method, RPA JA/03/01, which was used for the analysis was validated with an LOQ of 0.02 mg/kg for prothioconazole-sulfonic acid, 0.02 mg/kg for prothioconazole-desthio and 0.02 mg/kg for total prothioconazole.

Residues of the metabolites 1,2,4-triazole, triazolylalanine and triazolylacetic acid were also determined in this study, but the results are not summarised here as these analytes are not included in the residue definition for monitoring or risk assessment.

Procedural recoveries at fortification levels of 0.02–5 mg/kg were within the acceptable range of 70–120% for prothioconazole-desthio, prothioconazole-sulfonic acid and prothioconazole in each matrix. The prothioconazole recovery was the sum of prothioconazole-desthio and prothioconazole-sulfonic acid from recovery samples fortified with prothioconazole only.

Residues of prothioconazole were almost exclusively on the outside of the corn grain, and were strongly concentrated ($90\times$) in the aspirated grain fraction, and slightly concentrated in the bran ($1.3\times$). Prothioconazole residues do not concentrate in starch, oil, grits, flour or meal ($< 1\times$) during processing of corn grain. The results are summarised in Table 30.

Table 21 Residues of prothioconazole in corn processed fractions

Processed Fractions	Total prothioconazole residue (mean) mg/kg	Processing factor	Reference
Corn grain	0.072		Krolski & Harbin, 2008, RAJAP001
Aspirated grain fractions	6.50	90	
Starch	< 0.02	< 0.28	
Oil (wet milled)	< 0.02	< 0.28	
Grits	< 0.02	< 0.28	
Flour	0.041	0.57	
Meal	0.031	0.43	
Bran	0.094	1.31	
Oil (dry milled)	< 0.02	< 0.28	

Processing Oilseed Rape to Meal and Refined Oil

A field trial to measure the magnitude of prothioconazole residues in canola seed, canola meal and canola refined oil was previously evaluated by the 2008 JMPR and reported in the 2008 JMPR Evaluation (Prothioconazole – Table 81). The 2008 meeting concluded that no concentration ($< 0.7\times$) of the total prothioconazole derived residues was seen in canola meal and refined oil. The processing factors derived from this study on canola are summarized in Table 22.

Table 22 Residues of prothioconazole in canola processed fractions

Processed Fractions	Total prothioconazole residue mg/kg	Processing factor	Reference
Canola seed	0.03		2008 JMPR
Canola meal	< 0.02	< 0.7	
Refined oil	< 0.02	< 0.7	

An additional oilseed rape processing study (Freitag & Hoffmann, 2010, 08-3112) was submitted. The oilseed rape seed samples originate from a trial (08-2112-02) conducted as part of study of Freitag, Reineke & Krusell, 2010, 08-2112.

Seed samples were processed into screw pressed oil, pomace, meal, solvent extracted oil, crude oil, pre-clarified crude oil, neutralised crude oil and refined oil, simulating commercial practices.

After defrosting, rape seed samples were dried at 35 °C for 30 hours to a moisture content of 6–10%. The conditioned seed was cleaned manually using a sieve to remove parts of coarse stalks and weed seeds. The conditioned and cleaned rape seeds were pressed in a screw press yielding screw-pressed oil, and pomace.

An aliquot of the pomace was milled (distance of the rolls: 2.0 mm) and sub-samples extracted using a small technical extraction device. The extraction was conducted in two steps. The first extraction step started with addition of n-hexane to the pomace. The n-hexane circulated through the pomace for about 2 hours. During the circulation, the n-hexane was heated up to approx. 60 °C. Residual solvent was removed from the solvent-oil-mixture (miscella) using a rotary evaporator at approx. 50 °C, yielding solvent extracted oil. The solvent-extracted meal was sampled after storing at room temperature for approximately one day.

The two oil fractions obtained (screw-pressed oil and solvent extracted oil) were mixed yielding the sample of crude oil. The crude oil was filtered, yielding the sample of pre-clarified crude oil. The pre-clarified crude oil was heated up to 60–70 °C while stirring. After addition of 10% water, the mixture of water and crude oil was heated up to 85–90 °C and maintained at 85 °C for approximately 45 minutes while stirring. After phase separation, the watery phase including mucilage was removed. To the oily phase approximately 1% of concentrated phosphorus acid was added at 60 °C while stirring. The mixture was heated up to approximately 85 °C and maintained at that temperature for approximately 45 minutes while stirring. Immediately before switching off the stirrer, 10% water was added. The mixture of water and oily phases remained at approximately 85 °C until separation of the phases, and the watery phase including flocculated precipitation was then removed. After determination of the acid-number, the oily phase was heated up to approximately 90 °C while stirring. A few grams of a 7% sodium hydroxide solution (amount depending on acidity of the oil phase) were added and the mixture was stirred for approximately 20 minutes. After addition of 10% water and further 5 minutes of stirring the stirrer was switched off, the phases were allowed to separate and the watery phase was removed. The process was repeated as the acid-number of the oil was above 0.12. After the second neutralisation process, the acid value was below 0.12 and an aliquot of neutralised crude oil was sampled.

The remaining neutralised crude oil was heated up to 90 °C while stirring and washed by the addition of 10% water. The mixture was stirred for 20 min at 90 °C. After phase separation the watery phase was removed. These steps were repeated until the pH of the washing water was in the range 7-8 and the soap content of the oil was $\leq 0.01\%$. The oil was heated up to approximately 95 °C while stirring. After addition of citric acid (60 mg/kg oil), the oil was dried under vacuum. The oil was heated up to 95 °C while stirring. After addition of 1% podsol (referring to the used oil) the oil was bleached for 5 min without vacuum and 20 min with vacuum. The podsol was removed by filtration under vacuum. The oil was heated under vacuum up to 240 °C while stirring. After reaching 160 °C,

steam was transferred through the oil in order to expel fatty acids, odour and taste influencing compounds as well as other volatile compounds. The mixture stayed at 240°C for about 20 minutes. After cooling to 160 °C, the steam supply was stopped and then the oil was dried under vacuum until a temperature of ≤ 80 °C was reached. The refined oil was sampled.

All processed fractions were stored frozen (-18 °C) prior to analysis. seed was analysed within 645 days of sampling, and all processed fractions were analysed within 349 days of processing, which fall within the stability period of 3 years as confirmed by previous studies. Residues of prothioconazole-desthio were determined by HPLC/MS/MS using method 01013. The LOQ was 0.01 mg/kg in all matrices. Procedural recoveries in seed and oil at fortification levels of 0.01–0.10 mg/kg were within the acceptable range of 70–120%, RSD < 20%, for prothioconazole-desthio in each matrix.

In this study, samples were also analysed for residues of the hydroxyl metabolites (prothioconazole- α -hydroxy-desthio, prothioconazole-3-hydroxy-desthio, prothioconazole-4-hydroxy-desthio, prothioconazole-5-hydroxy-desthio and prothioconazole-6-hydroxy-desthio) and for residues of 1,2,4-triazole, triazole acetic acid, triazole lactic acid and triazole alanine. The results are not summarised here as none of these analytes are included in the residue definition for monitoring or risk assessment.

Results show that prothioconazole-desthio residues do not concentrate in meal, screw-pressed oil or refined oil ($\leq 1\times$), but do concentrate in crude oil and solvent extracted oil ($2\times$) during processing of rape seed. The results are summarised in Table 23.

Table 23 Residues of prothioconazole in oilseed rape processed fractions

Processed Fractions	Prothioconazole-desthio residue mg/kg	Processing factor	Reference
Oilseed rape seed	0.01		Freitag & Hoffmann, 2010, 08-3112
Screwpressed oil	0.01	1	
Pomace	0.01	1	
Meal	< 0.01	<1	
Solvent extracted oil	0.02	2	
Crude oil	0.02	2	
Preclarified crude oil	0.02	2	
Neutralised crude oil	0.01	1	
Refined oil	< 0.01	<1	

Based on the available processing studies, the processing factors that have been calculated are summarized in Table 24.

RESIDUE ON ANIMAL PRODUCTS

Residues in Animal Commodities

In addition to those commodities which had been evaluated by the previous Meetings, the following commodities could result in residues in animal tissues, milk, and eggs: sweet corn stover, field corn stover, popcorn stover, soya bean hay and peanut fodder.

APPRAISAL

Prothioconazole was evaluated first time by the 2008 JMPR. The residue definition for plant commodities for enforcement and dietary risk assessment was prothioconazole-desthio. The residue definition for animal commodities for enforcement was prothioconazole-desthio and for dietary risk assessment was the sum of prothioconazole-desthio, prothioconazole-desthio-3-hydroxy, prothioconazole-desthio-4-hydroxy and their conjugates, expressed as prothioconazole-desthio. The residue was considered to be not fat-soluble for the purposes of residue definition.

The 2008 JMPR established, for prothioconazole-desthio, an ADI of 0–0.01 mg/kg bw and ARfD of 0.01 mg/kg bw for women of child bearing age and 1 mg/kg bw for the general population.

The Forty-fifth Session of CCPR scheduled prothioconazole for periodic re-evaluation of residues by the 2014 JMPR. For the 2014 Meeting data were provided on blueberry, corn, cranberry, cucurbits, potato, sweet corn peanut and soya bean together with current use recommendations and analytical methods used in supervised trials.

Methods of analysis

A number of validated analytical methods for the determination of residues in plant, animal tissue, milk and soils were evaluated by the 2007 and 2008 JMPR Meetings. The Meeting received the basic analytical methods with minor modifications which were validated to determine residues in crops that

had been used in the residue trials. An analytical method was also provided for the determination of residues of prothioconazole in animal matrices.

The trials carried out in the USA/Canada used method RPA JA/03/01 or the modified method JA-001-P04-02 which involve extraction with methanol, hydrogen peroxide and sodium bicarbonate at an elevated temperature. This converts prothioconazole to a mixture of prothioconazole-sulfonic acid, while prothioconazole-desthio is extracted unchanged. After purification steps, the residues are analysed by LC-MS/MS. The LOQ of these methods is 0.02 mg/kg for prothioconazole-sulfonic acid and 0.02 mg/kg for prothioconazole-desthio.

The trials carried out in Brazil, EU and Australia used methods 01013, 00598/M001 and ATM-0053 in which residues of prothioconazole and prothioconazole-desthio are extracted with acetonitrile/water containing cysteine hydrochloride. After purification steps, dependent on the method, the analytes are analysed by LC-MS/MS. The LOQ of these methods is 0.01 mg/kg (or 0.05 mg/kg for forage and straw matrices) for prothioconazole and prothioconazole-desthio.

Storage Stability under Frozen Conditions

Information relating to storage stability of residues in wheat, canola (seed, pod, straw), spinach (leaves), sugar beet (root, leaf with root collar), tomato (fruit) and field pea (dried) was evaluated at the 2008 JMPR Meeting. This showed that residues of prothioconazole-desthio were stable over a frozen storage period of up to 36 months in wheat and at least 24 months for the other crops. Residues of prothioconazole and prothioconazole-desthio were stable in wheat hay and straw, canola seeds, mustard greens, turnip root and tomato fruit over a frozen storage period of 36–42 months.

An additional freezer storage stability study for residues of prothioconazole and prothioconazole-desthio (JAU 6476-desthio) in wheat (forage, straw, grain, bran and flour), canola (seed and oil), mustard greens, tomato (fruit and paste) and turnip roots was performed.

No significant degradation of prothioconazole-desthio was observed in any matrix analysed over the 3-year frozen storage period.

The stability of parent prothioconazole varied from 57 days up to 378 days without showing any dependency on the sample matrix. However, metabolism studies indicated that after foliar application prothioconazole rapidly degraded to prothioconazole-desthio and polar metabolites being converted to the sulfonic acid derivative, which is measured by the analytical method. Therefore the relative instability of parent compound does not affect the validity of the desthio residues measured in supervised trials.

Results of supervised residue trials on crops

Supervised trials have been conducted to support MRLs for the following crops or groups of crops: blueberry, cranberry, cucurbits (cucumber, summer squash and melon), sweet corn, soya bean, potato, maize (field corn, popcorn) and peanuts.

In trials conducted in the USA, Canada and Brazil, residues of prothioconazole sulfonic acid (JAU 6476 sulfonic acid), prothioconazole-desthio (JAU 6476 desthio) and total prothioconazole (JAU 6476) were determined and reported. In trials conducted in Australia, residues of prothioconazole (JAU 6476), prothioconazole-desthio (JAU 6476 desthio) and total prothioconazole (JAU 6476) were determined and reported. However, only the residues of prothioconazole-desthio have been used for calculation of MRL, HR and STMR values in accordance with the residue definition. The residues of prothioconazole-desthio are expressed as mg prothioconazole-desthio equivalents/kg.

Bush berries

Blueberry

Eleven supervised trials were conducted in 2010 in the USA and Canada matching the US GAP (2 × 200 g ai/ha nominal rate at 6–7 days intervals, 7-day PHI) for the bush berry subgroup.

Prothioconazole-desthio residues from trials on blueberries were: 0.15, 0.22, 0.26, 0.28, 0.42, 0.52, 0.56, 0.60, 0.65, 0.70 and 0.87 mg/kg.

Taking into account that blueberry is the representative commodity for the subgroup; the Meeting estimated a maximum residue level of 1.5 mg/kg, a HR of 0.87 mg/kg and a STMR of 0.52 mg/kg for prothioconazole-desthio residues for the bush berry subgroup.

Low growing berries

Cranberry

Six supervised trials were conducted in 2010 in the USA according to the US GAP (2 × 186 g ai/ha nominal rate at 7-10 days intervals, 45-day PHI)

Prothioconazole-desthio residues from trials on cranberries were: ≤ 0.02 (3), 0.03 (2) and 0.09 mg/kg.

The Meeting estimated maximum residue level of 0.15 mg/kg, HR of 0.09 mg/kg and STMR of 0.025 mg/kg for prothioconazole-desthio residues for cranberry.

Fruiting vegetables, Cucurbits

Eight supervised trials were conducted in 2010 on *cucumber*, eight trials on *musk melon* and eight trials on *summer squash* in the USA according to US GAP (one soil +2 × 200 g ai/kg nominal rate at 7-10 days intervals, max 600 g ai/season, 7-day PHI).

Prothioconazole-desthio residues from trials on cucumber were: 0.02, 0.02, 0.03, 0.03, 0.04, 0.05, 0.05, 0.06 mg/kg.

Prothioconazole-desthio residue concentrations from trials on musk melon were: 0.03, 0.06, 0.06, 0.06, 0.07, 0.15, 0.15 mg/kg.

Prothioconazole-desthio residue concentrations from trials on summer squash were: < 0.02 (5), 0.03, 0.05 and 0.06 mg/kg.

The Meeting noted that the GAP in USA is for cucurbit vegetables, the residue populations were not significantly different and the median residues were within the 5 times range, and agreed to combine the datasets. Residues in the 24 trials were: < 0.02 (5), 0.02 (2), 0.03 (4), 0.04, 0.05 (3), 0.06 (6), 0.07 and 0.15 (2) mg/kg.

The Meeting noted that the ARfD would be exceeded by 150% for watermelon. As no alternative GAP for fruiting vegetables was available, watermelon was not included in the recommendation for the crop group fruiting vegetables, cucurbits.

The Meeting estimated a maximum residue level of 0.2 mg/kg, HR of 0.15 mg/kg and STMR of 0.045 mg/kg prothioconazole-desthio residues for fruiting vegetables, cucurbits (except watermelon).

Fruiting vegetables, Other Than Cucurbits

Sweet corn

Twelve supervised trials were conducted on sweet corn in the USA at 4 × 200 g ai/ha matching the current US GAP. The PHI for sweet corn forage and ears is 0 days and 14 days for fodder.

Prothioconazole-desthio residue concentrations in corn ears were: < 0.018 in all samples.

The Meeting estimated a maximum residue level of 0.02 mg/kg, and HR and STMR values of 0.018 mg/kg for sweet corn.

*Pulses**Soya beans*

Residue data on soya beans from 19 trials conducted in the USA were previously evaluated by the 2008 and 2009 JMPR Meetings. The current US GAP for soya beans permit 3 applications at 88–175 g ai/ha rate at 10–21 day intervals with a PHI of 21 days.

The average prothioconazole-desthio residues in soya bean samples derived from trials corresponding to the current US GAP were: < 0.05 (16), 0.051, 0.055 and 0.105 mg/kg

Ten supervised trials were conducted in 2012–2013 season on soya bean in Brazil matching the GAP for Brazil (4×87.5 g ai/ha, PHI 30 days). The prothioconazole-desthio residues were reported as the parent compound. Applying the conversion factor of 0.907 (312.20/344.26) the residues expressed as prothioconazole-desthio were: $< 0.009 \times 4$, 0.009×2 , 0.018, 0.027, 0.036 and 0.091 mg/kg.

The Meeting noted that the US trials resulted in higher residues and used those values. The meeting estimated a maximum residue level of 0.2 mg/kg and STMR value of 0.05 mg/kg.

*Root and tuber vegetables**Potato*

A total of twenty supervised trials were conducted in 2005 and 2010 as potato seed-piece treatments in Belgium, France, Germany, Italy, the Netherlands, Spain and the UK at maximum GAP (up to 0.64 g ai/100 kg seed, equivalent to 16 g ai/ha) or higher rate. The potatoes were harvested at maturity. The prothioconazole-desthio residues were < 0.01 mg/kg in all samples take 90–136 days after seed treatment.

Taking into account that the LOQ of the enforcement method is 0.02 mg/kg, the Meeting estimated a maximum residue level of 0.02* mg/kg, HR and STMR values of 0.01 mg/kg for potato.

*Cereal grains**Maize*

Twenty supervised trials were conducted in 2006 on field corn and three trials on popcorn in the USA (4×200 g ai/ha at 7–14 days apart, 0 day PHI for forage and 14 days for grain and fodder).

The prothioconazole-desthio residues in maize grain samples collected at 14 days after last application were: < 0.018 (17), and 0.05 mg/kg,

Ten supervised trials were conducted in 2011–2012 on corn in Brazil according to the GAP (2×70 –87.5 g ai/ha, at minimum 15 days, 15 days PHI).

The prothioconazole-desthio residues in maize grain samples collected at 14–15 days after last application were: < 0.01 (10) mg/kg.

A total of twenty supervised trials were conducted in 2007, 2008 and 2011 on maize/corn in Europe matching the GAP of the Czech Republic (2×125 g ai/ha, PHI 35 days) and Italy (2×125 g ai/ha, retreatment at a minimum of 14 days, 35 days or non-specified PHI).

The prothioconazole-desthio residues in all of immature and mature maize grain samples collected from 17 days onward were: < 0.01 (20) mg/kg.

The Meeting considered that all maize grain/seed samples (47) contained non-detectable residues regardless of maturity and time between last application and sampling, except in one trial where residues of up to 0.05 mg/kg residue was measured.

The Meeting estimated a maximum residue level of 0.1 mg/kg and STMR value of 0.018 mg/kg for maize and popcorn.

*Oilseeds**Peanuts*

Residue data on peanuts from trials conducted in the USA had been evaluated by the 2009 JMPR. Residues of prothioconazole-desthio were < 0.02 mg/kg in 12 trials matching the USA GAP (4 × 200 g ai/ha, PHI 14 days).

Eight supervised trials were conducted in 2011–2012 in Australia. Four trials included plots which were treated according to the GAP for peanut in Australia (4 times 120–192 g ai/ha at 10–14 days apart, 28-day PHI), and four trials included plots which were treated with higher number of applications and a shorter PHI (up to 21 days). Samples were taken immediately before the last application and 0, 7, 14–15 and 20–21 days after.

The prothioconazole-desthio residues in all samples collected from Day 0 to day 29 days were: < 0.01 mg/kg.

The Meeting confirmed its previous recommendations of 0.01* mg/kg.

Primary feed commodities

Descriptions of trial conditions and residues are described under relevant food commodities. The residue data relevant to the feed commodities are summarized below.

Maize and sweet corn forage and fodder

Prothioconazole-desthio residue concentrations in sweet corn forage from trials conducted at 4 × 200 g ai/ha were: 1.31, 1.50, 1.89, 1.94, 1.98, 2.08, 2.12, 2.37, 2.82, 3.20, 3.75 and 4.08 mg/kg.

Prothioconazole-desthio residue concentrations in field corn forage from trials based on the USA GAP for corn are: 0.71, 1.67, 1.75, 1.84, 1.90, 1.96, 2.14, 2.15, 2.19, 2.20, 2.27, 2.41, 2.58, 2.62, 2.65, 2.99 (2), 3.06, 3.44 and 3.60 mg/kg.

The Meeting noted that the GAP in USA for sweet corn and maize is the same and that the residue populations were not significantly different, and agreed to combine the datasets.

Residues in the trials were: 0.71, 1.31, 1.50, 1.67, 1.75, 1.84, 1.89, 1.90, 1.94, 1.96, 1.98, 2.08, 2.12, 2.14, 2.15, 2.19, 2.20, 2.27, 2.37, 2.41, 2.58, 2.62, 2.65, 2.82, 2.99 (2), 3.06, 3.44, 3.60, 3.75 and 4.08 mg/kg.

Residues in forage from the European trials were much lower (< 0.2 mg/kg) than from the trials conducted according to the USA GAP, and therefore the Meeting used the US trial data for the estimation of residue levels.

The Meeting estimated highest residue of 4.08 mg/kg and median residue of 2.15 mg/kg for sweet corn and filed maize forage.

Prothioconazole-desthio residue concentrations in sweet corn stover from trials conducted at 4 × 200 g ai/ha were: 0.67 (2), 0.71, 0.82, 0.90, 0.98, 1.45, 1.68 (2), 1.70, 3.61 and 5.88 mg/kg.

Prothioconazole-desthio residue concentrations in field corn stover from trials based on the USA GAP for corn were: 0.67 (2), 0.71, 0.82, 0.90, 0.98, 0.99, 1.09, 1.45, 1.68 (2), 1.70, 2.22, 2.32, 2.35, 2.42, 2.90, 3.18, 3.22, 3.42, 3.48, 3.59, 3.61, 3.68, 3.78, 3.89, 4.05, 4.47, 4.66, 5.88, 6.16 and 6.70 mg/kg.

Prothioconazole-desthio residue concentrations in popcorn stover from trials based on the USA GAP for corn were: 2.46, 2.51 and 4.43 mg/kg.

The Meeting noted that the GAP in the USA is for sweet corn and maize is the same and the residue populations were not significantly different, and agreed to combine the datasets. Residues in the trials were: 0.99, 1.09, 2.22, 2.32, 2.35, 2.42, 2.46, 2.51, 2.90, 3.18, 3.22, 3.42, 3.48, 3.59, 3.68, 3.78, 3.89, 4.05, 4.43, 4.47, 4.66, 6.16 and 6.70 mg/kg.

The Meeting estimated a maximum residue level of 15 mg/kg (dry weight basis) highest residue of 6.7 mg/kg and median residue of 3.48 mg/kg for sweet corn and field maize stover.

Soya bean forage and hay

The Meeting received information on residues in soya bean forage and hay. However, the samples were taken at 7 days PHI, which did not correspond to the current US GAP and therefore could not be used for the estimation of residue levels.

Peanut fodder

Prothioconazole-desthio residue concentrations in peanut hay from trials based on the Australian GAP for peanuts were: 1.14, 1.15, 7.00 and 11.60 mg/kg.

The Meeting estimated highest and median residues of 11.6 mg/kg and 4.08 mg/kg, respectively, for peanut hay.

Fate of residue during processing

Processing Corn

Field corn was treated at 5× total seasonal rate. Subsamples of corn grain were removed for analysis, aspirated grain fractions were generated, and the remaining grain was used to generate the required processed commodities of starch, oil (wet and dry milled, refined, bleached, and deodorized), grits, flour, meal and bran. Processing was performed using procedures that simulated commercial practices.

The processing factors calculated from total prothioconazole residues were: starch (< 0.28), oil, wet milled (< 0.28), grits (< 0.28), flour (0.57), meal (0.43), bran (1.31), oil, dry milled (< 0.28).

The Meeting noted that the major part of the residue is prothioconazole-desthio and concluded that the results of processing study can be used for estimation of the processing factors for prothioconazole-desthio. The Meeting estimated STMR values (mg/kg) for maize starch (0.0050), maize flour (0.010), and refined maize oil (0.0050).

Processing rape seed

Rape seed was sampled following treatment with prothioconazole, 2×120 g/ha. The conditioned and cleaned rape seeds were pressed in a screw press, yielding screw pressed oil, and pomace. An aliquot of pomace was extracted twice with hexane. The screw pressed oil and extracted oil were combined to obtain crude oil, which was neutralized and processed to obtain refined oil.

The processing factors calculated were: screw pressed oil (1), pomace (1), meal (< 1), solvent extracted oil (2), crude oil (2), pre-clarified crude oil (2), neutralized crude oil (1) and refined oil (< 1)

The Meeting estimated STMR-P values for rape seed oil, edible of 0.02 mg/kg based on the STMR of 0.02 estimated by the 2009 JMPR

Residues in Animal Commodities

The following commodities evaluated by the present and previous Meetings could result in residues in animal tissues, milk, and eggs: sweet corn forage and stover, field corn forage and stover, popcorn forage and stover, soya bean hay and peanut fodder (dry), grains, straw and fodder (dry) of cereal grains.

Livestock dietary burden

The maximum and mean dietary burdens were calculated using the highest residues or median residues of prothioconazole-desthio estimated by the current Meeting on a basis of the OECD Animal Feeding Table. The calculated maximum and mean animal burdens are summarized below

Summary of livestock dietary burdens (ppm of dry matter diet)

	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	4.04	3.32	12.36	5.47	21.6 ^a	5.50 ^c	3.15	3.15
Dairy cattle	10.63	4.85	10.89	4.94	18.42 ^b	5.50 ^d	7.66	5.25
Broilers	2.86	2.86	1.17	1.17	1.18	1.18	0.29	0.29
Layers	2.86	2.86 ^f	3.33 ^e	1.71	1.18	1.18	1.72	1.72

^a Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian meat

^b Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

^c Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian meat.

^d Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

^e Highest maximum poultry dietary burden suitable for MRL estimates for poultry meat and eggs.

^f Highest mean poultry dietary burden suitable for STMR estimates for poultry meat and eggs.

Animal commodity maximum residue levels

The 2009 JMPR summarized the total prothioconazole desthio residues (mg/kg) in edible tissues of dairy cattle after 28 days of dosing with prothioconazole-desthio:

Tissue	4 ppm dose		25 ppm dose		100 ppm dose	
	Range	Mean	Range	Mean	Range	Mean
Liver	0.02-0.05	0.04	0.18-0.26	0.22	0.61-1.6	0.95
Kidney	0.01-0.04	0.02	0.11-0.17	0.14	0.41-1.1	0.65
Muscle	< 0.01	< 0.01	< 0.01	< 0.01	0.01-0.03	0.02
Fat	< 0.01	< 0.01	0.01-0.02	0.01	0.03-0.14	0.07
Milk	< 0.004	< 0.004	< 0.004	< 0.004	0.013-0.02	0.017

The maximum dietary burden for beef cattle remained the same as was estimated by the 2009 JMPR. The maximum dietary burden for dairy cattle is 18.42 ppm which is smaller than the 25 ppm dose and no detectable residue can be expected in milk.

The mean dietary burden for beef and dairy cattle is 5.5 ppm, which is higher than the 4.8 ppm estimated by the 2009 JMPR. However the STMR values estimated by the 2009 JMPR cover the likely median residues.

The Meeting confirmed its previous recommendations for maximum residue levels, HR and median residues for mammalian meat, and edible offal and milk.

The 2008 Meeting concluded that the feeding study on poultry did not reflect the residue composition in feed and could not be used for estimation of residue levels.

RECOMMENDATIONS

On the basis of the data from supervised trials and farm animal feeding studies reported by the 2006 JMPR, the Meeting concluded that the residue levels listed below are appropriate for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for enforcement and dietary risk assessment) for plant commodities: *prothioconazole-desthio*.

Definition of the residue (for enforcement and dietary risk assessment) for animal commodities: *the sum of prothioconazole-desthio. (M04), prothioconazole-desthio-3-hydroxy (M14), prothioconazole-desthio-4-hydroxy (M15), expressed as prothioconazole-desthio after correction for molecular weight.*

Commodity		MRL mg/kg	STMR mg/kg	HR mg/kg
CCN	Name			
FB 2006	Bush berries	1.5	0.52	0.87
FB0265	Cranberry	0.15	0.025	0.9
VC 0046	Fruiting vegetables, Cucurbits, except watermelon	0.2	0.045	0.15
VO 0447	Sweet corn	0.02	0.018	0.018
VD 0541	Soya bean	0.2	0.05	
GC 0656	Popcorn	0.1	0.018	
VR 0589	Potato	0.02(*)	0.01	0.01

	Maize starch		0.0028	
OR 0495	Rape oil refined		0.02	

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intake (IEDI) for prothioconazole-desthio was calculated from the recommendations for STMR-s for raw agricultural commodities in combination with consumption data for corresponding food commodities. The results are shown in Annex 3 to the 2014 Report.

The IEDI of the 17 GEMS/Food cluster diets were in the range of 0–3 % of the maximum ADI of 0.01 mg/kg bw. The Meeting concluded that the long-term intake of residues from uses of prothioconazole considered by the Meeting is unlikely to present a public health concern.

Short-term intake

The International Estimated Short-term Intake (IESTI) for prothioconazole-desthio was calculated from the recommendations for HR and STMR-s for raw agricultural commodities in combination with consumption data for corresponding food commodities. The results are shown in Annex 4 to the 2014 Report.

The IESTI for women of child bearing age is 0–100% of the ARfD of 0.01 mg/kg bw. The IESTI for the rest of the population is 0–1 % of the ARfD of 1 mg/kg bw.

For watermelon the IESTI represented 150% of the ARfD of 0.01 mg/kg bw. No alternative GAP was available. On the basis of information provided to the JMPR it was not possible to conclude that the estimate of short-term intake of prothioconazole, from the consumption of watermelon was less than the ARfD. The Meeting did not estimate MRL for watermelon.

The other commodities considered by the JMPR were within 0–100% of ARfD for women of child bearing age and 1% of general population. The Meeting concluded that the short-term intake of prothioconazole when used in ways that have been considered by the MPR is unlikely to present public health concern.

PYMETROZINE (279)

The first draft was prepared by Mr Christian Sieke, Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

Pymetrozine is a pyridine azomethine insecticide used to control homopteran insects (aphids and whiteflies) as well as pollen beetles selectively. Although it has no knockdown effect, pymetrozine rapidly affects the feeding behaviour of the insect pests. It was considered for the first time by the 2014 JMPR for toxicology and residues.

IDENTITY

ISO common name	Pymetrozine
Chemical name	
IUPAC	(E)-4,5-dihydro-6-methyl-4-(3-pyridylmethyleneamino)-1,2,4-triazin-3(2H)-one
CA	4,5-dihydro-6-methyl-4-[(E)-(3-pyridinyl-methylene)amino]-1,2,4-triazin-3(2H)-one
CAS No.	123312-89-0
CIPAC No.	593
Structural formula	
Molecular formula	C ₁₀ H ₁₁ N ₅ O
Molecular mass	217.2 g/mol

The pymetrozine molecule contains a double bond about which E/Z isomerism is possible. However, pymetrozine technical material is manufactured by a process that yields almost exclusively the E isomer.

Specifications

Specifications for pymetrozine were not yet developed by FAO.

Physical and chemical properties

Formulations

Pymetrozine is primarily available as a 500 g/kg WG formulation.

METABOLISM AND ENVIROMENTAL FATE

Metabolism studies were conducted using [Pyridine-5- ^{14}C]-pymetrozine (pyridine-label) and [Triazine-6- ^{14}C]-pymetrozine (triazine-label). The position of the label for both substances is presented in the following figures:

Figure 1 [Pyridine-5- ^{14}C]-pymetrozine

Figure 2 [Triazine-6- ^{14}C]-pymetrozine

Chemical names, structures and code names of metabolites and degradation products of pymetrozine are shown below.

Known metabolites of pymetrozine

<i>Code Names</i>	<i>Chemical Abstracts Name (IUPAC Name), molecular formula, molar mass</i>	<i>Structure</i>	<i>Where found</i>
Parent pymetrozine, CGA 215944	4,5-dihydro-6-methyl-4-[(3-pyridinylmethylene)-amino]-1,2,4-triazin-3[2H]-one		Rat, goat, hen Rice, cotton, potato, tomato, rotational crops
CGA 359009, 2U/IA12	4,5-dihydro-5-hydroxy-6-methyl-4-[(3-pyridinylmethylene)-amino]-1,2,4-triazin-3(2H)-one		Rat, goat, hen Rice, potato, tomato
CGA 323584	4,5-dihydro-5-oxy-6-methyl-4-[(3-pyridinylmethylene)-amino]-1,2,4-triazin-3(2H)-one		Rice, tomato
CGA 300407	3-pyridinecarboxaldehyde (nicotinealdehyde)		Rat, goat, hen Rice, potato, tomato
CGA 128632 incl. conjugates	3-pyridinemethanol		Hen Rice, cotton, potato, tomato, rotational crops
CGA 180777	3-pyridinecarboxylic acid (nicotinic acid)		Rat, goat, hen Rice, cotton, potato, tomato, rotational crops
CGA 180778	3-pyridinecarboxamide (nicotinamide)		Rat, goat, hen Rice, potato, tomato, rotational crops
CGA 96956	1-methyl-3-pyridinecarboxylic acid (trigonelline)		Rice, cotton, potato, tomato, rotational crops
CGA 319251	6-hydroxynicotinic acid		Tomato

Code Names	Chemical Abstracts Name (IUPAC Name), molecular formula, molar mass	Structure	Where found
CGA 294849	4-amino-6-methyl-1,2,4- triazine-3,5(2H,4H)-dione		Rat, goat, hen Rice, cotton, potato, tomato, rotational crops
GS 23199 incl. conjugates	6-methyl-1,2,4-triazine- 3,5(2H,4H)-dione		Rat, goat, hen Rice, cotton, potato, tomato, rotational crops
CGA 266591	2,3,4,5-tetrahydro-3,5-dioxo- 1,2,4-triazine-6-carboxylic acid		Rotational crops
CGA 215525	4-amino-6-methyl-1,2,4-triazin- 3(2H)-one		Rat Potato, tomato
CGA 249257	4,5-dihydro-6-methyl-1,2,4- triazin-3(2H)-one		Rat, goat, hen Rice, potato, tomato
I _{A7}	4,5-dihydro-6-methyl-4-[(3-(1- methyl-6-oxo-1,6- dihydropyridinylmethylene)- amino]-1,2,4-triazin-3(2H)-one		Hen
CGA 245342	4,5-dihydro-6-methyl-4-[(3-(1- oxy)-pyridinyl-methylene)- amino]-1,2,4-triazin-3(2H)-one		Goat
CGA 313124	4,5-dihydro-6-hydroxymethyl- 4-[(3-pyridinyl- methylene)amino]-1,2,4- triazin-3(2H)-one		Rat, goat

Code Names	Chemical Abstracts Name (IUPAC Name), molecular formula, molar mass	Structure	Where found
5U/I _{A2}	4,5-dihydro-6-carboxy-4-[(3-pyridinyl methylene)-amino]-1,2,4-triazin-3(2H)-one		Rat, goat
II _{A2}	phosphate conjugate of CGA 313124		Goat
I _{A17}	hydroxylated 3-pyridinecarboxaldehyde		Goat
CGA259168	N-(4,5-dihydro-6-methyl-3,5-dioxo-1,2,4-triazin-4(2H)-yl)-acetamide		Rat, hen

Animal metabolism

The Meeting received metabolism studies on laboratory animals, poultry and lactating goats using the pyridine- and the triazine-label of pymetrozine.

The metabolism of pymetrozine in livestock animals was intensive, showing only minor amounts of unchanged parent substance in all matrices. The major degradation steps are:

- oxidation at the triazine-methyl group leading to alcohol CGA313124, and subsequently to the corresponding carboxylic acids (A2 and 5U)
- oxidation at the triazine methylene group leading to metabolite CGA359009, and subsequently after cleavage between the triazine and pyridine ring to triazine-specific CGA 294849 and GS23199
- cleavage reaction between the triazine and pyridine ring systems leading by various reaction mechanisms to triazine-specific compounds CGA215525, CGA249257, CGA259168, and pyridine-specific metabolites CGA180777, CGA 180778 and CGA300407.

Laboratory animals

In the rat the extent of oral absorption is high (> 80%), based on urinary and biliary data. Pymetrozine is widely distributed in the body. High concentrations of both triazine- and pyridine-labelled material were found in the liver and kidney. The labelled material was rapidly excreted via urine (50–75% in 24 hours). Absorbed pymetrozine was extensively metabolized, with unmetabolized parent compound representing approximately 10% of the excreted radiolabel. Compounds containing both ring structures represented over 50% of the identified metabolites. The kinetics, excretion pattern, tissue distribution of radioactivity and metabolite profile were similar for both radiolabelled sites and administered dose levels as well as when the administration of radiolabelled pymetrozine was preceded by 14 days of administration of the unlabelled material (see WHO Monograph).

Lactating goats

The metabolic fate of [pyridine-5-¹⁴C]-pymetrozine in lactating goats was investigated by Rümbeili (1994, PYMET_018). The compound was administered to two lactating goats (35 kg bw and 49 kg bw) in gelatine capsules at 0.39 mg/kg body weight, corresponding to a level of 7.5 ppm in the feed, for four consecutive days. Excreta and milk were collected daily. The animals were slaughtered approximately 6 hours after the last dose. Muscle, omental fat, peritoneal fat, liver, kidney, blood, bile and content of gastrointestinal tract/rumen were collected.

Radioactivity was measured using liquid scintillation counting. Thin-layer chromatography, high performance liquid chromatography and high voltage electrophoresis were used to identify and characterise radioactive components in sample extracts.

The total recovery of the administered radioactivity was 86.5 %. The majority of the recovered radioactivity was found in the urine (52.4%) and faeces (14.7%). Of the administered radioactivity 3.1% were excreted via milk.

Radioactive residues in the edible tissues, muscle, omental fat, peritoneal fat, liver and kidney were between 0.03–1.95% of the administered dose. There was 0.58% of the dose remaining in leg muscle, 0.03% in tenderloin, 1.95% in liver and 0.15% in kidney.

A summary of the recovered radioactivity is presented in Table 1.

Table 1 Recovered radioactivity from goat tissues and excreta after administration of [pyridine-5-¹⁴C]-pymetrozine

Tissue	Mean radioactivity (mg/kg or mg/L pymetrozine eq.)	Mean radioactivity (% of total dose)
Milk (0–78 h)	0.326	3.14
Leg muscle	0.068	0.58
Tenderloin	0.069	0.03
Omental fat	0.026	0.03
Perirenal fat	0.032	0.02
Kidney	0.718	0.15
Liver	1.479	1.95
Faeces (0–78 h)	1.693	14.73
Urine (0–78 h)	7.927	52.37
Cage debris	–	0.65
Cage wash	–	2.43
Blood	0.069	0.25
Bile	1.303	0.02
GIT/rumen	0.669	10.18
Total excreted		73.33
Total recovery		86.54

Unchanged pymetrozine was present in small amounts ranging between 1.6% in liver tissue and 10.8% in muscle and were equivalent to 0.01 mg eq/kg or less in all samples except liver and kidney where the equivalent residues was 0.02 mg eq/kg and 0.07 mg eq/kg, respectively.

In tissue nicotinamide (CGA180778) was a major metabolite found in muscle (44.2%), fat (23.7%), liver (36.5%) and kidney (27.4%).

The hydroxylated pymetrozine derivative CGA313124 was found as a residue in muscle (10.2%), fat (6.8%), liver (3.0%) and kidney (11.3%) with residues greater than 0.01 mg eq/kg in liver and kidney. CGA313124 was also the major metabolite in milk at 36.3% of the radioactive residue. The phosphate conjugate of CGA313124 was also found in milk, accounting for an additional 38.9% of the radioactive residue.

For the composition of radioactive residues in milk and tissues please see Table 2.

The metabolism of lactating goats using [triazine-6-¹⁴C]-pymetrozine was investigated by Rumbeli (1994, PYMET_019). Two animals (37 & 41 kg bw) were administered doses equivalent to 0.54 mg/kg bw or 10 ppm in the diet for a period of four consecutive days. Excreta and milk were collected daily. The animals were slaughtered approximately 6 hours after the last dose. Muscle, omental fat, peritoneal fat, liver, kidney, blood, bile and content of gastrointestinal tract/rumen were collected.

Radioactivity was measured using liquid scintillation counting. Thin-layer chromatography, high performance liquid chromatography and high voltage electrophoresis were used to identify and characterise radioactive components in sample extracts.

The total recovery of the administered radioactivity was 83.4 %. The majority of the recovered radioactivity was found in the urine (47.1%) and faeces (16.6%). Of the administered radioactivity 3.7% were excreted via milk.

Radioactive residues in the edible tissues, muscle, omental fat, peritoneal fat, liver and kidney were between 0.02–1.09% of the administered dose. There was 0.38% of the dose remaining in leg muscle, 0.02% in tenderloin, 1.09% in liver and 0.09% in kidney.

A summary of the recovered radioactivity is presented in Table 4.

Table 4 Recovered radioactivity from goat tissues and excreta after administration of [triazine-6-¹⁴C]-pymetrozine at 10 ppm

Tissue	Mean radioactivity (mg/kg or mg/L pymetrozine eq.)	Mean radioactivity (% of total dose)
Milk (0–78 h)	0.447	3.71

Total excreted		70.11
Total recovery		83.35

Unchanged pymetrozine was present in small amounts ranging between 2.3% TRR in liver tissue and 10% TRR in muscle.

In tissue the hydroxylated pymetrozine derivative CGA313124 was found as a major residue in fat (24.7% TRR) and kidney (15.1% TRR) and in concentrations of 0.051 mg eq/kg in liver. CGA313124 was also the major metabolite in milk with 40% of the TRR. The phosphate conjugate of CGA313124 was also found in milk, accounting for an additional 40.7% TRR.

In kidney, 5U/I_{A2}, which represents the carboxylic acid of pymetrozine, was also identified as a major metabolite (11.7% TRR, 0.067 mg eq/kg).

For the composition of radioactive residues in milk and tissues please refer to Table 5.

Laying hens

The metabolic fate of [pyridine-5-¹⁴C]-pymetrozine was studied in five laying leghorn hens by Rümblei (1994, PYMET_020). The compound was administered in gelatine capsules at 0.82 mg/kg body weight, corresponding to a level of 10.8 ppm in the diet, for four consecutive days. Excreta and eggs were collected daily. The animals were slaughtered approximately 6 hours after the last dose. Muscle, skin with attached fat, peritoneal fat, liver, kidney and content of gastrointestinal tract were collected.

Radioactivity was measured using liquid scintillation counting. Thin-layer chromatography, high performance liquid chromatography and high voltage electrophoresis were used to identify and characterise radioactive components in sample extracts.

The total recovery of the administered radioactivity was 79.0%. The gastrointestinal tract was not analysed, which may account for most of the remaining administered radioactivity. The majority of the radioactivity (77.0%) was found in the excreta. Radioactive residues in the edible tissues were 0.27% TRR in lean meat, 0.05% TRR in skin and fat, 0.77% TRR in liver, 0.11% TRR in kidney and 0.02% TRR in eggs. A summary of the recovered radioactivity is presented in Table 7.

Unchanged pymetrozine was present in very small amounts only detectable in egg white (4.9% TRR) and kidney (0.2% TRR).

In all tissues and eggs CGA180777 (nicotinic acid) & CGA180778 (nicotinamide) were the major residue present at 8.6 % TRR to 76.5% TRR.

The only other major metabolites identified were IA7 (skin + fat: 16.6% TRR, egg white: 15.4% TRR and kidney: 12.5% TRR) and CGA300407 (egg white: 11.1% TRR).

For the composition of radioactive residues in milk and tissues please refer to Table 8.

Figure 3 Metabolic pathway of pymetrozine in animals

Plant metabolism

The fate of pymetrozine in plants was investigated following foliar and granular application of [pyridine-5-¹⁴C]- and/or [triazine-6-¹⁴C]-radiolabelled active substance to tomato, potato, cotton and rice.

In the first weeks after treatment most of the residue was found on the leaf surface, consisting of unchanged parent substance. Within 4 weeks most of the residue is taken up by the plant and metabolised. Main metabolic steps are oxidation to CGA359009 and CGA323584, cleavage of the parent showing both pyridine and triazine metabolites and finally incorporation into glucose, lignin and protein. A proposed metabolic pathway scheme is presented in Figure 4.

Tomato

The metabolism of pymetrozine was investigated in tomatoes after three spray applications with [triazine-6-¹⁴C]-pymetrozine by Sandmeier (1999, PYMET_022). Fruit bearing plants were treated with rates equivalent to 0.47 kg ai/ha per application with one week intervals. The plants were protected by a plastic housing and watered by irrigation to avoid run-off of the residues. Samples (mature fruit and leaves) were harvested 3, 7 and 14 days after the last treatment. All samples were stored for a period of 6 months or less.

Tomatoes were dipped and rinsed in methanol. The washings were combined prior to analysis by radio-assay and TLC. Washed tomatoes homogenised in the presence of liquid nitrogen. The total

radioactive residues in tomatoes and leaves were determined by liquid scintillation counting after combustion of the homogenised samples.

The homogenised plant material was extracted with methanol:water (8:2). This procedure was repeated twice with tomato samples and three times with leaf samples until the last extract contained less than 5% of the radioactivity of the first extract. A Soxhlet extraction with methanol was carried out and the unextracted radioactivity was determined by combustion analysis. Characterisation and identification of radioactive components was performed with HPLC-MS using electro spray ionisation (ESI) and atmospheric pressure ionisation (APCI) techniques.

The TRR in fruit was similar at the three sampling intervals: 0.58 mg/kg pymetrozine equivalents after 3 days, 0.57 mg/kg pymetrozine equivalents after 7 days and 0.51 mg/kg pymetrozine equivalents after 14 days. The TRR in leaves decreased from 27.9 mg/kg pymetrozine equivalents, 3 days after the final treatment to 21.6 and 17 mg/kg pymetrozine equivalents after 7 and 14, respectively. Surface washings of the fruit contained 68, 59 and 48.6% of the TRR at intervals of 3, 7 and 14 days, respectively, after the final application (see Table 13).

Table 13 Summary of the distribution of radioactivity and residual [triazine-6-¹⁴C]-pymetrozine in tomato plants

Pymetrozine was the major residue in fruits ranging from 56.8% TRR after 3 days to 31.9% TRR after 14 days. No other fraction accounted for more than 10% of TRR in fruit except CGA 294849 after 14 days (13.5% TRR, 0.0691 mg eq/kg).

In an older set of studies also conducted by Sandmeier (1992, PYMET_023 & 1993, PYMET_024) the distribution and degradation of [triazine-6-¹⁴C] pymetrozine was studied in field grown tomatoes after foliar application. Three months old tomato plants (with green tomatoes, approx. 2 cm in diameter) were twice treated in an interval of 7 days with a WP formulation at a rate of about 0.25 kg ai/ha each.

The sampling followed two strategies. In a short-term experiment plant material (tomatoes and leaves) was sampled about 1 and 4 hours; 1, 2 and 7 days after the last application. The long-term experiment involved sampling 26 and 49 days. All samples were analysed within 22 months.

Leaves and tomatoes were shortly washed with MeOH/H₂O. After cold extraction a soxhlet extraction with methanol was performed. The unextracted radioactivity was determined by combustion of the dry material. The radioactivity was measured with a scintillation counter or by autoradiography. Besides the TLC Liquid Chromatography, HPLC, chemical reactions and enzyme cleavage were used to characterise fractions. Quantification of metabolites was performed by 2D TLC.

In the short-term experiment about 50% of the initial radioactivity was found after seven days in the treated leaves and fruits. Most of the residue was present on the surface consisting of unchanged parent substance. However, a quick and steady absorption into the plants was observed. In the extracts, the amount of pymetrozine was lower than on the surface, indicating a quick degradation within the plants. An overview of the radioactivity found in tomato samples is presented below. All samples were analysed only for the amount of pymetrozine present.

Table 17 Penetration of radioactivity and residual [triazine-6-¹⁴C]-pymetrozine in tomato leaves and fruits

Interval	Plant part	Total residue	Pymetrozine	Surface wash		Extracts			Total

In the long-term experiment the composition of the radioactive residues in tomato leaves and fruits was investigated. After 26 and 49 days the parent substance was extensively metabolized. Although pymetrozine was still present as the only major metabolite in treated plant parts (8.6–17.2% TRR), most of the recovered radioactivity was distributed into minor metabolites or characterised.

Distribution and degradation of [pyridine-5-¹⁴C]-pymetrozine were studied by Gross (1994, PYMET_025) in field-grown tomatoes protected by a plastic housing. Three month old tomato plants (with green tomatoes approximately 2 cm diameter) were treated twice at 14 days interval with approximately 0.25 kg ai/ha formulated in a WP product. Whole plants were sampled approximately 3 hours and 15 days after the first application, and at 1 hour, 7 days (first mature fruit) and 27 days (maturity) after the second application.

Tomatoes were rinsed in methanol:water (1:1 v/v). The total radioactive residues were determined by liquid scintillation counting after combustion of the homogenised samples. The homogenised plant material was extracted thrice with methanol:water (8:2). The combined extracts were used for determination of the parent by TLC. A Soxhlet extraction with methanol was also carried out and the unextracted radioactivity was determined by combustion analysis.

Characterisation and identification of radioactive components was performed with TLC, ion exchange LC, HPLC using authentic standards of metabolites as reference compounds, and GC-MS.

The first mature tomato fruits were harvested 7 days after the second treatment. Total residues were 0.229 mg eq/kg with a parent content of 0.072 mg eq/kg. Total residues in leaves were 7.432 mg eq/kg with a parent content of 2.221 mg eq/kg.

At harvest (27 days after the second treatment), total residues reached 0.173 mg eq/kg in tomato fruit and 2.433 mg eq/kg in leaves. Parent residues were 0.016 mg eq/kg and 0.286 mg eq/kg in fruit and leaves respectively. The radioactivity of the surface of tomato fruit decreased from nearly 90% 1 hour after the first treatment to less than 10% 15 days later.

An overview of the total radioactive residues and their extractability is presented in Table 19.

	Fruit	0.173	0.016		81.9	0.4	4.2	92.3

The composition of radioactive residues showed unchanged pymetrozine as the only significant residue directly after application. Most of the parent was located on the fruit and leaf surface. Within the first days after treatment the active substance is absorbed and in plants degraded into various minor metabolites. The major metabolite identified was CGA96956, representing up to 70% of the TRR in fruits and leaves. The only other major metabolite found in fruits and leaves was CGA128632 present up to 19.5% of the TRR.

Potato

For the investigation of the plant metabolism of pymetrozine in potato a study was conducted by Fleischmann (2000, PYMET_026) involving treatment either with [triazine-¹⁴C]-pymetrozine or [pyridine-¹⁴C]-pymetrozine formulated as a WP product. The plants were treated with three foliar sprays in one week intervals. The applications using [triazine-¹⁴C]- and [pyridine-¹⁴C]-pymetrozine were conducted with 0.15 kg ai/ha each (total rate 0.45 kg ai/ha) or at exaggerated rates of 1.05 kg ai/ha each (total rate 3.1 kg ai/ha). The first of the three foliar spray applications was 61 days after planting. Potato foliage and tubers were harvested 7, 14 and 29 days after the third application.

Samples were extracted with acetonitrile:water (8:2) or methanol:water (8:2) and purified using C₁₈ SPE techniques. Unextracted radioactivity in tubers were refluxed with neutral solvent acetonitrile/water or methanol/water. Additional radioactive residues were released after treatment with enzymes and then refluxing with acid or an alternative sequence refluxing with H₂O and then refluxing with base. Extracts were characterised by reverse phase HPLC and 2D-TLC. Radioactivity in liquid samples and extracts were determined by LSC.

The TRR in potatoes treated at a rate of 3 × 0.15 kg ai/ha with [triazine-¹⁴C]-pymetrozine were 0.13, 0.12 and 0.11 mg eq/kg pymetrozine equivalents in tubers and 11.7, 8.5 and 6.4 mg eq/kg pymetrozine equivalents in foliage harvested at 7, 14 and 29 days after the final application, respectively. The TRR in potatoes treated with rates of 3 × 1.05 kg ai/ha were 0.34, 0.41 and 0.37 mg eq/kg in tubers and 46.2, 37.2 and 40.4 mg eq/kg in foliage harvested after 7, 14 and 29 days, respectively.

Potatoes treated at a rate of 3×0.15 kg ai/ha with [pyridine- ^{14}C]-pymetrozine had TRRs of 0.26, 0.31 and 0.36 mg eq/kg in tubers and 8.2, 6.8 and 7.8 mg eq/kg in foliage harvested at 7, 14, and 29 days, respectively. The treatments with 3×1.05 kg ai/ha using [pyridine- ^{14}C]-pymetrozine resulted in tuber residues of 0.8, 0.8 and 1.1 mg eq/kg and foliage residues of 29.4, 31.4 and 35.6 mg eq/kg at the same respective harvest intervals.

A summary of the total radioactive residues is presented in Table 23.

Table 23 Summary of extraction of potato samples following treatment with [pyridine-5- ^{14}C]- and [triazine-6- ^{14}C]-pymetrozine

DAT: days after treatment

The triazine radiolabelled tuber extracts showed a complex mixture of aqueous soluble polar moieties separated into at least 11 fractions by reverse phase HPLC. Approximately 30% of the tuber TRR eluted in four early eluting HPLC regions. The largest early eluting HPLC region (T3) was 13% to 15% TRR and was further characterised as a mixture of multiple components.

In tubers the major metabolites identified were pymetrozine (1–4% TRR), GS-23199 (approximately 2% TRR) and its glycoside conjugate (3–5% TRR), CGA-249257 (1–2% TRR) and CGA-294849 (1–3% TRR). The major residues in foliage extracts were pymetrozine (3–9% TRR) and the glycoside of GS-23199 (9–16% TRR). Other identified components in the foliage were GS-23199 (1–2% TRR), CGA-249257 (1–2% TRR) and CGA-294849 (1–3% TRR).

The pyridine radiolabelled residues from tubers were primarily identified as CGA96956 (“trigonelline”, 54–75% TRR), monosaccharide conjugates of CGA-180777 (12–22% TRR), CGA-180777 (1–5% TRR), CGA-180778 (< 2% TRR), CGA-128632 (approximately 1% TRR) and pymetrozine ($\leq$ 2% TRR).

The major residues in foliage were identified as CGA96956 ("trigonelline", 3–6% TRR), CGA180777 (< 1% TRR), CGA180778 (< 2% TRR), glycoside conjugate of CGA128632 (10–17% TRR), CGA128632 ($\leq$ 2% TRR) and pymetrozine (5–18% TRR).

In two older studies the behaviour and metabolism of [triazine-6-¹⁴C]-pymetrozine (Nicollier, 1994, PYMET_027) and [pyridine-5-¹⁴C]-pymetrozine (Nicollier, 1994, PYMET_028) were studied in field grown potato plants. Forty-one day old potato plants were treated with one of the labelled compounds twice at 20 day interval at a rate of 0.2 kg ai/ha each.

Samples of the foliage were collected 1 h and 20 days after the first application and 1 h, 29 d and 55 d after the last application. The tubers were collected at maturity 55 d after the final treatment.

For the analysis the tubers were peeled. All samples were homogenized and extracted with methanol:water (8:2). The remaining residues were soxhlet extracted with methanol. The identification of residues was performed by TLC and high voltage electrophoresis. Total radioactive residues were determined by combustions and LSC.

Following foliar application of pymetrozine to potatoes most of the residue was recovered from the leaves. Directly after treatment the parent substance was the major residue (42–57% TRR). However, the rates quickly declined within the first 20 days after treatment to less than 5% of the TRR in the leaves. In tubers the TRR was very low (0.051–0.072 mg eq/kg). No parent substance was identified in tuber peel or flesh (see Table 29).

Table 29 Composition and extractability of radioactive residues from potatoes following application of pymetrozine at rates of 2 × 0.2 kg ai/ha

The identification of the residue following application of [pyridine-5-¹⁴C]-pymetrozine revealed CGA180777 (22.2% TRR) and its conjugates (29.1% TRR) as the major residue in the tubers. CGA96956 was also present as a major metabolite (25.1% TRR), while only traces of unchanged parent were detected. In the foliage the parent was the major residue directly after treatment. After 20–55 days, pymetrozine was strongly degraded, leaving only 0.4–0.9% of the TRR in the leaves. Most of the radioactivity was recovered as conjugated of CGA168632.

After application of [triazine-6-¹⁴C]-pymetrozine GS23199 was the only major metabolite in the tubers (11% TRR). Identical to the pyridine-label, the parent substance was only detectable in traces. In the foliage pymetrozine was mainly present after treatment. The degraded residue after 20–55 days was the glucose conjugate of GS23199 (0.3–18.5% TRR).

A summary of the characterised and identified radioactive residues is presented in Tables 30 and 31.

Rice

The metabolism of pymetrozine in paddy rice following foliar treatment was investigated using [pyridine-5-¹⁴C]-pymetrozine (Sandmeier, 1994, PYMET_029) and [triazine-6-¹⁴C]-pymetrozine (Sandmeier, 1994, PYMET_030). The rice plants grown in containers with paddy water were treated once with a foliar application equivalent to 0.25 kg ai/ha 45 days before harvest. Samples of rice foliage were taken 19 days (approx. 75% maturity), and samples of grains, husks and straw 45 days after application (full maturity).

The homogenised samples were extracted with methanol/water five times. The combined extracts were used for TLC analysis. After cold extraction a hot microwave extraction with 1-propanol/water (80:20) was performed. Besides the TLC with various solvent systems the Liquid Chromatography with different columns was used. Total radioactive residue were measured by combustion and LSC.

TRR levels found in the samples were present at comparable concentrations for both labels. In the foliage 1.72–2.09 mg eq/kg were found. In the grain and in straw TRR levels were 0.137–0.243 mg eq/kg and 5.31–6.34 mg eq/kg, respectively. Husks contained 0.57–1.7 mg eq/kg, but were not further analysed for the composition of the residue.

The identification of the radioactivity revealed unchanged pymetrozine as the major residue in foliage (86–89% TRR) and in straw (63–74% TRR). No other major metabolites were found. In the grain the unextracted residue was high, representing 63–86% of the TRR. No further characterisation of the unextracted residue was conducted. Most of the radioactivity identified for the pyridine-label was present as CGA180777 and its conjugates (6.7% TRR each). For the triazine-label only minor metabolites were found (< 2.3% TRR each).

A summary on the TRR levels found in the samples and on their composition is presented below.

For the granular application of pymetrozine to paddy rice two studies were conducted using [pyridine-5-¹⁴C]-pymetrozine (Sandmeier, 1995, PYMET_031) and [triazine-6-¹⁴C]-pymetrozine

(Sandmeier, 1995, PYMET_032). Two weeks old rice plants in a small seedling box were treated with 5% granules (GR 5) at application rates corresponding to 0.6 kg ai/ha. One day after application the seedlings (including the soil) were transferred into six containers. Foliage was sampled 1, 41 (25% maturity) and 69 days (50% maturity) after application, and grains, husks and straw 116 days (maturity) after application. Samples were analysed within two months after sampling.

The extraction of samples was made with methanol (80%). After the cold extraction a hot microwave extraction in 1-propanol was performed. The extracts were used for TLC, liquid chromatography and hydrolysis or enzymatic cleavage. Unextracted residues in straw were further addressed by means of acidic microwave extraction (n-propanol/ 0.1 N HCl, 80:20), further residue hydrolysis by boiling 2 N NaOH and subsequent extract acidification and concentration to precipitate the lignin fraction. TLC analysis was performed with the extracts. In grain, unextracted radioactivity was released with 0.05 N NaOH. After neutralisation and precipitation of protein/starch with ethanol, the resulting extract was subjected to TLC analysis after evaporation and solubilisation in methanol/water. Remaining unextracted radioactivity was determined by combustion.

Total radioactive residues were highest in foliage directly after treatment with 33.15–42.4 mg eq/kg, but declined to 0.72–0.82 mg eq/kg within 69 days. At harvest dry straw gave TRR levels of 2.59–2.63 mg eq/kg. In the grain the radioactivity was much lower (0.205–0.523 mg eq/kg).

The identification of the residues showed unchanged parent as the major residue only in foliage directly after application (37.6–59.7% TRR). In all other samples pymetrozine was present at low amounts not exceeding 8.3% of the TRR. The pyridine-label specific metabolites CGA96956 and CGA180777 including its glucose-conjugate were the major residues identified. Following application of the triazine-labelled pymetrozine no major metabolites were found.

For both labels a major part of the radioactivity remained unextracted, representing 40–50% TRR in straw and 56–86% TRR in the grain. The characterisation of the unextracted radioactivity revealed incorporation into glucose and related natural components like starch.

A summary of the radioactive residues found and their composition is presented below.

Cotton

The investigation on the metabolism of pymetrozine in cotton under glasshouse conditions was reported in two studies by Gentile (1995, PYMET_033 and 1996, PYMET_034). [Pyridine-5-¹⁴C] or [triazine-6-¹⁴C] pymetrozine formulated as WP 25 product were applied twice with over-the-top spraying involving application rates equivalent to 0.2 kg ai/ha per treatment. The applications were performed with one week intervals ending directly before blooming of the plants.

One hour after each application leaf samples were collected. At green boll stage, 52 days after the second application, bolls and leaves were taken. At maturity, 93 days after the second application, each plant was separated into old-leaves, new leaves, stems, hulls, fibres and seeds.

Each of the plant parts collected after 93 days were homogenised and five times extracted with methanol-water. Enzymatic cleavage (overnight with cellulase) of the methanolic seeds extract was performed. The combined extracts were used for parent and metabolite quantification by 1-dimensional or 2-dimensional TLC. After the cold extraction a soxhlet extraction with methanol was performed. The non-extractable radioactivity was determined by combustion. The analytical procedure was identical for all plant parts except seeds for which the ground material was first extracted twice with hexane to remove oil. Unextracted radioactivity of new-leaves, fibres and seeds was further extracted with 2 N HCl. The released radioactivity was derivated (methylation and acetylation) and analysed by PEI-cellulose- and silica gel-TLC.

Identification of the radioactivity in the samples collected after 93 days revealed pymetrozine as the major residue in leaves, stems, hulls and the extracted oil. In addition CGA96956 was a major residue in most matrices being present at levels up to 50% of the TRR in the seeds. The oil extraction showed that it remains in the seed meals and is not present in oil. A summary of the residues found in cotton is presented in Tables 35 and 36.

Figure 4 Proposed metabolic pathway of pymetrozine in plants

Environmental fate in soil

For the investigation of the environmental fate of pymetrozine the Meeting received studies on hydrolysis and the behaviour in confined and field rotational crops.

In buffer solutions pymetrozine is quickly degraded within hours to days at pH values below 7. The main degradation product was CGA215525.

In confined rotational crop studies conducted at rates equivalent to 0.41 kg ai/ha pymetrozine was only found in traces. Major metabolites found were CGA96956, CGA266591 and GS23199, mostly conjugated with glucose.

In field rotational crop studies conducted with four applications of 0.1 kg ai/ha each for tomato, lettuce or peppers, no detectable residues of pymetrozine or GS23199 were found (LOQ: 0.02 mg/kg).

Hydrolysis

The stability of pymetrozine in sterile buffer solutions was investigated using [pyridine-5-¹⁴C]-pymetrozine (Kirkpatrick, 1995, PYMET_036) and [triazine-6-¹⁴C]-pymetrozine (McDonald, 1996, PYMET_037).

For the pyridine-label buffer solutions at pH 1, 5, 7 and 9 were incubated at 25 °C for up to 35 days. The concentrations used were 5 mg pymetrozine per litre. Total recovery rates of the applied radioactivity were always near 100%.

The samples incubated at 25 °C the nature of the radioactive residues were further investigated. CGA300407 was the only identified degradation product.

The triazine-label aqueous buffered solutions with pH 1, 5, 7 and 9 were incubated at 25, 50 and 70 °C. The nominal concentration of pymetrozine in all buffered solutions was 5 mg/L. Samples were collected at day zero and varying intervals up to 30 days.

Total recovery rates of the applied radioactivity were always near 100%. However, the proportion of the parent substance declined depending on the pH and the incubation temperature.

Confined rotational crop studies

For the investigation of pymetrozine in rotational crops several plots were conducted in the USA by Fleischmann (1998, PYMET_035). Each plot received one treatment to the bare soil of either [pyridine-5-¹⁴C]- or [triazine-6-¹⁴C]-pymetrozine at rates equivalent to 0.41 kg ai/ha. Wheat, radish and mustard were planted in the treated soil 30, 60, 95, 122 and 361 days after test substance application.

Total radioactive residues (TRR) in plant samples were determined by radiocombustion/LSC. Samples were extracted with acetonitrile:water (4:1 v/v) or methanol:water (4:1 v/v). Homogenates were filtered and the filter cake re-extracted at least 2× with solvent. Total extractable radioactivity was determined by summing the radioactivity in the combined filtrates and unextracted radioactivity in the residue was determined by combustion/LSC.

Acetonitrile:water extracts were cleaned-up on C₁₈ SPE cartridges. After concentration, solubilised residues were partitioned between water and water-immiscible solvents. Selected liquid and solid samples were treated with glucosidase, cellulase or cellulase/cellobiase in acetate buffer, with 0.1 M to 6 M HCl under reflux, or with acetylating or methylating agents for component characterisation and identification.

The post-extraction solids were sequentially subjected to neutral solvent reflux, 1% sodium chloride reflux, cellulase/cellobiase treatment, dilute acid reflux, dilute base reflux, strong acid reflux and strong base reflux to further characterise the extracted radioactivity.

Total radioactive residues in edible commodities at their respective harvest intervals were in the range of 0.018–0.049 mg eq/kg (wheat grain), 0.025–0.133 mg eq/kg (mustard leaves) and 0.026–0.061 mg eq/kg (radish tubers) for [triazine-6-¹⁴C]-pymetrozine and of 0.036–0.109 mg eq/kg (wheat grain), 0.011–0.053 mg eq/kg (mustard leaves) and 0.014–0.042 mg eq/kg (radish tubers) for [pyridine-5-¹⁴C]-pymetrozine.

In potential feed items residues were 0.047–0.48 mg eq/kg and 0.021–0.228 mg eq/kg in wheat forage and fodder for triazine-6-¹⁴C]- and [pyridine-5-¹⁴C]-label, respectively.

DAA = Days after application

The identification of the radioactive residues in wheat revealed only minor levels of pymetrozine present in forage and fodder after application of the triazine-label (0.003–0.01 mg eq/kg, 2.2–4.0% TRR). In grain sown after a 30 day plantback interval CGA96956 was the only major metabolite detected (0.013 mg eq/kg, 16.1% TRR). No other metabolite exceeded a level of 0.01 mg eq/kg or 10% TRR for both labels.

Following application of the triazine-label major residues in forage and fodder were CGA96956 (up to 0.021 mg eq/kg, 31.7% TRR) and CGA180777 including its glucose-conjugate (up to 0.016 mg eq/kg, 24% TRR). For the triazine-label CGA266591 and GS23199 and the glucose-conjugates of both represented major residues in forage and fodder.

^a G7—mixture of a glycoside of CGA266591 (G7b) and a glycoside of a 1,2,4-triazine-3-one-6-carboxylic acid (G7a)

In mustard the identification of radioactive residues showed only traces of unchanged pymetrozine (0.001–0.003 mg eq/kg).

Following application of the pyridine-label, no identified residue exceeded a level of 0.01 mg eq/kg. Major residues were CGA180777 including its glucose conjugate (up to 0.008 mg eq/kg, 16.7% TRR) and CGA180778 (up to 0.004 mg eq/kg, 17% TRR).

After treatment with triazine-labelled pymetrozine the glucose conjugate of GS23199 was the major residue for the 30d plant-back interval (0.05 mg eq/kg, 37.5% TRR) and the 361 d plant-back interval (0.008 mg eq/kg, 13.5% TRR). After a plant-back interval of 122 d the glucose conjugate of CGA266591 (0.024 mg eq/kg, 33.7% TRR) and CGA266591 itself (0.006 mg eq/kg, 8.2% TRR) were the major residues.

In radish the composition of the radioactivity was comparable to the other crops investigated. Unchanged pymetrozine was only present in traces (< 0.001–0.006 mg eq/kg, up to 4.6% TRR). Major residues identified were CGA96956 (up to 0.005 mg eq/kg, 27.7% TRR) for the pyridine-label and as CGA266591-gluc. (up to 0.029 mg eq/kg, 28.9% TRR) and GS23199-gluc. (up to 0.032 mg eq/kg, 30.1% TRR) for the triazine-label.

Two additional study on the uptake of residues from soil were conducted by Gross (1995, PYMET_038) and Sandmeier (1993, PYMET_039). [Pyridine-5-¹⁴C]- or [triazine-6-¹⁴C]-pymetrozine were applied to bare soil at application rates equivalent to 0.5 kg ai/ha and 0.46 kg ai/ha, respectively. After selected plantback intervals (PBI) lettuce (PBI 36–63 d), wheat (PBI 91–106 d), sugar beets (PBI 285–307 d) and maize (PBI 285–307 d) were planted and grown to maturity.

Total radioactive residues in the samples were determined by combustion and LSC. Except for stalks of maize and wheat and wheat husks, which all contained no parent residues above the LOQ of the method (0.001–0.007 mg eq/kg), no identification of the radioactive residue was performed.

In the following table the TRR levels found are summarised.

Table 60 Total radioactive residues in rotational crops after application of 0.5 kg [pyridine-5-¹⁴C]- or 0.46 kg [triazine-6-¹⁴C]-pymetrozine per ha to bare soil

Crop	Description	[pyridine-5- ¹⁴ C]-pymetrozine			[triazine-6- ¹⁴ C]-pymetrozine

Figure 5 Proposed metabolic pathway of pymetrozine in rotational crops

Field rotational crop studies

In the USA (California, Florida and New York) four supervised field rotational crop studies have been performed by Joseph (1998, PYMET_040). Pymetrozine as a 50% WP formulation was applied four times at 7-day intervals to target crops of tomatoes, peppers, cucumbers and lettuce 0.1 kg ai/ha. Treated crops were harvested immediately after the final application and rotational crops wheat, turnips and lettuce were planted approximately 30 days after the final application and grown to maturity. All samples collected were analysed for parent pymetrozine and the metabolite GS23199.

Table 61 Residues of pymetrozine and GS23199 in rotational crops following foliar application of pymetrozine

RESIDUE ANALYSIS

Analytical methods

For pymetrozine, analytical methods were provided following a comparable pattern. The samples (plants and animals) are extracted using aqueous borate buffer/methanol or in case of fatty matrices n-hexane. After filtration and a clean-up with C18 SPE the residue is measured by HPLC-MS/MS with two specific mass transition for each analyte. All methods were validated with an LOQ of 0.01 mg/kg.

The applicability of multi residue methods was not investigated.

Plant materials

Method REM 154.09 (Crook, 2007, PYMET_041; Jones, 2012, PYMET_042; Amic, 2012, PYMET_043)

The analytical method REM 159.09 using HPLC-MS/MS was developed for the determination of pymetrozine in plant matrices with an LOQ of 0.01 mg/kg in high water content, acidic, high oil content and dry commodities.

Samples are extracted by homogenisation with aqueous borate buffer (pH 9)/methanol (24/1 v/v) for 3–5 minutes. Extracts are centrifuged for 5 minutes. For oilseed rape, 0.3 g C₁₈ silica is added to each aliquot (5 mL) and samples are shaken manually, vortexed and then centrifuged. Aliquots were transferred into appropriate vessels, evaporated to dryness and then reconstituted in 5 mM ammonium acetate solution. Final determination is performed by LC-MS/MS monitoring the m/z 218.1–105.1 for the primary transition and the m/z 218.1–78.2 for the confirmatory transition.

Table 64 Recovery data for method REM 159.09 in plant matrices (LC-MS/MS, m/z: 218.1 → 105.1 & m/z: 218.1 → 78.2)

Method REM 154.04 (Tribolet, 1995, PYMET_044; Tribolet, 1998, PYMET_045)

The analytical method REM 154.04 using HPLC-UV was developed for the determination of pymetrozine in plant matrices with an LOQ of 0.02 mg/kg in high water content, high oil content and dry commodities.

The crop matrix is extracted by homogenising and shaking with 0.05 M borate buffer (pH 9) and methanol. The extract is filtered and made to volume with methanol. An aliquot is diluted with borate buffer and evaporated to approximately 6 mL volume at 40 °C (high oil content crops are extracted with hexane at this stage). The extract is cleaned up on an SPE silica cartridge, and the eluate evaporated to dryness. The residue is taken up in acetone and cleaned up on a C₁₈ SPE column. The elute is evaporated to dryness and the residue reconstituted in water for analysis by HPLC with UV detection at 300 nm.

Method AG-643 (Joseph, 1996, PYMET_046; Mayer, 1996, PYMET_047; Joseph, 1999, PYMET_048)

The analytical method AG-643 using HPLC-UV was developed for the determination of pymetrozine in plant matrices with an LOQ of 0.02 mg/kg in high water content and high oil content commodities.

Crop matrix is extracted by shaking with 0.05 M borate buffer in methanol. The extract is diluted and an aliquot reduced in volume by evaporation. The extract is cleaned up on a diatomaceous earth SPE cartridge and then on a silica SPE cartridge. The eluate is reconstituted in mobile phase and analysed by HPLC with UV detection (300 nm).

Method GRM018.01A (Crook, 2007, PYMET_049)

The analytical method GRM018.01A using HPLC-MS/MS was developed for the determination of pymetrozine and CGA300407 in plant matrices with an LOQ of 0.005 mg/kg in high water content and acidic commodities.

The crop matrix is extracted with methanol:aqueous borate buffer pH 9 (36:4 v/v). The homogenate is filtered and the filtrate washed with methanol to give an extract concentration of 0.1 g/mL. The extract is evaporated under an air stream and the residue made up to 2 mL with 5 mM ammonium acetate. This final extract is analysed by LC-MS/MS for pymetrozine (m/z 218 $\rightarrow$ 105) and CGA300407 (m/z 108 $\rightarrow$ 80 & m/z 108 $\rightarrow$ 53) residues.

Method for rice (Wu, 2009; PYMET_050)

This specialised method was developed for data generation purposes in supervised field trials on rice. Parent pymetrozine is analysed by UPLC-MS/MS (m/z 218 → 105 & 218 → 79) with a LOQ of 0.001–0.005 mg/kg in dry matrices.

The crop matrix is extracted with methanol:aqueous borate buffer. The homogenate is filtered and the filtrate washed with methanol. The extract is evaporated by rotary evaporator. This final extract is analysed for pymetrozine residue by UPLC-MS/MS to an LOQ of 0.001–0.005 mg/kg (m/z 218 → 105 & 218 → 79).

Table 68 Recovery data for a specialised rice method (UPLC-MS/MS, m/z: 218 → 105 & m/z: 218 → 79)

Animal materials

Method GRM018.03A (Class, 2011, PYMET_051; Schwarz & Class, 2011, PYMET_052; Jones, 2012, PYMET_053)

The analytical method GRM018.03A using HPLC-MS/MS was developed for the determination of pymetrozine in animal commodities with an LOQ of 0.01 mg/kg in all tissues, eggs and milk.

Samples of milk, eggs, meat, liver and kidney are extracted by homogenisation with acetonitrile/water (9/1, v/v). Extracts are centrifuged and the supernatant is decanted. Sodium tetraborate solution (0.2 M) is added and the volume of the sample is made up to 100 mL with acetonitrile/water (9/1, v/v). The extract is purified using C₁₈-treated silica product and centrifuged. An aliquot of the resulting solution is taken, diluted in acetonitrile: ammonium acetate (1/4, v/v).

Samples of fat are dissolved in hexane and sonicated. The samples are then extracted with acetonitrile. Sodium tetraborate solution (0.2M) is added and the volume of the sample is made up to 50 mL with acetonitrile/water (9/1, v/v) prior to being frozen at -18 °C for 2 hours. The extract is then cleaned up using C₁₈-treated silica product and centrifuged. An aliquot of the resulting solution is diluted in acetonitrile/ ammonium acetate (1/4, v/v).

Final determination is performed by HPLC-MS/MS (m/z: 218 → 105 & m/z: 218 → 79).

Method GRM018.06A (Amic, 2011, PYMET_054; Jones, 2012, PYMET_053)

The analytical method GRM018.06A using HPLC-MS/MS was developed for the determination of CGA313124 and its phosphate conjugate in animal commodities with an LOQ of 0.01 mg/kg in all tissues, eggs and milk.

Samples are extracted by homogenisation twice with methanol/ultra pure water (90/10 v/v). Milk samples and whole blood samples are extracted for the first homogenisation with methanol only. Extracts are filtered and made up to a volume of 150 mL with methanol. An aliquot (30 mL) is then evaporated to an aqueous residue. Milk samples are then placed in an oven at 60 °C for 30 minutes. The extract is purified on a C₁₈ solid phase extraction (SPE) cartridge using methanol as the eluent. The eluent is collected and then evaporated to dryness. The dry extract is dissolved in methanol/ultra pure water (10/90, v/v), followed by final determination of the pymetrozine metabolite CGA313124 by LC-MS/MS (m/z 234.2 → 105.1 & 234.2 → 78.1).

Table 70 Recovery data for method GRM018.06A determining CGA313124 in animal matrices (LC-MS/MS, m/z: 234.2 → 105.1 & m/z: 234.2 → 78.1)

Method AG-644 (Joseph, 1996, PYMET_055; Wang, 1997, PYMET_056)

Method AG-644 was developed for the determination of pymetrozine in animal products (meat, fat, liver, kidney, milk and eggs) using HPLC-UV (300 nm).

The sample was homogenised twice with acetonitrile/water (9 + 1, v/v), followed by filtration and passing of the extract through a C₁₈ SPE cartridge. After addition of Borax buffer to the eluate, the solution is evaporated of solvent until only an aqueous phase remains. The analyte is partitioned into ethyl acetate on an Extrelut cartridge, followed by evaporation of the organic phase to dryness. Cleanup of residue is performed on a silica SPE cartridge, eluted with methanol. The final determination was performed by HPLC on a two-column switching system (column 1: CN; column 2: C₁₈ reversed phase) with UV-detection (300 nm).

Method AG-658 (Joseph, 1996, PYMET_057)

Method AG-658 was developed for the determination of CGA313124 in animal tissues (meat, fat, liver and kidney) and of CGA 313124 and its phosphate conjugate in milk using HPLC-UV (300 nm).

Samples are extracted by homogenisation twice with methanol/water (90/10 v/v). Milk samples are extracted for the first homogenisation with methanol only. Extracts are filtered and passed through a C₁₈ SPE cartridge. Methanol is then evaporated from the resultant extract. Milk samples are placed in an oven at 60 °C for 30 minutes. The aqueous extract is filtered using a phenyl SPE cartridge and the eluate is then diluted with water. A C₁₈ SPE cartridge is used to perform a solvent exchange into methanol before the methanol solution is evaporated to dryness. The analyte is dissolved in methylene chloride/methanol (90/10 v/v), followed by final determination of CGA313124 by HPLC with UV detection (300 nm).

Stability of pesticides in stored analytical samples

Plant matrices

Tribolet (1996, PYMET_058)

Samples of tomatoes, potatoes and cottonseed were separately fortified with pymetrozine at a nominal rate of 0.5 mg/kg. A sample of 2.5–2.8 kg was homogenised under addition of dry-ice to keep the sample frozen. During the homogenization a solution containing pymetrozine was added to reach the desired final concentration. The sample was split into sub-samples for storage.

Two sub-samples were taken and analysed for residues of the fortified material immediately following fortification. The results of these samples revealed an insufficient homogenization, resulting

in a recombination of all samples and further homogenization after 8 days. The rehomogenized samples were stored deep frozen below -18 °C for up to 24 months with duplicate sub-samples being taken at intervals of 1, 2, 4, 6, 12, 18 and 25/26 months and analysed for residues of pymetrozine.

Table 73 Recovered pymetrozine residues in stored plant commodities after storage up to 25 months

Tribolet (2001, PYMET_060)

Specimens of dried hops were individually fortified with pymetrozine and GS23199 at a rate of 5 mg/kg for each analyte. Three replicate specimens of each plant matrix were analysed at zero time and two replicate specimens of each plant matrix were removed after 0, 3, 6, 9 and 12 months storage at a nominal temperature of $\leq -18^{\circ}\text{C}$ and analysed. In parallel analysis of two freshly prepared fortified specimens was performed on each date of analysis.

Schulz (2011, PYMET_061)

Samples of peach (fruit without stone), melons, cucumber, lettuce and oranges were homogenized under addition of dry ice and separately fortified with pymetrozine at a nominal rate of 0.5 mg/kg. Two sub-samples were immediately taken and analysed for residues of pymetrozine. The remaining samples were stored deep frozen at approximately -18 °C for up to 24 months with duplicate sub-samples being taken at intervals and analysed for residues.

Table 76 Recovered pymetrozine residues in stored plant commodities after storage up to 24 months

Animal matrices

Boyette (1998, PYMET_063)

Samples of beef muscle, beef liver and milk were separately fortified with pymetrozine or CGA313124 at a nominal rate of 0.2 mg/kg. Two sub-samples were immediately taken and analysed for residues of the fortified materials. The remaining samples were stored deep frozen at approximately -20 °C for up to 18 months with duplicate sub-samples being taken at intervals and analysed for residues.

Table 78 Residues of pymetrozine and CGA313124 in animal commodities after storage at -20 °C

USE PATTERN

Pymetrozine is a systemic neuroactive insecticide; however, its mode of action in the nervous system is unknown. It is used in a large variety of fruit and vegetable crops, oilseeds and rice against aphids and other suckling insects close to harvest.

Table 79 List of uses of pymetrozine

^a The group includes: (Arracacha, Arrowroot, Bean yam, Cassava, Chayote, Chinese artichoke, Chufa, Dasheen, Edible canna, Ginger, Jerusalem artichoke, Leren, Sweet potato, Tanier, Yam, Turmeric)

Residues resulting from supervised trials on crops

Residue levels were reported as measured. Application rates were always reported as pymetrozine equivalents. When residues were not detected they are shown as below the LOQ, e.g., < 0.01 mg/kg. Application rates and spray concentrations have generally been rounded to two significant figures. HR and STMR values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. These results are underlined.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for % recovery.

Pymetrozine—supervised residue trials

+adj. = With adjuvant

DAT = Days after last treatment

BBCH 18 8 = True leaves unfolded

BBCH 41 = Heads begin to form: the two youngest leaves do not unfold

BBCH 42 = 20% of the expected head size reached

BBCH 43 = 20% of the expected head size reached

BBCH 47 = 70% of the expected head size reached

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of residue during processing

The hydrolysis of pymetrozine under processing conditions was investigated by Morgenroth (1999, PYMET_170). [Pyridine-5-¹⁴C]pymetrozine was incubated in aqueous buffer solutions at a nominal concentration of 5 mg/L under three sets of conditions, each designed to simulate an appropriate process: 90 °C (pH 4, 20 minutes) to simulate pasteurisation, 100 °C (pH 5, 60 minutes), to simulate boiling, baking and brewing, and 120 °C (pH 6, 20 minutes) to simulate sterilisation.

Total recovered radioactivity was measured for each test solution. Radioactive components were characterised by fractionation and co-chromatography with authenticated reference compounds using HPLC, TLC and identities were confirmed by HPLC/MS.

Table 109 Hydrolysis of pymetrozine under simulated processing conditions

Compound	Concentration (% of applied radioactivity)								
	pH 4, 90 °C, 20 min (pasteurisation)			pH 5, 100 °C, 60 min (boiling, baking, brewing)			pH 6, 120 °C, 120 min (sterilisation)		
	1	2	Mean	1	2	Mean	1	2	Mean
Pymetrozine	66.4	66.9	66.6	57.6	57.7	57.6	93.3	93.2	93.2

Total	100	99.3	99.6	99.9	99.5	99.7	99.4	99.2	99.2

Residues after processing

The fate of pymetrozine during processing of raw agricultural commodity (RAC) was investigated in tomatoes and sweet peppers using important processing procedures. As a measure of the transfer of residues into processed products, a processing factor was used, which is defined as:

$$\text{Processing factor (Pf)} = \frac{\text{Residue in processed product (mg/kg)}}{\text{Residue in raw agricultural commodity (mg/kg)}}$$

If residues in the RAC were below the LOQ, no processing factor could be derived. In case of residues below the LOQ, but above the LOD in the processed product, the numeric value of the LOQ was used for the calculation. If residues in the processed product were below the LOD, the numeric value of the LOQ was used for the calculation but the PF was expressed as “less than” (e.g. < 0.5).

All samples were analysed within the maximum storage interval identified for tomatoes (6 months) and peppers (one month).

A summary of all processing factors for pymetrozine relevant for the estimation of maximum residue levels of the dietary intake is given in Table 113.

Tomato

A study on the behaviour of pymetrozine during processing of tomatoes was conducted by Gasser (2002, PYMET_171). Protected tomatoes grown in Switzerland were treated three times with 0.9 kg pymetrozine/ha. Samples were harvested 3 days after the last application. Tomatoes were used for the production of washed tomatoes, tomato juice, tomato puree and canned tomatoes. One full mass balance study was conducted to determine the accountability of the residue, and two follow-up studies were conducted to determine residue transfer into the processed commodities.

- The washed tomatoes were produced by washing for 2 minutes in cold running water.
- Tomato juice was produced by quartering and blanching the washed tomatoes followed by sieving to remove the peel and seeds (wet pomace). The raw juice was pasteurised (20 minutes at 99 °C).
- Tomato puree was produced by concentrating raw juice to approximately 30% dry matter and then pasteurising (20 minutes at 93–95 °C).
- Canned tomatoes were produced by blanching washed tomatoes to remove the peel. The peeled tomatoes and portion of tomato juice from the juicing process were then sterilised in tins.

Table 110 Summary of pymetrozine residues in tomato and processed commodities from a trial conducted in Switzerland

Commodity	Residues (mg/kg)			Processing factors (mean)
	Balance 1	Follow-up 1	Follow-up 2

Puree after pasteurisation	< 0.02	< 0.02	< 0.02	< 0.03, < 0.03, < 0.03 (< 0.03)
Canned tomato production				
Unprocessed fruit	0.58	–	–	–
Peeled fruit	< 0.02	–	–	< 0.03
Peels	0.06	–	–	0.1
Waste water	< 0.02	–	–	< 0.03
Sterilised canned fruit	< 0.02	< 0.02	< 0.02	< 0.03, < 0.03, < 0.03 (< 0.03)

A total of three additional follow-up studies on tomatoes were conducted, two by Joseph (1996, PYMET_172 ,PYMET_173, PYEMT_174 & PYMET_175) in the USA and one by Tribolet (1999, PYMET_176) in Switzerland.

In the US trials tomatoes were processed according to common commercial practice. A flow-chart of all processing steps involved is presented in Figures 6 and 7. Samples of pomace (wet, dry), puree, juice and canned tomatoes were analysed for residues of pymetrozine and GS23199.

Figure 6 Processing of tomatoes—Part 1

Figure 7 Processing of tomatoes—Part 2

In the follow-up study in Switzerland conducted by Tribolet field tomatoes were sprayed three times with application rates of 0.45 kg ai/ha each. The tomatoes were processed into washed fruits, peeled fruits, preserves, paste and juice on laboratory scale.

For peeled tomatoes the peel was removed with a knife after heating in lukewarm water.

For juicing, 10% water were added and the mixture was boiled for 2–3 minutes. After passing through a strainer the raw juice was collected. The juice was pasteurised before canning.

Tomato paste was also prepared by adding 10% water and boiling for 2–3 min. After passing through a strainer, the juice was concentrated to 27% dry weight, filled into cans and pasteurized.

For tomato preserves peeled fruits (see above) were filled into cans and approximately the same amount of tomato juice was added. The cans were closed and pasteurized at 94 °C.

A summary of all residues and the resulting processing factors for processed tomatoes is presented below:

Table 111 Summary of follow-up studies involving processing of tomatoes

Sweet pepper

The influence of processing to pymetrozine residues in sweet peppers was investigated by Gasser (2003, PYMET_177). Protected peppers grown in Switzerland were treated three times with 0.54 kg pymetrozine/ha. Samples were harvested 3 days after the last application. Peppers were used for the production of washed fruit, cut fruit and cooked fruit.

The washed peppers were produced by washing for 2 minutes in a vessel using cold running water.

Cooked fruit was produced by removing seed and the inner waste portion from the washed peppers, quartering the fruit and cooking in water for 15 minutes at 98–100 °C.

In the following table the residues found and the corresponding processing factors are summarised:

Table 112 Processing of sweet peppers following application of 3×0.45 kg pymetrozine/ha

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

For the estimation of residues of pymetrozine and its metabolite CGA313124 in animal matrices a lactating cow feeding study was submitted to the Meeting.

Lactating cows

Residues in lactating cows were investigated by Joseph (1997, PYMET_178, PYMET_179 & PYMET_180). Eleven lactating Holstein dairy cows (*Bos taurus*; three cows/treatment group, one control cow) were dosed orally, via capsule, for 28 consecutive days with pymetrozine with either 0 ppm (control, 0×), 1 ppm (1× dose group), 3 ppm (3× dose group), or 10 ppm (10× dose group).

Milk was collected twice daily. On day 29 after the administration of the first dose, the animals were sacrificed and liver, kidney, round and tenderloin muscle and omental and perirenal fat were collected for analysis. For the depuration group (10×), milk for analysis was additionally sampled during the depuration phase. The animals were sacrificed approximately 20–24 h after the final administration.

Tissue and milk samples were analysed for pymetrozine and CGA313124 residue by methods AG-644 (LOQ: 0.01 mg/kg) and AG-658 (LOQ: 0.01 mg/kg) described in the analytical methods section. The samples were stored deep-frozen before analysed for 10–12 months.

In the following table the residues of pymetrozine and CGA313124 in milk and tissues are summarized. In the control animal no detectable residues of pymetrozine or CGA313124 were found:

Table 114 Residues of pymetrozine and CGA313124 in cow tissues and milk following administration of pymetrozine at 1, 3 and 10 ppm in the diet

APPRAISAL

Pymetrozine is a pyridine azomethine insecticide used to control homopteran insects (aphids and whiteflies) as well as pollen beetle selectively. Although it has no knockdown effect, pymetrozine rapidly affects the feeding behaviour of the insect pests. It was considered for the first time by the 2014 JMPR for toxicology and residues.

The IUPAC name of pymetrozine is (E)-4,5-dihydro-6-methyl-4-(3-pyridylmethyleneamino)-1,2,4-triazin-3(2H)-one.

The pymetrozine molecule contains a double bond about which E/Z isomerism is possible. However, pymetrozine technical material is manufactured by a process that yields almost exclusively the E isomer.

Pymetrozine labelled either in the pyridine- or triazine-moiety was used in the metabolism and environmental fate studies.

The following abbreviations are used for the metabolites discussed below:

CGA128632	3-pyridinemethanol	
CGA180777 (nicotinic acid)	3-pyridinecarboxylic acid	
CGA180778 (nicotinamide)	3-pyridinecarboxamide	
CGA313124	4,5-dihydro-6-hydroxymethyl-4-[(3-pyridinyl-methylene)amino]-1,2,4-triazine-3(2H)-one	
U5/I _{A2}	4,5-dihydro-6-carboxy-4-[(3-pyridinyl methylene)-amino]-1,2,4-triazine-3(2H)-one	
I _{A7}	4,5-dihydro-6-methyl-4-[(3-(1-methyl-6-oxo-1,6-dihydropyridinyl)methylene)-amino]-1,2,4-triazine-3(2H)-one	
IA17	hydroxylated 3-pyridinecarboxaldehyde	
CGA259168	N-(4,5-dihydro-6-methyl-3,5-dioxo-1,2,4-triazine-4(2H)-yl)-acetamide	
CGA294849	4-amino-6-methyl-1,2,4-triazine-3,5(2H,4H)-dione	
CGA96956 (trigonelline)	1-methyl-3-pyridinecarboxylic acid	

GS23199	6-methyl-1,2,4-triazine-3,5(2H,4H)-dione	
CGA359009	4,5-dihydro-5-hydroxy-6-methyl-4-[(3-pyridinylmethylene)-amino]-1,2,4-triazine-3(2H)-one	
CGA215525	4-amino-6-methyl-1,2,4-triazine-3(2H)-one	
CGA300407 (nicotinealdehyde)	3-pyridinecarboxaldehyde	
CGA266591	2,3,4,5-tetrahydro-3,5-dioxo-1,2,4-triazine-6-carboxylic acid	

Animal metabolism

Information was available on metabolism of pymetrozine in laboratory animals, lactating goats and laying hens.

In the rat the extent of oral absorption is high (> 80%), based on urinary and biliary data. Pymetrozine is widely distributed in the body. High concentrations of both triazine- and pyridine-labelled material were found in the liver and kidney. The labelled material was rapidly excreted via urine (50–75% in 24 hours). Absorbed pymetrozine was extensively metabolized, with unmetabolized parent compound representing approximately 10% of the excreted radiolabel. Compounds containing both ring structures represented over 50% of the identified metabolites. The kinetics, excretion pattern, tissue distribution of radioactivity and metabolite profile were similar for both radiolabelled sites and administered dose levels as well as when the administration of radiolabelled pymetrozine was preceded by 14 days of administration of the unlabelled material (see WHO Monograph).

One study on the metabolism in lactating goats was available for each of the labels. Over four consecutive days the goats received daily doses of radiolabelled pyridine-¹⁴C- or triazine-¹⁴C-pymetrozine at rates equivalent to 7.5 ppm (0.39 mg/kg bw) or 10 ppm (0.54 mg/kg bw) in the diet, respectively. In both studies approximately 5-6% of the total dose was recovered from milk or tissues of the animals. Most of the administered radioactivity was recovered in faeces (15–17%) and urine (47–52%).

Following application of pyridine-¹⁴C-pymetrozine highest TRR levels were found in liver (1.5 mg eq/kg), kidney (0.72 mg eq/kg) and milk (0.33 mg eq/kg). Into muscle (0.068 mg eq/kg) and fat (0.027 mg eq/kg) the overall transfer of radioactivity was minor.

Parent pymetrozine was identified in all tissues and milk, however only in muscle (11% TRR) the contribution to the TRR was more than 10 %. In tissues nicotinamide (CGA180778), which is

formed by cleavage of the parent substance, was the major residue representing 44% TRR in muscle, 24% TRR in fat, 37% TRR in liver and 27% TRR in kidney.

In most tissues CGA313124 (pymetrozine-hydroxy) was also a major metabolite identified with levels of 10% TRR in muscle and 11% TRR in kidney. In milk, CGA313124 (36% TRR) and its phosphate conjugate (39% TRR) were the only major metabolites identified. In addition, I_{A17} was present in liver at 10% of the TRR.

For the triazine-¹⁴C-label again highest TRR levels were found in liver (1.1 mg eq/kg), kidney (0.57 mg eq/kg) and milk (0.45 mg eq/kg). Muscle (0.047 mg eq/kg) and fat (0.098 mg eq/kg) contained lower residues.

Unchanged pymetrozine was again found in all tissues and milk, but only in muscle as a major residue representing 10% of the TRR. In tissues CGA313124 was the dominant residue found in levels of 9.5% TRR in muscle, 25% TRR in fat, 5% TRR in liver and 15% TRR in kidney. In kidney 5U/I_{A2} was another major metabolite present at 12% of the TRR. Several triazine-based cleavage products were identified, however at individual levels below 10% TRR each.

In milk, again CGA313124 (40% TRR) and its phosphate conjugate (41% TRR) were the only major metabolites identified.

For laying hens groups of hens received daily doses of [pyridine-¹⁴C]-pymetrozine or [triazine-¹⁴C]-pymetrozine at rates equivalent to approximately 10 ppm for four consecutive days (0.79 mg/kg bw). The animals were sacrificed ca. 6 hours after the last dose. Approximately 0.4–1.3% of the total dose in both studies was recovered from eggs or tissues of the animals. Most of the radioactivity administered was found in the excreta (76–81% AR). Total radioactive residues were 0.006–0.016 mg eq/kg in eggs, 0.021–0.043 mg eq/kg in muscle, 0.019–0.024 mg eq/kg in fat, 0.16–0.54 mg eq/kg in kidney and 0.11–0.99 mg eq/kg in liver. For both labels parent pymetrozine was found in very low levels, not exceeding 5% of the TRR. In meat, fat and eggs yolk it was below the LOQ of the method or was undetected.

Following administration of the pyridine-¹⁴C-label, nicotinamide (CGA180778) was the major residue in meat (77% TRR), skin + fat (63% TRR), egg white (28% TRR) and liver (70% TRR). In kidney, nicotinic acid (CGA180777) was the major residue, representing 65% of the TRR. Further major metabolites identified were I_{A7}, present at levels of 17% TRR in skin + fat, 15% TRR in egg white and 13% TRR in kidney as well as CGA300407 with 11% TRR in egg white.

For the triazine-¹⁴C-label CGA259168 was the major residue in meat (39% TRR), skin + fat (24% TRR), egg white (45% TRR), egg yolk (13% TRR) and kidney (11% TRR). I_{A7} was mainly found in kidney (49% TRR), followed by liver (27% TRR), skin + fat (22% TRR) and egg white (11% TRR). The only other major metabolite found was CGA294849 present in meat at levels of 11% of the TRR.

In summary pymetrozine is quickly degraded in goats and hens. A large quantity of the parent molecule is cleaved, resulting in formation of nicotinic acid (up to 65% TRR) and nicotinamide (up to 70% TRR) for the pyridine-moiety and several metabolites for the triazine-moiety. Another important metabolic step is the oxidation of the parent to CGA313124, which is found in most tissues and mainly in milk, including its phosphate conjugate (up to 40% and 41% TRR, respectively).

In goats, I_{A17} represented up to 10% TRR in the liver. In hen tissues, pymetrozine is also metabolised into I_{A7} (13–41% TRR in fat, egg white and kidney). Both metabolites were not identified in the rat.

Plant metabolism

The Meeting received plant metabolism studies for pymetrozine following foliar application of either [pyridine-¹⁴C]-pymetrozine or [triazine-¹⁴C]-pymetrozine to tomatoes (protected), potatoes, paddy rice and cotton (protected). For paddy rice, the metabolism following granular application was also investigated.

Following foliar application of [pyridine-¹⁴C]-pymetrozine to tomatoes at rates of 2×0.25 kg ai/ha, total radioactive residues in the fruits declined from 1 mg eq/kg (1h) to 0.23 mg eq/kg (7 days) and finally to 0.016 mg eq/kg 27 days after the last application. In the leaves corresponding TRR levels were 14 mg eq/kg (1 hour), 7.4 mg eq/kg (7 days) and 2.4 mg eq/kg (27 days).

In the samples collected directly after treatment (1 hour), pymetrozine located in the fruit and leaf surface was the dominant residue, representing 78% TRR and 60% TRR, respectively.

After 15 days, the pymetrozine surface residues declined to 5.9% TRR in the fruits and 16% TRR in the leaves. Most of the radioactivity was recovered in the extracts. In the fruits, trigonelline (CGA96956) was the only major residue representing 70% of the TRR. In leaves, trigonelline (26% TRR) and sugar conjugates of CGA128632 (23% TRR) were major residues besides the parent.

[Triazine-¹⁴C]-pymetrozine was applied to tomato plants with three foliar application with 0.47 kg ai/ha each. In the fruits collected (3, 7 and 14 days after treatment) TRR levels were 0.51–0.58 mg eq/kg. In the leaves TRR levels declined from 28 mg eq/kg (3 d) to 22 mg eq/kg (7 days) and finally to 17 mg eq/kg (14 days).

In all samples unchanged pymetrozine was the major residues, representing 32–57% TRR in the fruits and 31–50% TRR in the leaves. The only other major metabolite identified was CGA294849 present at levels of 14% TRR in fruits collected 14 days after harvest.

In the first study investigating the metabolism of pymetrozine in potatoes either [pyridine-¹⁴C]- or [triazine-¹⁴C]-pymetrozine were applied to potato plants with three foliar sprayings at rates of 0.15 kg ai/ha (low-dose) or 1.05 kg ai/ha (high-dose) each 61 days after planting. In the foliage samples collected after 7, 14 and 19 days TRR levels were 6.4–11.7 mg eq/kg following low-dose and 29–46 mg eq/kg following high-dose treatment. In the tubers TRR levels amounted 0.11–0.36 mg eq/kg (low-dose) and 0.34–1.1 mg eq/kg (high-dose).

For the [pyridine-¹⁴C]-label, trigonelline (CGA96956) was the major residue in tubers (7, 14 and 29 days after last treatment) representing 54–75% of the TRR. In addition, nicotinic acid (CGA180777) and its glycoside represented major residues present up to 22% of the TRR. Unchanged parent pymetrozine was detected in all samples, however its levels did not exceed 2.2% of the TRR. No further major metabolites were identified in the tubers.

In the foliage, unchanged pymetrozine was present at higher levels of up to 18% TRR in day 7 samples. The only major metabolite present was CGA128632 and its glycoside, representing 1.1–3.1% TRR and 9.5–18% TRR, respectively. The major part of the radioactivity in the foliage remained unextracted (54–70% TRR).

For the [triazine-¹⁴C]-label, neither parent (0.2–4.9% TRR) nor metabolites (up to 5.7% TRR) represented major residues in tubers. Most of the radioactivity was distributed into multiple minor fractions too low for identification. The foliage showed GS23199 (1.4–2.4% TRR) and its glycoside (7.6–16% TRR) as major residues. Parent pymetrozine was found in lower amounts of 6.3–10% of the TRR. Again, the amount of unextracted radioactivity in the foliage was high, representing 37–45% of the TRR.

In two additional studies either [pyridine-¹⁴C]- or [triazine-¹⁴C]-pymetrozine were applied to potato plants with two foliar sprayings at rates of 0.2 kg ai/ha each. In the leaves, residues declined from 9.5–11 mg eq/kg (1h after treatment) to 1.3–1.8 mg eq/kg (55 days, final harvest). Special investigation of radioactive residues in new leaves above or below the treated plant parts reveals approximately 3–4 times higher residues on the upper leaves than in the lower leaves. In tuber collected 55 days after the final application, TRR levels were 0.051–0.072 mg eq/kg.

The identification of the radioactivity in the tubers showed no pymetrozine above the LOQ of 0.001 mg eq/kg. The only major residues identified were nicotinic acid (CGA180777) and its glycoside for the pyridine-label (22 and 29% TRR, respectively) and GS23199 (11% TRR) and its glycoside (1.7% TRR) for the triazine-label.

In the foliage pymetrozine was the dominant residue directly after treatment (42–58% TRR). In samples collected after longer intervals, the radioactivity was distributed into several minor fractions mostly too low for identification. The only identified major metabolite was conjugated CGA128632 (up to 28% TRR) for the pyridine-label. Unextracted radioactivity in potato foliage averaged at 36% TRR for both labels.

Paddy rice was treated with either [pyridine-¹⁴C]- or [triazine-¹⁴C]-pymetrozine with one foliar treatment of 0.25 kg ai/ha 45 days before harvest. TRR levels found were 1.7–2.1 mg eq/kg in foliage (19 days after treatment), 5.3–6.3 mg eq/kg in straw and 0.14–0.24 mg eq/kg in grain (both samples 45 days after treatment).

The identification of the radioactivity in foliage and straw showed unchanged pymetrozine as the only major residue, representing 86–89 % TRR and 63–74% TRR, respectively.

In the grain no metabolites were identified exceeding 10% TRR. The parent substance was detected in all samples, however its levels were low (0.8–2.3% TRR). In the grain 63–86% of the TRR remained unextracted.

In addition paddy rice was treated with granules of [pyridine-¹⁴C]- or [triazine-¹⁴C]-pymetrozine at rates corresponding to 0.6 kg ai/ha to seedling boxes. Foliage was collected 1, 41 and 69 days later, grain husks and straw at maturity after 116 days.

Total radioactive residues were highest in foliage directly after treatment with 33–42 mg eq/kg and declined to 0.72–0.82 mg eq/kg after 69 days. At harvest dry straw contained TRR levels of 2.6 mg eq/kg. In the grain the radioactivity was much lower, representing 0.21–0.52 mg eq/kg.

In the foliage parent pymetrozine was the major residue directly after treatment (1 day, 38–60% TRR), but quickly declined to < 10% TRR in all other samples collected after a longer interval. In grain, pymetrozine was not found above the LOQ of 0.001 mg eq/kg (0.2% TRR).

Major metabolites identified in foliage and straw after application of pyridine-¹⁴C-pymetrozine were trigonelline (CGA96956) with 9.5–28% TRR and free and conjugated nicotinic acid (CGA180777) with a total of 17–26% TRR. For the triazine-¹⁴C-label no metabolites exceeding 10% of the TRR were identified except for CGA359009 (15% TRR) and GS23199 (17% TRR) in foliage samples one day after treatment.

Grain contained very few identified metabolites. The only major metabolites were trigonelline (CGA96956, 11% TRR) and free and conjugated nicotinic acid (CGA180777, 26% TRR). Most of the radioactivity in grain remained unextracted (56–86% TRR).

The metabolism of pymetrozine in cotton was investigated by application of either [pyridine-¹⁴C]- or [triazine-¹⁴C]-labelled active substance under glasshouse conditions. The plants were treated with two foliar spraying at rates equivalent to 0.2 kg ai/ha each. After 93 days samples of treated leaves (0.6–5.9 mg eq/kg), new grown leaves (0.03–0.2 mg eq/kg), stem (1.6–1.7 mg eq/kg), hulls (2.7–4.8 mg eq/kg) fibres (0.065–0.17 mg eq/kg) and seeds (0.043–0.21 mg eq/kg) were collected.

For the [pyridine-¹⁴C]-label unchanged pymetrozine was the major residue in all green plant parts, hulls and fibres, representing 28–83% of the TRR. The only metabolite exceeding 10% of the TRR in the plant was trigonelline (CGA96956, 0.6–23% TRR). In the seeds pymetrozine was detected at levels of 7.4–9% of the TRR. Most of the parent substance (35–58%) was found in cotton oil extracted from the seeds. The major residues in the seeds was trigonelline (CGA96956), representing 50% of the TRR.

For the [triazine-¹⁴C]-label only pymetrozine was present in major amount in the plant (28–66% TRR). Minor residues identified were CGA294849 and GS23199 (< 4% TRR each). In the seeds pymetrozine was present at TRR levels of 7.4%. On processing of seeds, 35% of the parent substance was recovered in the oil.

In summary pymetrozine is deposited on the plant surface and more or less quickly adsorbed. Unchanged parent represented 7.4–75% of the TRR in treated parts. In the plant tissue, the active substance is quickly degraded by cleavage, forming nicotinic acid, nicotinamide or trigonelline from

the pyridine-moiety. Additional major metabolites found were CGA359009 (rice: 15% TRR), GS23199 including conjugates (potato tuber: 13% TRR; potato foliage: 18% TRR; rice: 17% TRR) and CGA294849 (tomato fruits: 14% TRR).

CGA128632 including its conjugates, which were major metabolites in tomato foliage (23% TRR) and potato foliage (up to 36% TRR) were not identified in the rat.

Environmental fate in soil

The Meeting received information on the fate of pymetrozine under aqueous hydrolysis. In addition, the Meeting received information on the uptake and metabolism of pymetrozine in rotational crops under confined and field conditions.

Hydrolysis in aqueous buffer solutions revealed a moderate to quick decline of the parent under acidic conditions (pH5 or less) while samples at pH 7 and pH 9 were stable (> 90% remaining). The major degradation products identified were CGA300407 for the pyridine-label and CGA215525 for the triazine-label, which are formed by direct cleavage of the parent molecule.

Confined rotational crop studies on mustard greens, radish and wheat were conducted at rates equivalent to a soil application of 0.41 kg ai/ha using either [pyridine-¹⁴C]- or [triazine-¹⁴C]-pymetrozine. Plantback intervals were 30, 60, 90, 120 and 360 days. Total radioactive residues in edible commodities were in the range of 0.018–0.049 mg eq/kg (wheat grain), 0.025–0.13 mg eq/kg (mustard leaves) and 0.026–0.061 mg eq/kg (radish tubers) for [triazine-6-¹⁴C]-pymetrozine and of 0.036–0.11 mg eq/kg (wheat grain), 0.011–0.053 mg eq/kg (mustard leaves) and 0.014–0.042 mg eq/kg (radish tubers) for [pyridine-5-¹⁴C]-pymetrozine. In potential feed items TRR levels were 0.047–0.48 mg eq/kg and 0.021–0.23 mg eq/kg in wheat forage and fodder for [triazine-6-¹⁴C]- and [pyridine-5-¹⁴C]-label, respectively.

In all crop samples unchanged pymetrozine was found in minor amounts not exceeding 10% of the TRR. Highest concentrations were found in wheat forage (0.011 mg/kg) while all other matrices with detected residues gave concentrations between 0.001 mg/kg and 0.01 mg/kg.

In crops planted in soil treated with [pyridine-¹⁴C]-pymetrozine nicotinic acid incl. its glycoside (CGA180777, up to 24% TRR or 0.016 mg eq/kg), trigonelline (CGA96956, up to 32% TRR or 0.021 mg eq/kg), nicotinamide (CGA180778, up to 17% TRR, 0.005 mg eq/kg) and CGA-128632-glycoside (up to 11% TRR, 0.011 mg eq/kg) were found as major metabolites.

After application of [triazine-¹⁴C]-pymetrozine most of the radioactivity was represented by GS23199 and its glycosides (total up to 39% TRR or 0.056 mg eq/kg in wheat forage) or CGA266591 (up to 34% TRR or 0.027 mg eq/kg).

For longer plantback intervals, unextracted radioactivity increased ranging from 19–78% TRR.

Two additional studies investigating the uptake of total radioactive residues from the soil, either [pyridine-¹⁴C]- or [triazine-¹⁴C]-pymetrozine were applied to bare soil at rates equivalent to 0.5 kg ai/ha. Lettuce, wheat, sugar beet and maize were cultivated as succeeding crops after plantback intervals of 63, 91 or 307 days.

TRR levels found in the various matrices were low. In edible commodities TRR levels from all plantback intervals were between 0.002–0.01 mg eq/kg. In feed commodities TRR levels ranged up to 0.061 mg eq/kg in wheat straw.

Field rotational crop studies were conducted on four locations in the USA. Pymetrozine was applied to either tomatoes, peppers, cucumbers or lettuce at rates of 4 × 0.1 kg ai/ha (7 day interval). After 30 days the crop was destroyed and wheat, turnips or lettuce were planted as rotational crops. In all samples collected (mature and immature) no pymetrozine or GS23199 above their LOQ of 0.02 mg/kg were found. However, for GS23199 no hydrolysis step was conducted to release conjugates, which posed the main part of total GS23199 identified in confined rotational crop studies.

In summary the Meeting concluded that the transfer of residues into rotational crops is low. Parent pymetrozine is quickly degraded, not resulting in significant residues at harvest.

The metabolite GS23199, mainly present as sugar-conjugate, was the major residue in most samples (up to 39% TRR). Its concentrations ranged up to a maximum of 0.056 mg eq/kg in wheat forage. In edible commodities highest residues were found in mustard leaves amounting 0.008 mg eq/kg. Approximating the maximum seasonal application rate of 0.45 kg ai/ha based on the submitted GAPs and the involved interception of the treated crop, the Meeting concluded that no residues of GS23199 (including its sugar conjugate) above 0.01 mg/kg are expected in edible commodities obtained from rotational crops.

Other potential metabolites formed are either identical to naturally occurring substances (CGA180777 and CGA180778) or also present at levels below 0.01 mg/kg under confined conditions (e.g., CGA266591).

Methods of residue analysis

The Meeting received analytical methods for the analysis of pymetrozine in plant and animal matrices. The basic principle employs extraction by homogenisation with aqueous borate buffer/methanol or n-hexane with acetonitrile/water partitioning for fatty samples. The extracts were cleaned by C18 solid-phase extraction. Residues are determined by liquid chromatography (LC) in combination with tandem mass spectroscopy (MS/MS) or UV (300 nm). The methods submitted are suitable for measuring residues with a LOQ of 0.01 mg/kg (LC-MS/MS) to 0.02 (HPLC-UV).

In addition specialised methods using LC-MS/MS methods for measuring the metabolites CGA300407 (LOQ: 0.005 mg/kg, high water and acidic matrices) and CGA313124 (LOQ: 0.01 mg/kg, animal matrices) were submitted.

The application of multi-residue methods was not tested.

In-trial validation of the analytical methods submitted was achieved at LOQs of 0.001 mg/kg up to 0.05 mg/kg, depending on the matrix.

Stability of residues in stored analytical samples

The Meeting received information on the storage stability of pymetrozine in plant and animal matrices. In addition the storage stability of GS23911 was investigated in plant matrices and the storage stability of CGA313124 in animal matrices.

Plant matrices

In fortified samples, depending on the matrix, parent pymetrozine decomposes rather quickly. In different studies the following intervals were identified, which showed at least 70% of the initial pymetrozine concentration:

Oranges	at least 24 months
Peaches	up to 1 month
Tomato, fruits	up to 6 months
Tomato, paste	up to 6 months
Cucumbers	up to 2 months
Melons	at least 24 months
Lettuce	up to 1 month
Potatoes	up to 1 month
Cottonseed	at least 25 months
Cotton oil	at least 24 months

The Meeting noted that pymetrozine residues may degrade in stored samples, however the effect is strongly depending on the specific commodity. No reasons for the observed degradation could be identified. Due to the inconsistency within commodity groups (e.g., like for cucurbits), more data on the storage stability for each commodity is required.

One study investigating the storage stability of incurred residues in plant commodities was submitted involving re-analysis for stored samples after 8–13 months. However, since the initial analysis of the samples was performed after 9–14 months, which is longer than the maximum storage interval identified, the data was not considered appropriate to conclude on the overall stability of the residue.

Animal matrices

Definition of the residue

Nicotinic acid (CGA180777) and nicotinamide (CGA180778) were identified as major residues (up to 77% TRR) in livestock animals, however due to their natural occurrence (Vitamin B group) they are not suitable as a marker substance for enforcement purposes in animal commodities. Parent pymetrozine was present in all goat tissues, most hen tissues and eggs (for eggs triazine-label only), however only in low amounts up to 11% TRR. In milk no parent pymetrozine was found. Nearly the entire residue was identified as CGA313124 and its phosphate conjugate. The Meeting recognized that pymetrozine is strongly metabolized in livestock animals. However, being the only representative analyte in most commodities, the Meeting concluded that parent pymetrozine is a suitable marker for the purpose of MRL setting in animal tissues and eggs. For milk, the residue for enforcement purposes is defined as CGA313124. Analytical methods are capable of measuring pymetrozine in animal matrices and CGA313124 in milk at LOQs of 0.01 mg/kg each.

In hens tissues and eggs CGA259168 (up to 45% TRR), I_{A7} (up to 49% TRR) and CGA294849 (up to 11% TRR) were major residues present at concentrations up to 0.079 mg eq/kg at 10 ppm dose. Parent pymetrozine itself was a minor residue in all samples. CGA294849 was identified as a minor metabolite in hens muscle and liver, representing up to 9% of TRR. The Meeting concluded, that parent pymetrozine is a relevant residue for the dietary intake of poultry tissues and eggs.

The significance of the animal metabolites CGA245342, CGA294849, I_{A7} and I_{A17} was assessed with the TTC approach based on exposure levels related to the uses evaluated. Exposure to I_{A17} did not exceed the TTC value for chronic exposure of 0.0025 µg/kg bw per day (EMEA for genotoxic impurities) as well as the single-exposure TTC of 0.2 µg/kg bw. CGA245342 and I_{A7} gave estimated exposure levels below 1.5 µg/kg bw per day (Cramer Class III), respectively. Based on the assessed uses, these metabolites are not considered relevant for the dietary intake.

CGA294849 was also assessed with the TTC approach with the major part of the exposure resulting from plant commodities. CGA294849 has a structural alert for genotoxicity but has not been tested. Since the exposure assessment exceeded the applicable TTC values, no conclusion on the relevance of CGA294849 for dietary intake assessment can be made.

In all samples residue concentrations in fat tissues were in the same order of magnitude as in muscle tissues. The log P_{ow} of pymetrozine is < 0. The Meeting decided that residues of pymetrozine are not fat soluble.

In plants following foliar treatment, pymetrozine was the major residue in plant parts directly contacted, representing 28–89% of the TRR. The major degradation products in all matrices were either trigonelline (CGA96956) present at level between 9–70% of the TRR or nicotinic acid (CGA180777) present up to 26% TRR, depending on the label. The pyridine-cleavage product CGA128632 (including sugar conjugates) was a major metabolite in tomato fruits (11% TRR) and in tomato and potato foliage (up to 26% TRR). The counterpart for the triazine-moiety was identified as GS23199 (including sugar conjugates) representing 11–18% of the TRR in rice straw and potato foliage. The metabolic pattern in rotational crops was comparable to the degradation products identified in primary treated crops.

The Meeting concluded that pymetrozine is present in major amounts in most plant matrices and therefore qualifies as a marker substance for enforcement purposes. The major plant metabolites trigonelline (CGA96956) and nicotinic acid (CGA180777) occur naturally in plants and are unspecific markers for the residue. Analytical methods are capable of measuring pymetrozine in all plant matrices at a LOQ of 0.01 mg/kg.

For dietary intake purposes nicotinic acid (CGA180777) and trigonelline (CGA96956) add insignificantly to natural background levels. The Meeting noted that no metabolism study on leafy crops was submitted. In the foliage of tomatoes and potatoes used as a substitute, the cleavage products CGA128632 (up to 26% TRR) and GS23199 (up to 18% TRR) and their sugar conjugates were major residues. However, CGA128632 was not found in rats. In addition, CGA294849 was found in tomato fruit representing 7.4% TRR after 3 days increasing to 14% TRR after 14 days.

The Meeting also noted that pymetrozine may degrade under acidic food processing condition, resulting in the formation of CGA300407 (up to 42% TRR), based on hydrolysis data for pyridine-labelled active substance. The hydrolysis of triazine-labelled active substance conducted at pH5 (25 °C and 75 °C), showed CGA215525 as the major degradation product (up to 48% TRR). No data on hydrolysis under simulated processing conditions were submitted for the triazine-label.

Besides parent pymetrozine, which is a major residue in plant commodities and should to be taken into account for dietary intake assessment, the relevance of the plant metabolites GS23199, CGA128632 and CGA294849 as well as of the degradation products formed during processing (CGA215525 and CGA300407) was assessed with the TTC approach.

Based on the exposure levels (IEDI and IESTI) estimated for the uses evaluated, GS23199 (Cramer Class III) and CGA215525 (Cramer Class III) were not considered relevant for dietary intake.

CGA128632 has therapeutic uses as a vasodilator with a minimal therapeutic dose of 1 mg/kg bw. In view of the margin compared to the estimated exposure levels (> 1000 to the IEDI and > 50 to the maximum IESTI), CGA128632 is not considered a relevant metabolite of pymetrozine for dietary intake.

CGA294849 was also assessed with the TTC approach with the major part of the exposure resulting from plant commodities. CGA294849 has a structural alert for genotoxicity but has not been tested. Since the exposure assessment exceeded the applicable TTC values, no conclusion on the relevance of CGA294849 for dietary intake assessment can be made.

The processing degradate CGA300407 does not have a structural alert for genotoxicity but the Meeting was made aware that positive genotoxicity results, in vitro and in vivo, exist for this compound. No conclusion on the relevance of CGA300407 can be made.

If future uses for pymetrozine result in changes of the dietary intake, reconsideration on the relevance of metabolites in plant and animal matrices and after processing may become necessary.

Definition of the residue for compliance with MRL for plant commodities, mammalian tissues, poultry tissues and eggs: *pymetrozine*

Definition of the residue for compliance with MRL for milk: *CGA313124 (4,5-dihydro-6-hydroxymethyl-4-[(3-pyridinyl-methylene)amino]-1,2,4-triazine-3(2H)-one)*

Definition of the residue for dietary intake in plant and animal commodities: *a conclusion could not be reached*

The residue is not fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised trial data for applications of pymetrozine on various fruit and vegetables crops as well as for oilseeds and rice conducted in China, Europe and the USA.

The Meeting recognized that pymetrozine may degrade under freezer storage conditions. All supervised field trials exceeding the maximum storage interval identified for the specific commodities are not taken into account for the evaluation of GAPs and the resulting residues. In addition residues of pymetrozine were considered stable in all plant commodities for maximum storage period of one months.

Citrus fruits

Pymetrozine is registered in Portugal for the use on citrus fruit at rates of 1×0.01 kg ai/hL with a PHI of 21 days. Supervised field trials conducted in the Europe according to this GAP were submitted.

In lemons (whole fruits) residues of pymetrozine were (n=4): 0.02, 0.02, 0.03, 0.07 mg/kg.

In mandarins (whole fruits) residues of pymetrozine were (n=4): < 0.02, 0.02, 0.03, 0.03 mg/kg.

In oranges (whole fruits) residues of pymetrozine were (n=13): 0.006, 0.007, 0.01, 0.012, < 0.02, 0.02(4), 0.03, 0.04, 0.05 and 0.06 mg/kg.

The Meeting noted that pymetrozine is registered in Portugal for the whole citrus group. Supervised field trials on oranges, lemons and mandarins indicated no significant difference in the datasets (Kruskal-Wallis-Testing). Therefore the Meeting decided to extend its estimations on the whole group of citrus fruits based on the combined dataset from all three commodities:

Pymetrozine residues in citrus fruits (n=21): 0.006, 0.007, 0.01, 0.012, < 0.02, < 0.02, 0.02(7), 0.03(4), 0.04, 0.05, 0.06 and 0.07 mg/kg.

In the pulp (flesh) corresponding residues were (n=21): < 0.005(4) and < 0.02(17) mg/kg.

The Meeting estimated a maximum residues level of 0.15 mg/kg for pymetrozine in citrus fruit and a median and highest residue of 0.02 mg/kg in citrus pulp.

Pome fruit

Pymetrozine is registered in Italy for the use on apples and pears at a rate of 1×0.25 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in Italy according to this GAP were submitted.

However, the Meeting noted that for pome fruit no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability in pome fruits is required to assess the validity of the supervised field trials.

Apricot

Pymetrozine is registered in Belgium for use on apricots at the rate of 2×0.1 kg ai/ha with a PHI of 21 days. Supervised field trials were conducted in Europe at rates of 3×0.25 kg ai/ha.

The supervised field trials submitted for apricots were all conducted as decline studies. Since the active substance almost completely degraded within the 21 days investigated, the Meeting concluded that the additional treatment in comparison to the GAP from Belgium has no influence on the residue concentrations at harvest, allowing the use of the proportionality approach to adjust for the higher application rates involved.

Pymetrozine residues in apricots treated with 3×0.25 kg ai/ha were (n=4): $< 0.01(3)$ and 0.01 mg/kg.

Under consideration of a proportionality factor of 0.4 (0.1 kg ai/ha divided by 0.25 kg ai/ha), scaled residues were (n=4): 0.004 and $< 0.01(3)$ mg/kg.

Based on scaled residues from Europe, the Meeting estimated a maximum residues level of 0.01 mg/kg and a median and highest residue of 0.01 mg/kg for pymetrozine in apricots.

Peach and nectarines

Pymetrozine is registered in Spain for the use on peach and nectarines at the rate of 2×0.25 kg ai/ha with a PHI of 14 days. Supervised field trials were conducted in Europe at rates of 3×0.25 kg ai/ha.

The supervised field trials submitted for peaches were all conducted with one additional application compared to the GAP. However, taking into account low residues in samples analysed directly before the final treatment and the results from decline studies on peaches, the Meeting concluded that the additional treatment does not add significantly to the residue concentrations at harvest.

Pymetrozine residues in peach (n=6): $< 0.01(4)$, 0.04, 0.04 mg/kg.

Based on the dataset on peach the Meeting estimated a maximum residues level of 0.07 mg/kg, a median residue of 0.01 mg/kg and a highest residue of 0.04 mg/kg for pymetrozine in peach. The Meeting decided to extrapolate the estimations also to nectarines.

Strawberries

Pymetrozine is registered in Belgium for the use on field and protected strawberries at the rate of 3×0.2 kg ai/ha with a PHI of 3 days. Supervised field trials conducted in United Kingdom matching the GAP were submitted.

Pymetrozine residues in field strawberries were (n=2): 0.02 and 0.06 mg/kg.

Pymetrozine residues in protected strawberries were (n=2): 0.12 mg/kg.

The Meeting concluded that the data submitted for the use of pymetrozine on strawberries was insufficient for a maximum residue level estimation.

Broccoli

Pymetrozine is registered in Belgium for the use on broccoli at rates of 3×0.2 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in Switzerland and United Kingdom matching the GAP were submitted.

However, the Meeting noted that for broccoli no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability in broccoli is required to assess the validity of the supervised field trials.

Cauliflower

Pymetrozine is registered in Belgium for the use on cauliflower at rates of 3×0.2 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in France and Switzerland matching the GAP were submitted, however all samples were cut into segments at harvest before storage.

In 2013 the JMPR pointed out that cutting of large commodities in the field is against the recommended Codex sampling procedure and may cause problems due to an enhanced degradation of the residue. Testing strategies to investigate the stability of the residue were outlined in the 2013 JMPR Report. However, for pymetrozine such data was not submitted. In view of the short interval of the storage stability in various matrices, the possible effect of cutting cannot be assessed.

The Meeting decided that the data on cauliflower is invalid for recommendations of maximum residue levels for pymetrozine.

Head cabbage

Pymetrozine is registered in Germany for the use on head cabbage at rates of 3×0.2 kg ai/ha with a PHI of 7 days. Supervised field trials conducted in Europe matching the GAP were submitted. However some of the samples were cut into segments at harvest before storage, making them invalid for the assessment (see cauliflower).

In Portugal the use of pymetrozine is registered on head cabbage at rates of 3×0.2 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in Europe matching the GAP were submitted.

However, the Meeting noted that for cabbages no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability in head cabbage is required to assess the validity of the supervised field trials.

Cucumbers

Pymetrozine is registered in Greece for the use on protected cucumbers at rates of 2×0.45 kg ai/ha with a PHI of 3 days. Residue data from Europe under protected conditions matching GAP application rates were submitted.

However, the supervised field trials submitted for cucumbers were all conducted with one additional application compared to the GAP. Taking into account the low residues in samples analysed directly before the final treatment and the results from decline studies on cucumbers, the Meeting concluded that the additional treatment does not add significantly to the residue concentrations at harvest.

Pymetrozine residues in cucumbers (n=8): 0.045, 0.07, 0.08, 0.083, 0.088, 0.09, 0.11 and 0.21 mg/kg.

Four additional trials on cucumbers matching the GAP from Greece were reported, but the samples were stored 3-10 months before analysis, which is longer than the maximum storage interval of 2 month for pymetrozine in cucumbers.

The Meeting estimated a maximum residues level of 0.3 mg/kg, a median residue of 0.0855 mg/kg and a highest residue of 0.21 mg/kg for pymetrozine in cucumbers.

Melons

Pymetrozine is registered in Portugal for the use on protected melons at rates of 3×0.3 kg ai/ha with a PHI of 3 days. Supervised field trials conducted in Europe matching the GAP were submitted. However some of the samples were cut into segments at harvest before storage, making them invalid for the assessment (see cauliflower). Residues in the remaining trials were:

Pymetrozine residues in whole melon fruits (n=2): 0.045 and 0.16 mg/kg.

The Meeting concluded that the data submitted for the use of pymetrozine on melons was insufficient for a maximum residue level estimation.

Peppers, sweet

Pymetrozine is registered in Czech Republic for the use on protected sweet peppers at rates of 3×0.36 kg ai/ha with a PHI of 3 days. Supervised field trials conducted in Europe under protected conditions matching the GAP were submitted.

Pymetrozine residues in protected sweet peppers (n=8): 0.16, 0.43, 0.43, 0.54, 0.64, 0.83, 1.1 and 1.4 mg/kg.

The Meeting estimated a maximum residues level of 3 mg/kg, a median residue of 0.59 mg/kg and an highest residue of 1.4 mg/kg for pymetrozine in pepper, sweet.

Tomatoes

Pymetrozine is registered in The Netherlands for the use on protected tomatoes at rates of 3×0.45 kg ai/ha with a PHI of 1 day. Supervised field trials conducted in Europe under protected conditions matching the GAP were submitted.

Pymetrozine residues in protected tomato fruits (n=8): 0.08, 0.14, 0.18, 0.27, 0.3, 0.33, 0.39 and 0.77 mg/kg.

The Meeting estimated a maximum residues level of 1.5 mg/kg, a median residue of 0.285 mg/kg and a highest residue of 0.77 mg/kg for pymetrozine in tomatoes.

Leafy vegetables, except brassica leafy vegetables

Pymetrozine is registered in the USA for the use on leafy vegetables at rates of 2×0.1 kg ai/ha with a PHI of 7 days. Supervised field trials conducted in the USA on head lettuce, leaf lettuce and spinach matching the GAP were submitted. However, most of the trials were stored for more than 1 months, which was identified as the maximum storage interval without a significant degradation of the residues. The results from trials analysed within this interval were:

Pymetrozine residues in head lettuce (n=2): < 0.02 and 0.1 mg/kg.

The Meeting concluded that the data submitted for the use of pymetrozine on leafy vegetables, except brassica leafy vegetables, was insufficient for a maximum residue level estimation.

Potatoes

Pymetrozine is registered in the United Kingdom for the use on potatoes at rates of 2×0.15 kg ai/ha with a PHI of 7 days. Supervised field trials conducted in Northern Europe at a higher rate of 2×0.2 kg ai/ha were submitted.

Pymetrozine residues in potato tubers (n=4): < 0.01(4) mg/kg.

The Meeting concluded that the data submitted for the use of pymetrozine on potatoes was insufficient for a maximum residue level estimation.

Asparagus

Pymetrozine is registered in the USA for the use on asparagus in vegetative state at rates of 6×0.1 kg ai/ha to the mature ferns with a PHI of 170 days. Supervised field trials conducted in the USA on asparagus treated with rates of 3×0.19 kg ai/ha were submitted involving PHIs of 172-267 days. The results were:

Pymetrozine residues in asparagus (n=6): $< 0.02(6)$ mg/kg.

Although samples of asparagus were stored longer than the maximum storage interval of 1 month for this commodity, the Meeting concluded to make estimations for the commodity. Taking into account the insignificant amounts of pymetrozine found in samples from confined rotational crop studies and the long interval between treatment and harvest without a direct application to the harvested commodity, the Meeting estimated a maximum residues level of 0.02^* mg/kg and a median and highest residue of 0 mg/kg for pymetrozine in asparagus.

Celery

Pymetrozine is registered in the USA for the use on celery at rates of 2×0.1 kg ai/ha with a PHI of 7 days. Supervised field trials conducted in the USA matching the GAP were submitted.

However, the Meeting noted that for celery no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability in celery is required to assess the validity of the supervised field trials.

Artichoke, globe

Pymetrozine is registered in France for the use on globe artichokes at rates of 2×0.2 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in France matching the GAP were submitted.

Pymetrozine residues in artichokes (n=3): $< 0.02(3)$ mg/kg.

The Meeting concluded that the data submitted for the use of pymetrozine on artichoke is insufficient for a maximum residue level estimation.

Rice

Pymetrozine is registered in China for the use on rice at rates of 2×0.15 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in China matching the GAP were submitted.

However, in the supervised field trials no data on the maximum storage interval between sampling and analysis were reported. In addition, storage stability data for cereal commodities was not provided, denying an assessment on the validity of the trials.

The Meeting concluded that the data submitted for the use of pymetrozine on rice is insufficient for a maximum residue level estimation.

Pecan

Pymetrozine is registered in the USA for the use on pecans at rates of 2×0.14 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in the USA matching the GAP were submitted.

However, the Meeting noted that for pecan no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability in pecan is required to assess the validity of the supervised field trials.

Chestnut, hazelnut and walnut

Pymetrozine is registered in France for the use on chestnut, hazelnut and walnut at rates of 2×0.1 kg ai/ha with a PHI of 14 days. Supervised field trials on walnuts conducted in France matching the GAP were submitted.

However, the Meeting noted that for chestnuts, hazelnuts or walnuts no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability for respective commodities is required to assess the validity of the supervised field trials.

Rape

Pymetrozine is registered in Belgium, France and Germany for the use on oilseed rape rates of 1×0.075 kg ai/ha at BBCH 59 (first petals visible, flower buds still closed). The PHI is covered by the growth stage. Supervised field trials conducted in Northern and Southern Europe at slightly exaggerated rates of 1×0.1 kg ai/ha were submitted.

However, the Meeting noted that for rape seeds no data on the storage stability were provided. In view of the general degradation of pymetrozine in stored commodities, specific data on the storage stability in rape seeds is required to assess the validity of the supervised field trials.

Cotton

Pymetrozine is registered in Greece for the use on cotton rates of 2×0.2 kg ai/ha with a PHI of 35 days. Supervised field trials conducted in Southern Europe matching the registered application rate but with one additional treatment were submitted.

Pymetrozine residues in delinted seeds (n=6): $< 0.02(6)$ mg/kg.

The Meeting estimated a maximum residues level of 0.02 mg/kg and a median residue of 0.02 mg/kg for pymetrozine in cotton seeds.

Animal feeds

Rice straw

Pymetrozine is registered in China for the use on rice at rates of 2×0.15 kg ai/ha with a PHI of 14 days. Supervised field trials conducted in China matching the GAP were submitted.

However, in the supervised field trials no data on the maximum storage interval between sampling and analysis were reported. In addition, storage stability data for cereal commodities was not provided, denying an assessment on the validity of the trials.

The Meeting concluded that the data submitted for the use of pymetrozine on rice straw is insufficient for an estimation.

Cotton seed hulls

Pymetrozine is registered in Greece for the use on cotton rates of 2×0.2 kg ai/ha with a PHI of 35 days. Supervised field trials conducted in Southern Europe matching the registered application rate but with one additional treatment were submitted.

Pymetrozine residues in cotton seed hulls (n=6): $< 0.02(4)$, 0.02 and 0.02 mg/kg.

The Meeting estimated a maximum residues level of 0.04 mg/kg and a median residue of 0.02 mg/kg for pymetrozine in cotton seed hulls.

Fate of residues during processing

The Meeting received information on the hydrolysis of radio-labelled pymetrozine as well as processing studies using unlabelled material in tomatoes and sweet peppers.

In a hydrolysis study using [pyridine- ^{14}C]-pymetrozine typical processing conditions were simulated (pH 4,5 and 6 with 90°C, 100°C and 120°C for 20, 60 and 20 minutes). While no degradation of the residue was observed under pH6 (120°C for 20 minutes), a significant loss of parent substance occurred at pH 4 and pH5. The cleavage product CGA300407 was identified as the primary degradation product present at 33% of the TRR at pH4 and at 42% of the TRR at pH5.

No hydrolysis study simulating processing conditions was conducted using [triazine-¹⁴C]-pymetrozine. However, the hydrolysis in buffer solutions for the environmental fate was investigated showing an identical degradation of the active substance. The counterpart to CGA300407 was identified as CGA215525, which is expected to pose the remaining part of the residue in processed products.

The fate of pymetrozine residues has been examined simulating household and commercial processing of tomatoes and sweet peppers. Estimated processing factors for the commodities considered at this Meeting are summarised below.

Raw commodity	Processed commodity	Pymetrozine		
		Individual processing factors	Mean or best estimate processing factor	Median residue in mg/kg
Tomato (median: 0.285 mg/kg)	Juice, raw	0.05	0.05	0.014
	Puree	< 0.03(4), < 0.4	< 0.03	0.008
	Paste	< 0.04, < 0.4	< 0.22	0.063
	Canned/preserve	< 0.03(4), 0.07	0.03	0.008
	pomace, wet	0.08, < 0.4	0.24	0.068
Sweet pepper median: 0.59 mg/kg)	Cooked fruit	< 0.02(3)	< 0.02	0.012

The Meeting considered that maximum residue levels for processed commodities are covered by their raw agricultural commodities.

Residues in animal commodities

Farm animal feeding studies

The Meeting received feeding studies involving pymetrozine on lactating cows.

Three groups of lactating cows were dosed daily at levels of 1, 3 and 10 ppm in the diet for 28 consecutive days. Milk was collected throughout the whole study and tissues were collected on day 29 within 24 hrs after the last dose.

In milk and tissues of all dose groups no detectable residues of pymetrozine above the LOQ of 0.01 mg/kg were found.

The metabolite CGA313124 was also not found in tissues. In milk, CGA313124 was not detected for the 1ppm dose group but was present at levels of 0.02 mg/kg for the 3 ppm group and of 0.05 mg/kg for the 10 ppm group.

The Meeting noted that tissue samples were stored up to 10-13 months, which is longer than the maximum storage interval identified for pymetrozine in muscle. However, taking into account that based on goat metabolism studies liver is expected to be the tissue with highest residue concentrations, which was analysed for the parent residue within the interval supported by storage stability data, the general result of pymetrozine residues being <0.01 mg/kg in cow tissues is accepted.

Estimated maximum and mean dietary burdens of livestock and animal commodities maximum residue levels

Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6 of the 2014 Report. The calculations were made according to the livestock diets from US-Canada, EU, Australia and Japan in the OECD Table (Annex 6 of the 2006 JMPR Report).

	Livestock dietary burden, pymetrozine, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max.	mean	max.	mean	max.	mean	max.	mean
Beef cattle	< 0.01	< 0.01	none	none	0.03	0.03	none	none
Dairy cattle	< 0.01	< 0.01	none	none	0.03 ^a	0.03 ^b	none	none
Poultry - broiler	none	none	none	none	none	none	none	none
Poultry - layer	none	none	none	none	none	none	none	none

^a Highest maximum beef or dairy cattle burden suitable for MRL estimates for mammalian meat and milk

^b Highest mean beef or dairy cattle burden suitable for median estimates for mammalian meat and milk
none no relevant feed items

Animal commodity maximum residues levels

For beef and dairy cattle maximum and mean dietary burdens of 0.03 ppm were estimated, respectively. In farm animal feeding studies on lactating cows no detectable residues of pymetrozine in tissues were found for all dose groups up to 10 ppm.

The Meeting estimated median and highest residue values of 0 for mammalian meat, edible offal and fat and corresponding maximum residue levels of 0.01* mg/kg.

For milk, CGA313124 was not detected in the milk samples for the 1 ppm group. Under consideration of the maximum and mean dietary burden for dairy cattle being 33 times lower than this dose level, the Meeting estimated a maximum residue level of 0.01* mg/kg and a median residue of 0 mg/kg, respectively for milks.

For poultry no relevant feed items were identified. The Meeting estimated median and highest residue values of 0 mg/kg for poultry meat, edible offal of and fat as well as for eggs. The Meeting also estimated maximum residue levels of 0.01* mg/kg for poultry meat, edible offal of and fat as well as for eggs.

RECOMMENDATIONS

Definition of the residue for compliance with MRL for plant commodities, mammalian tissues, poultry tissues and eggs: *pymetrozine*

Definition of the residue for compliance with MRL for milk: *CGA313124 (4,5-dihydro-6-hydroxymethyl-4-[(3-pyridinyl-methylene)amino]-1,2,4-triazine-3(2H)-one)*

Definition of the residue for dietary intake in plant and animal commodities: *a conclusion could not be reached*

The residue is not fat-soluble.

FURTHER WORK OR INFORMATION

- storage stability data on more individual commodities
- supervised field trials analysed within the maximum storage periods
- stability data for pymetrozine during homogenization of field samples
- field rotational crop studies including analysis of conjugates
- applicability of multi-residue analytical methods
- a hydrolysis study simulating industrial processing using [6-triazine-¹⁴C]-pymetrozine
- processing data including analysis of CGA300407 and CGA215525

DIETARY RISK ASSESSMENT

Because the Meeting was unable to conclude on the toxicological relevance of the metabolites CGA294849 and CGA300407, the Meeting could not reach a conclusion on a residue definition for the dietary intake.

As a result, long- and short-term dietary intake assessments could not be conducted.

PYRACLOSTROBIN (210)

The first draft was prepared by Dr Ursula Banasiak, Delegate of the Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

The fungicide pyraclostrobin belonging to the strobilurin group was first evaluated for toxicology by the JMPR in 2003 where an ADI of 0–0.03 mg/kg bw per day and an ARfD of 0.05 mg/kg bw per day were established. The 2004 JMPR concluded that the residue definition for plant commodities for compliance with MRL values and for dietary risk assessments was parent pyraclostrobin and estimated a number of maximum residue levels. The compound was re-evaluated for residues by the JMPR in 2006, 2011 and 2012.

Pyraclostrobin was listed by the Forty-fifth Session of the CCPR (2013) for the review of an additional MRL for apricots.

The 2011 JMPR withdraw the previous group MRL recommendation of 1 mg/kg for Stone fruits and estimated different maximum residue levels for the individual commodities; cherries, plums, peaches and nectarines, but made no recommendation for apricots. The 2014 JMPR received GAP information and residue trial data for pyraclostrobin in apricots.

USE PATTERN

The information available to the 2014 JMPR on registered uses of pyraclostrobin in stone fruits, apricot, plums, peaches and nectarines is summarized in Table 1. Copies of labels including an English translation, where appropriate, were made available to the Meeting.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The current Meeting received information on two field trials of pyraclostrobin residues in apricots in 2013 in Southern Europe. The applications were done by foliar spray three times at rates of 0.05 kg ai/ha at 30–31, 17 and 3 days before harvest. Specimens of apricot fruits were collected at the day of the last application and 3, 6–7 and 13–14 days thereafter. Residues were analysed with method 535/1 (determination via LC/MS, see JMPR 2011) with mean recovery rate of 87.6% for pyraclostrobin at fortification levels from 0.01 to 1.0 mg/kg. Residues were corrected to the whole fruit (stone + flesh) with the pulp/whole fruit correction factor, which was calculated by dividing flesh weight by the weight of the whole fruit. The results are summarized in Table 2.

Table 2 Pyraclostrobin residues in apricots

APPRAISAL

Pyraclostrobin was first evaluated for toxicology by the JMPR in 2003 where an ADI of 0–0.03 mg/kg bw per day and an ARfD of 0.05 mg/kg bw per day were established. The 2004 JMPR evaluated the residue behaviour of the fungicide and concluded that the residue definition for both, plant and animal commodities was parent pyraclostrobin for compliance with MRL values as well as for dietary risk assessments. The compound was re-evaluated for residues several times by the JMPR since 2006 and was listed by the 45th Session of the CCPR (2013) for the review of an additional MRL for apricot.

The 2011 JMPR withdraw the formerly group MRL recommendation of 1 mg/kg for stone fruits and estimated different maximum residue levels for the single commodities cherries, plums

(including prunes), peach and nectarine but did no recommendation for apricot. The 2014 JMPR received GAP information and residue data of pyraclostrobin in apricot.

Results of supervised residue trials in crops

Stone fruits

The maximum GAP for the use of pyraclostrobin in stone fruits was from Canada and the USA, consisting of 5×0.13 kg ai/ha and a PHI of 0 days. Labels for alternative use patterns of pyraclostrobin in France and Italy on apricots, plums, peach and nectarine were submitted with application of 3×0.04–0.05 kg ai/ha and a PHI of 3 days.

The 2011 JMPR estimated for pyraclostrobin residues different maximum residue levels, STMRs and HRs for cherries, plums, peach and nectarine. The 2011 Meeting noted that the estimations for peach and nectarine were based on an alternative GAP (France) as the evaluation based on the maximum GAP of the USA exceeded the ARfD. The residue data on which the estimations were based are summarized as follows:

Crop	2011 Estimation, mg/kg			Residue data, mg/kg	Region, application kg ai/ha, PHI
	MRL	STMR	HR		
Cherries	3	0.51	1.57	0.03, 0.27, 0.38, 0.42, 0.47, 0.5, <u>0.51</u> , 0.56, 0.63, 0.82, 1.06, 1.08, 1.57	USA, 5×0.13, 0 days
Plums	0.8	0.09	0.40	0.02, 0.02, 0.04, 0.05, 0.06, 0.07, 0.09, <u>0.09</u> , 0.12, 0.19, 0.22, 0.34, 0.38, 0.40, 0.40	USA, 5 × 0.13, 0 days
Peach, nectarine	0.3	0.07	0.13	< 0.02, 0.03, 0.04, 0.05, <u>0.07</u> , <u>0.07</u> , 0.08, 0.11, 0.12, 0.13	South-EU, 3×0.04–0.05, 3 days

The current Meeting received information on two field trials for pyraclostrobin uses on apricots in 2013 in Italy and Spain. Three foliar sprays at rates of 0.05 kg ai/ha were made matching the French and Italian GAP. The residues were 0.08 (2) mg/kg in fruits at a 3-days PHI.

The Meeting noted that the two residue values on apricots of 0.08 mg/kg are in the same order of magnitude as the residues in peaches matching the alternative European GAP (3×0.04–0.05, PHI 3 days).

The Meeting concluded that the MRL of 0.3 mg/kg, the STMR of 0.51 mg/kg and the HR of 1.57 mg/kg established for cherries should be extrapolated to the whole Stone fruits subgroup 003A Cherries (includes all commodities in this subgroup). The meeting withdrew its previous recommendation of 0.3 mg/kg for the single commodity cherries.

The Meeting decided that the maximum residue level of 0.8 mg/kg, the STMR of 0.09 mg/kg and the HR of 0.40 mg/kg established for plums should be extrapolated to the whole stone fruit subgroup 003B for Plums. The meeting withdrew its previous recommendation of 0.8 mg/kg for the single commodity Plums (including prunes).

The Meeting decided that each maximum residue level of 0.3 mg/kg, the STMR of 0.07 mg/kg and the HR of 0.13 mg/kg established for peaches and nectarines should be extrapolated to the whole stone fruit subgroup 003 C for Peaches (including nectarines and apricots). The meeting withdrew its previous recommendation of 0.3 mg/kg for the individual commodities peaches and nectarines.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for dietary risk assessment.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for plant and animal commodities: Pyraclostrobin.

The residue is not fat-soluble.

CCN	Commodity name	MRL, mg/kg		STMR mg/kg	HR mg/kg
		Proposed	Previous		
FS 003C	Peaches (including Nectarine and Apricots) (includes all commodities in this subgroup)	0.3		0.07	0.13
FS 003A	Cherries (includes all commodities in this subgroup)	0.3		0.51	1.57
FS 003B	Plums (includes all commodities in this subgroup)	0.8		0.09	0.40
FS 0013	Cherries	W	0.3		
FS 0014	Plums (including Prunes)	W	0.8		
FS 0245	Nectarine	W	0.3		
FS 0247	Peach	W	0.3		

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of pyraclostrobin were calculated for the 17 GEMS/Food cluster diets using STMRs and STMR-Ps estimated by the JMPR in 2004, 2006, 2011, 2012 and 2014. The results are shown in Annex 3 to the 2014 Report.

The ADI is 0–0.03 mg/kg bw and the calculated IEDIs were 1–6% of the maximum ADI. The Meeting concluded that the long-term intake of residues of pyraclostrobin resulting from the uses considered by the JMPR is unlikely to present a public health concern.

Short-term intake

The International Estimated Short Term Intake (IESTI) for pyraclostrobin was calculated by the current Meeting for apricot. The results are shown in Annex 4 to the 2014 Report.

For the commodities considered by the 2014 JMPR, the IESTI represented 0–30% of the ARfD for the general population and 0–40% for children. The Meeting concluded that the short-term intake of residues of pyraclostrobin, when used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

SEDAXANE (259)

The first draft was prepared by Dr Michael Doherty, United States Environmental Protection Agency, Washington, DC, USA

EXPLANATION

Sedaxane is a mixture of two *cis* isomers 2'-[(1*RS*,2*RS*)-bicycloprop-2-yl]-3-(difluoromethyl)-1-methylpyrazole-4-carboxanilide, and two *trans* isomers 2'-[(1*RS*,2*SR*)-bicycloprop-2-yl]-3-(difluoromethyl)-1-methylpyrazole-4-carboxanilide (IUPAC). This fungicide was first evaluated by the JMPR in 2012, the Meeting derived an ADI of 0–0.1 mg/kg bw and an ARfD of 0.3 mg/kg bw. The Meeting determined that the residue definitions for MRL compliance and the estimation of dietary intake, for both plant and animal commodities, is parent sedaxane and that the residue is fat-soluble.

Sedaxane was listed by the Forty-fifth Session of the CCPR for the evaluation of additional maximum residue levels. The 2014 Meeting received residue data reflecting use of sedaxane as a seed treatment on corn/maize, pulses, potatoes, and sorghum. In addition to evaluating those crops, the Meeting was asked to consider use on rice, without residue data, on the basis of residue data supplied to the 2012 and 2014 Meetings for other grains.

RESIDUE ANALYSIS

Analytical Methods

The analytical method used in the residue and processing studies is the same as that reviewed and deemed acceptable for data collection and enforcement purposes by the 2012 Meeting (Specht method P-14.141). The reported LOQ is 0.005 mg/kg for the *cis* isomers and the *trans* isomers, each, with an overall LOQ of 0.01 mg/kg in plant and animal matrices.

USE PATTERN

Information on the registered uses of sedaxane for the relevant crops, along with copies of labels, were provided to the 2014 Meeting (Table 1).

Table 1 Registered uses of sedaxane for corn/maize, pulses, potatoes, rice, and sorghum

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue trials were reported with sufficient details for evaluation, including field conditions, application parameters, planting dates, storage conditions and durations, and procedural recoveries. Separate residue values are reported, as measured, for the *cis* and *trans* isomers of sedaxane. Generally, two samples were collected from treated plots and one sample from control plots. Mean residue values suitable for maximum residue level and STMR estimation are underlined in the tables. For all crops and matrices except potato, residues of each isomer were < 0.005 mg/kg (i.e., < 0.01 mg/kg combined) in all samples.

Storage stability data were not submitted to the 2014 Meeting. Data evaluated by the 2012 Meeting showed that residues of sedaxane are stable under frozen conditions for at least 2 years in wheat grain and straw, spinach, potato, orange, lentils, and soya beans. The 2014 Meeting has translated those storage stability data to the pulse, potato, corn, and sorghum samples in this evaluation.

The 2014 Meeting received data from supervised trials depicting residues in the following crops grown from treated seeds:

Commodity	Group	Table No.
Sweet Corn	VO Fruiting Vegetables, other than Cucurbits	2
Beans, dry	VD Pulses	3
Pea, dry	VD Pulses	4
Potato	VR Root and tuber vegetables	5

Sorghum, fodder, forage	AS Straw, fodder and forage of cereal grains and grasses	11

Fruiting Vegetables, other than Cucurbits

Sweet Corn (Corn-on-the-cob)

Thirteen supervised trials were conducted on corn in Canada and the USA during the 2008 (USA) and 2010 (Canada) growing seasons. Of these, six were conducted with sweet corn varieties (* in table); for the remaining seven trials, ears were harvested prior to maturity to simulate sweet corn. Sedaxane was applied as a seed treatment at a nominal rate of 40 g ai/100 kg seed. Commodities were collected at normal commercial harvest and were stored frozen for up to 10 months (0.8 years). Trials conducted in the same location and with the same variety were not considered to be independent.

Pulses

Beans, dry

Thirteen independent supervised trials were conducted in dry beans in Canada and the USA during the 2010 growing season. Sedaxane was applied as a seed treatment at a nominal rate of 5 g ai/100 kg seed, except for two trials (Fresno, CA; Parkdale, OR) in which the application rate was ca. 12 g ai/100 kg seed. Commodities were collected at normal commercial harvest and were stored frozen for up to 402 days (1.1 years).

Pea, dry

Ten independent supervised trials were conducted in dry pea in Canada and the USA during the 2010 growing season. Sedaxane was applied as a seed treatment at a nominal rate of 5 g ai/100 kg seed. Commodities were collected at normal commercial harvest and were stored frozen for up to 401 days (1.1 years).

*Root and Tuber Vegetables**Potato*

Thirty-one independent supervised trials were conducted in potato in Canada and the USA during the 2010 growing season. Sedaxane was applied as a seed treatment at a nominal rate of 2.5 g ai/100 kg seed, except for trials in Campbell, MN and Rupert, ID in which the application rates were 4.5 and 5.2 g ai/100 kg seed, respectively. Commodities were collected at normal commercial harvest and were stored frozen for up to 292 days (0.8 years).

Cereal Grains

Maize and popcorn

Twenty supervised trials were conducted in corn in Canada and the USA during the 2008 (USA) and 2010 (Canada) growing seasons. Of these, one trial was conducted with popcorn. Sedaxane was applied as a seed treatment at a nominal rate of 40 g ai/100 kg seed. Two trials were conducted at an exaggerated rate (120 g ai/100 kg seed). Commodities were collected at normal commercial harvest and were stored frozen for up to 10 months (0.8 years). Trials conducted in the same location and with the same variety were not considered to be independent.

Legume animal feeds

Bean (forage and hay)

Seven independent supervised trials were conducted in beans in Canada and the USA during the 2010 growing season. Sedaxane was applied as a seed treatment at a nominal rate of 5 g ai/100 kg seed, except for two trials (Fresno, CA; Parkdale, OR) in which the application rate was ca. 12 g ai/100 kg seed. Commodities were collected at normal commercial harvest and were stored frozen for up to 402 days (1.1 years). Forage was collected from only five of the seven trials.

Straw, fodder, and forage of cereal grains

Maize

Twenty-three supervised trials were conducted in maize, from which animal feeds were harvested, in Canada and the USA during the 2008 (USA) and 2010 (Canada) growing seasons. Sedaxane was applied as a seed treatment at a nominal rate of 40 g ai/100 kg seed. Commodities were collected at

normal commercial harvest and were stored frozen for up to 10 months (0.8 years). Trials conducted in the same location and with the same variety were not considered to be independent.

Sorghum

Twelve supervised trials were conducted in sorghum in the USA during the 2010 growing season. Sedaxane was applied as a seed treatment at a nominal rate of 40 g ai/100 kg seed. Commodities were collected at normal commercial harvest and were stored frozen for up to 9.5 months (0.8 years). Trials conducted in the same location and with the same variety were not considered to be independent.

FATE OF RESIDUES IN STORAGE AND PROCESSING

A high-temperature hydrolysis study was reviewed by the 2012 Meeting, which concluded that sedaxane is stable under conditions representative of pasteurization, baking, and sterilization. The 2014 Meeting received data showing residues of sedaxane in raw commodities and processed commodities of field corn and potato.

Corn

In the field corn study conducted at 120 g ai/100 kg seed (ca. 2.4× GAP), corn grain was randomly taken from bulk treated and untreated samples. The grain was aspirated and screened to remove impurities and then tempered in preparation for dry milling or steeped in water/sulphurous acid in preparation for wet milling. For dry milling, the kernels were cracked using a disc mill and then dried, screened, and separated into bran, germ, grits, meal, and flour. The product was again aspirated to remove bran, germ with attached hull/endosperm, and large grits. The remaining product underwent additional screening, milling, and sifting. Grits, meal, and flour were separated using a Forsberg gravity separator. An aliquot of germ collected from the dry milling process was heated, flaked, and batch extracted with hexane to produce crude oil, which was additionally processed into refined, neutral oil. For wet milling, steeped corn was passed through a disc mill and centrifuged to remove germ and hulls, which were then dried, aspirated, and screened. The cornstock was milled and screened to produce gluten and starch. Starch was dried to a final moisture content of 15%. Wet-milled germ was moisture conditioned, heated, flaked, and pressed to expel crude oil. The resulting press cake was extracted with hexane to generate more crude oil. Crude oil was refined into neutral oil.

For all samples, including the raw commodity, residues of sedaxane were < 0.01 ppm; therefore, processing factors could not be derived.

Potato

In the potato processing study, tubers from an exaggerated-rate trial (5 g ai/100 kg seed, 2× GAP) were harvested, analysed for residues, and processed into flakes, chips, and wet peel. Samples of tubers were stored for up to 8.3 months and samples of the processed commodities were stored for up to 6.2 months. All samples were stored frozen (ca. -10 °C).

Potatoes were cleaned prior to processing by soaking in 32–37 °C for 5–10 minutes to loosen foreign material. The potatoes were then brushed and rinsed, and then peeled in a mechanical peeler. The removed peel was dewatered in a basket centrifuge. Any green or bruised areas of the peeled

potatoes were removed. For granule/flake production, peeled potatoes were sliced (ca. 1 cm) and washed to remove starch. The potato slices were cooked in hot water (71–74 °C, 20 min.), cooled (32 °C, 20 min.), and then steamed (94–100°C, 35–40 min.) for final cooking. The cooked slices were then flash dried, rolled to a thickness of 0.18–0.25 mm, and adjusted to a moisture content of 8–12% as necessary. The material was then milled and screened to produce flakes and granules. For fried chip production, the peeled potatoes were sliced (1.5 mm) and rinsed to remove starch. After the surface moisture was removed, the slices were fried (177–191 °C, 45–75 sec.) in vegetable oil.

Residues of sedaxane did not concentrate in flakes/granules or in chips, but did concentrate in wet peel.

Table 12 Summary of residues and processing factors for sedaxane in potato

Commodity	Report-Trial	Residue (ppm)	Mean residue (ppm)	Processing factor	Mean processing factor
Tubers (prior to processing)	TK0049813-15	0.0131, 0.0125, 0.0100	0.012	n.a.	n.a.
	TK0049813-16	0.0138, 0.0170, 0.0138	0.015	n.a.	
Flakes/Granules	TK0049813-15	0.0124	0.012	1.0	0.83
	TK0049813-16	0.0090	0.0090	0.61	
Chips	TK0049813-15	0.0075	0.0075	0.63	0.57
	TK0049813-16	0.0075	0.0075	0.50	
Wet Peel	TK0049813-15	0.0360	0.036	3.0	4.3
	TK0049813-16	0.0819	0.082	5.5	

Residues of sedaxane are not expected to concentrate in processed potato commodities except for wet peel, for which residues increased by ca. 4.3-fold relative to the washed tuber.

APPRAISAL

Sedaxane was first evaluated by the JMPR in 2012. The 2012 Meeting concluded that the residue definition for MRL compliance and estimation of dietary intake is sedaxane. An ADI of 0–0.1 mg/kg bw and an ARfD of 0.3 mg/kg bw were established. The residue was determined to be fat-soluble. The 2012 Meeting noted that none of the uses resulted in residues in human foods and that those uses are unlikely to present a public health concern.

The Forty-fifth Session of the CCPR listed sedaxane for the evaluation of additional MRLs. The 2014 Meeting received information on GAP and supervised residue trials reflecting the use of sedaxane as a seed treatment on corn/maize, pulses, potatoes, and sorghum. In addition to evaluating those crops, the Meeting was asked to consider use on rice, without residue data, on the basis of residue data supplied to the 2012 and 2014 Meetings for other grains.

Methods of analysis

Acceptable analytical methods were developed and validated for determination of sedaxane and its metabolites in plant and animal matrices. The methods were evaluated by the 2012 Meeting. The reported LOQ for the sedaxane *cis* and *trans* isomers, each, was 0.005 mg/kg, while the LOQ for all metabolites was 0.01 mg/kg in all matrices (plant and animal).

Results of supervised residue trials on crops

Supervised residue trials submitted for evaluation were as seed treatments and were conducted in Canada and/or the USA. All of the trials submitted to the 2014 Meeting are supported by storage

stability data evaluated by the 2012 Meeting. Residue values listed below reflect the average for each field trial, unless otherwise noted.

Sweet corn

The critical GAP for sweet corn is from the USA at 40 g ai/100 kg seed. In 13 trials, conducted at rates ranging from 29.7 to 51.2 g ai/100 kg seed, residues of sedaxane were < 0.01 mg/kg in all samples.

Based on the results of previously evaluated metabolism data from wheat (2012 Meeting) and on the results of the submitted residue trials, the Meeting agreed that no sedaxane residues are expected in sweet corn (corn-on-the-cob).

The Meeting estimated a maximum residue level of 0.01* mg/kg for sedaxane on sweet corn (corn-on-the-cob), an HR of 0.01 mg/kg and a STMR of 0 mg/kg.

Pulses (Beans, dry and peas, dry)

The critical GAP for beans, dry and peas, dry is from Canada and the USA for use as a seed treatment at a rate of 5 g ai/100 kg seed.

Eleven trials were conducted on dry bean matching GAP in Canada (5) and the USA (6), with an additional two trials in the USA conducted at approximately a 2.5-fold exaggerated rate.

Ten trials were conducted on dry pea matching GAP in Canada (8) and the USA (2).

Sedaxane residues in harvested dry beans and dry peas from all trials (n=21), including the exaggerate-rate trials, were: < 0.01 mg/kg. Based on the results of previously evaluated metabolism data from soya beans (2012 Meeting) and on the results of the submitted residue trials, the Meeting agreed that no sedaxane residues are expected in pulses.

The Meeting estimated a maximum residue level of 0.01* mg/kg for sedaxane on pulses and an STMR of 0 mg/kg. The Meeting recommended that the individual MRL for soya bean, dry be withdrawn.

Potato

The critical GAP for potato is from Canada, as a seed-piece treatment, at a rate of 2.5 g ai/100 kg seed. Twenty-nine trials were conducted matching GAP in Canada (13) and the USA (16). Three additional trials were conducted in the USA; one at approximately a 0.4× rate and two at approximately a 2× exaggerated rate.

Sedaxane residues in harvested tubers from all at-GAP trials (n=29) were: ≤0.01 (28) and 0.018 mg/kg.

The Meeting estimated a maximum residue level of 0.02 mg/kg for sedaxane on potato, an STMR of 0.01 mg/kg, and an HR of 0.02 mg/kg (from a single sample).

Cereal Grains

Maize and popcorn

The critical GAPs are from Chile for maize (50 g ai/100 kg seed) and from the USA for popcorn (40 g ai/100 kg seed). No trials from Chile were provided; however, data from 15 trials with rates ranging from 40–51.2 g ai/100 kg seed were available from the USA depicting residues of sedaxane in maize. In addition, there are two trials conducted at an exaggerated rate of 120 g ai/100 kg seed.

Sedaxane residues in maize from all trials (n=15) were: < 0.01 mg/kg.

Sorghum

The critical GAP for sorghum is from Canada and the USA as a seed treatment at a rate of 5 g ai/100 kg seed. Twelve trials were conducted at an 8-fold exaggerated rate (ca. 40 g ai/100 kg seed) in the USA, of which ten were determined to be independent.

Sedaxane residues in sorghum grain from all trials (n=10) were: < 0.01 mg/kg.

The Meeting noted that while there are no GAP registrations for cereal grains as a group, there are GAPs around the world with GAPs covering the major cereal grain commodities. Based on the results of previously evaluated metabolism data from wheat (2012 Meeting) and on the results of the submitted residue trials for maize and sorghum, the Meeting agreed that no sedaxane residues are expected in cereal grains.

The Meeting estimated a maximum residue level of 0.01* mg/kg for sedaxane on cereal grains and an STMR of 0 mg/kg, and recommends that the individual MRLs for barley, oats, rye, triticale, and wheat be withdrawn.

Legume animal feeds

The critical GAP is for beans, peas, and lentils from Canada and/or the USA as a seed treatment at a rate of 5 g ai/100 kg seed. Fifteen trials were conducted matching GAP in Canada and the USA from which forage and/or hay were harvested. An additional trial was conducted in the USA at approximately a 2.5-fold exaggerated rate.

Sedaxane residues in bean and pea forage (n=5) and hay (n=16) from all trials, including the exaggerate-rate trial, were: < 0.01 mg/kg.

The Meeting estimated a maximum residue level of 0.01* mg/kg and a median residue of 0 mg/kg for sedaxane in bean fodder and pea hay or pea fodder (dry).

The Meeting estimated a highest residue of 0.01 mg/kg and a median residue of 0 mg/kg for sedaxane in bean fodder and pea vines.

Straw, fodder, and forage of cereal grains

The critical GAP for maize is from Chile as a seed treatment at a rate of 50 g ai/100 kg seed. Nineteen trials (15 independent) were conducted at GAP in Canada and the USA from which fodder (stover) and/or forage were harvested.

Sedaxane residues in maize fodder (stover; n=15) and forage (n=15) were: < 0.01 mg/kg.

The critical GAP for sorghum is from the USA and Canada as a seed treatment at a rate of 5 g ai/100 kg seed. Twelve trials were conducted at an 8-fold exaggerated rate (ca. 40 g ai/100 kg seed) in the USA, of which ten were determined to be independent.

Sedaxane residues in sorghum forage and stover (n=10) were: < 0.01 mg/kg.

The 2014 Meeting estimates for sorghum forage (dry), a highest residue of 0.01 mg/kg, and a median residue of 0 mg/kg.

The 2012 Meeting estimated residues of sedaxane in barley, oats, rye, triticale, and wheat straw and fodder, on an as-received basis at 0.075 mg/kg (HR) and 0.01 mg/kg (STMR). In estimating those residues, the 2012 meeting noted that these commodities are not always readily distinguishable in trade and the preference for having a common MRL.

Based on the rationale of the 2012 Meeting and on the results from the maize and sorghum residue trials, the 2014 Meeting agreed to estimate residues of sedaxane in straw, fodder of cereal grains and grasses (including buckwheat fodder) (straws and fodders, dry at a maximum residue level of 0.1 mg/kg).

The Meeting estimates a highest residue of 0.075 mg/kg, and a median of 0.01 mg/kg (as received).

The Meeting withdraws its previous recommendations for straw and fodder (dry) of barley, oat, rye, triticale, and wheat.

Fate of residue during food processing

Residues of sedaxane are stable to hydrolysis (2012 JMPR).

The Meeting received processing studies for corn and potato. In the corn study, residues of sedaxane were < 0.01 mg/kg in all commodities.

Raw agricultural commodity (RAC)	STMR, mg/kg	Processed commodity	Processing factor	STMR-P, mg/kg
Potato tuber	0.01	Flakes/granules	0.83	0.0083
		Chips	0.57	0.0057
		Wet peel	4.27	0.0427

Residues in animal commodities

The 2014 Meeting evaluated sedaxane residues in animal feed items from pulses, cereal grains (corn, rice, and sorghum), and potato in addition to the feed items evaluated by the 2012 Meeting (cereal grains) as listed in the OECD feeding table.

Estimated maximum and mean dietary burdens of livestock

Estimated dietary burdens for Australia, the EU, Japan, and the US/Canada are summarized below. The livestock diets are summarized in Annex 6 to the 2014 Report.

Livestock Dietary Burdens (ppm of dry matter diet) for Sedaxane.

Livestock	Australia		EU		Japan		US/Canada	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Cattle (beef)	0.106	0.057	0.199	0.169	0.006		0.150	0.126
Cattle (dairy)	0.090	0.039	0.168	0.136	0.014		0.080	0.054
Poultry (broiler)			0.010	0.008				
Poultry (layer)			0.023	0.012				

For all livestock, the sedaxane burdens based on the EU animal diets (bold values in the table) reflect the highest burdens for both MRL estimation (maximum diet) and STMR estimation (mean diet).

Animal commodities residue level estimation

In a cattle feeding study evaluated at the 2012 Meeting, residues in all commodities were < 0.01 mg/kg at all dose levels (0.11–2.2 ppm). The 2012 Meeting estimated a maximum residue level of 0.01* mg/kg and STMR and HR values of 0 mg/kg for mammalian commodities.

The 2014 Meeting confirms the previous recommendations.

In a poultry metabolism study evaluated by the 2012 JMPR Meeting, laying hens were dosed at a rate equivalent to 20 ppm (dry matter basis) in their diet. Sedaxane was < 0.01 mg/kg in all tissues at that dose level. Based on the results of that study, the 2012 Meeting estimated a maximum residue level of 0.01* mg/kg and STMR and HR values of 0 mg/kg for poultry commodities.

The 2014 Meeting confirms the previous recommendations.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for plant and animal commodities: *sedaxane*.

The residue is fat-soluble.

CCN	Commodity Name	MRL, mg/kg		STMR, mg/kg	HR, mg/kg
		New	Previous		
GC 0640	Barley	W	0.01*		
AS 0640	Barley straw and fodder, dry	W	0.01*		
AL 0061	Bean fodder	0.01*		0	
GC 0080	Cereal grains	0.01*		0	
AS 0647	Oat straw and fodder, dry	W	0.01*		
GC 0647	Oats	W	0.01*		
AL 0072	Pea hay or pea fodder (dry)	0.01*		0

AF 0645	Maize forage			0	
AF 0651	Sorghum forage (green)			0	
AF 5249	Corn forage			0	
AL 1030	Bean forage (green)			0	
AL 0528	Pea vines			0	
	Potato, wet peel			0.0427	

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of sedaxane were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the current and previous Meetings. The ADI is 0–0.1 mg/kg bw and the calculated IEDIs were 0–0% of the maximum ADI (0.1 mg/kg bw). The Meeting concluded that the long-term intakes of residues of sedaxane, when used in ways that have been considered by the JMPR, are unlikely to present a public health concern.

Short-term intake

The International Estimated Short-Term Intakes (IESTI) of sedaxane were calculated for food commodities and their processed commodities using HRs/HR-Ps or STMRs/STMR-Ps estimated by the current Meeting. The ARfD is 0.3 mg/kg bw and the calculated IESTIs were 0% of the ARfD for all commodities. The Meeting concluded that the short-term intake of residues of sedaxane, when used in ways that have been considered by the JMPR, is unlikely to present a public health concern.

SPIRODICLOFEN (237)

The first draft was prepared by Mr David Lunn, New Zealand Food Safety Authority, Wellington, New Zealand

EXPLANATION

Spirodiclofen, a ketoenol (tetronic acid) insecticide was evaluated for the first time by the 2009 JMPR, where an ADI of 0–0.01 mg/kg bw was established and it was agreed that an ARfD was not necessary, residue definitions were proposed and maximum residue levels were recommended for a number of uses where GAP and supporting information were available.

The 2009 JMPR established residue definitions for spirodiclofen:

- For plant products (compliance with MRLs and dietary intake estimation): *spirodiclofen*
- For animal products (compliance with MRLs): *spirodiclofen (fat soluble)*
- For animal products (dietary intake assessment): *sum of spirodiclofen and spirodiclofen-enol, expressed as spirodiclofen.*

Spirodiclofen was listed by the Forty-fifth Session of the CCPR (2013) for the review of additional maximum residue levels for blueberries and avocados and the 2014 JMPR received GAP and residue information for these crops.

METHODS OF RESIDUE ANALYSIS

Analytical methods

The 2009 JMPR reviewed and summarised analytical method descriptions and validation data for spirodiclofen and some of its metabolites in crop, processed commodities and animal commodities, including the HPLC/MS-MS multi-residue method 109351 (validated for the determination of parent spirodiclofen in plant commodities with high acid content, high water content and high fat content) and the HPLC/MS-MS method BA-001-P06-01 (validated for the determination of parent spirodiclofen and metabolites (3) in apples, grapes and their processed fractions).

The analytical method used in the supervised residue trials on blueberry was a modification of Method 109351 (i.e., without the ENVI-Carb or amino-cartridge clean-up steps) and involved extraction with acetonitrile/water/20% cysteine hydrochloride (200:100:1), filtration with Celite, acidification with HCl, partitioning into dichloromethane, evaporation and re-suspension acetonitrile/formic acid prior to analysis by HPLC/MS-MS (triple-quad, positive MRM mode). The reported LOQ of this method was 0.01 mg/kg. [Ref: 109351-1]

Table 1 Recoveries of spirodiclofen with HPLC/MS-MS method 109351

Commodity	LOQ (mg/kg)	Recovery type	spike level (mg/kg)	recoveries % range (mean)	SD (n)	Reference
blueberry	0.01	validation	0.01	88-120 (103)	16 (3)	IR4 PR-09679
			0.2	93-100 (97)	4 (3)	
			5.11	93-103 (97)	5 (3)	
		procedural	0.01	81-109 (93)	9 (14)	
			5.11	85-98 (92)	4 (14)	

Samples from the supervised trials on avocados were analysed using a modification of the HPLC/MS-MS Method BA-001-P06-01 (i.e., with the addition of cysteine hydrochloride to the acetonitrile/water extraction solvent) and involved acetonitrile/water extraction, the addition of isotopic internal standards and filtration prior to analysis for parent spirodiclofen by HPLC/MS-MS (positive MRM mode). The reported LOQ of this method was 0.01 mg/kg. [Ref: BA-001-P06-01]

Table 2 Recoveries of spirodiclofen with HPLC/MS-MS method BA-001-P06-01

Commodity	Reported LOQ (mg/kg)	Recovery type	spike level (mg/kg)	recoveries % range (mean)	SD (n)	Reference
avocado	0.01	validation	0.01	100-116 (109)	5 (7)	RABAP001
		procedural	0.01	93-109 (101)	6 (2)	
			0.5	95-101 (98)	3 (3)	
			1.0	98-105 (101)	4 (3)	

Stability of residues in stored analytical samples

The 2009 JMPR reviewed freezer storage stability studies on a range of representative substrates and concluded that spirodiclofen was stable when stored frozen for at least 13 months in crops with high water content (peach), at least 24 months in crops with high acid content (citrus, grapes), 16 months in crops with oil content (almond nutmeat, dry hop cones), at least 8 months in fruit juice (apple juice, grape juice), and at least 10 months in dried fruit (dried apples, raisins, dried plums).

The Meeting received additional spirodiclofen storage stability studies on blueberry [Ref: IR4 PR-09679] where untreated samples from the field trials were fortified with 0.2 mg/kg spirodiclofen and stored for 47–51 weeks at or below -12 °C.

Samples were taken for extraction and analysis after 47–51 weeks, with the stored control samples being freshly fortified and analysed concurrently to determine the procedural recovery efficiency. Analysis was by LC-MS/MS (Method 109351, with procedural recovery rates of 78–101% in samples fortified at 0.01 mg/kg to 5.1 mg/kg). After 47–51 weeks storage, measured residues of spirodiclofen in stored samples were 85% of the spiked level.

Table 3 Stability of residues in plant matrices fortified with spirodiclofen and stored at ≤ -4 °C

Commodity	Fortification (mg/kg)	Storage interval (weeks)	Spirodiclofen residues (mg/kg)	% Remaining	Procedural recovery (%)
blueberry	0.2	47	0.18, 0.18, 0.17	85	82% at 0.01 mg/kg 81% (at 0.2 mg/kg) 87% at 5.1 mg/kg

USE PATTERNS

Information on GAP in USA was provided to the Meeting for foliar applications to blueberries and avocados and these are summarised in Table 4.

Table 4 Registered uses of spirodiclofen (240 g ai/litre SC formulation)

Crop	Country	Application				Max/season		PHI (days)	Remarks:
		method	kg ai/ha	kg ai/hL	water L/ha	no	kg ai/ha		
Bush berries (004B)									
Blueberries	Canada	spray	0.31		100-1000	1	0.31	7	
Assorted tropical and sub-tropical fruits – inedible peel-large (006B)									
Avocado ^a	USA	spray	0.31-0.35		468	1	0.35	2	

^a GAP is for Avocados and also Black sapote, Canistel, Mamey sapote, Mango, Papaya, Sapodilla, Star apple.

RESIDUES RESULTING FROM SUPERVISED TRIALS

The Meeting received new information on supervised field trials involving foliar applications of spirodiclofen to the following crops.

Crop group	Code	Crop	Source	Table
Bush berries	004B	Blueberries	USA, Canada	Table 5
Assorted tropical and sub-tropical fruits – inedible peel (large)	006B	Avocado	USA	Table 6

The supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation including procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for recovery.

Intervals of freezer storage between sampling and analysis were recorded for all trials and were covered by the conditions of the freezer storage stability studies.

Results from replicated field plots are presented as individual values. When residues were not detected they are shown as below the LOQ (e.g., < 0.01 mg/kg). Residues and application rates have been rounded to two significant digits (or if close to the LOQ, rounded to one significant digit). Average values and proportionally adjusted residues have been calculated from the residue results prior to rounding and the results from trials used for the estimation of maximum residue levels have been (underlined).

Bush berries

Blueberries

Results from supervised trials from USA and Canada on highbush and lowbush blueberries were provided to the Meeting. In these trials, one foliar application of spiroadiclofen (SC 240 formulation) was applied without spray adjuvant to mature bushes using backpack 1–6 nozzle boom sprayers or tractor-mounted airblast sprayer. Plot sizes in these trials ranged from 33–167 square metres.

Duplicate samples of at least 0.9 kg fruit were taken from at least 12 bushes/plot at maturity or when 70–80% of fruit were ripe, frozen within 24 hours of sampling and stored at -12 °C for up to 327 days before berries were extracted and analysed for spiroadiclofen using LC/MS/MS Method 109351 within 1 day of extraction. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–0.5 mg/kg spiroadiclofen ranged from 81–109%.

Assorted tropical and sub-tropical fruits – inedible peel- large (006B)

Avocado

Results from supervised trials from USA on avocado were provided to the Meeting. In these trials, one foliar application of spiroadiclofen (SC 240 formulation) was applied without spray adjuvant, as either a dilute spray (1800–3700 litres/ha) or a concentrate spray (330–650 litres/ha) to mature trees using airblast sprayers. Plot sizes in these trials ranged from 125–372 square metres with a minimum of 4 trees.

Duplicate samples of at least 2 kg mature fruit were frozen within 9 hours of sampling and stored at -15 °C for up to 10 months before whole fruit were extracted and analysed for spiroadiclofen using LC/MS/MS Method BA-001-P06-01 within 4 days of extraction. The reported LOQ was 0.01 mg/kg and the mean recovery rates in samples spiked with 0.01–1.0 mg/kg spiroadiclofen ranged from 98–101%.

APPRAISAL

Spirodiclofen, a ketoenol (tetronic acid) insecticide was evaluated for the first time by the 2009 JMPR, where an ADI of 0–0.01 mg/kg bw was established and it was agreed that an ARfD was not necessary. Residue definitions were proposed and maximum residue levels were recommended for a number of uses where GAP and supporting information were available.

Residue definitions established by the 2009 JMPR are:

- For plant products (compliance with MRLs and dietary intake estimation): *spirodiclofen*
- For animal products (compliance with MRLs): *spirodiclofen (fat soluble)*
- For animal products (dietary intake assessment): *sum of spirodiclofen and spirodiclofen-enol, expressed as spirodiclofen.*

Spirodiclofen was listed by the Forty-fifth Session of the CCPR (2013) for the review of additional MRLs for blueberries and avocados and the 2014 JMPR received GAP and residue information for these crops.

Methods of analysis

The 2009 JMPR reviewed and summarised analytical method descriptions and validation data for spirodiclofen and some of its metabolites in crop, processed commodities and animal commodities, including the HPLC-MS-MS multi-residue method 109351 (validated for the determination of parent spirodiclofen in plant commodities with high acid content, high water content and high fat content) and the HPLC/MS-MS method BA-001-P06-01 (validated for the determination of parent spirodiclofen and metabolites (3) in apples, grapes and their processed fractions).

These methods, with minor modifications were validated and used in the supervised residue trials on blueberry (Method 109351) and avocado (Method BA-001-P06-01) with an LOQ of 0.01 mg/kg.

Stability of residues in stored analytical samples

The 2009 JMPR reviewed freezer storage stability studies on a range of representative substrates and concluded that in stored frozen analytical samples, spirodiclofen was stable for at least 13 months in crops with high water content (peach), 24 months in crops with high acid content (citrus, grapes), 16 months in crops with oil content (almond nutmeat, dry hop cones), 8 months in fruit juice (apple juice, grape juice) and 10 months in dried fruit (dried apples, raisins, dried plums).

The Meeting received additional spirodiclofen storage stability studies on blueberry, showing that residues were stable in blueberry analytical samples stored frozen for at least 12 months.

Results of supervised residue trials on crops

The Meeting received new information on supervised field trials involving foliar applications of spirodiclofen to blueberries and avocados.

Blueberries

Results from supervised trials from USA and Canada on highbush and lowbush blueberries were provided to the Meeting.

The critical GAP for blueberries is in Canada, one application of 0.31 kg ai/ha with a PHI of 7 days. In trials from North America matching this GAP, spirodiclofen residues were: 0.38, 0.5, 0.51, 0.58, 0.7, 0.84, 0.99, 1.1, 1.1, 1.5, 1.5 and 2.3 mg/kg (n=12).

The Meeting estimated a maximum residue level of 4 mg/kg and an STMR of 0.92 mg/kg for spirodiclofen on blueberries.

Avocado

Results from supervised trials from USA on avocado were provided to the Meeting.

The critical GAP for avocados is in USA, one application of up to 0.35 kg ai/ha with a PHI of 2 days. In trials from USA matching this GAP, spirodiclofen residues were: 0.04, 0.07, 0.07, 0.15 and 0.47 mg/kg.

The Meeting estimated a maximum residue level of 0.9 mg/kg and an STMR of 0.07 mg/kg for spirodiclofen on avocado.

Farm animal dietary burden

As neither of these commodities are livestock feed items, the Meeting agreed that the 2009 JMPR conclusions and maximum residue level recommendations for livestock commodities did not need to be reviewed.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with the MRL and for the estimation of dietary intake for plant commodities: *spirodiclofen*

Definition of the residue for compliance with the MRL for animal commodities: *spirodiclofen*

Definition of the residue for the estimation of dietary intake for animal commodities: *sum of spirodiclofen and spirodiclofen-enol, expressed as spirodiclofen.*

The residue is fat soluble

CCN	Commodity	MRL (mg/kg)		STMR
	Name	New	Prev	
FB 0020	Blueberry	4.0		0.92
FI 0326	Avocado	0.9		0.07

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDI) for spirodiclofen was calculated from recommendations for STMRs for raw commodities in combination with consumption data for corresponding food commodities. The results are shown in Annex 3 to the 2014 Report.

The International Estimated Daily Intakes (IEDI) of in the 17 GEMS/Food cluster diets, based on the estimated STMRs were in the range 1–8% of the maximum ADI of 0.01 mg/kg bw. The Meeting concluded that the long-term intake of residues of spirodiclofen from uses considered by the Meeting is unlikely to present a public health concern.

Short-term intake

No ARfD was considered necessary. The Meeting concluded that the short-term intake of residues of spirodiclofen from uses considered by the Meeting is unlikely to present a public health concern.

SULFOXAFLOR (252)

First draft was prepared by Dr Paul Humphrey, Australian Pesticides and Veterinary Medicines Authority, Canberra, Australia

EXPLANATION

Sulfoxaflor is the first member of the novel sulfoximine class of insecticides. It controls insects via a unique interaction with the insect nicotinic acetylcholine receptor and has a broad lack of cross-resistance to other insecticides.

Sulfoxaflor was evaluated by JMPR in 2011. An ADI and AfRD of 0–0.05 mg/kg bw and 0.3 mg/kg bw respectively were established by the 2011 Meeting. A residue definition of *sulfoxaflor* was established for both compliance and dietary risk assessment in both plant and animal commodities.

After the subsequent meeting of CCPR, the proposed MRLs for citrus fruits, pome fruits, stone fruits and tree nuts were held at Step 4 because the GAP reviewed by JMPR differed from the registered USA GAP.

The Meeting received information on registered use patterns in pome fruit, stone fruit, citrus fruit and tree nuts in Australia and the USA. The residue trial data submitted to the 2011 Meeting for these crops was reconsidered against the registered GAPs.

USE PATTERN

Information on registered uses made available to this Meeting is shown in Table 1.

Table 1 Registered uses of sulfoxaflor on citrus fruits, pome fruits, stone fruits and tree nuts

Crop	Country	Formulation		Application					PHI [days]

Crop	Country	Formulation		Application					PHI [days]
		g ai/L or [g ai/kg]	Type	Method	Timing [Interval - days]	Rate [g ai/ha]	Concentration [g ai/100 L]	Maximum [g ai/ha/year] or (no. per crop)	
Stone fruits (Crop Group 12) including apricot, nectarine, peach, plum, prune, sweet cherry, tart cherry	USA	[500]	WG	Foliar	7	96	–	298 g ai/ha/year (4)	7
Tree Nuts									
Tree nuts (Crop Group 14) including almonds, cashew, chestnut, filbert (hazelnut), macadamia nut, pecan, walnut	USA	[500]	WG	Foliar	7	96	–	298 g ai/ha/year (4)	7

RESIDUES RESULTING FROM SUPERVISED TRIALS

The Meeting received no new information on residues resulting from supervised trials.

The citrus fruits, pome fruits, stone fruits and tree nuts data evaluated at JMPR 2011 which are tabulated below, were also evaluated for this appraisal, with reference to the submitted labels showing registered uses for these crops in Australia and the USA. The tables of residues data have been taken essentially unaltered from the 2011 evaluation, but with the addition of a column in the citrus, pome and stone fruits tables expressing the applied active as grams per 100 L, as well as *g ai/ha*, to enable easier comparison with Australian GAP for citrus, pome and stone fruits, which are expressed as concentrations. In addition, when two trials were performed at the same location in the same year and differ only by variety of fruit or nut, they have been separated by a dotted line in the tables and the highest residue from one trial only has been used in the estimation of an MRL and STMR.

Group	Commodity	Country	Table No.
FC Citrus Fruits	Grapefruit	USA	2
	Lemons	USA	3

APPRAISAL

Sulfoxaflor was first evaluated for residues and toxicological aspects by the 2011 JMPR. The 2011 Meeting established an ADI of 0–0.05 mg/kg bw and an ARfD of 0.3 mg/kg bw. The 2011 Meeting established a residue definition of sulfoxaflor for both compliance and dietary risk assessment in both plant and animal commodities. The 2011 Meeting estimated a number of maximum residue levels prior to registration of sulfoxaflor in any country as a pilot project.

After the subsequent meeting of CCPR, the proposed MRLs for citrus fruits, pome fruits, stone fruits and tree nuts were held at Step 4 because the provisional GAP reviewed by JMPR differed from the GAP finally approved in the USA.

The 2014 Meeting received information on registered use patterns for citrus fruit, pome fruit, stone fruit and tree nuts from the manufacturer and the residue data for those crops evaluated by the 2011 Meeting are reconsidered here against the submitted GAPs.

Results of supervised residue trials on crops

Citrus Fruit—Grapefruit, Lemon and Oranges

Registered use patterns from Australia and the USA were submitted. Supervised trial data for citrus were available from Australia, Brazil, and the USA.

Australian GAP for citrus fruit is for application at 9.6 g ai/100L (maximum of two applications, maximum 192 g ai/ha/single application, 1 day PHI).

USA GAP for citrus fruit is for application at 96 g ai/ha (14 day retreatment interval, maximum of four applications maximum 298 g ai/ha/ year, 1 day PHI).

None of the citrus fruit trials were conducted in accordance with the USA GAP. The majority of the Australian trials in oranges and mandarins were conducted at Australian GAP, while USA trials in oranges, grapefruit and lemons approximated Australian GAP after scaling.

The Meeting considered that US and Australian citrus fruit growing practices are similar, and noted the 2013 Meeting General Consideration item number 2.8 (Guidance for Use of Residue Trial Data from Different Geographical Locations for Estimation of Pesticide Residue Levels).

The Meeting determined that trials for all fruit will be related to Australian GAP for citrus fruit. The Meeting decided to use the concept of proportionality to estimate residue levels in citrus fruit in comparison to the Australian GAP where required. Scaled results for citrus fruit were within a range of 0.67–2.2× GAP, within the acceptable range for use of proportionality. Scaled results are indicated by an (s).

Grapefruit

Residue trials were conducted in grapefruit in the USA, approximating the critical GAP in Australia after scaling.

The results for grapefruit at a 1-day PHI after 2× 15.1–19.4 g ai/100L applications were: 0.010, 0.013, 0.016, 0.024, 0.11, and 0.13 mg/kg.

Residues in whole grapefruit after scaling to the Australian GAP were ≤ 0.01 (×3, all s), 0.015 (s), 0.064 (s) and 0.066 (s) mg/kg, where (s) indicates a result scaled to account for application rates outside $\pm 25\%$ of GAP.

Residues in pulp of grapefruit, in ranked order after scaling, were ≤ 0.01 (×3, all s) mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg for the subgroup shaddocks or pomelos. The Meeting noted that sulfoxaflor has systemic properties and considered that three edible portion data points was not sufficient for estimation of STMR and HR values. Therefore, the Meeting estimated an STMR of 0.0125 mg/kg and an HR of 0.066 mg/kg for sulfoxaflor in shaddocks or pomelos, based on the whole fruit data.

Lemons and limes

Residue trials were conducted in lemons in the USA, approximating the critical GAP in Australia after scaling.

Results for whole lemons at a 1-day PHI after $2 \times 16.2\text{--}21.2$ g ai/100L were: < 0.01 (2), 0.083, 0.11, and 0.29 mg/kg.

Residues in whole lemons after scaling to the Australian GAP where required were < 0.01 ($\times 2$, both s), 0.038 (s), 0.055 (s) and 0.17 (s) mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg for the subgroup lemons and limes, together with an STMR of 0.038 mg/kg, and an HR of 0.17 mg/kg.

Oranges and mandarins

Residue trials were conducted in oranges, in Australia approximating the critical GAP in Australia.

Residues of sulfoxaflor in whole oranges from the Australian trials at a 1-day PHI after $2 \times 6.4\text{--}20.2$ g ai/100L applications were: 0.09, 0.15, 0.16, 0.33, 0.41, and 0.43 mg/kg.

Scaled residues in whole oranges from the Australian trials with scaling to the Australian GAP where necessary were 0.09, 0.15, 0.19 (s), 0.24 (s), 0.33, and 0.43 mg/kg.

Residues trials were conducted in mandarins in Australia, at GAP.

Residues in whole mandarins from the Australian trials at a 1-day PHI after $2 \times 7.6\text{--}9.6$ g ai/100L applications were: 0.15, 0.28, 0.34, and 0.44 mg/kg.

The Meeting noted that the medians for the Australian datasets for oranges and mandarins differed by less than fivefold (medians differed by a factor of only 1.4 $\times$). The similarity of the datasets was further confirmed by the Mann-Whitney U-test. The Meeting concluded that the orange and mandarin datasets were mutually supportive and agreed to combine them for the purpose of estimation of maximum residue levels for the subgroups oranges, sweet, sour and mandarins.

The combined Australian data set for oranges and mandarins is 0.09, 0.15 (2), 0.19, 0.24, 0.28, 0.33, 0.34, 0.43, and 0.44 mg/kg.

The Meeting estimated maximum residue levels of 0.8 mg/kg for the subgroup oranges, sweet, sour and the subgroup mandarins, together with STMR values of 0.26 mg/kg and HR values of 0.44 mg/kg.

The Meeting withdrew the previous maximum residue level recommendation of 0.9 mg/kg for sulfoxaflor in citrus fruit.

Pome fruit - Apples and Pears

Registered use patterns from Australia and the USA were submitted. Supervised trials data were available for apples and pears from Australia/ New Zealand, Europe, and the USA.

Australian GAP for pome fruit is for application at 9.6 g ai/100L (maximum of two applications, maximum 192 g ai/ha/ single application, 7 day PHI).

USA GAP for pome fruit is for application at 96 g ai/ha (7 day retreatment interval, maximum of four applications maximum 298 g ai/ha/ year, 7 day PHI).

The Meeting noted that none of the trials were conducted in accordance with the USA GAP, while a number of the trials from both Australia/New Zealand and the USA matched the Australian GAP.

The Meeting considered that the US and Australian pome fruit growing practices are similar, and noted the 2013 Meeting General Consideration item number 2.8.

The Meeting determined that trials for both apples and pears will be related to Australian GAP for pome fruit. The Meeting decided to use the concept of proportionality as appropriate to estimate residue levels in pome fruit in comparison to the Australian GAP (trials for which proportionality was used were within 1.3–2.2 $\times$ GAP, within the acceptable range).

Residue trials were conducted in apples and pears in Australia/ New Zealand, approximating the GAP in Australia.

Results in apples and pears from the Australia/New Zealand trials at a 7-day PHI after 2× 9.1–16.1 g ai/100L applications were 0.02, 0.065, 0.07, 0.11, 0.14, 0.19, and 0.22 mg/kg.

Residues in apples and pears from the Australia/New Zealand trials were 0.015 (s), 0.039 (s), 0.07, 0.11, 0.14, 0.19, and 0.22 mg/kg (STMR = 0.11 mg/kg), where (s) indicates a result scaled to account for application rates outside ± 25% of GAP.

Residue trials were conducted in apples and pears in the EU. Results at a 7-day PHI after 2× 10.1–21.0 g ai/100L applications were: 0.052, 0.058, 0.074, 0.078, 0.099, 0.10, 0.18 (3), and 0.27 mg/kg.

Residues in apples and pears from the European trials scaled according to the Australian GAP are: 0.025 (s), 0.028 (s), 0.036 (s), 0.048 (s), 0.071 (s), 0.078, 0.082 (s), 0.082 (s), 0.086 (s), and 0.13 (s) mg/kg (STMR = 0.075 mg/kg).

Residue trials were conducted in apples and pears in the USA.

USA apple and pear results at a 7-day PHI after 2× 7.4–19.8 g ai/100L applications were: < 0.01, 0.039, 0.040, 0.043, 0.056, 0.063, 0.064, 0.066, 0.068, 0.072, 0.075, 0.089, 0.12, 0.13, 0.16, 0.18, and 0.26 mg/kg.

Residues in apples and pears from the USA trials scaled to the Australian GAP where necessary were < 0.01 (s), 0.039, 0.040, 0.043, 0.043 (s), 0.045 (s), 0.055 (s), 0.056, 0.057 (s), 0.063, 0.066, 0.068, 0.075 (s), 0.092 (s), 0.16, 0.18, and 0.23 mg/kg (STMR = 0.057 mg/kg).

The Meeting considered that the seven data points from the Australia/New Zealand apple and pear trials were not sufficient for estimation of a group maximum residue level for pome fruit. The Meeting noted that results from Europe and the USA relevant to the Australian GAP were available and combined the Australian, European and USA data sets:

- < 0.01, 0.015, 0.025, 0.028, 0.036, 0.039 (2), 0.040, 0.043, 0.043, 0.045, 0.048, 0.055, 0.056, 0.057, 0.063, 0.066, 0.068, 0.07, 0.071, 0.075, 0.078, 0.082 (2), 0.086, 0.092, 0.11, 0.13, 0.14, 0.16, 0.18, 0.19, 0.22, and 0.23 mg/kg

The Meeting estimated a maximum residue level of 0.3 mg/kg for sulfoxaflor in pome fruit, together with an STMR of 0.067 mg/kg and an HR of 0.23 mg/kg.

The Meeting withdrew the previous maximum residue level recommendation of 0.4 mg/kg for sulfoxaflor in pome fruit.

Stone Fruit

Registered use patterns from Australia and the USA were submitted. Supervised trial data were available for apricot (Australia and New Zealand), cherries (Australia, EU and USA), nectarine (Australia and New Zealand), peach (Australia, EU and USA) and plums (Australia and USA).

Australian GAP for stone fruit is for application at 7.2 g ai/100L (maximum of two applications, maximum 144 g ai/ha/ single application, 7-day PHI).

USA GAP for stone fruit is for application at 96 g ai/ha (7-day retreatment interval, maximum of four applications maximum 298 g ai/ha/ year, 7-day PHI).

Insufficient trials were conducted in accordance with the USA GAP, while a significantly greater number were conducted in accordance with the Australian GAP, and further trials could be related to the Australian GAP through the use of proportionality (trials for which results were scaled were within 1.3–2.9× of GAP, within the acceptable range).

The Meeting considered that the US and Australian stone fruit growing practices are similar, and noted the 2013 Meeting General Consideration item number 2.8.

Therefore trials for all stone fruit will be related to the Australian GAP for stone fruit.

Cherries subgroup

A total of 14 trials on cherries were available from Australia/ New Zealand (1 each), Europe (6), and USA (6).

Australia/New Zealand cherry results at a 7-day PHI after 2×9.7 – 16.3 g ai/100L applications were 0.35 and 0.38 mg/kg.

Residues of sulfoxaflor in cherries from Australia were: 0.17 (s) and 0.35 mg/kg (STMR = 0.26 mg/kg) where (s) indicates a result scaled to account for application rates outside $\pm 25\%$ of GAP.

European cherry results at a 7-day PHI after 2×10.1 – 20.1 g ai/100L applications were: 0.54, 0.77, 0.80, 0.90, 0.98 and 1.5 mg/kg.

Residues of sulfoxaflor measured in cherries from in Europe in accordance with Australian GAP (scaled where necessary) were: 0.29 (s), 0.32 (s), 0.33 (s), 0.38 (s), 0.42 (s), and 0.54 (s) mg/kg (STMR = 0.355 mg/kg).

USA cherry results at a 7-day PHI after 2×8.6 – 21.0 g ai/100L applications were: 0.55, 0.59, 0.76, 1.0, and 1.2 (2) mg/kg.

Residues of sulfoxaflor in cherries from USA in accordance with the Australian GAP (scaled where necessary) were: 0.24 (s), 0.26 (s), 0.26 (s), 0.42 (s), 0.46 (s) and 1.2 mg/kg (STMR = 0.34 mg/kg).

The Meeting noted that there were insufficient residue trials conducted in Australia/New Zealand in accordance with the Australian GAP, and combined the Australia, American and European datasets for the purpose of estimating a maximum residue level for the cherries subgroup.

Residues in cherries from trials conducted in Australia/New Zealand, EU countries and the USA were:

- 0.17, 0.24, 0.26 (2), 0.29, 0.32, 0.33, 0.35, 0.38, 0.42 (2), 0.46, 0.54, and 1.2 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg for the subgroup cherries, together with an STMR of 0.34 mg/kg, and an HR of 1.24 mg/kg (unrounded result).

Peaches subgroup

A total of five trials on nectarines were available from Australia and New Zealand. The results for nectarines at a 7-day PHI after 2×9.8 – 19.7 g ai/100L applications were: 0.10, 0.11, 0.12, 0.14, and 0.18 mg/kg.

Residues of sulfoxaflor in nectarines from Australia and New Zealand were: 0.037 (s), 0.054 (s), 0.061 (s), 0.10 (s) and 0.12 (s) mg/kg (STMR = 0.061 mg/kg) where (s) indicates a result scaled to account for application rates outside $\pm 25\%$ of GAP.

Two trials on apricots were available from Australia and New Zealand. The results for apricots at a 7-day PHI after 2×9.5 – 14.8 g ai/100L applications were: 0.15 and 0.42 mg/kg.

Residues of sulfoxaflor apricots from Australia/New Zealand in accordance with the Australian GAP (scaled where necessary) were: 0.11 (s) and 0.20 (s) mg/kg (STMR = 0.155 mg/kg).

Eight trials in peaches were conducted in Australia and New Zealand. The results at a 7-day PHI after 2×9.7 – 19.8 g ai/100L applications were: 0.012, 0.11, 0.11, 0.12, 0.14, 0.15, 0.24, and 0.27 mg/kg.

Residues of sulfoxaflor in peaches from Australia and New Zealand (scaled to the Australian GAP where required) were: < 0.01 (s), 0.040 (s), 0.050 (s), 0.052 (s), 0.057 (s), 0.094 (s), 0.16 (s) and 0.20 (s) mg/kg (STMR = 0.0545 mg/kg).

The Meeting noted that the GAP under consideration is for Australia, and that a large regional (Australia/New Zealand) data set for the peach group is available (15 trials in total for peaches, nectarines and apricots), and that the median values of these data sets are within a factor of $5 \times$ each

other (the medians differed by a maximum factor of 2.8×). The Meeting agreed to combine the Australia/New Zealand peach, nectarine and apricot data for the purpose of estimating a maximum residue level for the peach subgroup:

- < 0.01, 0.037, 0.04, 0.05, 0.052, 0.054, 0.057, 0.061, 0.094, 0.10, 0.11, 0.12, 0.16, and 0.20 (2) mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg for the subgroup peaches, together with an STMR of 0.061 mg/kg and an HR of 0.2 mg/kg.

Plums

A total of seven trials on plums were available from Australia (1) and USA (6).

The Australian result for plums at a 7-day PHI after 2× 19.2 g ai/100L applications was: 0.020 mg/kg.

Residues of sulfoxaflor measured in plums from Australia were: < 0.01 (s) mg/kg where (s) indicates a result scaled to account for application rates outside ± 25% of GAP.

The USA results for plums at a 7-day PHI after 2× 6.9–20.9 g ai/100L applications were: 0.030, 0.054, 0.066, 0.090, 0.11, and 0.26 mg/kg.

Residues of sulfoxaflor in plums from the USA in accordance with the Australian GAP (scaled where necessary) were: 0.020 (s), 0.028 (s), 0.038 (s), 0.039 (s), 0.06 (s) and 0.26 mg/kg.

Residues in plums from trials conducted in Australia and the USA were: < 0.01, 0.020, 0.028, 0.038, 0.039, 0.06, and 0.26 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg for the subgroup plums, together with an STMR of 0.038 mg/kg, and an HR of 0.26 mg/kg.

The Meeting withdrew the previous maximum residue level recommendation of 3 mg/kg for sulfoxaflor in stone fruit.

Tree Nuts

USA GAP for tree nuts (Crop Group 14) including almonds, cashew, chestnut, hazelnut, macadamia, pecan and walnut is for application at 96 g ai/ha (7 day retreatment interval, maximum of four applications maximum 298 g ai/ha/ year, 7 day PHI).

Residues data from trials conducted in the USA were available for almonds and pecans. However, the trials do not match the USA GAP, with only two applications being made at a rate of 200–205 g ai/ha with a 7-day PHI. The Meeting therefore did not estimate maximum residue levels, STMRs or HRs for the tree nut group.

The Meeting agreed to withdraw the previous maximum residue level recommendation of 0.015 mg/kg for sulfoxaflor in tree nuts.

Animal feeds

Almond hulls

Residue data for sulfoxaflor in almond hulls were available to the Meeting. However, as the trials were not conducted in accordance with the USA GAP for almonds, the Meeting did not estimate a median residue value.

Fate of residues during processing

The 2011 Meeting received information on the fate of sulfoxaflor residues during the processing of apple to juice, sauce and wet and dry pomace; cherry to dried cherries, jam and juice and oranges to juice, wet and dry pulp, oil and peel.

Calculated processing factors are summarized in the following table based on the JMPR 2014 recommendations for MRLs and STMRs. Factors are indicated with a '<' (less-than) sign when the residue in the processed commodity is below the LOQ of the analytical method. The calculation is then made on the LOQ of the analytical method and the residue concentration of the RAC (raw agricultural commodity).

Processes included in the table are those that lead to STMR-P or HR-P values useful for dietary intake estimations or for livestock dietary burden calculations.

Raw Agricultural Commodity (RAC)	Processed Commodity	Best Estimate Processing Factor (PF)	RAC MRL (mg/kg)	RAC STMR (mg/kg)	RAC HR (mg/kg)	Processed commodity STMR-P (mg/kg)	Processed commodity HR-P (mg/kg)
Apple	Wet pomace	1.1	0.3	0.067	0.23	0.074	–
	Dry pomace	4.2				0.28	–
	Juice	0.4				0.027	–
	Sauce	0.6				0.040	–
Cherry	Juice	0.8	1.5	0.34	1.24	0.27	–
	Jam	1.1				0.37	–
	Dried	5.1				1.73	6.32
Orange	Juice	0.14	0.8	0.26	0.44	0.036	–
	Wet pulp	2.5				0.65	–
	Dried pulp	8.3				2.16	–
	Oil	< 0.2				< 0.052	–
	Peel	5.6				1.46	2.45

Animal commodities

The Meeting recalculated the livestock dietary burden based on the uses considered by the current Meeting and by the 2011 Meeting on the basis of diets listed in the FAO Manual Appendix IX (OECD Feedstuff Table).

The maximum dietary burden is 3.22 ppm for beef and dairy cattle, while the mean dietary burden is 1.26 ppm for beef and dairy cattle. The values calculated by the 2011 Meeting were: maximum dietary burden of 3.04 ppm for beef cattle and 2.68 ppm for dairy cattle, and a mean dietary burden of 0.91 ppm for both dairy and beef cattle. Interpolation of these values between the appropriate feeding levels in the lactating cattle feeding study considered by the 2011 Meeting showed that no changes to the maximum residue levels estimated by the 2011 Meeting for milks, edible offal (mammalian) or meat (from mammals other than marine mammals) were required.

The maximum and mean dietary burdens for poultry (both layers and broilers) are 0.93 and 0.31 ppm respectively. These have changed very little from the values determined by the 2011 Meeting (maximum and mean values of 0.89 and 0.30 ppm respectively).

The Meeting confirmed its previous recommendations for meat (from mammals other than marine mammals), edible offal (mammalian), milks, poultry meat, poultry, edible offal of, and eggs.

The Meeting noted that the 2011 Meeting did not estimate maximum residue levels for mammalian fats (except milk fats) or poultry fats.

The Meeting noted the STMR values of 0.03 mg/kg and HR value of 0.073 mg/kg estimated by the 2011 Meeting for the fat compartment of mammalian meat (from mammals other than marine mammals). Noting that the dietary burden has not significantly increased, the Meeting estimated a maximum residue level of 0.1 mg/kg for mammalian fats (except milk fats), together with an STMR of 0.03 mg/kg and an HR of 0.073 mg/kg.

The Meeting noted the STMR values of 0.005 mg/kg and HR value of 0.021 mg/kg estimated by the 2011 Meeting for the fat compartment of poultry meat. Noting that the dietary burden has not significantly increased, the Meeting estimated a maximum residue level of 0.03 mg/kg for poultry fats, together with an STMR of 0.005 mg/kg and an HR of 0.021 mg/kg.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for plant and animal commodities: *sulfoxaflor*

The residue is not fat soluble

The Meeting estimated the maximum residue levels and STMR values shown below.

Commodity		MRL, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
CCN	Name	New	Previous

DIETARY RISK ASSESSMENT

Long-term intake

The evaluation of sulfoxaflor has resulted in recommendations for MRLs and STMRs for raw and processed commodities. The International Estimated Daily Intakes for the 17 GEMS/Food cluster diets, based on estimated STMRs were in the range 1–7% of the maximum ADI of 0.05 mg/kg bw (Annex 3 of the 2014 Report).

The Meeting concluded that the long-term intake of residues of sulfoxaflor, from uses that have been considered by the JMPR, is unlikely to present a public health concern.

Short-term intake

The International Estimated Short Term Intake (IESTI) for sulfoxaflor was calculated for the plant and livestock commodities (and their processing fractions) for which new STMRs and HRs were

estimated and for which consumption data were available. The results are shown in Annex 4 to the 2014 Report.

The IESTI varied from 0–9 % of the ARfD (0.3 mg/kg bw). The Meeting concluded that the short-term intake of residues of sulfoxaflor, from uses that have been considered by the JMPR, is unlikely to present a public health concern.

THIAMETHOXAM (245)

First draft prepared by Ms C.M. Mahieu and Ms T. van der Velde-Koerts, National Institute for Public Health and the Environment (RIVM), The Netherlands

EXPLANATION

Thiamethoxam and clothianidin (including CGA322704 as a metabolite of thiamethoxam) were evaluated for toxicology and residues as a new compound in 2010, resulting in a number of MRL recommendations. Additional residue data for both compounds were evaluated in 2011 and 2012. The residue definition for thiamethoxam in plant commodities for enforcement is thiamethoxam, while the residue definition for dietary risk assessment is thiamethoxam and the metabolite CGA322704 (clothianidin), considered separately. The residue definition for clothianidin in plant commodities for enforcement and dietary risk assessment is clothianidin.

For the current evaluation the Meeting received data on analytical methods, use patterns, and supervised residue trials in support of the use on avocado, hops, legume vegetables and mint (USA IR-4 programme) and persimmon (Republic of Korea, (RoK)). Summaries of the trials have been provided to support MRL recommendations for thiamethoxam and clothianidin on the respective crops.

RESIDUE ANALYSIS

The Meeting received descriptions of analytical methods used for analysis of thiamethoxam and CGA322704 in mango, persimmon, avocado, fresh beans, mint and hop samples from the trials.

Method AG-675 (used for avocado, mint and hop samples) has been evaluated previously for other animal and plant commodities by the JMPR in 2010. Crop specific modifications are described below. Method REM 197.03 was used on the trials in beans. This method has also been evaluated by the JMPR in 2010. The current Meeting received additional validation data, based on historical findings, for the analytical method REM 179.06 of thiamethoxam and clothianidin. The results are summarized below. The two analytical methods LC-MS/MS Method 954/2010 and Method HPLC/DAD to determine thiamethoxam and CGA322704 (clothianidin) in mango and persimmon, respectively, were not previously evaluated by the JMPR and are described below.

Validation results are required for every commodity submitted for MRL-setting: at least one full validation for a commodity within the five defined crop groups (high acid content, high water content, high oil content, high protein content, high starch content) and a reduced validation for every other commodity within a certain crop group. Where validation results do not meet the criteria given below, this is indicated.

When the analytical method is validated according to a full validation scheme, it means that

- at least 5 recovery experiments per level were conducted on at least 2 levels (LOQ and $10\times$ LOQ) and average recovery per level was shown to be between 70–120% and the relative standard deviation (RSDr or CV) per level was shown to be $< 20\%$,
- at least two control samples were analysed and were shown to be below $0.3\times$ LOQ and
- the calibration was conducted with at least 5 single points or at least 3 duplicate points and was shown to be linear (either standards in solvent or matrix matched standards).
- When the analytical method is validated according to a reduced validation scheme, it means that
- a full validation is available for a crop in the same crop group (high acid content, high water content, high oil content, high protein content, high starch content);
- at least 3 recovery experiments per level were conducted on at least 2 levels (LOQ and $10\times$ LOQ) and the average recovery per level was shown to be between 70–120% and the relative standard deviation (RSDr or CV) per level was $< 20\%$;

- at least two control samples were analysed and shown to be below $0.3 \times \text{LOQ}$
- the calibration was conducted with at least 5 single points or at least 3 duplicate points and was shown to be linear (only relevant for matrix matched standards; standards in solvent are already covered by full validation).

LC-MS/MS Method 054/2010

For the trials on mango [Thirion, 2013a-c, A9795B_11446, 11447 and 11448] performed in 2012/2013 the SABS In-house method was used with reference 054/2010.

Dried mango samples (processing study) were first soaked in water. Subsamples of (fresh) mango (10 g) were extracted with water/methanol (1:1) and filtered through a funnel with Celite. The extract was diluted with water and adjusted to pH with a 10% NH_3 solution. Clean-up was performed by elution with water and methanol over a SPE cartridge and evaporated to dryness. The residue was redissolved in methanol/water (1:1 v/v) and filtered for LC-MS/MS analysis using m/z 292 to 211 for thiamethoxam and m/z 250 to 132 for CGA322704.

The LC-MS/MS SABS In-House method 054/2010 was validated for determination of thiamethoxam and CGA322704 (clothianidin) residues in mango and whole fruit (peel and flesh together, peel and dried mango in the range of 0.01 mg/kg-1.0 mg/kg with a limit of quantification of 0.1 mg/kg. Acceptable concurrent recovery data were obtained for thiamethoxam (66–102, 9–10% RSD) and CGA322704 (clothianidin) (60–96, 7–13% RSD) in each matrix at 0.01–1 mg/kg. The specificity of the method was demonstrated by analysing control samples of each matrix. No background interference was experienced at the limit of quantification of 0.01 mg/kg. Linearity was demonstrated by using linear regression analysis of the detector response area of both compounds against the compounds in the calibration standard (calibration curves existed of at least four different concentrations of the two compounds).

HPLC/DAD method (persimmon), further to be referred to as Method MFDS201304

In the residue trials for persimmon [Kim, 2012, MFDS201304] a HPLC/DAD analytical method, not previously described in JMPR 2010, 2011, or 2012, was used. Fresh persimmon (25 g) was extracted with acetone and filtered over filter paper. The flask and filter cake were rinsed again with acetone. The combined filtrate and rinsate was partitioned with a mixture of water, NaCl and dichloromethane (100:50:100 v/v). The organic layer was filtered through an anhydrous Na_2SO_4 layer (20 g). The filter cake was rinsed with dichloromethane. The pooled organic extract was evaporated to dryness at 40 °C by rotary vacuum evaporation. The residue was redissolved with 5 mL of methanol:water (50:50 v/v) solution. Samples were analysed by HPLC with diode array detector (DAD) with a mobile phase of methanol:water of 30:70 (first experiment) or 25:75 (second experiment). The reported LOQ was 0.02 mg/kg for both parent and CGA322704 (clothianidin).

There was no interference with other substances observed at the retention times of thiamethoxam and CGA322704 (clothianidin) above 30% of the LOQ. Acceptable concurrent recovery data were obtained for each analyte (85.9–99.4%) at 0.02, 0.2, and 2 mg/kg spike levels. Linearity was demonstrated by using linear regression analysis of the detector response area of both compounds against the compounds in the calibration standard (calibration curves existed of at least four different concentrations of the two compounds).

Method AG-675

For the trials on avocado [Syngenta, 2008, 464507, T010202-06], hops [Syngenta, 2013a, A9549C_50012, TK0053990 and Starner, 2006, CGA293343/2850, 08451] and mint and mint oil [Syngenta, 2001, 406892, 07362] LC-MS/MS method AG-675 was used. This method has been evaluated by the JMPR in 2010 for various animal and plant matrices (e.g. apple, cotton seed, sorghum forage), but not yet for avocado, mint and hop.

Avocado samples (fruits without stones) were extracted with acetonitrile/water (80:20 v/v), filtered through Celite under vacuum, and the diluted extracts analysed directly by LC-MS/MS using m/z 292 to 211 for thiamethoxam and m/z 250 to 132 for CGA322704.

Mint top samples (leaves and stems) were extracted with acetonitrile/water (80:20 v/v), filtered under vacuum, and the filter cake re-extracted. The combined filtered extracts were cleaned-up by liquid/liquid partition followed by GPC. The resulting extracts were analysed directly by LC-MS/MS using m/z 292 to 211 for thiamethoxam and m/z 250 to 132 for CGA322704.

For mint oil, the extraction procedure was not necessary. The mint oil was diluted with the GPC mobile phase (ethyl acetate/cyclohexane, 50:50 v/v) and cleaned-up by GPC. The resulting extract was analysed directly by LC-MS/MS using m/z 292 to 211 for thiamethoxam and m/z 250 to 132 for CGA322704.

Hop samples (dry cones) were extracted with acetonitrile/water (80:20 v/v), filtered through Celite under vacuum, and the filter cake re-extracted. Aliquots of the combined filtered extracts were concentrated, buffered with 50 mM sodium phosphate, filtered and cleaned-up by solid phase extraction (SPE) using phenyl sorbent cartridges. The resulting extracts were diluted and analysed by LC-MS/MS using m/z 292 to 211 for thiamethoxam and m/z 250 to 132 for CGA322704.

Method REM 179.06

For the trials on fresh beans [Kang, 2005a, CGA293343/2217, CEMR-2185, Kang 2005b, CGA293343/2218, CEMR-2186, Rawle, 2005a, CGA293343/2203, CEMR-2011, Rawle, 2005b, CGA293343/2204, CEMR-2202, Kang, 2005c, CGA293343/2633, CEMR-2322] method REM 179.06 was used to establish the residue levels. This method has been evaluated JMPR evaluation 2010. For the current evaluation, the Meeting received an independent method validation for this method.

Independent method validation REM 179.06

Method REM 179.06 was subject to an independent laboratory validation for residue analysis of several crops. The validation consists of a collation of data retrieved for the commodity crops as specified in the OECD Guidance on pesticide Residue Analytical Methods and an additional dry matrix [Anderson and Crook, 2013, CGA293343_11624, TK0122383]. The recovery data are included in tables 1 (thiamethoxam) and 2 (GA322704 (clothianidin)). Sufficient recovery data are available for the majority of the described crops (high water content crops, high protein content crops, high starch content crops, high acid content crops and dry content crops for both thiamethoxam as well as for CGA322704 (clothianidin)). The method has however been used only on a limited number and range of high oil content crops. At present insufficient recovery data are available to permit extrapolation to all high oil content crops. The LOQ of the method is 0.02 mg/kg for each analyte for all crops tested. Linearity was sufficiently demonstrated.

Table 1 Analytical recoveries for spiked thiamethoxam in various substrates using method REM 179.06 LC-MS/MS

Stability of pesticide residues in stored analytical samples

The freezer storage stability of thiamethoxam and metabolite CGA322704 (clothianidin) at residue concentrations was already established for by the JMPR 2010 evaluation of thiamethoxam in apples, tomatoes, potato tubers, rape seed, maize grain, cranberries, hops, barley grain, barley hay, barley straw, pearled barley and barley flour. Thiamethoxam, and metabolites CGA322704 (clothianidin) and CGA265307 were apparently stable at residue concentrations in the various substrates tested at the freezer temperatures and test durations. The durations of test were mostly 1–2 years, but some were less. Test temperatures were mostly approximately -18 °C to -20 °C, but other storage temperatures were used in some storage stability tests, e.g., between -26 °C and -4 °C. The JMPR 2010 evaluation of clothianidin has established that parent clothianidin was stable when stored at temperatures of -10 °C or lower for at least 24 months in crops with high water content (apple, Japanese pear, apricot, peach, cauliflower, head cabbage, cucumber, tomato, lettuce, maize and forage), for at least 18 months in crops with high acid content (cranberries and grapes), for at least 24 months in crops with high oil content (dry soya beans, cottonseed, rape and seed), for at least 24 months in crops with high starch content (maize grain, rice grain, sugar beet roots and potatoes), for at least 10 months in dry tea leaves, for at least 24 months in maize straw, for at least 2 months in tomato paste, for at least 4 months in cotton meal, and for at least 4 months in cotton oil. The storage stability data as provided in the different residue trials submitted for the current evaluation have been summarized in Table 3.

Table 3 Storage stability data of thiamethoxam and CGA322704 (clothianidin)

Commodity	Residue	Storage time (days)	% remaining mean range RSD _r	concurrent recovery	reference, method
persimmon	Thiamethoxam Fresh	31-52	95.1%, RSD 2.1 (n=5)	89.2-94.8% (fortification level 0.02, 0.2, 2.0 mg/kg)	Kim 2012, MFDS201304, HPLC/DAD 2011 data

Crop	Country	Form	Application				PHI, days
			Method	Rate kg ai/ha	Spray conc, kg ai/hL	Number (max rate/season)	
				0.0700		(max 0.210 kg ai/ha)	
Persimmon (Japanese)	Korea	(10%) WG	Foliar	- ^f	0.005	3 (interval 10 days)	7

^a Do not exceed 0.21 kg ai/ha (equiv. to 0.188 lbs ai/acre) per growing season. Minimum of 7 days interval. Do not use less than 467 L/ha (50 GPA) for ground application. Use sufficient water volume to cover all foliage.

^b Indoor and outdoor use, according to Portuguese label. Interval of 7 days. For outdoor use only apply after flowering.

^c Only indoor use according to Portuguese label.

^d Apply specified dosage in sufficient water volume to ensure uniform application and incorporation into the soil using one of the following methods: 1. Apply a surface band on each side of the row out to the plant canopy drip line or within the vegetation free herbicide strip, followed by sufficient irrigation to incorporate the product into the plants root zone. 2. apply by chemigation into the root zone through low-pressure microsprinkler, trickle or drip type irrigation systems. 3. hill drench in sufficient water to ensure incorporation into the root zone followed by irrigation.

^e 0.11-0.21 and 0.21-0.28 kg product/ha (equiv. to 1.5-3.0 or 3.0-4.0 oz product/A) for peppermint and spearmint. Max of 0.21 kg ai/ha (equiv. to 0.188 lb ai/A) per growing season. Do not use less than 467 L/ha (50 GPA) for ground application. Use sufficient water volume to cover all foliage. Minimum interval 14 days.

^f The spray application is commonly conducted until the fluid is dripping down the leaves.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised residue trials of thiamethoxam for avocado, mango, fresh common beans, hops, mint, and persimmon. The commodities are grouped into Codex commodity groups.

Crop group	Commodities	Table No.
Pome fruit	Persimmon: Korea	Table 5
Assorted tropical fruits – inedible peel	Avocado: USA	Table 6
Assorted tropical fruits – inedible peel	Mango: South Africa	Table 7
Legume vegetables	Fresh beans: Portugal	Table 8
Fresh herbs	Mint: USA	Table 9
Dried herbs	Hops: USA	Table 10

Application rates and spray concentrations have been rounded to three figures; residues have been rounded to two figures. Residue data are recorded unadjusted for percentage recoveries or for residue values in control samples unless otherwise stated. Unquantifiable residues are shown as below the reported LOQ (e.g. < 0.01 mg/kg). Where multiple samples were taken from a single plot or where multiple analyses were conducted on a single sample, the average value is reported. Where results from separate plots with distinguishing characteristics such as different formulations, crop varieties or treatment schedules were reported, results are listed separately for each plot. Residues from the trials conducted according to critical GAP have been used for the estimation of maximum residue levels, STMR and HR values. Those results are underlined.

The residues presented in the tables are given as individual compounds (parent and CGA322704, separately).

Pome fruits

Japanese persimmon

Six supervised residue field trials were conducted on Japanese persimmon in the 2011–2012 growing season in the Korea [Kim, 2012, MFDS201304].

Small plots (80 m²) of 12–32 year old persimmon trees were treated three times with a WG formulation at a nominal rate of 156–438 g ai/ha (all with spray concentrations of 0.005 kg ai/hL) with a 10–11 days interval at growth stage BBCH 77–79. The plots were treated as indicated in Table 5 using a hand sprayer.

Samples of persimmon (6–51 kg) were taken at maturity at six time points after the final application. Growth stages were not reported. Seeds and stalk were removed from the persimmon before preparation. Subsequently, the samples were chopped and thoroughly mixed. All samples were stored frozen for 31–52 days (2011 trials) and 14–35 days (2012 trials) at -20 °C. The stability of thiamethoxam and clothianidin (CGA322704) during storages was tested (recovery was 85.9–95.1% for the 2011 trials and 81–85% for 2012 trials).

Samples were analysed for parent and clothianidin (CGA322704) with a HPLC/DAD method (Method MFDS201304) with an LOQ of 0.02 mg/kg. The method is described in the analytical section of the evaluation.

Concurrent recoveries were 89.2–94.8% and 85.9–99.4% for parent and CGA322704, respectively at fortification levels of 0.02, 0.2 and 2.0 mg/kg in the 2011 trials and 83.1–93.5% and 81.5–85.5% for parent and CGA322704, respectively at fortification levels of 0.02, 0.2, 0.5 and 2.0 mg/kg in the 2012 trials.

Note: The analytical method is considered valid in the range 0.02–2.0 mg/kg for the determination of thiamethoxam and CGA322704 in persimmon.

^b Trials were performed in the same region (<10 km apart)

Assorted (sub) tropical fruits with inedible peel

Avocado

Supervised residue field trials were conducted on avocado in the 2006–2007 growing seasons in the USA and Mexico [Syngenta, 2008, 464507, T010202-06]. Plots (size not reported) of avocado trees were treated thrice with a 25 WG formulation at an application rate of approximately 70 g ai/ha (0.0625 lbs ai/A) using boom sprayers using 93–3738 L/ha (10–400 GPA).

Avocados were harvested at two time points after the final application at maturity (growth stages not reported). Samples were collected from (24 fruits from at least 4 separate trees) reaching at least 2 kg. Stems and pits were removed at time of sampling. All samples were stored frozen for a maximum of 9 months at -20 °C. This storage period is covered by the storage stability studies (24 months).

Samples were analysed for parent and its metabolite CGA322704 using HPLC-MS/MS method Syngenta Analytical Method AG-675, with an LOQ of 0.01 mg/kg for parent and metabolite. Residues of thiamethoxam and CGA322704 from the trials are summarised in Table 6. Residues of each of these analytes from untreated plots were less than the LOQ (0.01 mg/kg). Average concurrent recoveries at 0.01 and 0.14 mg/kg were within 70–120% for each analyte (range 72–99%).

Note: The analytical method is considered valid in the range 0.01–0.14 mg/kg for the determination of thiamethoxam and CGA322704 in avocado.

^a Results are the average of two replicate analytical samples. Original data $\times$ 0.80 conversion factor to represent the RAC whole fruit (original data representing the fruit without the stone).

Mango

The Meeting received information on supervised residue trials on mango conducted in South Africa in the growing seasons 2003/2004 and 2011/2012. The data from 2003/2004 were already evaluated by the JMPR in 2010. The data from 2011/2012 were submitted to supplement the original studies [Thirion, 2013a, Syngenta A9795B_11446, 2418/F787] and the results are presented in Table 7. In addition residue data for thiamethoxam after an exaggerated application (3X) were generated for determining processing factors for thiamethoxam and CGA322704 in mango [Thirion, 2013b, and c, Syngenta A9795B_11447, 2418/F788 and Syngenta A9795B_1148, 2418/G676]. These results are summarized in the section on processing.

Plots (462–1111 trees/ha, 5–8 trees/plot) of mango trees were treated once with a 240 SC formulation at an application rate of 6 or 12 ml diluted in 1 or 2 litre of water and poured around the tree with a jug at a rate of , respectively 1.4 or 2.9 g/tree.

Mangoes were harvested at maturity at one or more time points after the treatment. Samples were collected (8–24 fruits from at least 8 separate trees) ranging from 1.3 to >6 kg. Despite picking more than 12 items (21 to 24) in trial ZA13 RMG 001-2012, the samples sizes were < 2 kg at BBCH 75 and 76 (DAT 61 and 74, respectively). The samples sizes at DAT 118 and more were $\geq$ 3.4 kg. In addition, at DAT 89, 79 and 81 in the same trail only 8 items were picked instead of the required 12. In the other three trials the weight of the sample and the number of picked fruits was sufficient. All samples were stored frozen at <-18 °C and processed and analysed within one year. This storage period is covered by the storage stability studies (24 months).

Samples were analysed for parent and its metabolite CGA322704 using SABS in-house Method No 054/2010 with an LOQ of 0.01 mg/kg for both parent and metabolite. Results were not corrected for control levels (< 0.01 mg/kg for each analyte) nor for average concurrent method recoveries (72–92% for each analyte at 0.01, 0.03, 0.05 and 0.10 mg/kg). Residues of thiamethoxam and CGA322704 from the trials are summarised in Table 7.

n.a. = not applicable

^a In accordance with OECD Guideline Test No. 509 (crop field trial) the residues were determined in flesh and skin after removal of the stone and calculated to and expressed as whole fruit.

Legume vegetables

Fresh beans with pods

Eight residue trials were conducted on fresh beans in the 2003 and 2004 in Spain [Kang, 2005a, CGA293343/2217, CEMR-2185, Kang 2005b, CGA293343/2218, CEMR-2186, Rawle, 2005a, CGA293343/2203, CEMR-2201, Rawle, 2005b, CGA293343/2204, CEMR-2202, Kang, 2005c, CGA293343/2633, CEMR- 2322]. Beans were treated with a WG formulation at a nominal rate of 100 g ai/ha at growth stage BBCH 65–89 and again 6–7 days later (BBCH 71–89). Small plots (23–46 m²) were treated as indicated in table 8 using boom sprayers with a spray volume of approximately 1000 L/ha.

Samples of fresh beans with pods (1.0–2.4 kg) were taken at maturity at three time points after the final application within growth stages BBCH 71–78. In the 2004 trials also samples of remaining plant (5.7–14 kg) were taken at the same stages. Samples were collected at random from the whole plot. Plant samples were collected without roots. All samples were stored frozen at -18 °C. No data on storage duration were submitted. As the study was completed within a year, the storage duration is <365 days and sufficiently covered by the storage stability studies performed in a large variety of crops.

Samples were analysed for parent and CGA322704 with LC-MS/MS analytical method REM 179.03 with an LOQ of 0.02 mg/kg. Results were not corrected for control levels (< 0.01 mg/kg for each analyte) nor for average concurrent recoveries (69–95% and 76–117% for parent and CGA322704, respectively at fortification levels of 0.02 and 0.20 mg/kg) in the different studies. Residues of thiamethoxam and CGA322704 from the trials are summarized in Table 8.

^a Mean of three values

^b BBCH growth stage is included to demonstrate that the samples were collected at the green stage of the beans. BBCH 79 is before ripening of the fruit (beans get hard). This process starts at BBCH 81 to 89.

Fresh herb

Mint

Five supervised residue field trials were conducted on mint in 2000–2001 in the USA [Syngenta, 2001, 406892, 07362]. The trials were not previously evaluated by the JMPR.

Plots (61–293 m²) of mint received three foliar applications at an interval of 13–15 days and a rate of approximately 70 g ai/ha (0.066 lbs ai/A, with a total of 0.198 lb ai/A) per treatment with a WG formulation, using 245–300 L water/ha (20–50 GPA). At two sites one additional plot received three applications at an intended rate of 370 g ai/ha (5×) each for a total of 1.1 kg ai/ha with an interval of 13–14 days. Six or 7 days after the last treatment at least 1.8 kg of mature mint tops (leaves and stem) were harvested. Mint oil was distilled from additional tops (sample size 0.9 kg) collected from the 5X tops (see section on processing).

All samples were stored frozen for a maximum of 482 days (tops) or 502 days (oil) at < 0 °C. This storage period is covered by the storage stability (452 days for tops and 465 days for oil).

Samples were analysed for parent and its metabolite CGA322704 using LC-MS/MS Method No AG-675 with an LOQ of 0.05 mg/kg for both parent and metabolite (see analytical section). Results were not corrected for control levels (< 0.05 mg/kg for each analyte) nor for average concurrent method recoveries (77–85% (parent) and 92–96% CGA322704) for each analyte at 0.05, 0.50 and 5.0 mg/kg). Residues of thiamethoxam and CGA322704 from the trial are summarised in Table 9.

Table 9 Residues of thiamethoxam and metabolite CGA322704 (clothianidin) in mint after pre-harvest treatment (tops)

^a Results are mean of 2 replicates.

Dried herbs

Hops

Supervised residue field trials were conducted on hops in 2006 and 2011 in the USA [Syngenta, 2013a, A9549C_50012, TK0053990]. The trials conducted in 2006 were evaluated by the JMPR 2010 and not further addressed in this evaluation.

In the newly submitted study [Syngenta, 2013a, A9549C_50012, TK0053990] plots (size not reported) of hop were treated once with a SG formulation at an application rate of approximately 140 g ai/ha (0.125 lbs ai/A) by soil surface band application, using 187–467 L/ha (20–50 GPA). Sixty five days after treatment the hop was harvested and dried (confirmed in personal communication with manufacturer, Syngenta 08092014).

Samples of at least 0.45 kg (1 lb) of dry cones were collected. All samples were stored frozen for a maximum of 8.5 months at -10 to -20 °C. This storage period is covered by the storage stability studies (24–40 months) already evaluated by the JMPR in 2010.

Samples were analysed for parent and its metabolite CGA322704 using LC-MS/MS Syngenta Method No AG-675 with an LOQ of 0.01 mg/kg for both parent and metabolite. Results were not corrected for control levels (< 0.01 mg/kg for each analyte) nor for average concurrent method recoveries (79.9–92.4% for each analyte at 0.01 and 1.0 mg/kg). Residues of thiamethoxam and CGA322704 from the trial are summarised in Table 10.

Legume vegetables animal feeds

Several residue trials were conducted on fresh beans in Spain. These have been summarized in the relevant residue section. In four of these residue trials [Kang, 2005c, Syngenta CGA293343/2633, CEMR-2322] residue data in remaining plant material, after removal of beans with pods and roots, was also reported. Details of the trials are provided under legume vegetables: fresh beans with pods. The residue data relevant to bean forage are summarized in Table 11.

^a BBCH growth stage is included to demonstrate that the samples were collected at the green stage of the beans. BBCH 79 is before ripening of the fruit (beans get hard). This process starts at BBCH 81 to 89.

^b Perona beans is a Spanish variety of flat pod beans (vining variety).

FATE OF RESIDUES IN STORAGE AND PROCESSING

In processing

The Meeting received processing studies on the magnitude of residues in processing studies with mangoes and mint.

The processing factors (residue processed commodity divided by residue RAC) were calculated separately for parent thiamethoxam and metabolite CGA322704 (clothianidin).

Mango processing

A field trial was conducted in the South Africa in 2001/2012 [Thirion, 2013b and c, Syngenta A9795B_11447, 2418/F788 and Syngenta A9795B_11448, 2418/G676] to measure the magnitude of thiamethoxam residues in mango processed commodities. The mango trees were treated once with the thiamethoxam formulated product, Actara 240 SC (Code No A9795B), at a rate of 18 ml product/tree or 4.32 g ai/tree. The applications were done when the trees were in the flowering state early in the season. The fruit was harvested when they were commercially ready for processing (BBCH 85–87). Mango pulp and dried mangoes were processed from the fruit, analysed and the processing factors were calculated. The residues in the whole fruit as well as in the peel were also determined. SABS In-house Method No. 054/2010 viz *The determination of Residues of Thiamethoxam and CGA 322 704 in Crops by LC-MS/MS*.

Dried fruit: Three samples were taken from each plot, one sample for determination of residues in the whole fruit (> 2.5–5 kg), one (< 2.5–5 kg) sample serving as for a contingency sample, and one sample (34–42 kg) for processing of pulp and drying. From the bulk 5 kg samples were taken for processing of pulp and drying, respectively. For processing the fruit was peeled and the flesh removed from the stones. The stone was discarded. Flesh and peel were kept for further analyses. The flesh of the fruit was preserved with sodium metabisulphite and dried in an automatic electrical drying oven by using the following temperature and humidity program: 60 °C at 40% relative humidity for 360 min; 57 °C at 27% relative humidity for 60 minutes; 55 °C at 18% relative humidity for 360 minutes. The moisture content after processing ranged between 9.1 and 9.9% in both studies.

Table 12 Residues of thiamethoxam and CGA322704 after processing of mangoes

The effect of processing on the nature of residues was not specifically investigated. The processing factors for both the parent and the metabolite CGA322704 indicate that no significant changes are expected to occur with regard to the nature of the residues during drying process of mangoes.

Mint processing

Two supervised residue trials with spearmint were conducted in the USA in 1999 [Syngenta, 2001, 406892, 07362]. Three foliar applications were made with an exaggerated rate (5×) of 370 g ai/ha, with a spray interval of 13–15 days. The applications were made with a backpack sprayer at a spray volume of 296 L/ha. The last application was made at (early) bud stage (26 July, 1999 and June 17, 1999 for trial WI25 and WA*18, respectively). Mature tops were harvested at normal commercial harvest, 7 days after the last application. Tops were harvested manually. Dead and/or senesced leaves were removed. The tops were processed into oil using standardised procedures designed to simulate relevant industrial processes. All weight fractions have been corrected for subsampling and represent weight fractions for trial 99-WI25 and 99-WA*18, respectively.

Oil processing

Large samples of fresh mint plants were collected. About 1.1 kg from each sample was distilled immediately after harvest, using a mint still and boiler for distillation (at steam pressure of 75 psi, pot pressure of 1–1.5 psi and distillate temperature of -1 to 7 °C for 1.5–2.5 hours. For analysis, the (2 g) oil was diluted with GPC mobile phase (50% ethyl acetate/50% cyclohexane). Clean up was done by injection in GPC, followed by evaporation of the eluate to ~0.5 mL at 35–40 °C on a Turbovap. The sample was dissolved in a total volume of 4.0 mL using acetonitrile.

Mint oil samples were stored at < 0 °C for a maximum of 502 days prior to analyses. Mint top samples were stored at < 0 °C for a maximum of 482 days. This storage period is sufficiently covered by the storage stability (452 days for tops and 465 days for oil). Samples were analysed for parent and CGA322704 using LC-MS/MS Method No AG-675 with an LOQ of 0.05 mg/kg for both parent and metabolite. Samples were analysed for parent and its metabolite CGA322704. Residues of thiamethoxam and CGA322704 and processing factors from the trial are summarised in Tables 13 and 15.

Results were not corrected for control levels (< 0.05 mg/kg for each analyte) nor for average concurrent method recoveries (77–85% (parent) and 92–96% (CGA322704) at 0.05, 0.50 and 5.0 mg/kg in tops and 92–116% (parent) and 92–111% (CGA322704) at 0.05, 0.50 and 5.0 mg/kg in oil).

Note: The analytical method is considered valid in the range 0.05–5.0 mg/kg for the determination of thiamethoxam and CGA322704 in mint.

Table 13 Residues of thiamethoxam and CGA322704 (clothianidin) and processing factors in mint tops and processed mint (oil)

Processing studies summary

An overview of calculated processing factors for mango and mint is given in Tables 14 and 15 for thiamethoxam and CGA322704 (clothianidin), respectively.

Table 14 Overview of processing factors for thiamethoxam in mango and mint

Compound	Processed fraction	Processing Factor (n=2-4)
Mango	Pulp	0.6 (4)
Mango	Dried	5.9 (4)
Mint	Aspirated oil	< 0.02 (2)

Table 15 Overview of processing factors for metabolite CGA322704 (clothianidin) in mango and mint

Compound	Processed fraction	Processing Factor (n=2-4)
Mango	Pulp	0.8 (4)
Mango	Dried	6.3 (4)
Mint	Aspirated oil	< 0.2 (2)

APPRAISAL

SEE ALSO CLOTHIANIDIN (238)

Thiamethoxam is a neonicotinoid compound with broad-spectrum insecticidal properties. The compound was evaluated by the JMPR in 2010 (T, R), 2011 (R) and 2012 (R). The 2010 Meeting established an ADI for Thiamethoxam of 0–0.08 mg/kg bw and an ARfD of 1 mg/kg bw. It was listed by the Forty-fifth Session of CCPR (2013) for the evaluation of 2014 JMPR for additional MRLs.

The residue definition for enforcement for thiamethoxam in plant and animal commodities is thiamethoxam. The residue for dietary risk assessment for plant and animal commodities (except poultry) is thiamethoxam and clothianidin (considered separately). The residue definition for risk

assessment dietary intake for poultry is the sum of thiamethoxam, CGA 265307 and MU3, expressed as thiamethoxam and clothianidin (clothianidin to be considered separately from thiamethoxam). In the current appraisal CGA322704 is referred to as clothianidin.

At the 2014 JMPR Meeting residue data were submitted to support maximum residue level recommendations for use of thiamethoxam on several crops. Residue trials were conducted to support use avocado, mango, beans, mint and hops. In addition, trials were submitted by Republic of Korea to support the use on persimmon. Summaries of the trials have been provided to support the recommendations for thiamethoxam and clothianidin on the respective crops.

Methods of Analysis

The Meeting received additional validation data for the analytical method REM 179.06 (evaluated by the 2010 Meeting) of thiamethoxam and clothianidin.

Most of the methods used in the supervised residue trials had previously been evaluated (2010 JMPR) and determined parent compound thiamethoxam and the metabolite clothianidin. Samples were extracted with methanol:water. The final residue could then be determined by HPLC-MS/MS. The Meeting considers validation of the method sufficient for the respective crops with an LOQ of 0.01 mg/kg for parent and its metabolite, respectively. The analytical methods not previously evaluated, but used in the trials for the current evaluation (LC-MS/MS Method 954/2010 and Method HPLC/DAD) were sufficiently validated.

Stability of pesticide residues in stored analytical samples

At the 2010 JMPR, thiamethoxam and clothianidin were shown to be stable for 1–2 years when stored frozen at < -18 °C or lower for a large range of commodities. The stability in the crops under evaluation in 2014 was sufficiently demonstrated in the respective residue trials.

Results of supervised residue trials on crops

The Meeting received supervised trials data for persimmon, avocado, mango, beans, mint (herbs) and hops.

Pome fruit

Residue data in support of the use of thiamethoxam and clothianidin on pome fruit (apples and pears) were previously evaluated by the 2010 JMPR. In 2010 insufficient data were submitted for the use of clothianidin on persimmons to lead to a maximum residue level recommendation (not yet categorized under pome fruit at that time). No data were previously submitted to support the use of thiamethoxam on persimmons.

The critical GAP for thiamethoxam on persimmon in Republic of Korea is for 3 foliar applications at 0.005 kg ai/hL (interval of 10 days) and a PHI of 7 days, until “leaves are dripping”. The Meeting received two independent trials that were performed according to the Korean critical GAP using an application rate of 0.005 kg ai/hL.

As the GAPs for pome fruit and persimmon are different, a specific maximum residue level for persimmon would need to be estimated. However, the Meeting agreed that the dataset was insufficient for the estimation of a maximum residue level for persimmon.

The Meeting confirmed the maximum residue level, STMR and HR for thiamethoxam and clothianidin in pome fruit as recommended by the 2010 JMPR Meeting.

Assorted tropical and sub-tropical fruits – inedible peel

Supervised trials were available for avocado and mango. The use of thiamethoxam and/or clothianidin on avocados had not been previously evaluated by the JMPR. The use of thiamethoxam on mango was evaluated by the 2010 JMPR, but there were insufficient data to support a maximum residue

level recommendation. The Meeting had not previously received residue data supporting the use of clothianidin on mangoes.

Avocado

The critical GAP for use on avocado's in the USA is for 3 foliar directed applications at 0.070 kg ai/ha (minimum interval of 7 days) and no PHI.

Five field trials involving the use of thiamethoxam (3 foliar applications at approximately 70 g ai/ha, with a 6–7 day interval and PHI of 3 days) on avocados were performed in the USA (3) and in Mexico (2) in 2006 (4) and 2007 (1). Thiamethoxam residues on whole fruit (RAC) were not reported. Using a conversion factor to correct from flesh and peel to whole fruit ($0.8 \times$ residue level), calculated residue levels in whole fruit were: < 0.01, 0.03, 0.06, 0.10, and 0.24 mg/kg (n=5). Converted clothianidin residues in RAC were: < 0.01, < 0.01, < 0.01, 0.016, and 0.016 mg/kg (n=5).

The Meeting agreed that the dataset for avocados matching the USA critical GAP could be used to support a maximum residue level recommendation for avocados, and estimated a maximum residue level of 0.5 mg/kg for thiamethoxam and a maximum residue level of 0.03 mg/kg for clothianidin on avocado.

The residue data for estimating the STMR and HR (flesh+peel) were: < 0.01, 0.04, 0.08, 0.12, and 0.30 mg/kg (n=5), resulting in an STMR and HR of 0.08 mg/kg and 0.30 mg/kg, respectively for thiamethoxam.

Clothianidin residues (flesh+peel) were: < 0.01, < 0.01, < 0.01, 0.02, and 0.02 mg/kg (n=5), resulting in STMR and HR estimates of 0.01 and 0.02 mg/kg, respectively.

Mango

Field trials involving the use of thiamethoxam on mango were performed in South Africa. Eight trials in 2003–2005 were evaluated by the JMPR in 2010. Trials performed 2011–2012 were submitted to the 2014 Meeting.

The critical GAP for use of thiamethoxam on mangoes in the South Africa is a single soil application at 1.44 g ai/tree poured from a jug with a PHI of 130 days. Seven residue trials (three in 2003/2005 and four in 2011/2012) matched the South African GAP, using a single soil application at a rate of 1.44 g ai/tree and a PHI of 130 days. Thiamethoxam residues (whole fruit) were: 0.01, 0.02, 0.02, 0.02, 0.036[#], 0.08[#], and 0.088[#] mg/kg. Clothianidin residues were: < 0.01, 0.01, 0.01, < 0.02[#], < 0.02[#], < 0.02[#] and 0.02 mg/kg. The values identified with [#] are residue data of flesh and peel corrected for stone using a default conversion factor of 0.8, because the weights of the different fractions of the fruit were not reported in the 2010 evaluation.

The Meeting agreed that the dataset for mangoes matching the South African critical GAP could be used to support a maximum residue level recommendation for mangoes, and estimated a maximum residue level of 0.2 mg/kg for thiamethoxam on mango. For clothianidin the Meeting estimated a maximum residue level of 0.04 mg/kg.

For the STMR and HR estimates the residue data excluding the stone are used. Thiamethoxam residues (flesh+peel) were: 0.01, 0.03, 0.03, 0.03, 0.04, 0.10, and 0.11 mg/kg, resulting in a STMR and HR of 0.03 and 0.11 mg/kg, respectively for thiamethoxam. Clothianidin residues (flesh and peel) were: 0.01, < 0.02, 0.02, 0.02, 0.02, 0.02, and 0.02 mg/kg. The Meeting estimated STMR and HR values of 0.02 and 0.02, respectively for clothianidin.

Legume vegetables

The Meeting received data on the use of thiamethoxam on fresh beans. A Portuguese label for use of thiamethoxam on fresh beans was submitted to the Meeting. The label included indoor use (foliar application and drip irrigation) and outdoor use (foliar application).

Indoor use: No data were submitted to support the indoor use (neither the foliar, nor the drip irrigation uses).

Outdoor use: The use of thiamethoxam on beans and peas had been evaluated by the 2010 Meeting. In 2010 the data reviewed covered seed treatment use; therefore the datasets could not be combined. According to the 2010 evaluation there was no GAP for clothianidin on legume vegetables. The critical GAP for outdoor use of thiamethoxam is a double foliar application of 100 g ai/ha, with an interval of 7 days and a PHI of 3 days.

Eight field trials involving fresh beans (with pods) were conducted in 2003 and 2004 in Spain. The critical GAP for outdoor use was supported with seven trials using two foliar applications of 93–113 g ai/ha (total rate of 200 g ai/ha within $\pm 25\%$ range), 6–8 day interval and 3 day PHI. Thiamethoxam residues were: 0.03, 0.08, 0.08, 0.08, 0.09, 0.16, and 0.18 mg/kg.

The Meeting agreed that the dataset for fresh beans matching the Portuguese critical GAP for outdoor use could be used to support a maximum residue level recommendation for fresh beans, and estimated a maximum residue level of 0.3 mg/kg for thiamethoxam in fresh beans.

The Meeting estimated STMR and HR values of 0.08 and 0.18 mg/kg, respectively for thiamethoxam in fresh beans.

The same trials were used for clothianidin. The residues were: 0.04, 0.04, 0.06, 0.07, 0.08, 0.09, and 0.10 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg for clothianidin and STMR and HR values of 0.07 mg/kg and 0.10 mg/kg, respectively for clothianidin in fresh beans.

Fresh herbs

The Meeting received data on the use of thiamethoxam on mints. No uses of thiamethoxam or clothianidin on fresh herbs (mints) have previously been evaluated by the JMPR.

Mints

Field trials involving the use of thiamethoxam on mint were performed in the USA in 1999.

The critical GAP for mint in the USA is 3 foliar applications of 0.070 kg ai/ha (minimum interval 14 days, maximum total rate of 0.21 kg ai/ha per season) and PHI of 7 days. Five trials matched this GAP (3×0.072 – 0.074 kg/ai/ha, interval 13–15 days, PHI 6–7 days), although slightly higher applications rates were used ($< 25\%$ difference). Thiamethoxam residues were: 0.24, 0.28, 0.34, 0.36, and 0.86 mg/kg.

The Meeting agreed that the dataset on mints matching the USA GAP could be used to support a maximum residue level recommendation for mints and estimated a maximum residue level of 1.5 mg/kg for thiamethoxam on mint and STMR and HR values of 0.34 and 0.86 mg/kg, respectively for thiamethoxam.

The same trials were used to derive the residue levels for clothianidin. Residues were: 0.06, 0.07, 0.11, 0.11, and 0.12 mg/kg.

The Meeting agreed that the dataset on mints could be used to support a maximum residue level for mints and estimated a maximum residue level of 0.3 mg/kg for clothianidin and STMR and HR values of 0.11 mg/kg and 0.12 mg/kg, respectively for clothianidin.

Dried herbs

The Meeting received data on the use of thiamethoxam on hops. The use of thiamethoxam on hops was evaluated by the 2010 Meeting. No maximum residue level was recommend due to the limited dataset ($n=3$). The JMPR has not evaluated any uses for clothianidin on dried herbs.

Hops

Field trials involving hops were performed in the USA in 2002 (three evaluated by JMPR 2010) and 2011 (one submitted in 2014).

The critical GAP for hops in the USA is a single soil surface treatment (band application with incorporation) at a rate of 0.14 kg ai/ha and a PHI of 65 days. The trials performed in the USA matched this GAP (1×0.13–0.14 and PHI 62–66 days).

Thiamethoxam residues in hops (dried cones) were: < 0.025, 0.027, 0.029, and 0.055 mg/kg. The Meeting agreed that the dataset for hops matching the USA GAP could be used to support a maximum residue level recommendation for hop, and estimated a maximum residue level of 0.09 mg/kg for thiamethoxam on dried hops. The Meeting estimated STMR and HR values of 0.028 and 0.055 mg/kg, respectively for thiamethoxam.

Clothianidin residues were: < 0.025, 0.025, 0.027, and 0.028 mg/kg. The Meeting estimated a maximum residue level of 0.07 mg/kg for clothianidin on hops. The Meeting estimated STMR and HR values of 0.026 and 0.028 mg/kg, respectively for clothianidin, respectively.

Legume animal feeds

The Meeting received data on the outdoor use of thiamethoxam on fresh beans. The use of thiamethoxam on beans and peas has been evaluated by the 2010 Meeting, but only covered seed treatment uses and provided residue data for thiamethoxam and clothianidin in pea vines and pea hay/fodder (dry), but not for bean forage. No residue data for clothianidin in legume animal feeds was available.

Bean forage

The Portuguese outdoor GAP for use of thiamethoxam on beans is a foliar application 2×100 g ai/ha, with a PHI of 3 days and a minimum interval of 7 days.

Outdoor use

Eight field trials involving fresh beans (with pods) were conducted in 2003 and 2004 in Spain. The application rates used were two foliar applications of 69–113 g ai/ha with an interval of 6–8 days and a PHI of 3 days. Matching the Portuguese GAP. Residues in bean forage were determined in four field trials. Thiamethoxam residues in bean forage (rest of plants harvested at BBCH < 80) were: 0.56, 0.82, 0.93, and 1.4 mg/kg. Clothianidin residues in bean forage were: 0.06, 0.07, 0.08, and 0.11 mg/kg.

The Meeting agreed that the dataset for fresh bean forage matching the outdoor Portuguese GAP could be used to estimate median residues of 0.87 and 0.075 mg/kg for thiamethoxam and clothianidin, respectively. The respective highest residues are 1.4 and 0.11 mg/kg.

Fate of residues during processing

Processing studies were undertaken for mango and mint. Processing factors based on the residue for parent and metabolite clothianidin are listed in the table below. Using the STMR_{RAC} obtained from the thiamethoxam use, the Meeting estimated STMR-Ps for processed commodities to be used in dietary intake calculations.

Commodity	PFs	PF (median or best estimate)	STMR-P = STMR _{pulp+peel} × PF (mg/kg)	HR-P = HR _{pulp+peel} × PF (mg/kg)	PFs	PF (median or best estimate)	STMR-P = STMR _{RAC} × PF (mg/kg)	HR-P = HR _{RAC} × PF (mg/kg)
	Parent thiamethoxam (STMR _{pulp+peel} = 0.03 mg/kg HR _{pulp+peel} = 0.11 mg/kg)				clothianidin (STMR _{pulp+peel} = 0.02 mg/kg, HR _{pulp+peel} = 0.02 mg/kg)			
Mango, dried flesh	4.0, 6.7, 7.3, 5.0	5.9	0.18	0.65	5.7, 8.4, 7.00, 4.00	6.3	0.13	0.13
Mint, oil	< 0.02, < 0.03	< 0.02	n.a.	n.a.	< 0.22, < 0.19	< 0.20	n.a.	n.a.

Residues in animal commodities

The Meeting estimated the dietary burden of thiamethoxam residues (thiamethoxam only, for CGA322704 see clothianidin appraisal 2014) on the basis of the livestock diets listed in the FAO manual appendix IX (OECD feedstuff table) using the OECD_Feed_Calculator_V1_4. Calculation from highest residue, STMR (some bulk commodities) and STMR-P values provides the levels in feed suitable for estimating MRLs, while calculation from STMR and STMR-P values from feed is suitable for estimating STMR values for animal commodities.

The Meeting recalculated the livestock dietary burden based on the uses presented by the 2010 JMPR and including the residue values for fresh bean forage from the 2014 JMPR Meeting. The maximum dietary burden for cattle for MRL (tissues) setting changed slightly from 5.2 to 6.1 ppm, and the mean dietary burden for cattle changed only marginally from 2.1 to 2.4 ppm. For residue level estimations in milk the dietary burden raised from 5.2 to 6.1 ppm (maximum) and from 1.6 to 2.4 ppm (mean). The new maximum dietary burden of thiamethoxam for poultry of 1.64 ppm is only marginally higher than the maximum dietary burden of 1.59 ppm as calculated by the Meeting in 2010, rounded both 1.6 ppm. The new mean dietary burden for poultry of 0.59 ppm is not changed since the evaluation in 2010.

The Meeting agreed that no new mean and maximum residue level estimations are needed and confirmed its previous recommendations.

Residue data for clothianidin used for the dietary burden calculation were derived from the 2010 JMPR appraisal for clothianidin, where the data from thiamethoxam and clothianidin use were combined and included the residue data on bean forage from the 2014 JMPR Meeting. For the dietary burden calculations and recommendations for animal commodities see appraisal clothianidin 2014.

RECOMMENDATIONS

THIAMETHOXAM

On the basis of the data from supervised residue trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

The 2011 Meeting recommended the following residue definition for thiamethoxam:

Definition of the residue for animal and plant commodities (for compliance with the MRL): *thiamethoxam*.

Definition of the residue for plants and animals (except poultry), (for estimation of dietary intake): *thiamethoxam and clothianidin* (considered separately).

Definition of the residue for poultry (for estimation of dietary intake): *sum of thiamethoxam, CGA 265307 and MU3, expressed as thiamethoxam and clothianidin* (clothianidin to be considered separately from thiamethoxam).

The residue is not fat-soluble.

Note that thiamethoxam metabolite CGA322704 (N-(2-chlorothiazol-5-ylmethyl)-N'-methyl-N"-nitroguanidine) will appear as clothianidin in the analytical method and residues of CGA322704 occurring in food are included in the clothianidin MRLs.

Metabolite CGA 265307: N-(2-chlorothiazol-5-ylmethyl)-N'-nitroguanidine.

Metabolite MU3: amino-[(2-chlorothiazol-5-ylmethyl)-amino]-methylene)-hydrazide.

	Commodity	THIAMETHOXAM Maximum residue level recommendations (mg/kg)		STMR or STMR-P (mg/kg)		HR or HR-P
CCN	Name	New	previous	new	previous	mg/kg
FI 0326	Avocado	0.5		0.08		0.30
VP 0061	Beans with pods	0.3		0.08		0.18
DH 1100	Hops	0.09		0.028		0.55

-	Mango pulp			0.02		0.07
-	Mango dried			0.18		0.65

^a It is noted that there are several types of mints (native mints HH0764, Vietnamese mint HH0765). The reported CCN code is listed for several types of mints, including spearmint and peppermint.

	Commodity	THIAMETHOXAM Maximum residue level recommendations	Median residue	Highest residue
CCN	Name	mg/kg	mg/kg	mg/kg
AL	Bean forage	n.a.	0.87	1.4

The recommendations for clothianidin resulting from thiamethoxam use are listed in the clothianidin appraisal 2014.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDI) of thiamethoxam, based on the STMRs estimated for 112 commodities, for the 17 cluster diets were in the range of 1-3% of the maximum ADI (0.08 mg/kg bw) (Annex 3 to the 2014 Report). The Meeting concluded that the long-term intake of residues of thiamethoxam resulting from its uses that have been considered by the 2010, 2011 2012 and the present Meeting is unlikely to present a public health concern.

For the International Estimated Daily Intakes (IEDI) for clothianidin resulting from thiamethoxam and clothianidin use see appraisal clothianidin 2014.

Short-term intake

The International Estimated Short Term Intake (IESTI) for thiamethoxam was calculated for food commodities and their processed fractions for which maximum residue levels were estimated and for which consumption data were available. The results are shown in Annex 4 to the 2014 Report.

The IESTI represented 0–1% of the ARfD (1.0 mg/kg bw). The Meeting concluded that the short-term intake of residues of thiamethoxam, when used in ways that have been considered by the present Meeting, is unlikely to present a public health concern.

For the International Estimated Short Term Intake (IESTI) for clothianidin resulting from thiamethoxam and clothianidin use see appraisal clothianidin (2014).

TRIADIMENOL (168)

The first draft was prepared by Mr Christian Sieke, Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

Triadimenol is a systemic fungicide formed as the primary metabolite of triadimefon but also used as an active substance on its own. Its main mode of action is an inhibition of the ergosterol biosyntheses in fungi. Triadimenol was evaluated by JMPR several times since 1978 and the last time in 2004 for toxicology, when an ADI of 0–0.03 mg/kg bw and an ARfD of 0.08 mg/kg bw was established and in 2007 for residues.

Definition of the residue in plant and animal commodities (for the estimation of dietary intake and for compliance with MRLs): *sum of triadimefon and triadimenol*

In 2007 the Meeting evaluated use patterns of triadimefon and triadimenol in grapes; however, a short-term dietary intake concern was identified without opportunity for an alternative GAP.

The current Meeting received new information on use patterns for triadimenol in grapes supported by new supervised residue trials on grapes from Europe.

ANALYTICAL METHODS

Method 01072/M001 (Bomke, S; 2010)

The basic principle of method 01072/M001 involves extraction of homogenized samples with methanol/water (4/1; v/v) by high-speed blending. After filtration, an aliquot of the extract was evaporated to dryness, re-dissolved under addition of deuterated internal standard, filtered and measured by LC-MS/MS (silica based C18-column using acetonitrile/water eluent).

The characteristic mass transition for triadimenol used for quantification are m/z 296.1 → 70.2 and m/z 298.0 → 70.1 for confirmation.

In the following table the recoveries in selected fortified samples are reported.

Table 1 Recovery data for method 01072/M001 in plant matrices (LC-MS/MS, m/z: 296.1 → 70.2 & m/z: 298.0 → 70.2)

Matrix	Fortification level (mg/kg)	n	Recovery range (%)	Recovery, mean (%)	RSD (%)	Analyte, reference, MRM transition
Lettuce	0.01	5	90–110	102	8	Triadimenol
	0.1	5	80–112	93	13	Bomke, S; 2010
Wheat grain	0.01	5	90–110	98	9	m/z: 296.1 → 70.2 (quantification)
	0.1	5	87–122	101	14	
Beans without pods	0.01	5	100–120	110	9	
	0.1	5	89–108	103	8	
Orange fruits	0.01	5	80–100	88	10	
	0.1	5	86–110	100	10

Wheat grain	0.01	5	90–120	102	11	m/z: 298.0 → 70.1 (confirmation)
	0.1	5	88–104	97	8	
Beans without pods	0.01	5	90–110	102	8	
	0.1	5	90–99	93	4	
Orange fruits	0.01	5	80–110	94	14	

	0.1	5	81–94	88	7	
Avocado fruits	0.01	5	90–100	96	6	
	0.1	5	92–107	98	6	

Method 00480/M001 (Bomke, S; 2010a)

The basic principle of method 01072/M001 involves extraction of homogenized samples by refluxing with methanol/water (7/3, v/v). After filtration, the extract was concentrated to the aqueous remainder. The remaining water was enzymatically hydrolysed to release conjugated residues (glucosides). An aliquot was purified on a SPE cartridge. The analytes were eluted with cyclohexane/ethyl acetate (85/15, v/v) and the eluate was evaporated to dryness. The remainder was resolved in internal standard solution and subjected to HPLC-MS/MS. The analytes were chromatographed by reversed-phase HPLC on a silica-based C18-column using a gradient acetonitrile/water eluent containing acetic acid.

The characteristic mass transition for triadimenol used for quantification are m/z 296.1 $\rightarrow$ 70.2 and m/z 298.0 $\rightarrow$ 70.1 for confirmation. For triadimenol-hydroxy, which is the remaining analyte after cleavage of conjugates, mass transition used for quantification are m/z 312.0 $\rightarrow$ 70.1 and m/z 314.0 $\rightarrow$ 70.1 for confirmation.

In the following table the recoveries in selected fortified samples are reported.

Table 2 Recovery data for method 01072/M001 in plant matrices (LC-MS/MS, m/z : 296.1 $\rightarrow$ 70.2 & m/z : 298.0 $\rightarrow$ 70.2)

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received additional information on supervised residue trials of triadimenol to grapes from Europe. In addition, a large dataset on grapes was reported in the 2007 JMPR Evaluation on triadimenol, which is repeated for consistency.

Application rates were reported as triadimenol. Unquantifiable residues are shown as below reported LOQ (< 0.01 mg/kg). Residue data are recorded unadjusted for percentage recoveries or for residues values in control samples, unless otherwise stated. Where multiple samples were taken from a single plot, individual values are reported. Where multiple analyses were conducted on a single sample, the average value is reported. Where results from separate plots with distinguishing characteristics such as different formulations, varieties or treatment schedules were reported, results are listed for each plot.

Residues from the trials conducted according to critical GAP have been used for the estimation of maximum residue levels. These results are underlined.

Triadimenol analysed with method 01072/M001

Triadimenol incl. conjugates and triadimenol-hydroxy incl. conjugates analysed with method 004800/M001

APPRAISAL

Triadimenol is a systemic fungicide formed as the primary metabolite of triadimefon but also used as an active substance on its own. Its main mode of action is an inhibition of the ergosterol biosyntheses in fungi. Triadimenol was evaluated by JMPR several times since 1978 and the last time in 2004 for toxicology, when an ADI of 0–0.03 mg/kg bw and an ARfD of 0.08 mg/kg bw was established and in 2007 and 2009 for residues.

Definition of the residue in plant and animal commodities (for the estimation of dietary intake and for compliance with MRLs): sum of triadimefon and triadimenol

In 2007 the Meeting evaluated use patterns of triadimefon and triadimenol in grapes; however, a short-term dietary intake concern was identified without opportunity for an alternative GAP. In 2009 the 2007 evaluation on the use on grapes was repeated by the JMPR, but again no alternative GAP could be identified.

The current Meeting received new information on use patterns for triadimenol in grapes supported by new supervised residue trials on grapes from Europe.

Methods of analysis

The 2007 Meeting evaluated several methods of analyses for triadimenol in different plant and animal matrices with a LOQ of 0.05 mg/kg (GC-FID or GC-MS), based on the multi-residue method DFG-S19.

To the 2014 Meeting two new analytical methods were provided measuring triadimenol, with a LOQ of 0.01 mg/kg. Both methods involve measurement by HPLC-MS/MS for triadimenol. One of these methods measures also triadimenol including sugar conjugates and triadimenol-hydroxy including sugar conjugates in plant matrices with a LOQ of 0.01 mg/kg. For the determination of conjugates enzymatic treatment may be included in the extraction procedure.

Stability of pesticide residues in stored analytical samples

In 2007 the Meeting concluded that triadimenol is stable in stored samples of plant and animal origin for at least 24 months.

Results of supervised residue trial on crops

Grapes

For grapes, two new GAPs from France and Spain have been submitted to the Meeting.

In France, triadimenol is registered for grapes involving three applications of 0.019 kg ai/ha each with a PHI of 21 days. Supervised field trials from Europe matching the GAP were already reported in 2007 (2 trials) and amended by new trial data submitted to the current Meeting (6 trials).

Residues of triadimenol in grapes matching the French GAP were: < 0.01, 0.01, < 0.02(2), 0.03, 0.04, 0.08 and 0.13 mg/kg.

In Spain triadimenol is registered for grapes involving four applications of 0.063 kg ai/ha each with a PHI of 15 days for table grapes and 21 days for wine grapes. Supervised field trials from Southern Europe and Turkey matching the GAP were already reported in 2007.

Residues of triadimenol in table grapes matching the GAP were: < 0.02, < 0.02, 0.02, 0.04(3), 0.05, 0.06, 0.07, 0.08, 0.1, 0.11 mg/kg.

Residues of triadimenol in wine grapes matching the GAP were: < 0.02(4), 0.02, 0.02, 0.03, 0.04(3), 0.1 mg/kg.

Based on the French GAP, the Meeting estimated a maximum residue level of 0.3 mg/kg and HR and STMR values of 0.13 mg/kg and 0.025 mg/kg for grapes, respectively

Fate of residues during processing

The 2007 Meeting estimated processing factors for triadimenol in grapes of 0.45 for juice, 0.42 for wine, 3.1 for raisins, 3 for wet pomace and 5.7 for dry pomace. No additional data were submitted to the current Meeting.

Based on these factors and the newly estimated STMR value of 0.025 mg/kg the Meeting estimated STMR-P values for juice of 0.011 mg/kg, for dried grapes (= raisins) of 0.078 mg/kg, for wet grape pomace of 0.075 mg/kg and for dry grape pomace of 0.14 mg/kg.

Based on the newly estimated STMR value of 0.025 mg/kg for wine grapes, the Meeting estimated STMR-P value of 0.01 mg/kg for wine.

For dried grapes the Meeting estimated a HR-P of 0.4 mg/kg and a maximum residue level of 1 mg/kg to replace its previous recommendation of 10 mg/kg.

Residues in animal commodities

In the 2007 evaluation for triadimenol grape pomace (wet) was already taken into account for the livestock animal dietary burden calculation based on a residue level of 0.5 mg/kg, which is higher than the estimated residue level of 0.075 mg/kg resulting from the current GAPs.

Therefore, the Meeting concluded that the contribution of triadimenol residues in grapes after treatment according to the evaluated GAPs does not influence the overall dietary burden of livestock animals, making a re-assessment of the residue situation in animal commodities unnecessary. The Meeting confirms its previous recommendations for triadimenol in animal commodities.

RECOMMENDATIONS

Definition of the residue in plant and animal commodities (for the estimation of dietary intake and for compliance with MRLs): sum of triadimefon and triadimenol

On the basis of the additional data from supervised trials on grapes the Meeting recommends the following maximum residue levels for triadimenol.

CCN	Commodity	Recommended MRL mg/kg		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		new	previous		
FB 0269	Grapes	0.3	–	0.025	0.13
DF 0269	Dried grapes	1 ^a	10 ^b	0.155	0.4

^a Based on uses for triadimenol

^b Based on uses on triadimefon and triadimenol

For dietary intake only

CCN	Commodity	STMR or STMR-P mg/kg	HR or HR-P mg/kg
JF 0269	Grapes juice	0.011	–
	Grape pomace, dry	0.14	–
	Grape pomace, wet	0.075	–
	Wine	0.01	–

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDI) of triadimefon and triadimenol was calculated from previously estimated STMRs in 2007 and the new STMRs in 2014 for raw and processed commodities in combination with consumption data for corresponding food commodities. The results are shown in Annex 3.

The IEDI of the 17 GEMS/Food cluster diets, based on the estimated STMRs represented 1–3% of the maximum ADI (0.03 mg/kg bw).

The Meeting concluded that the long-term intake of residues of triadimefon and triadimenol from the uses considered by the Meeting is unlikely to represent a public health concern.

Short-term intake

The International Estimated Short-Term Intake (IESTI) of triadimenol calculated on the basis of the estimations made by the 2014 JMPR represented for children 0–10% and for the general population 0–5% of the ARfD (0.08 mg/kg bw). The Meeting concluded that the short-term intake of triadimenol from the uses considered by the 2014 JMPR is unlikely to represent a public health concern.

TRIFORINE (116)

First draft prepared by Mr Makoto Irie and Ms Miki Matsui, Ministry of Agriculture, Forestry and Fisheries, Tokyo, Japan

EXPLANATION

Triforine is a systemic fungicide for control of blackspot, powdery mildew and rust. It was first evaluated by JMPR in 1978 (T, R) and the latest toxic review was in 1997 (T). The ADI for Triforine was established as 0–0.02 mg/kg bw and no ARfD was set up in previous JMPR. Triforine was scheduled at the 45th session of the CCPR (2013) for the periodic re-evaluation of toxicity and residues by the 2014 JMPR.

The residue data was submitted by the manufacturer and would support the following commodities: apples, blueberries, Brussels sprouts, cereal grains, cherries, common beans, apricots, currants (black, red white), fruiting vegetables, cucurbits, gooseberries, peaches, plums (including prunes), strawberries and tomatoes.

IDENTITY

Common name	Triforine
Chemical name	
IUPAC:	<i>N,N'</i> -{piperazine-1,4-diylbis[(trichloromethyl)methylene]} diformamide
CAS:	<i>N,N'</i> -[1,4-piperazinediylbis(2,2,2-trichloroethylidene)]bis[formamide]
CAS Registry No:	26644-46-2
CIPAC No:	360
Synonyms:	W 524, CME 102, SAG 102, Cela W524
Structural formula:	
Molecular formula:	C ₁₀ H ₁₄ Cl ₆ N ₄ O ₂
Molecular weight:	434.96

METABOLISM AND ENVIRONMENTAL FATE

The metabolism, distribution of triforine has been investigated in animals and plants. The fate and behaviour of triforine in animals, plants and the environment was investigated using the [^{14}C]-labelled test materials shown in Figures 1.

Figure 1 [^{14}C] and [^3H]-Labelled test materials used in animals, plants metabolism studies, and the environmental fate studies

The chemical structures of the major degradation compounds from the metabolism of triforine are provided below.

Compound name		Structure	Found in metabolism studies
WOS 2379	<i>N</i> -{2,2,2-trichloro-1-[4-(2-oxoacetyl)piperazin-1-yl]ethyl} formamide		Livestock, Soil
W 2379	Hydrate of <i>N</i> -(2,2,2-trichloro-1-[4-(2,2-dihydroxyacetyl)piperazin-1-yl]ethyl} formamide		Livestock

Compound name		Structure	Found in metabolism studies
W 1084	<i>N</i> -(2,2,2-trichloro-1-piperazin-1-yl-ethyl)formamide	 <chem>ClC(Cl)(Cl)CN1CCNCC1NC=O</chem>	Rat, Livestock, Plants
W 1069	<i>N</i> -(2,2,2-trichloro-1-piperazin-1-yl-ethyl)formamide hydrochloride	 HCl	Livestock, Plants, Soil
W 625	<i>N</i> -[2,2,2-trichloro-1-(4-formyl piperazin-1-yl)ethyl]formamide	 <chem>ClC(Cl)(Cl)CN1CCN(CC1NC=O)C=O</chem>	Plants, Soil
WOS 613	piperazine-1,4-dicarbaldehyde	 <chem>O=CNC1CCN(CC1)C=O</chem>	Plants
Piperazine		 <chem>C1CCNCC1</chem>	Plants, Soil

Animal metabolism

The Meeting received animal metabolism studies of triforine in rats, lactating goats and laying hens. The study on rats was evaluated by the WHO Core Assessment Group of the 2014 JMPR. A summary of the rat metabolism is given in this section.

Rats

Triforine is rapidly metabolized and excreted in rats. Highest residues were found in liver followed by kidney. Residues were lower in muscle and fat. The glucuronide of *N*-[2,2,2-trichloro-1-(piperazin-1-yl) ethyl]-formamide (W 1084), which was formed by the cleavage of a side chain, and the side-chain metabolites trichloroethanol including its glucuronide and *N*-acetylcysteine conjugate of 2,2,2-trichloroethylamine was detected in urine. W 1084 and triforine was detected in the faeces (Darda, 1974, Hawkins *et al.*, 1992).

Lactating goat

Study 1

The metabolism study for the lactating goats was performed with [piperazine-¹⁴C]-triforine (Ellgehausen, 1981: TF-440-013). Three lactating goats weighing approximately 20 kg were individually housed in cages and allowed free access to feed and water during the whole study. The test item was given as suspension in 0.5% CMC (Carboxymethyl Cellulose) in distilled water. It was administered by stomach tube to the three goats, one receiving 25 mg/kg bw and the other two receiving 100 mg/kg bw. Non-labeled triforine was given once daily for 7 days, thereafter on Day 8, 9 and 10, [¹⁴C]-labelled triforine was administered once daily.

Samples of milk were taken prior to the first treatment of [¹⁴C]triforine, during the dosing period twice daily, at 8 hours and 24 hours after treatment, and thereafter every 24 hours. Collection of urine and faeces was performed daily. The animals were sacrificed 6 days after the last treatment and the fat, muscle, heart, liver, mammary glands, kidneys, brain and blood removed for analysis. One goat (Goat C) was sacrificed 4 hours after the last treatment.

Goat	Average dose (mg/kg bw/day)	ppm in feed Based on feed consumption of 2 kg/day	Time between last treatment and sacrifice
A	24.41	250	6 days
B	97.98	1000	6 days
C	96.65	1000	4 hours

The radioactivity administered to the goats was rapidly eliminated. A total of 46.6% and 71.5% of the applied radioactivity were eliminated in urine and faeces in 24 hours by Goats A and B, respectively. In the following 5 days, a further 15.9 and 14.0% were excreted by Goats A and B, respectively. The radioactivity found at sacrifice in tissues, blood, and milk of Goats A and B amounted to an average of 1.6%, 0.3% and 0.3% of the applied radioactivity. Goat C sacrificed 4 hours after the last treatment showed higher values in tissues and blood, i.e. 6.1% and 0.8% respectively. Total recoveries of radioactivity from Goats A and B were 65.5% and 89.1% of the applied radioactivity, respectively.

The radioactivity in the milk was determined by combustion of 1 g aliquots. The radioactivity in urine was determined by direct liquid scintillation counting (LSC). The faecal samples were lyophilised, homogenized and removed for combustion followed by LSC of the radioactivity of carbon dioxide collected in scintillation cocktail. The radioactivity in blood was determined by combustion of 1 g samples. Tissues were solubilized overnight at 55 °C and radioassayed by LSC. The tissues, blood and milk samples were stored at -20 °C.

^a Treatment with [¹⁴C]-labelled triforine

Up to six metabolite fractions were isolated from urine and faeces extracts. The amount of triforine in urine and faeces ranged from 0.4% to 2.6% of the applied radioactivity. The major metabolite in urine was shown by co-chromatography to be W 1084. It amounted to 7.1% (Goat A) and 12.6% (goat B) of the applied radioactivity in urine and less than 1% in faeces.

The study was performed to determine the extractability of residues in liver, kidney and muscles of the goats and to determine the nature of the extractable radioactivity (Ellgehausen, 1982: TF-440-014). Until analysis the tissues were stored at -20 °C. Tissue samples (50 g) were extracted with acetone (100 mL) followed by methanol/water (8:2, 100 mL). Proteins of milk (100 g) were precipitated with acetone (200 mL) by centrifugation and removed. The protein precipitate was then extracted with acetone and methanol/water (8:2) as done with tissues. The organic solvent was evaporated and the remaining aqueous phase was partitioned with chloroform. The amount of extractables and non-extractables were determined by combustion and thin layer chromatography (TLC).

The residual radioactivity in the liver of Goat C, sacrificed 4 hours after the last administration of [¹⁴C]triforine was found to be extractable up to 68.4% TRR. This extractable radioactivity consisted of at least five metabolite fractions. M1 and M2 represented unknown polar metabolite fractions whereas WOS 2379 and W 1084 were characterized. The residual radioactivity in the liver of Goat B, sacrificed 6 days after the last treatment, was extractable up to 14.1% TRR. The metabolite pattern found was similar to that found in the extractables of the liver of Goat C. The predominant metabolite fraction was M1 representing 10.2% TRR. Triforine, WOS 2379 and W 1084 accounted only for 1.3%, 1.6% and 1.0% TRR, respectively.

The residual radioactivity in the kidneys of Goat B and C was extractable up to 17.9% and 78.2% TRR, respectively. These figures corresponded to 4.13 and 78.2 mg equiv/kg. The metabolite pattern of the extractables was similar to that found in the extractable of the liver. The predominant extractable fractions found in Goat C was polar unknown metabolite fraction M1 accounting for 31.1% TRR. Triforine, WOS 2379 and W1084 represented at the same time 19.3%, 8.4% and 18.5% TRR, respectively. Characterization of the extractable radioactivity of the kidneys of Goat B showed a similar metabolite pattern with regard to the relative amounts in the extracts. The

predominant extractable fraction was M1 accounting for 10.7% TRR. Triforine represented 3.6% TRR only.

Due to the low radioactivity concentration in muscle of Goat B and the low specific radioactivity, only muscles of Goat C were analyzed. The residual radioactivity accounted for 19.6 mg equiv/kg (78.7% TRR) was found to be extractable. Analysis by TLC showed that the predominant radioactive fraction was triforine with 40.6% TRR. The other metabolites accounted for 9.5% (W 1084), 13.0% (WOS 2379), 0.70% (M2) and 15.1% TRR (M1).

The radioactivity in the pooled milk fractions of Goat B sampled within 24 hours after the last administration of [^{14}C]triforine accounted for 49.6 mg equiv/kg.

Table 3 Extraction and characterization of residues in liver, kidney and muscle of Goat B sacrificed 6 days after the last treatment at 1000 ppm and Goat C sacrificed 4 hours after the last treatment at 1000 ppm

^a mg triforine equivalent/kg tissue

^b Not analyzed

The study was further performed for the investigation of the polar metabolite fractions and unextracted fraction (Schlüter, 1984: TF-440-015). The polar metabolite fraction M1 from Liver B, Liver C and milk was investigated. In all cases, thin layer chromatography showed that M1 consisted of a number of components that could not be well separated. Incubation with β -glucuronidase/aryl

sulphatase did not produce any difference in chromatographic profile indicating that M1 was not an easily hydrolyzed sulphate or glucuronide conjugate. When M1 was heated with strong acid piperazine was the only cleavage product. All the components in fraction M1 disappeared from the TLC plate and piperazine was formed.

Study 2

The adsorption, distribution, metabolism and excretion of radioactivity have been studied following repeated oral administration of [piperazine-¹⁴C]triforine to the dairy goat at a mean dose level of 67 mg/day (Richardson, 1994: TF-440-019). This was equivalent to a dietary inclusion of approximately 49 ppm (based on the food consumption of the goat during the study). One goat received five daily oral doses of [¹⁴C]triforine. The goat was given the dose in the morning before feeding but after milk and excreta collections. At study termination (*ca.* 6 h after the final dose) selected tissues were removed or sampled. The radiolabelled triforine derived material excreted was characterized using chromatographic procedures.

The overall recovery of the administered radioactivity was 72.3%, the majority of which was present in the urine (39.8%) and faeces (19.2%). Most of the remainder was associated with the contents of the gastro-intestinal tract (9.54%). Negligible radioactivity was recovered in cage washings/ debris (1.21%), milk (0.87%), tissues (0.82%) and residual carcass (0.88%).

From day 1, concentrations of radioactivity in whole milk were in the range 0.314 to 0.501 mg equiv/kg. Fractionation of 72–96 h whole milk showed that 32% of the radioactivity was found in cream and 76% was found in skim. Further fractionation showed that 7% of the radioactivity in the skimmed milk was found in the curds and 64% in whey. At *ca.* 6 h after the final dose, highest tissue residue levels were found in the liver (2.60 mg equiv/kg) and kidney (1.46 mg equiv/kg), with lower concentrations of 0.271 and 0.016 mg equiv/kg present in muscle and fat respectively.

Chromatography of the extracted radioactivity revealed metabolites with a wide range of polarity. TLC analysis proved to be the most efficient in terms of resolution of components. However given the very polar nature of some of the metabolites and low relative concentrations, the quality and hence the reproducibility of the chromatography in some solvent systems was poor. Comparison of the extracted radioactivity indicated that there were some similarities in the metabolite profiles for liver, kidney, muscle and urine; however, the metabolites in milk were very polar and more difficult to compare. The radioactivity which partitioned into organic solvent from liver extracts, kidney extracts, muscle extracts and urine all contained the same metabolites. The radioactivity which partitioned into the aqueous phase was more difficult to compare due to the polarity of the metabolites however there were some similarities in profiles for liver, kidney and muscle.

Piperazine was identified in liver extracts (5% TRR), in kidney extracts (6% TRR) and in urine (14% of the 96–102 h urine). W 1069 was identified as a minor metabolite in urine (8%).

The proportion of piperazine in tissue extracts, milk and urine was increased by acid treatment of the samples. These results when compared with the result of acid treatment of triforine hydrolysis products (which showed that the ring system was stable to this process) indicated that the increased proportion of piperazine arose from the cleavage of metabolites which featured remnants of one or both of the triforine side chains but without modification of the piperazine ring.

Unextracted residues in all tissues and milk were solubilized by 6 M acid treatment. Piperazine was identified in samples derived from the acid treatment of unextracted residues from liver but not in other samples (kidney and milk residues).

Laying hens

Study 1

The metabolism study for the laying hens was performed with [piperazine-¹⁴C]-triforine (Ellgehausen, 1981: TF-440-012). Six-month old laying hens (white leghorn hybrids) were housed individually in metabolism cages. They were allowed free access to food and water during the study. The test item was given as suspension in 0.5% CMC (Carboxymethyl Cellulose) in distilled water. It was administered once daily into the crop by intubation to three groups of hens. One group (Group A) received 25 mg/kg bw/day; the other two groups (Groups B and C) received 100 mg/kg bw/day. Non-labelled triforine was given daily for 7 days at the same rates thereafter on day 8, 9 and day 10, [¹⁴C]triforine was administered. Based on an assumed food consumption of 100 g diet per day and a hen body weight of 2 kg the 100 and 25 mg/kg dose were equivalent to 2000 ppm and 500 ppm dietary concentration, respectively.

Hen group	Average dose (mg/kg bw/day)	ppm in feed	Time between last treatment and sacrifice
A	23.40	500	7 days
B	96.79	2000	7 days
C	96.94	2000	4 hours

During the dosing period eggs were collected twice daily 8 hours and 24 hours after the treatment, thereafter every 24 hours. Collection of excreta was performed accordingly. The animals were sacrificed either 4 hours (Group C) or 7 days (Groups A and B) after the last treatment and the liver, heart, muscle, fat, and blood were sampled for analysis.

The eggs were divided into egg yolk/white and shells per group for each interval and pooled samples were homogenized. The subsamples were removed for combustion and radioactivity determination by liquid scintillation counting (LSC). The excreta samples per group for each interval were pooled, lyophilized, homogenized and subsamples were removed for combustion and radioactivity determination by LSC. Tissues and blood were solubilized overnight at 55 °C and direct radio-assayed by LSC. The tissues, blood and egg samples were stored until analysis at -20 °C.

The excreta samples during the experiment were pooled for intervals from day 8 to 8 hours after the last treatment and then thereafter to the end of experiment. The pools were homogenized and an aliquot of 50 g was taken for extraction. Each aliquot was extracted with acetone (3 × 200 mL) by strong agitation for 30 and finally 60 min. Thereafter the excreta samples were continuously extracted overnight in a Soxhlet apparatus. The radioactivity in the extracts was measured by LSC. TLC was used pre-coated silica gel 60 F 254 plates with various solvent systems. Three different solvent systems gave good separation of triforine and the available reference compound (W 1084).

The radioactivity administered to the hens was rapidly eliminated by the animals of all groups (53.7–83.6% in 56 hours after the first dose). In the following 7 days a further 10.2–14.8% of the administered radioactivity was excreted by the remaining groups giving 75.7% excreted from Group A and 93.8% from Group B.

At the lower dose level (Group A) the TRR ranged from < 0.05 mg/kg in fat to 1.80 mg/kg for liver. The corresponding figures at the higher dose level (Group B) were four times higher, clearly showing the direct correlation between dose level and tissue/organ residue. The animals of Group C, which received the same amount of triforine as Group B but which were killed 4 hours after the last treatment showed higher residual radioactivity in tissues and organs.

Table 5 Total radioactive residues in tissues of laying hens

TRR (mg triforine equivalent/kg)

	Blood	Heart	Liver	Muscle	Muscle forestomach	Fat
Group A	1.25	1.22	1.80	0.58	0.74	<0.05
Group B	4.30	4.37	5.89	1.86	3.10	0.25
Group C	23.5	28.7	140	14.1	21.4	2.26

The egg residues in Group A were on the average three times lower than in Group B or C. The highest values in eggs were found about 4 to 5 days after the first treatment with [^{14}C]triforine. No influence of the compound during the whole study on egg production was observed although the hens were dosed up to 100 mg/kg over a period of 10 days.

Table 6 Total radioactive residues in selected eggs of laying hens

NS: no egg sampling

T: Treatment with [^{14}C]triforine

Metabolites were characterized by extraction of excreta followed by TLC. Analysis of the pooled 0–56 and 56–216 hours excreta from high and low dose application showed in general the same pattern of metabolites in the extractables. The major metabolite fraction characterized by TLC was W 1084.

Study 2

The metabolism of triforine in laying hens was investigated after administration of [side chain- ^{14}C]triforine for 10 consecutive days at a dose of 32 ppm in the feed (Mayo, 1994: TF-440-020). The dose was administered orally via a gelatine capsule at a rate of 3.5 mg/hen/day. Combined excreta from five treated hens and from two control hens were collected at 24-hour intervals from 24 hours prior to the first treatment up to the time of sacrifice. Any eggs laid were collected prior to administration of the next treatment, labelled and stored at 4 °C prior to further treatment. Hens were sacrificed *ca.* 6 hours after the last treatment and the tissues taken for analysis. There was no visible fat on the skin. All samples were stored at < -15 °C prior to analysis.

The combined extracts of the excreta collected at day 10 were analyzed directly by radio-TLC. Metabolites were scraped from TLC plates and extracted from the silica with methanol and further purified by HPLC. Liver, muscle and egg white and yolk samples were extracted sequentially with acetone (twice), methanol/water 8:2 (twice) and finally with water (twice). Samples of egg white and liver were homogenized and pre-incubated with protease in buffer solution for 12–18 hours at 37 °C before the same extraction process. The residue from the yolk extraction was re-extracted with the same solvent mixtures once more followed by a final water extraction. Skin was extracted by dissolving the sample in hexane and extracting the residue three times with methanol/acetone (9:1). The hexane phase was back extracted five times with acetonitrile. The extracts were radio-assayed separately and combined as appropriate for chromatographic analysis.

Radioactivity recovered in excreta during the 10 days accounted for about 85% of the total cumulative dose with 1.5% remaining in the gastrointestinal tract after sacrifice. Recovery of radioactivity in the faeces had increased from 76% on Day 1 to 90% between Day 6 and Day 9. A slight decrease to 85% observed at Day 10 may be attributed to sacrifice at 6 hours after the last treatment. Concentration of radioactivity in eggs increased steadily during the 10 days to a peak value of 1.6 mg equiv/kg (yolk) and 0.19 mg equiv/kg (white).

^a Extraction after protease treatment

^b Representative pool from Day 7–9

Fraction A-K: Unidentified

Treatment of liver with protease reduced the unextracted radioactivity from 0.86 to 0.09 mg equiv/kg (51.2 to 5.3% TRR). Further quantities of the same radioactive components (mainly fraction A and component C/D) were extracted after the protease treatment. Identity of component C/D was confirmed by mass spectrometry as the sulphate conjugate of trichloroethanol. Protease treatment increased the amount of fraction A from 31.3% to 66.7% TRR. The fraction A in the protease-treated extract was separated into 5 separate components each of which accounted for 0.07–0.40 mg equiv/kg (4–24% TRR). The sulphate conjugate of trichloroethanol was present in liver accounting for 9% TRR. There appeared to be a small amount of triforine in liver (2.9% TRR, 0.05 mg/kg) before protease treatment but chromatography was poor. Treatment with β -glucuronidase/sulphatase or mild chemical hydrolytic treatment did not release any identifiable components. Strong acid/base hydrolysis generated some discrete less polar components.

The breast and thigh muscle was extracted separately and sub-samples were combined for chromatography. The main components were the trichloroethanol sulphate conjugate and W 1069 each accounting for about 22% TRR (0.05 mg equiv/kg). Triforine was present at 8.4% TRR (0.02 mg/kg).

Triforine accounted for 17.5% TRR (0.02 mg/kg) and the sulphate conjugate of trichloroethanol accounted for 35.9% TRR (0.03 mg equiv/kg) in fat. There were at least five other components but each was less than 0.01 mg equiv/kg.

Triforine was also found in skin at low levels (0.01 mg/kg). The main fraction corresponded to the retention time of the trichloroethanol sulphate (55.7% TRR, 0.13 mg/kg). There were at least five other components but each was less than 0.01 mg equiv/kg.

Treatment of egg white with protease reduced unextracted radioactivity from 0.09 to 0.04 mg equiv/kg (58.7 to 27.4% TRR). The major component was the Fraction A which accounted for 19% (0.03 mg/kg). It was further separated by TLC into two polar components. Triforine and the trichloroethanol sulphate conjugate were found in small amounts (0.01 and 0.02 mg/kg respectively). All other components were less than 0.01 mg/kg.

Treatment of egg yolk with protease reduced unextracted radioactivity from 0.30 to 0.15 mg equiv/kg (29.1 to 14.6% TRR). Hydrolytic treatment of the residue of protease treated egg yolk, after extraction, with acid separated this unextracted radioactivity into an acid treated extract and residue each accounting for either < 0.05 mg equiv/kg or < 10% egg yolk radioactivity. Increased amounts of the polar fraction A were extracted after the protease treatment. Fraction A was separated into two components each accounting for < 0.05 mg equiv/kg in egg yolk. The major component in egg yolk was the sulphate conjugate of trichloroethanol which accounted for 25% TRR. W 1069 was observed and accounted for a further 10% TRR. Component H (less polar than triforine) in egg yolk was not identified.

Summary of animal metabolism

The metabolism of ^{14}C labelled triforine has been studied in lactating goats and laying hens. Triforine is very rapidly degraded in the goat even at the high dose levels used in the metabolism studies. Oxidation and hydrolysis leading to removal of the side chains from the piperazine ring was the main route of degradation. Free piperazine was not a metabolite but piperazine was identified following the solubilization of the matrix components followed by strong acid hydrolysis. The main extracted product was triforine although there were higher amounts of a mixture of highly polar components which were not completely separated. They were not identified but appeared to yield mainly piperazine on reflux with hydrochloric acid.

As in the goat, one of the side chains was lost to form W 1069 and the carbon from the side chain was found mainly as trichloroethanol and its sulphate conjugate. The major portion of the residue even with a relatively short pre-slaughter interval was unextracted with a very thorough extraction sequence involving a range of solvent polarities and overnight contact with the matrix. It is possible that trichloroethanol was further metabolized into small fragments that were incorporated into the tissue and egg matrix components. It is assumed that W 1069 was further metabolized to piperazine containing compounds which would also be bound to matrix components.

Figure 2 Metabolic Pathway of Triforine in livestock

Plant metabolism

Plant metabolism studies were performed on apples, tomatoes and cucumber with triforine [^{14}C]-labelled in two carbons at the side chain, and on barley with triforine [^3H]-labeled at piperazine ring to track metabolites. Metabolites were identified using multiple chromatographic systems and authentic standards.

Apple

The metabolism of [^{14}C]triforine has been studied in apple fruits and leaves after five successive applications of a commercial formulation of 0.1% [side chain- ^{14}C]-triforine at 8-day intervals (Hawkins *et al*, 1993: TF-640-037). Three 2–3 year old container grown apple trees (variety Lord Lambourne) on semi-dwarf root stock were placed outdoors in a netted enclosure. Samples of [^{14}C]triforine (*ca.* 6 mg) were mixed with 25 μL blank formulation (EC 190 g/L) giving *ca.* 31 mg of formulation. This formulation was diluted with water to give a final concentration of 1.2 g/L. Specific amounts of the formulated [^{14}C]triforine were applied to either apples (100 μL) or leaves (100 μL) using a syringe. The treatment was applied as a series of small droplets at random over the surface of the apple/leaf. Treated apple fruits were harvested 2 weeks after the last of five successive applications. Translocation from treated leaves into untreated apple fruits was also investigated. Some additional apple fruits and leaves were sampled about 2 hours after one application.

The recovery of radioactivity from selected apple fruits and leaves was measured about 2 hours after one application. The remaining apple fruits were taken, along with the leaves and untreated apples, 14 days after the fifth application of [^{14}C]triforine. Surface washes on all treated samples were initiated on the day of sample collection and samples were stored at $< -15^\circ\text{C}$ overnight. The surface of each treated apple or leaf was washed by immersion in acetonitrile for 5 minutes during which time the container was placed in a sonic bath. The surface wash was then separated by decanting and the process repeated with two further acetonitrile washes. The volumes of the surface washes were measured and aliquots (approximately 100 μL) were removed for estimation of radioactivity by LSC. After the surface washes were completed the apple fruits were peeled and the

peel, flesh and leaves were separately homogenized with acetonitrile, sonicated and the samples were centrifuged. A further extraction was performed using acetonitrile: water (70:30).

Table 8 The distribution of radioactive residues in apple fruit and leaves

	2 hours after one application				2 weeks after five applications

Peel or leaf	0.4	0.4	2.9	4.8	1.4	4.5	5.7	25.4
Flesh	0.2	0.2	–	–	2.2	7.0	–	–
Unextracted	0.6	0.6	2.1	3.4	4.7	15.3	2.0	7.8
Total	95.8	100	59.9	100	32.2	100	22.3	99.9

After one application of [^{14}C]triforine three fruits and three leaves were taken for analysis. The radioactivity in the surface washes was 98.8% (fruit) and 91.8% (leaf) of TRR. Only small amount of radioactivity were in the remaining extracts of homogenized peel and flesh, 0.4 and 0.2% TRR respectively. Extracts of homogenized leaves contained 4.8% TRR. The mean concentrations in the treated fruits and leaves were 1.59 (fruit) and 92.4 (leaf) mg equiv/kg, respectively.

At harvest, after 5 successive applications of [^{14}C]triforine, 32.2% (fruit) and 22.3% (leaf) of the applied radioactivity was recovered. Acetonitrile surface washes of treated fruits at harvest contained 73.2% TRR. Extracts of peel and flesh homogenized with acetonitrile accounted for 4.5 and 7.0% TRR respectively. The mean concentration of 1.36 mg equiv/kg was recovered in the treated fruits.

At the time of harvest untreated fruits were taken from branches with treated leaves. The radioactivity in untreated fruits accounted for 0.0009 mg equiv/kg. Analysis of untreated fruits showed a very low degree of translocation during this period.

Samples of surface washes and extracts were pooled to give representative samples for both fruits and leaves, and analyzed directly by TLC or HPLC. Radiolabelled metabolites formed in the study were characterized by co-chromatographic comparison using two different systems.

Note: In order to provide material for duplicate chromatographic runs, surface washes and extracts containing most radioactive components were combined to obtain two pooled samples from different fruits and leaves.

The major component in surface washes and extracts of fruits was identified as triforine by co-chromatography with reference test substances using both normal phase TLC and reverse phase HPLC. Triforine accounted for 73–79% TRR at harvest. The final concentrations of triforine in the fruits at 2 weeks after the final application of triforine were 0.88–1.22 mg/kg.

Several minor components were observed in the extracts and each of these accounted for 1–2% TRR. Two of the identified metabolites, formed by degradation of the piperazine side chain, were the mono and di-formyl compounds W 625 and WOS 613. The third identified metabolite, formed by de-alkylation of one of the piperazine nitrogen, was the amine W 1069. A further three unidentified components A, B and C were also observed that did not co-chromatograph with the available reference compounds. All of these metabolites each accounted for 0.01–0.02 mg equiv/kg.

The nature of the radioactivity unextracted in the peel residue was investigated using some hydrolytic treatments. Apple peel was treated with pectinase enzyme, 0.6 M HCl at 37 °C for 18 hours and 6.0 M HCl at > 90 °C for 1 hour. After adjustment to pH 7 the aqueous layers were extracted with ethyl acetate. The treatments with pectinase and mild acid extracted only small amounts of radioactivity from peel (< 2%) but in these samples the unextracted residue amounted to > 10% recovered radioactivity. On hydrolysis with concentrated acid approximately 7% of the sample radioactivity was extractable. Attempts to chromatograph these extracts were unsuccessful due to the low levels of radioactivity. The radioactivity in the acid peel extract accounted for about 0.1 mg equiv/kg and in the unextracted residue accounted for about 0.09 mg equiv/kg.

Tomato

The metabolism of [¹⁴C]triforine has been studied in tomatoes and leaves after four successive applications of a commercial formulation of 0.1% [side chain-¹⁴C]-triforine at 8–10 days intervals (Hawkins *et al*, 1993: TF-640-038). Tomato plants (variety Moneymaker) were transplanted to 25 cm diameter plastic pots containing potting compost. The study was conducted in a controlled environment room with a daylength of 15 hours and day and night temperatures of 20.9 ± 1.1 °C. Samples of [¹⁴C]triforine (approximately 12 mg) were mixed with 50 µL blank formulation (EC 190 g/L) giving *ca.* 62 mg of formulation. This formulation was diluted with water to give a final concentration of 1.2 g/L. Specific amounts of the formulated [¹⁴C]triforine were applied to either tomatoes (100 µL) or leaves (200 µL) using a syringe. The treatment was applied as a series of small droplets at random over the surface of the tomato/leaf. The treated tomatoes were harvested at 2 hours and 3 days after the last of four successive applications. For comparison additional samples were taken 2 hours after the first application. Translocation from treated leaves into untreated tomatoes was also investigated.

The recovery of radioactivity from each treated tomato leaf was measured separately. Surface washes on all treated samples were collected on the day of sample collection and samples were stored at < –15 °C overnight. The surface of each treated tomato leaf was washed by immersion in acetonitrile for 5 minutes during which time the container was placed in a sonic bath. The surface wash was then separated by decanting, and the process repeated with two further acetonitrile washes. After the surface washes were completed the tomato fruit or leaf was homogenized with acetonitrile, sonicated and the sample centrifuged. The supernatant extract was removed and the process repeated (leaves at harvest were extracted a third time with acetonitrile: water (70:30 v/v)). The volumes of the surface washes and extracts were measured and aliquots (approximately 100 µL) were removed for estimation of radioactive content by LSC. The extracted residues were allowed to air-dry and the radioactive content determined by combustion of sub-samples. A similar extraction procedure was employed for the untreated tomatoes removed at harvest.

Unextracted	3.0	3.1	3.5	3.8		
Total	97.8	100.1	92.1	100.1		

Three tomatoes and two leaves were sampled for analysis 2 hours after the first application of [^{14}C]triforine. The radioactivity recovered in the surface washes was 95.6% (tomato) and 95.1% (leaf) TRR. Extracts of the homogenised tomato or leaf contained small amounts of radioactivity (3.7% TRR (tomato) and 1.9% TRR (leaf)). Radioactivity in the unextracted residues accounted for 0.7% TRR (tomato) and 3.1% TRR (leaf). The mean concentrations in whole tomato and leaf were 6.2 and 16.9 mg equiv/kg, respectively.

The initial surface washes of treated tomatoes at harvest contained 91.9% (harvest at 2 hours after the final application) and 90.9% (harvest at 3 days after the final application) of TRR. Acetonitrile extracts of homogenised tomatoes accounted for 5.8% TRR (2 hour harvest) and 6.2% TRR (3 day harvest). After this extraction, 2.3% TRR (2 hour harvest) and 2.8% TRR (3 day harvest) remained unextracted in the tomato residue. The TRR from the treated tomatoes accounted for mean concentrations of 15.6 (2 hour harvest) and 9.7 (3 day harvest) mg equiv/kg.

Leaves were only removed for analysis 3 days after the final application of [^{14}C]triforine. The TRR in these leaves accounted for a mean concentration of 89 mg equiv/kg.

At the time of harvest untreated tomatoes were taken from plants with treated leaves. The initial surface washes of the untreated tomatoes contained 18% TRR with 82% TRR in the remaining tomato flesh extract plus residue. The TRR in untreated tomatoes accounted for a mean concentration of 0.004 mg equiv/kg indicating a very low degree of translocation.

Samples of surface washes and extracts were pooled namely Pool 1 to 2 as in table below to give representative samples for both tomatoes and leaves and analyzed directly by TLC or HPLC. Radiolabelled metabolites formed in the study were characterized by co-chromatographic comparison using two different systems.

Note: In order to provide material for duplicate chromatographic runs, surface washes and extracts containing most radioactivity were combined to obtain two pooled samples from different fruits and leaves.

At 2 hours and 3 days after the final application only one major discrete component was observed in surface washes which accounted for 86.9–89.5% TRR. The major component in tomato extracts was also shown to co-chromatograph with triforine and accounted for 2.89–4.56% TRR. This major radioactive component was identified as triforine by co-chromatography with authentic test substance using both normal phase TLC and reverse phase HPLC. Triforine accounted for 91.4–92.7% TRR in in surface washes and extracts of tomatoes taken at 2 hours and 3 days after the final application of ^{14}C -triforine. In addition, W 1069, WOS 613 and W 625 were identified by co-chromatography with reference compounds in both normal phase TLC and reverse phase HPLC. Three further unidentified components A, B and C were observed that did not co-chromatograph with the available reference compounds. The major component present in the tomato at harvest was identified as triforine and accounted for means of 15.6 and 9.19 mg/kg in tomatoes taken 2 hours and 3 days after the final application of triforine respectively. The minor components W 1069, WOS 613, W 625 and each unidentified component (A-C) generally accounted for 0.02–0.1 mg equiv/kg. Radioactivity unextracted from the tomato accounted for 0.2–0.4 mg equiv/kg.

The unidentified radioactive components in the tomato extracts taken 3 days after the final application of [^{14}C]triforine were in the range of 0.02–0.05 mg equiv/kg. In order to provide further information to characterise these unidentified components, their partitioning behaviour was investigated (Hawkins *et al*, 1994: TF-640-040). Samples of the tomato extracts were diluted with water and extracted with ethyl acetate at both pH 2 and pH 9. In addition, further samples were incubated separately with β -glucuronidase/sulphatase and β -glucosidase. These incubates at pH 5

were also extracted with ethyl acetate. The radioactive components in these organic and aqueous layers were quantified by TLC and the partitioning behaviour of each component was calculated.

The unidentified metabolites A and B were shown to be polar water soluble components at pH 2 and 9 and were not hydrolysed with either β -glucuronidase/sulphatase or β -glucosidase. The metabolite C was partitioned between both the organic (ca 80%) and aqueous (ca 20%) layers at pH 2 and 9 but was entirely organo-soluble at pH 5 (after enzyme treatment). Component C was also not hydrolysed with the enzyme treatments.

Cucumber

The metabolism of [^{14}C]triforine has been studied in cucumbers and leaves after four successive applications of a commercial formulation of 0.1% [side chain- ^{14}C]-triforine at 7-day intervals (Hawkins *et al*, 1993: TF-640-039). Cucumber plants (variety Brunex F1) were transplanted to 25 cm diameter plastic plant pots containing potting compost. The study was conducted in a controlled environment room with a daylength of 15 hours and day and night temperatures of $21.8 \pm 0.5^\circ\text{C}$. Samples of [^{14}C]triforine (ca. 6 mg) were mixed with 25 μL blank formulation (EC 190 g/L) giving ca. 31 mg of formulation. This formulation was diluted with water to give a final concentration of 1.2 g/L. Specific amounts of the formulated [^{14}C]triforine were applied to either cucumbers (200 μL first application, 300 μL remaining applications) or leaves (200 μL) using a syringe. The treatment was applied as a series of small droplets at random over the surface of the cucumber/leaf. The treated cucumbers were harvested 3 days after the last of four successive applications. For comparison additional samples were taken 2 hours after the first application.

The recovery of radioactivity from selected sample cucumbers and leaves was measured about 2 hours after the first application. The remaining cucumbers were taken, together with the leaves and untreated cucumbers, 3 days after the fourth application of [^{14}C]triforine. Surface washes on all treated samples were collected on the day of sample collection and samples were stored at $< -15^\circ\text{C}$ overnight. Each treated cucumber or leaf was surface washed by immersion in acetonitrile for 5 minutes during which time the container was placed in a sonic bath. The surface wash was then separated by decanting and the process repeated twice, once with acetonitrile and once with acetonitrile: water (70:30 v/v). After the surface washes were completed the cucumber was peeled and the peel or flesh was homogenized with acetonitrile, sonicated and the sample centrifuged. Leaves removed at harvest were also extracted using this procedure. The supernatant extract was removed and the process repeated once with acetonitrile and once with acetonitrile: water (70:30 v/v). The volumes of the surface washes and extracts were measured and aliquots (ca. 100 μL) removed for estimation of radioactive content by LSC. The extracted residues were allowed to air-dry and the radioactive content determined by combustion of sub-samples. A similar extraction procedure was employed for the untreated cucumbers removed at harvest.

Table 12 The distribution of radioactive residues in cucumbers and leaves

	2 hours after one application (n = 3)				3 days after 4 applications (n = 12)			
	Cucumber		Leaf		Cucumber		Leaf	
	%AR	%TRR	%AR	%TRR	%AR	%TRR	%AR	%TRR

Surface wash	88.2	95.8	95.9	99.0	68.9	84.5	85.5	93.4
Peel or leaf	1.6	1.7	0.7	0.7	6.1	7.5	5.2	5.6
Flesh	1.3	1.4	—	—	1.1	1.4	—	—
Unextracted	1.0	1.1	0.3	0.4	5.5	6.7	1.0	1.1
Total	92.0	100	96.8	100.1	81.6	100.1	91.6	100.1

Three cucumbers and three leaves were sampled for analysis 2 hours after the first application of [^{14}C]triforine. The mean amounts of radioactivity recovered in the surface washes was 95.8% TRR (cucumber) and 99.0% (leaf) TRR. Extracts of the homogenized cucumber peel and flesh contained small amounts of radioactivity (1.7% and 1.4% TRR) and radioactivity extracted from the leaf contained 0.7% TRR. Radioactivity in the unextracted residues accounted for 1.1% TRR

(cucumber) and 0.4% TRR (leaf). The mean concentrations in whole cucumber and leaf were 0.57 and 81.5 mg equiv/kg, respectively.

The initial surface washes of treated cucumbers at harvest accounted for 84.5% TRR. Extracts of homogenised cucumber peel and flesh accounted for 7.5% TRR (peel) and 1.4% TRR (flesh). After these extractions, 6.7% TRR remained unextracted in the residues. The TRR from the treated cucumbers accounted for a mean concentration of 2.17 mg equiv/kg.

The surface washes of treated leaves at harvest contained 93.4% TRR. Acetonitrile extracts of the homogenised leaves contained 5.6% TRR whilst 1.1% TRR remained unextracted in the leaf residue. The TRR in the leaf accounted for a mean concentration of 114 mg equiv/kg.

At the time of harvest untreated cucumbers were taken from plants with treated leaves. The initial surface washes of the untreated cucumbers contained 25% of TRR with 75% in the remaining cucumber flesh extract plus residue. The TRR in untreated cucumbers accounted for a mean concentration of 0.0044 mg equiv/kg indicating a very low degree of translocation.

Unextracted	–	–	5.4 (0.12)	6.6 (0.14)	0.6 (0.01)	0.8 (0.02)	6.0 (0.13)	7.4 (0.16)

Note: In order to provide material for duplicate chromatographic runs, surface washes and extracts containing most radioactive components were combined to obtain two pooled samples from different fruits and leaves.

Three days after the final application only one major discrete component was observed in surface washes which accounted for 81–84% TRR. The major component in cucumber extracts was also shown to co-chromatograph with triforine and accounted for 3.3–5.6% TRR (peel) and 0.24–0.34% TRR (flesh). The major radioactive component was identified as triforine by co-chromatography with authentic test substance using both normal phase TLC and reverse phase HPLC. The total radioactivity associated with triforine in surface washes and extracts accounted for 86.9–87.5% TRR in cucumber taken 3 days after the final application of [^{14}C]triforine.

The extracts also contained several minor components each accounting for 0.3–2% TRR. Three of these were identified as the compounds W 1069, WOS 613 and W 625 by co-chromatography with reference compounds in both normal phase TLC and reverse phase HPLC. Three further unidentified components A, B and C were observed that did not co-chromatograph with the available reference compounds.

The major component present in the cucumber at harvest was identified as triforine and accounted for 1.9 mg/kg. The minor components W 1069, WOS 613, W 625 and unidentified

components A-C each accounted for 0.005–0.04 mg equiv/kg. Radioactivity unextracted from the cucumber accounted for 0.13–0.16 mg equiv/kg.

The unidentified radioactive components in the cucumber extracts taken 3 days after the final application of [^{14}C]triforine were in the range of 0.002–0.04 mg equiv/kg. In order to provide further information to characterise these unidentified components, their partitioning behaviour was investigated (Hawkins *et al*, 1994: TF-640-041). Samples of the cucumber extracts were diluted with water and extracted with ethyl acetate at both pH 2 and pH 9. In addition, further samples were incubated separately with β -glucuronidase/sulphatase and β -glucosidase. These incubates at pH 5 were also extracted with ethyl acetate. The radioactive components in these organic and aqueous layers were quantified by TLC and the partitioning behaviour of each component calculated.

The unidentified A and B were shown to be polar water-soluble components at pH 2 and 9 and were not hydrolysed with either β -glucuronidase/sulphatase or β -glucosidase. The unidentified C was partitioned between both the organic (40–80%) and aqueous (60–20%) layers at pH 2 and 9 but was entirely organo-soluble at pH 5 (after enzyme treatment).

Barley

Study 1

The metabolism of [^3H]triforine in barley plants has been studied (Rouchaud *et al*, 1977: TF-905-013). Barley plants (variety Hebe) were grown (33 plants/pot) in plastic pots (13 cm diameter), containing a mixture of sand and expanded perlite (1/1, v/v). Unlabelled triforine (30 mg/pot) and an equal weight of adjuvant powder were emulsified in water (30 mL/pot) and [^3H]triforine dissolved in methanol was added to the emulsion to give the preparation used for soil drenching. Three leaves were harvested at 15 and 30 days after treatment, immediately weighed and then homogenised (6 min, 4 °C) with ethanol. Each homogenate (3 mL) was filtered on glass filters, the solid residue washed on the filter with ethanol to remove any unbound label, dried under an infrared lamp and ^3H determined with a LSC.

The harvested leaves were frozen in plastic bags with an ethanol-solid CO_2 mixture and stored (-20 °C). The leaves (50 g), warmed up to room temperature, were homogenised with chloroform (300 mL). The supernatant was centrifuged and filtered, giving the primary chloroform extract and a solid residue. The primary chloroform extract was transferred to a separatory funnel and extracted with aqueous HCl, giving the secondary chloroform extract. The secondary chloroform extract was filtered through potassium carbonate and concentrated in a rotary vacuum evaporator. The hydrochloric acid extract was brought to pH 7 with aqueous 2.0 M and 0.1 M NaOH, and freeze-dried. The powder was put on a chromatographic column and eluted with the chloroform which had been used to rinse the dishes used in the freeze-drying. In some experiments, the hydrochloric acid extract was brought to pH 4 with aqueous 2.0 M and 0.1 M NaOH and freeze-dried. The identification of the radioactive TLC spots was made by comparison of their R_f values with those of standard compounds, using four TLC systems for each metabolite.

Each concentrate of the secondary chloroform and acid extracts was analysed by TLC using all four eluting solvents. The compositions of the two extracts, as shown by TLC, were different and no labelled compound was common to both. The secondary chloroform extract contained mostly triforine. In the hydrochloric acid extract, a metabolite was observed for which the chemical structure W 1084 was suggested. Another labelled compound in this extract was probably piperazine, the concentration of which increased with time after treatment. The amounts of piperazine observed were similar in freeze-dried pH 4 or pH 7 extracts. Triforine was found only in the secondary chloroform extract, and W 1084 and piperazine were present only in the 0.1 M HCl extract. None of these compounds was transformed into the others during the analytical process.

Table 14 Total percentage distribution of radioactivity in the leaves of barley plants treated with [^3H]triforine

	%TRR	
	15 days after treatment	30 days after treatment
Extract	76.9	61.8

Unidentified	4.1	3.2
0.1 M HCl extract	15.3	15.4
W 1084	12.9	8.4
Piperazine	0.3	4.0
Unidentified	2.1	3.0
Unextracted	23.1	38.2

Study 2

The leaves of barley plants root-treated with [^3H]-triforine (uniformly labelled in the piperazine ring) were analysed 30 days after treatment (Rouchaud *et al*, 1978: TF-640-008). The distribution of the methanol-soluble ^3H -constituents was similar to that of the chloroform soluble (Study 1): 45% triforine, 10% W 1084, 5% piperazine. Methanol extraction left a solid plant residue which contained 33% of the total ^3H which had been incorporated into the leaves. Methanol acidified with hydrochloric acid extracted a further 18% of the triforine-derived bound residues as W 1084 (8%) and piperazine (10%). In the plants, these compounds had thus been complexed to plant constituents.

Hot dimethyl sulphoxide (DMSO) extracted a further 13% of the total ^3H , leaving a solid residue (mainly cellulose) which contained 2% of ^3H , perhaps incorporated into the cellulose. Evaporation of the solvent from the DMSO extract gave a solid substance with the radioactivity (13%), which could not be extracted by methanol. A part (7%) of this radioactivity could be released by successive hydrolysis with aminoglucosidase and β -glucosidase, which generated a complex mixture of polar and water soluble unknown radioactive compounds not including piperazine. These latter compounds would be the products of extensive metabolism of triforine (and its metabolite piperazine) bound to, or incorporated into starch. Most (11%) of the radioactivity of this solid could be released by hydrochloric acid hydrolysis, which also generated a complex mixture of polar and water soluble unknown radioactive compounds not including piperazine; a part (4%) of them could have been associated with lignin in the plant.

Study 3

The metabolism of the [^3H]-triforine, uniformly labelled in the piperazine ring, has been studied in barley (Rouchaud *et al*, 1978: TF-640-010). Barley (variety Hebe) was sown and grown normally in an experimental field. At growth stage J (during the stem extension stage when the second node of the stem was formed and the next-to-last leaf was just visible), the aerial part of the plants was sprayed with an aqueous emulsion of a mixture of the commercial formulation of triforine and [^3H]-triforine. The total dose of 0.25 kg ai/ha was that of agronomic practice. Barley was harvested when ripe, and straw and grain were analysed separately.

The straw and grains were washed rapidly and successively with water and methanol, the washing liquids being discarded as they did not contain significant amount of radioactivity. Extraction with methanol was followed by centrifugation. The first extract was macerated for 72 hours at 20 °C (300 mL to 100 g straw/grains). Three sequential extractions (300 mL methanol) were performed and the methanol extracts were combined. The straw was chopped and the grain was ground for extraction. This process was repeated with a further four samples of grain (100 g each) to provide sufficient material for metabolite identification. The extracts were partitioned with chloroform against dilute HCl. The metabolites in both phases were separated by column chromatography and characterized by TLC. Metabolites were identified by cleaning up by a preparative TLC followed by derivatisation and confirmation by co-chromatography with derivatized reference compounds.

The total radioactivity concentration was 20 times higher in straw than in grain. In straw and grain respectively, 12 and 25% of the total incorporated radioactivity in each of these tissues were methanol soluble; this corresponded to the higher content of cellulosic and lignified tissues in straw than in grain, and the correspondingly higher solubilisation of the radioactive residues. The amount of methanol soluble radioactivity was 14 times higher in straw than in grain.

The methanol soluble radioactive residue contained the triforine and its metabolites which were free and unbound in barley straw and grain. No radioactive piperazine was observed, in spite of the high detection sensitivity for radioactivity. Triforine was identified and accounted for 0.034 mg/kg (18% TRR) in straw and 0.0018 mg/kg (13% TRR) in grain. W 1084 was identified at 0.009 mg/kg (7% TRR) in straw and 0.0006 mg/kg (7% TRR) in grain. Two other radiolabelled components were identified: Glycine was found at 0.043 mg/kg (33% TRR) in straw and 0.0033 mg/kg (34% TRR) in grain. Iminodiacetic acid was also identified at 0.021 mg/kg (17% TRR) in straw and 0.001 mg/kg (11% TRR) in grain.

Extraction of the grain with methanol left methanol-insoluble solids containing an amount of radioactivity (the bound residue) which represented 75% of the total radioactivity incorporated into the grain. Methanol acidified with hydrochloric acid extracted a further 7% TRR of the triforine-derived bound residues in the form of radioactive iminodiacetic acid (1.1% TRR), glycine (3.3% TRR), serine (0.9% TRR), ethanolamine (0.2% TRR) and unidentified compounds (1.5% TRR). Aqueous 0.03 M NaOH extracted a further 27% of the total tritium which had been incorporated by means of chemical bonds into the protein fraction; acid hydrolysis of the proteins yielded radioactive glycine (9.2% TRR), serine (3.9% TRR) and unidentified compounds (13.9% TRR) which could have been a mixture of a large number of other amino acids. The plant solids (which contained 41% of the total tritium) left after the alkaline aqueous extractions were processed and separated into tritiated cellulose (4% TRR) and starch (37% TRR) fractions. The starch was hydrolysed and the resulting glucose was converted into the osazone (34% TRR). After being recrystallized several times, the osazone contained a constant specific radioactivity, indicating that [^3H]-glucose was present. No piperazine was observed in the bound residues in the grain. (Rouchaud *et al*, 1979: TF-905-020)

Extraction of the straw with methanol left methanol-insoluble solids containing an amount of radioactivity (the unextracted residue) which represented 88% of ^3H (as with all the subsequently referred % of ^3H relative to the total of ^3H incorporated into the straw). Methanol acidified with hydrochloric acid extracted a further 8% TRR of the triforine-derived bound residues as radioactive iminodiacetic acid (0.4% TRR), glycine (3.2% TRR), serine (2.0% TRR), ethanolamine (0.2% TRR) and unidentified compounds (2.2% TRR). A neutral detergent solution extracted a further 3% of the radioactive triforine-derived bound residues as unidentified compounds; three radioactive compounds, which were dissolved by the acidified methanol and by the neutral detergent solution, were thus in the straw complexed to straw constituents. An acid detergent solution extracted a further 58% of the total ^3H , which was really incorporated by means of chemical bonds into the hemicelluloses fraction; the acid hydrolysis of the hemicelluloses yielded a mixture of monosaccharides which were derivatised into a mixture of osazones (50% TRR). The plant solids (which contained 19% of the total ^3H), remained after the acid detergent extraction, were processed and separated into the ^3H containing cellulose (13% TRR) and lignin (6% TRR) fractions. No piperazine was observed in the bound residues in the grain. (Rouchaud *et al*, 1979: TF-640-014)

Summary of plant metabolism

Triforine was the major component present in the edible portion of the harvested crops. Only small amounts of metabolites were observed and those identified contained the intact piperazine ring. In barley metabolism was much more extensive with more than 90% of the terminal residue in grain and straw being present as natural products either extractable with neutral solvent (monomers) or incorporated into plant polymers and only extractable after acid hydrolysis or digestion of the plant constituents. Triforine, glycine and iminodiacetic acid were present in small amounts in the methanol extracts of grain and straw with triforine predominating in both grain and straw. Triforine and extractable metabolites were all less than 0.01 mg/kg in harvested grain following application at approximately 0.25 kg ai/ha.

Figure 3 Metabolic pathway of triforine in plants

Environmental fate in soil

The Meeting received information on aerobic degradation in soil, photolysis on soil surface and hydrolytic degradation study. Because triforine is intended for use as foliar treatment, aerobic degradation, soil photolysis and hydrolytic degradation study relevant to the current evaluations are reported below (FAO Manual 2009).

The fate and behaviour of triforine in soils were investigated using [piperazine-¹⁴C] and [side chain-¹⁴C] labelled compounds.

Aerobic degradation

Study 1

The degradation of [piperazine- ^{14}C]-triforine in a silty loam soil and a sandy loam soil when incubated at 20 °C under aerobic and anaerobic conditions has been studied over a period of 184 and 60 days respectively (Rainford, 1990: TF-620-005). Throughout the study evolved CO_2 and organic volatiles were collected from the flasks of soil and aliquots removed for analysis. The soil was extracted using acetone and other solvents, including caustic extracts. The extracts were analyzed for [^{14}C]triforine and its degradation products by TLC. The mean overall recoveries of applied radioactivity for the aerobic and anaerobic incubates containing the sandy loam soil were $88.2 \pm 3.8\%$ and $79.9 \pm 5.7\%$ respectively and for the silty loam soil were $93.7 \pm 4.6\%$ and $92.6 \pm 5.9\%$ respectively. No significant production of $^{14}\text{CO}_2$ occurred before 3 weeks. After 184 days approximately 24% of the applied radioactivity had evolved as $^{14}\text{CO}_2$ from both soils under aerobic conditions. The distribution of radioactivity recovered from the two soil types under aerobic varied slightly. The applied radioactivity in the acetone extracts declined more quickly from the silty loam soil (80% at 0 day, 13% at 28 days and 1% at 184 days) than the sandy loam soil (85% at 0 day, 54% at 28 days and 18% at 184 days). In both soil types an increase in the proportion of applied radioactivity in the caustic extracts occurred reaching a maximum of 36% at 28 days for the silty loam soil and 23% at 42 days for the sandy loam soil. The percentage of applied radioactivity present as bound residues were higher in the silty loam soil (47% at 60 days) compared to that in the sandy loam soil (12% at 42 days).

Degradation half-lives of 35.8 and 69.6 days were determined for triforine in the silty and sandy loam soils respectively under aerobic conditions. After 184 days, approximately 0.35% and 6% of the applied radioactivity remained as triforine in the two soils respectively. The decline in triforine concentrations was accompanied by an increase in bound radioactivity and a large number of very minor degradation products. No one component at any time represented more than 3% of applied radioactivity. Very tentative identification of four degradates was made: W 625, WOS 2379, piperazine and W 1069. Due to the very low levels present there was no possibility of further identification of any of these degradates from samples obtained from this study.

Under aerobic conditions, [^{14}C]triforine is degraded to at least 14 degradates in silty loam and eight degradates in sandy loam when incubated for up to 184 days at 20 °C. No major degradates were produced. The rate of degradation in the silty loam exceeded that in the sandy loam. In both soil types, degradation was accompanied by the evolution of $^{14}\text{CO}_2$, indicating that degradation involved cleavage of the ring structure and bound residues.

Study 2

The aerobic degradation and metabolism of [side chain- ^{14}C]-triforine was investigated in a US soil (sandy loam) under laboratory conditions (20 ± 2 °C, in the dark) for 365 days (Wyss-Benz, 1993: TF-620-033). The test article was applied at a maximum recommended field rate of 0.38 kg ai/ha corresponding to 0.512 mg ai/kg dry soil in the top 5 cm or 0.051 mg ai/100 g soil sample. Duplicate soil samples were applied for 0, 7, 14, 28, 56, 84, 112, 147, 189, 238 and 365 days of incubation. Samples were submitted to several extractions with first acetonitrile, and then acetonitrile/water (1:1). Extracts of acetonitrile were combined, concentrated and submitted to TLC and HPLC analysis.

The mean recoveries from duplicate samples ranged from 91.0% to 106% of the radioactivity applied, with an average mean recovery from all samples of $97.1 \pm 5.6\%$. The radioactivity extracted from the soil decreased from 101% of the radioactivity applied (0.519 mg equiv/kg dry soil) on day 0 to 13.2% (0.067 mg equiv/kg) on day 365. The non-extracted radioactivity increased from 4.6% (0.024 mg equiv/kg) on day 0 to 38.2% (0.196 mg equiv/kg) on day 238, and then decreased slightly until day 365 to 35.0% (0.179 mg equiv/kg). The non-extracted radioactivity bound to the organic matter fractions was compared between day 147 and day 365. On day 147, 58.0% of the non-extracted radioactivity was found to be associated with fulvic acid, 9.9% with humic acids and 24.7% with

humic fraction. On day 365, 10% of the radioactivity proved to be more strongly bound as 32.5% were found in the humic fraction and only 49.8% in the fulvic acid fraction.

Mineralization of triforine took place from the beginning of the study, i.e. on day 7 with 1.3% (0.006 mg equiv/kg) and increased to 44.7% (0.229 mg equiv/kg) on day 365. No volatile compounds other than $^{14}\text{CO}_2$ could be detected. The mineralization was still detectable at the end of the study. The biomass was low at the beginning of the study but increased during the study from 6.0 mg C/100 g dry soils to 18.6 mg C/100 g dry soil on day 365. Most of the radioactivity extracted from the soil was identified as parent. The rate of disappearance was calculated using sampling intervals from day 0 to day 84 only. Half-life (DT_{50}) was determined by the first order reaction kinetics model as 23.9 days with a DT_{90} value of 79.3 days

Many minor degradation products were detected in the extracts during the study. Attempts were made to isolate degradates, however it was very difficult to identify them. One fraction was characterized as reference compound—the hydrochloride salt (W 1069), however the levels were small at a maximum of 0.08 mg/kg on day 56, decreasing until the end of the study to 0.026 mg/kg.

It can be concluded from this study that triforine was rapidly degraded and readily mineralized in the sandy loam soil under the chosen experimental conditions and that many minor degradation products representing < 0.01 mg equiv/kg were formed.

Study 3

The decomposition of triforine in five soils (Speyer 2.2, Riverside, Sion Hill, Middlefield and Silt loam) was studied in laboratory tests (Jones, 1989: TF-620-011). Treated soils were incubated aerobically at $20 \pm 3^\circ\text{C}$ in the dark. The concentration of triforine in each soil was determined at intervals of 0, 2, 8, 16, 32, 64, 100, 147 and 164 days after treatment.

Soil samples were extracted into acetone/chloroform (3:7). The extract was cleaned up by solid phase extraction chromatography using C_{18} bond elute columns. The final extract was then quantified by reverse phase HPLC using a variable wavelength UV absorbance detector. The limit of detection of the HPLC system was 0.1 mg/L of triforine. The microbial biomass was determined by monitoring the $^{14}\text{CO}_2$ evolution from duplicate samples of known masses of test soils fortified with [^{14}C]glucose.

The mean percent nominal recoveries of triforine from the fortified control soil samples ranged between 77 and 85% respectively. There was a significant reduction in the measured concentration of triforine. The DT_{50} values for the five soils ranged between 1 and 7 days.

Table 15 The DT_{50} and DT_{90} values for the five soils

Soil type	50% Degradation time	90% Degradation time
Speyer 2.2 (loamy sand)	7 days	116 days
Riverside (clay loam)	7 days	69 days
Sion Hill (sandy loam)	7 days	78 days
Middlefield (silty clay)	1 day	3 days
Silt loam (silt loam)	4 days	55 days

Soil photolysis

The artificial sunlight photodegradation of [piperazine- ^{14}C]triforine was studied on sandy loam soil. The artificial sunlight source was a xenon lamp that had a special energy distribution similar to that of natural sunlight (Saxena, 1990: TF-620-008). Soil samples in petri dishes were prepared and fortified with [^{14}C]triforine at concentration of 10 mg ai/kg. Soils samples were placed in a xenon lamp chamber and irradiated continuously (24 hours/day) at a temperature of 22.4 to 27.2 $^\circ\text{C}$. Dark control samples were placed in a glass chamber and maintained in the dark at 25 $^\circ\text{C}$. Traps for volatile components were connected to the irradiation and dark control chambers. In addition, a charcoal trap was connected to the irradiation chamber. Two soil samples were analyzed at hour 0, and then duplicated irradiated soil samples were removed for analysis after 1, 2, 4, 8, 10, 24, 30 and 48 hours

of irradiation. Samples were extracted with methanol: water (9:1). The extracts as well as the extracted soil (oxidized by combustion) were analyzed by liquid scintillation counting. The distribution of radioactivity in the methanol: water extract was determined by thin layer chromatography (TLC). The TLC plates were analyzed using a linear analyzer.

The recovery of applied radioactivity for the irradiated and dark control soil samples ranged from 92.2% to 104% and from 91.0% to 104%, respectively. The applied radioactivity remaining in the methanol: water extracts ranged from 97.9% to 72.1% for the irradiated samples and from 101.2% to 83.4% for the dark control samples. The applied radioactivity remaining in the methanol: water extracted soil ranged from a mean of 25.2% to 1.9% at all study intervals for the irradiated samples and from a mean of 1.9% to 18% for the dark control samples. The cumulative radioactivity in the traps was 0.5% or less at all study intervals for both test conditions.

Analysis of the methanol: water extracts of the study samples using TLC system showed that the [^{14}C]triforine degraded rapidly on soil when irradiated with a xenon lamp. The degradation was biphasic. The calculated degradation half-life of [^{14}C]triforine was 11.4 hours of artificial sunlight, equivalent to 0.5 natural sunlight days for phase 1 (hours 0 to 8). For phase 2 (hours 8 to 48), the half-life was 70.9 hours of artificial sunlight equivalent to 3.16 natural sunlight days. Radiolabelled triforine degraded under dark conditions, with a half-life of 76.5 hours. For the irradiated samples, [^{14}C]triforine was observed at all intervals by TLC analysis. Several peaks were observed: one had similar R_f value to that of non-radiolabelled standard W 1069. The maximum was 9.9% at hour 48. For the dark control samples, [^{14}C]triforine was observed at all intervals by TLC analysis. Several peaks were observed, the maximum was 10.3% at hour 24.

RESIDUE ANALYSIS

Analytical methods

Descriptions of analytical methods together with validation data for residues of triforine in plant and animal matrices were submitted to the Meeting. The methods rely on an initial extraction, usually with acetone. After solvent partition, the triforine and metabolites residues are degraded by heating with sulphuric acid. The residues of triforine and metabolites containing piperazine ring can be measured by the analysis of degradate (chloral hydrate) with GC-ECD, typically to an LOQ of 0.01 mg/kg.

Detailed descriptions of all these analytical methods are presented below.

Plant matrices

Cereals (green plants, straw, grain), fruit, vegetables, meat, milk, soil, water (102FX-522-009, TF-240-002)

Analyte: Triforine GC-ECD RU 3,26/12/10

LOD: 0.005–0.01 mg/kg

Description The samples are blended with acetone. After removal of the acetone by distillation the triforine in the remaining aqueous phase is partitioned into toluene. The toluene is evaporated and the active substance was degraded by heating with dilute sulphuric acid. Chloral hydrate thus formed is distilled, extracted with ethyl formate and determined by gas chromatography with an electron capture detector.

Plant and animal products (102AA-522-008, TF-244-006)

Analyte: W 1084 GC-ECD

LOD: 0.01 mg/kg

Description The samples are blended with acetone. After removal of the acetone by distillation the triforine is partitioned into toluene. The remaining aqueous phase contains W 1084, which is the main metabolite of triforine especially in animals. The aqueous solution is heated with dilute sulphuric acid. Chloral hydrate formed is distilled, extracted with ethyl formate and determined by gas chromatography with an electron capture detector.

Chicory, carrot, red beet, Brussels sprout, white cabbage (102AX-522-015, TF-244-010)

Analyte: Triforine GC-ECD
 LOQ: 0.01 mg/kg
 Description: The samples are extracted with acetone. After filtration and evaporation of acetone, triforine is partitioned from the remaining aqueous solution into dichloromethane. The solvent is evaporated and the active substance degraded by heating with dilute sulphuric acid. Chloroform that is formed is determined by head-space gas chromatography with an electron capture detector.

Cherry, peach, plum, prune (TF-244-011)

Analyte: Triforine, W 1084, 2,2,2-trichloroethanol, WOS 2379, W 625 GC-ECD FAMS 041-01
 LOQ: 0.01 mg/kg
 Description: The homogenised samples are diluted with water and sulfuric acid is added. Triforine, W 1084, WOS 2379 and W 625 are degraded by heating. Chloral hydrate and 2,2,2-trichloroethanol are separated by distillation, extracted with ethyl formate and determined by capillary gas chromatography with an electron capture detector.

Green peppers, tomatoes, eggplant, Japanese persimmon (SAI No.135)

Analyte: Triforine LC-MS
 LOQ: 0.01 mg/kg
 Description: The samples are homogenised with acetone. The sample solution is purified with a graphite carbon mini-column, a C₁₈ mini-column and a silica gel mini-column. The elution is evaporated and dissolved with methanol. The residue is determined by LC-MS.

Blueberry and tomato (2040W)

Analyte: Triforine LC-MS/MS
 (m/z 435→390 for quantification, 435→215 for confirmation)
 LOQ: 0.01 mg/kg for blueberries and tomatoes, 0.05 mg/kg for tomato paste
 Description: The samples are extracted with acetone. The extract is subjected to further clean-up involving three SPE cartridge (ENVI-Carb, C₁₈ and Silica gel) clean-ups. The final samples are analysed by LC-MS/MS for quantitation of triforine.

The recoveries from plant matrices obtained during method validation are summarized in Table 16.

Table 16 Summary of recovery data for triforine and its metabolites fortified into plant matrices

Animal matrices

Animal product (102FX-523-001, TF-245-001)

Analyte: Triforine, W 1084, W 2379

GC-ECD

LOD: 0.001 mg/kg for milk and 0.003 mg/kg for the other materials (muscle, liver, kidney and fat)

Description The samples are blended with acetone. The organic solvent is removed by distillation. Triforine and possible metabolites containing the $\text{Cl}_3\text{C-CH}$ group (W 1084, W 2379) are degraded by heating with dilute sulphuric acid. Chloral hydrate formed is distilled, extracted with ethyl formate and determined by gas chromatography with an ECD.

Milk (TF-245-002)

Analyte: Triforine, W 1084, Trichloroethanol GC-ECD FAMS 037-01

LOQ: 0.001 mg/kg for triforine and trichloroethanol, 0.002 mg/kg for W 1084

Description The sample is diluted with water and sulphuric acid is added. Triforine and W 1084 are degraded by heating. Chloral hydrate formed and 2,2,2-trichloroethanol are separated by distillation, extracted with ethyl formate and determined by capillary gas chromatography with an ECD.

Bovine tissue (kidney, liver, muscle), fat and cream (TF-245-003)

Analyte: Triforine, W 1084, Trichloroethanol GC-ECD FAMS 038-01

LOQ: 0.01 mg/kg

Description The homogenised samples are diluted with water and sulphuric acid is added. Triforine and W 1084 are degraded by heating. Chloral hydrate formed and 2,2,2-trichloroethanol are separated by distillation, extracted with ethyl formate and determined by capillary gas chromatography with an ECD.

Egg (TF-245-005)

Analyte: Triforine, W 1084, Trichloroethanol GC-ECD FAMS 084-01

LOQ: 0.01 mg/kg

Description The homogenised samples are diluted with water and sulphuric acid is added. Triforine and W 1084 are cleaved upon heating. Chloral hydrate formed and 2,2,2-trichloroethanol are separated by distillation, extracted with ethyl formate and determined by capillary gas chromatography with an ECD.

The recoveries from animal matrices obtained during method validation are summarized in Table 17.

Stability of pesticide residues in stored analytical samples

The Meeting received data on the stability of triforine residues in apples, cherries, plums, peaches, blueberries and hops (cones and processed fractions) samples stored frozen.

The freezer stability study of triforine was conducted on apples, cherries, peaches and blueberries (Eich, 1979: TF-326-010). Untreated samples of blueberries, cherries, apples and peaches were chopped and fortified with triforine at 0.1 or 1 mg/kg respectively. The homogenised samples were stored deep frozen (-20 °C) for different time periods up to 12 months. Samples were analyzed after storage using GC-ECD method RU 3, 26/12/10.

Table 18 Recovery of triforine from stored fortified samples

Storage interval	Residue (mg/kg)	
	0.1 mg/kg fortification	1.0 mg/kg fortification
Apples		
0 month	0.10	0.92

4 months	0.10	0.78
12 months	0.11	0.92

Means values of two replicates, corrected by procedural recovery.

The storage stability of triforine was investigated under frozen conditions (Weeren, 1994: TF-326-025). Samples of hops and the processed fractions were fortified with triforine at a level of up to 100 mg/kg. Samples were stored in a freezer at -18 °C and analyzed using analytical method RU 3, 26/12/10 after 1, 15, 30, 59, 96, and 180 days of storage.

Table 19 Recovery (%) of triforine from stored fortified samples of hops and processed fractions

Storage interval	Green cones

8 months	82	75, 81, 87	81

Triforine is registered in many countries for the control of various fungal diseases on fruits, fruiting vegetables, legumes, tree nuts, etc. The Meeting received labels in the countries of North and South America, Africa, Asia and Oceania. The information available to Meeting on registered uses of triforine is summarized in Table 21 below.

Table 21 Registered uses of triforine on crops

^a NS: not shown

^b May be applied 2 weeks after petal fall (mid-summer) if necessary.

^c Apply maximum six times in seasons of extreme disease pressure.

^d Use the indicated doses in mL/100 L of water to dilute applications (Python). In concentrated sprays, doses are per hectare should be used. Using lower doses under normal pressure conditions. In case of severe attacks or extreme conditions, using a high dose and smaller range.

^e Apply the sufficient to wet the plant with the mixture until it drops.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on triforine supervised field trials for the following crops.

Group	Commodity	Table
Pome fruits	Apple	Table 22–25
	Pear	Table 26
Stone fruits	Cherry	Table 27, 28
	Plum (including Prune)	Table 29–31
	Apricot	Table 32, 33
	Nectarine	Table 34
	Peach	Table 35–39
Berries and other small fruits	Raspberry	Table 40
	Blueberry	Table 41
	Black currant	Table 42
	Grape	Table 43–45

Group	Commodity	Table
Fruiting vegetables, Cucurbits	Cranberry	Table 46
	Strawberry	Table 47–49
	Cucumber	Table 50, 51
	Squash	Table 52, 53
	Melon	Table 54–56

	Egg plant	Table 60, 61
	Tomato	Table 62–64
	Common Bean	Table 65, 66
Legume vegetables		
Cereal grains	Barley	Table 67
	Wheat	Table 68, 69
Straw, fodder and forage of cereals	Barley straw and forage	Table 70
	Wheat straw and forage	Table 71

Triforine formulation was applied for foliar treatment. Each of the field trial sites generally consisted of untreated control plot and treated plot. Application rates and spray concentrations have generally been rounded to two significant figures.

Residue values from the trials, which have been used for the estimation of maximum residue levels, STMRs and HRs, are underlined.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Date of analyses and duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except when residues were found in samples from control plots. Residue data are not corrected for percent recovery.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Most field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Pome fruits

Apple

Three residue trials in apples were conducted in the USA. Triforine was quantified by GC-ECD with a LOQ of 0.004 mg/kg.

Three residue trials in apples were conducted in the USA. Method RU3, 26/12/10 was used to analyze apple fruits samples for the residues of Triforine. Triforine was quantified by GC-ECD with a LOQ of 0.006 mg/kg.

One residue trial in apples was conducted in Canada. Triforine was quantified by GC-ECD with a LOQ of 0.005 mg/kg.

Three residue trials in apples were conducted in Australia. Method RU3, 26/12/10 was used to analyze apple fruits samples for the residues of Triforine. Triforine was quantified by GC-ECD with a LOQ of 0.05 mg/kg.

One residue trial in apples was conducted in Germany. Method RU3, 26/12/10 was used to analyze apple fruits samples for the residues of Triforine. Triforine was quantified by GC-ECD with a LOQ of 0.01 mg/kg.

Seven residue trials in apples were conducted in France. Method RU3, 26/12/10 was used to analyze apple fruits samples for the residues of Triforine. Triforine was quantified by GC-ECD with a LOQ of 0.01 mg/kg.

Two residue trials in apples were conducted in Brazil. Method RU3, 26/12/10 was used to analyze apple fruits samples for the residues of Triforine. Triforine was quantified by GC-ECD with a LOQ of 0.02 mg/kg.

Peach

Nineteen residue trials in peaches were conducted in USA. Method RU3, 26/12/10 was used to analyze peach fruits samples for the residues of Triforine. Triforine was quantified by GC-ECD with a LOQ of 0.001–0.01 mg/kg.

One residue trials in peaches was conducted in Canada. Triforine was quantified by GC-ECD with a LOQ of 0.01 mg/kg.

Total three residue trials in peaches were conducted in France and Greece. Triforine was quantified by GC-ECD with a LOQ of 0.01 mg/kg.

Two residue trials in peaches were conducted in Japan. Triforine was quantified by LC-MS with a LOQ of 0.01 mg/kg.

Two residue trials in peaches were conducted in Brazil. Triforine was quantified by GC-ECD with a LOQ of 0.01 mg/kg.

Two residue trials in peaches were conducted in South Africa. Triforine was quantified by GC-ECD with a LOQ of 0.1 mg/kg.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In Processing

The Meeting received information on the fate of triforine residues during the processing of plums, grapes, tomatoes and hops.

The Meeting did not receive information on supervised field trials with hops. Therefore, the study on processing of hops is not summarized in this report.

Plum

The plum samples were treated with formulation containing triforine as active ingredient. The analytical material was shipped under deep-frozen conditions. The samples were stored in a deep-freeze compartment in the dark. The plum samples were heated to make processed commodities (compote, stewed and jam).

The samples were blended with acetone. After removal of the acetone by distillation, triforine in the remaining aqueous phase was partitioned into toluene. The toluene was evaporated and the

active substance degraded by heating with diluted sulfuric acid. Chloral hydrate thus formed was distilled and determined by GC-ECD (RU 3, 26/12/10).

Grapes

The samples were blended with acetone. After removal of the acetone by distillation, triforine in the remaining aqueous phase was partitioned into toluene. The toluene was evaporated and the active substance degraded by heating with diluted sulfuric acid. Chloral hydrate thus formed was distilled and determined by GC-ECD (RU 3, 26/12/10). The LOQ was 0.01 mg/kg. Procedural recoveries were 90% for fruits, 111% for juice and 95% for wine, respectively.

Tomato

Study 1

Fresh tomatoes were dipped in a spray wash of EC formulation solution diluted to 1.3% or 4%. After treatment the fruits were dried under room temperature for one day. Five kg of treated tomatoes were homogenized and the juice was separated by a suction filter. 300 g juice was concentrated by freeze drying to water content of 16% for purée, 28% for ketchup and 73% for dehydrated pulp.

Fifty grams of chopped tomatoes, 50 g juice or the whole quantity of each material were extracted with acetone. The solvent was removed and the residues partitioned into toluene. The organic phase was separated and evaporated. After addition of sulphuric acid, triforine was decomposed in the heat. Chloral hydrate formed was distilled and determined by GC-ECD.

Study 2

At two locations (California and New York) processing tomatoes were treated at the normal application rate (0.183 kg ai/ha) and five times rate (0.964 kg ai/ha) and processed into tomato juice, wet pomace, dry pomace, paste or puree, and ketchup in order to determine possible residues in these commodities. Field samples were received in good condition frozen in dry ice and transferred to freezer at -20 °C.

The samples were washed and chopped in mechanical slicer. The tomato juice was preheated at 82.2 °C, sterilized at 126.6 °C and filled at 87.7 °C with 60 g salt tablet in can. Tomato juice was boiled in a vacuum kettle for 2.5 hours with constant stirring to prepare paste.

The residues were extracted using standard method via Chloral hydrate formation and analysis determined by GC-ECD.

Study 3

The test substance, formulated as a dispersible concentrate (190 g triforine/L), was applied four times as a foliar treatment at an exaggerated (5×) application rate. The target application rate for each event was 1.95 kg ai/ha. Bulk tomato samples were shipped ambient to the processing facility, where tomato puree and paste were produced. Those samples were shipped frozen to the analytical laboratory and maintained in frozen storage until analysis. Following extraction and clean-up, triforine residues were separated and measured using HPLC-MS/MS. The LOQ was defined as 0.01 mg/kg. The overall mean procedural recovery was 77%, with a RSD of 8.8%.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

The Meeting received a lactating goat feeding study.

Lactating goat

The study was designed to determine the residues of triforine found in milk and tissues following oral administration to lactating goats (Eichler, 1974: TF-440-016). Three groups of goats, each group containing three animals, were orally dosed with triforine for 30 days at dosages of approximately 5, 15 and 50 mg triforine per animal per day. This would be equivalent to total dietary residues of approximately 5, 15 and 50 ppm feed. Dose levels were based on a nominal feed intake of 1 kg (dry matter equivalent) per day for a goat. The concentrate mixture with flour containing triforine was used for administration.

Milking was done daily at morning and evening. The pooled samples of day 3, 5, 8, 11, 15, 22, 29 and of day 31 were stored deep frozen (-20 °C) until analysis. At the morning of day 31, all goats were sacrificed and the edible tissues (liver, kidney, muscle and fat) from each animal were collected. All samples were stored at -20 °C until they were analyzed. The storage period was between 1 day and 4 weeks.

The analytical procedures consider both triforine and those metabolites containing Cl₃C-CH group. The results were expressed as triforine equivalents and corrected with recoveries. The chopped samples were extracted with acetone and the extracts were concentrated by rotary evaporation. The remaining aqueous phase was mixed with sulphuric acid and distilled under nitrogen. To the aqueous solution of chloral hydrate formed, sodium chloride was added. The chloral hydrate was extracted with ethyl formate and quantified as chloral hydrate using gas chromatography with an electron capture detector. The LOQ of this method in milk and tissues was 0.001 mg/L and 0.003 mg/kg, respectively. Concurrent recoveries obtained from control samples spiked with the test item were reported to be 80 ± 10%.

No residues were detected in milk from the lowest dose level with the exception of two animals on day 29 (traces only considered as outliers). Residues in milk from group of 15 ppm feed were at the level of 0.001–0.003 mg/L on sampling days 8, 22 and 29. The milk collected on the other days did not contain detectable residues. At the high dose group (50 ppm feed), residue levels reached a plateau at the level of 0.002–0.010 mg/L after 3 days. One day after the last administration, no residues were detected in milk. The results indicate no increase of the residues during the treatment phase and a rapid decline in levels detected in milk during the last part of the withdrawal period.

Table 77 Residues of triforine and those metabolites containing Cl₃C-CH group in whole milk

Day	Residues, mg/L			
	Control	5 ppm feed	15 ppm feed	50 ppm feed

31	< 0.001 (3)	< 0.001 (3)	< 0.001 (3)	< 0.001 (3)

In tissues, no significant residues were detected in the fat, liver, kidney and muscle of 5 ppm and 15 ppm feed groups except several samples from 15 ppm feed animals exceeding slightly the LOQ. In the 50 ppm feed group, residues were detected in all of the analyzed tissues with the exception of muscle in an animal and fat of all animals. The maximum values in kidney and liver were 0.009 and 0.012 ppm, respectively.

APPRAISAL

Triforine is a systemic fungicide for control of powdery mildews, rusts, scabs and rots. It was first evaluated by JMPR in 1977 (T), 1978 (T, R) and lastly in 1997 (T). The ADI for Triforine was 0–0.02 mg/kg bw and no ARfD was recommended by the previous JMPR. Triforine was scheduled at the Forty-fifth Session of the CCPR (2013) for the periodic re-evaluation of toxicity and residues by the 2014 JMPR.

The Meeting received information on identity, physical and chemical properties, animal and plant metabolism, environmental fate in soil, analytical methods, storage stability, use patterns, supervised trials, farm animal feeding studies and fates of residues in processing.

N,N'-{piperazine-1,4-diylbis[(trichloromethyl)methylene]} diformamide

In this appraisal, the following abbreviated names were used for metabolites.

WOS 2379	W 1084/W 1069	W 625	W 2379
			
<i>N</i> -[2,2,2-trichloro-1-[4-(2-oxoacetyl)piperazin-1-yl]ethyl]formamide	<i>N</i> -(2,2,2-trichloro-1-piperazin-1-yl-ethyl)formamide/hydrochloride	<i>N</i> -[2,2,2-trichloro-1-(4-formylpiperazin-1-yl)ethyl]formamide	Hydrate of <i>N</i> -[2,2,2-trichloro-1-[4-(2-oxoacetyl)piperazin-1-yl]ethyl]formamide

Animal metabolism

The Meeting received animal metabolism studies with triforine in rats, lactating goat and laying hens. The metabolism and distribution of triforine in animals were investigated using the [^{14}C -piperazine] and [^{14}C -side chain]-labelled triforine.

Metabolism in rats was summarized and evaluated by the WHO panel of the JMPR in 2014.

Triforine is rapidly metabolized and excreted in rats. Highest residues were found in liver followed by kidney. Residues were lower in muscle and fat. Radioactive residues were identified in the excreta only. *N*-[2,2,2-trichloro-1-(piperazin-1-yl)ethyl]-formamide (W 1084), which is formed by the cleavage of a side chain, was the major component in urine of rats. It was excreted in urine as the glucuronide. The side-chain metabolites trichloroethanol including its glucuronide and *N*-acetylcysteine conjugate of 2,2,2-trichloroethylamine was detected in urine. W 1084 and triforine were detected in the faeces of rats.

Lactating goats were administered with [piperazine- ^{14}C]-triforine as an oral dosage equivalent to a dietary level of 250 or 1000 ppm once daily for 3 consecutive days. The goats were sacrificed 4 hours or 6 days after the last treatment.

Radioactivity administered to the goats was rapidly eliminated in urine and faeces. A total of 47% and 72% of the applied radioactivity were eliminated in 24 hours, and a further 16 and 14% were excreted in the following 5 days by the 250 ppm and the 1000 ppm dose group goats, respectively.

Up to 68% of the residual radioactivity in the liver of goat sacrificed 4 hours after the last treatment was extracted. The extracted radioactivity consisted of at least five metabolite fractions. M1 and M2 represented unknown polar metabolite fractions whereas WOS 2379 and W 1084 were characterized. The fraction M1 represented 18% TRR. Triforine, WOS 2379 and W 1084 accounted for 15%, 15% and 13% TRR, respectively. Up to 14% of the residual radioactivity in the liver of goat sacrificed 6 days after the last treatment was extracted. This metabolite pattern was similar to that in the extracted radioactivity of the liver of goat sacrificed 4 hours after the last treatment.

Seventy-eight percent of the residual radioactivity in the kidneys of goats sacrificed 4 hours after the last treatment was extracted. The metabolite pattern of the extracted radioactivity was similar to that in the extracted radioactivity of the liver. The predominant fraction found in the extracted radioactivity of goat sacrificed 4 hours after the last treatment was metabolite fraction M1 (31% TRR). Triforine, WOS 2379 and W1084 represented 19%, 8.4% and 19% TRR, respectively. Analysis of the extracted radioactivity of the kidneys of a goat sacrificed 6 days after the last treatment showed a similar metabolite pattern in terms of their relative amounts in the extracts. The predominant fraction was M1 accounting for 11% TRR. Triforine represented 3.6% TRR.

Seventy-nine percent of the residual radioactivity in the muscle of goat sacrificed 4 hours after the last treatment was extracted. The predominant radioactive fraction was triforine at 41% TRR. The other metabolites accounted for 9.5% (W 1084), 13% (WOS 2379), 0.70% (M2) and 15% TRR (M1).

In one study, laying hens were orally administered with [piperazine-¹⁴C]-triforine at the dietary dose equivalent to 500 or 2000 ppm in the feed once daily for 3 consecutive days. The hens were sacrificed 4 hours or 7 days after the last treatment.

The radioactivity administered to the hens was rapidly eliminated (54–84% in 56 hours after the first dose). In the following 7 days a further 10–15% of the administered radioactivity was excreted (76% excreted from 500 ppm dosed hens and 94% from 2000 ppm dosed hens).

The highest values in eggs were found about 4 to 5 days after the first treatment with [¹⁴C] triforine.

In the other study, laying hens were administered with [side chain-¹⁴C]-triforine for 10 consecutive days at a dose of 32 ppm in the feed. Radioactivity recovered in excreta during the 10 days accounted for about 85% of the total cumulative dose.

Total radioactivity in eggs increased steadily during the 10 days to a peak value of 1.6 mg equiv/kg (yolk) and 0.19 mg equiv/kg (white). The major components in egg white and egg yolk were the fraction A which accounted for 48% TRR (0.08 mg/kg) and the sulphate conjugate of trichloroethanol which accounted for 25% TRR (0.25 mg/kg), respectively. W 1069 was observed and accounted for 10% TRR (0.10 mg/kg) in egg yolk. Triforine accounted for 13% TRR (0.02 mg/kg) and 2.1% TRR (0.02 mg/kg) in egg white and egg yolk, respectively.

The fraction A in the protease-treated extract of liver was separated into five components each of which accounted for 0.07–0.40 mg equiv/kg (4–24% TRR). The sulphate conjugate of trichloroethanol was present in liver accounting for 9% TRR. There appeared to be a small amount of triforine in liver (2.9% TRR, 0.05 mg/kg).

The main components in muscle were the trichloroethanol sulphate conjugate and W 1069 each accounting for about 22% TRR (0.05 mg equiv/kg). Triforine was present at 8.4% TRR (0.02 mg/kg).

Triforine accounted for 18% TRR (0.02 mg/kg) and the sulphate conjugate of trichloroethanol accounted for 36% TRR (0.03 mg equiv/kg) in fat.

Triforine was also found in skin at low levels (0.01 mg/kg). The retention time of the main fraction corresponded to that of trichloroethanol sulphate (56% TRR, 0.13 mg/kg).

In animal metabolism studies, triforine, W 1084/W 1069, WOS 2379 and trichloroethanol sulphate were predominantly found in tissues of lactating goats and laying hens. The major component in milk and egg white was the polar fraction consisting of several components but they were not identified. Triforine was identified in egg white and egg yolk. Excretion, distribution and triforine and its metabolites found in excreta of lactating goats and laying hens were similar to those in rats.

Plant metabolism

The Meeting received plant metabolism studies performed on apples, tomatoes and cucumber with triforine ¹⁴C-labelled in two carbons at the side chain, and on barley with triforine ³H-labelled at piperazine ring ([side chain-¹⁴C] and [piperazine-³H]).

In an outdoor apple metabolism study, a number of fruits or leaves of apple were treated at random on the surface with [side chain-¹⁴C]-triforine at a rate of 1.2 g ai/L in a series of small droplets. Treated apple fruits were harvested 2 weeks after the last of five successive applications with 8-day intervals. After five successive applications of [¹⁴C] triforine, 32% (fruit) and 22% (leaf) of the applied radioactivity were recovered. On an average, 1.36 mg equiv/kg was recovered in the treated fruits.

The major component in the surface washes and extracts of fruits was identified as triforine accounted for 73–79% TRR (0.88–1.2 mg/kg) two weeks after the last application. Several minor components were observed in the extracts and each of them accounted for 1–2% TRR.

In an indoor tomato metabolism study, a number of fruits or leaves of tomato were treated at random on the surface with [side chain- ^{14}C]-triforine at a rate of 1.2 g ai/L in a series of small droplets. The treated tomatoes were harvested at 2 hours and 3 days after the last of four successive applications with 8–10 days intervals. The initial surface washes of treated tomatoes at harvest contained, on an average, 92% (2 hours after the last application) and 91% (3 days after the last application) of TRR. Acetonitrile extracts of washed and homogenised tomatoes accounted for, on an average, 5.8% TRR (2 hours after the last application) and 6.2% TRR (3 days after the last application). The TRR from the treated tomatoes accounted for, on an average, 16 (2 hours after the last application) and 9.7 (3 day after the last application) mg equiv/kg.

Triforine in the surface washes and extracts accounted for 91–93% TRR (7.6–19 mg/kg) in tomatoes taken at 2 hours and 3 days after the final application of [^{14}C] triforine. The extracts also contained several minor components each accounting for, on an average, 0.05–1.1% TRR.

In an indoor cucumber metabolism study, a number of fruits or leaves of cucumber were treated at random on the surface with [side chain- ^{14}C]-triforine at a rate of 1.2 g ai/L in a series of small droplets. The treated cucumbers were harvested 3 days after the last of four successive applications at 7-day intervals. The surface washes of treated cucumbers at harvest contained, on an average, 85% of TRR. Extracts of washed and homogenised cucumber peel and flesh accounted for, on an average, 7.5% TRR (peel) and 1.4% TRR (flesh). The TRR from the treated cucumbers accounted for, on an average, 2.2 mg equiv/kg.

The major radioactive component was identified as triforine in the surface washes and extracts accounted for 87–88% TRR (1.9 mg/kg) in cucumber taken 3 days after the final application of [^{14}C] triforine. The extracts also contained several minor components each accounting for means of 0.3–2% TRR.

In the first indoor barley metabolism study, [piperazine- ^3H]-triforine was applied to barley plants grown in plastic pots as soil drenching. The leaves were harvested at 15 and 30 days after treatment.

Triforine was identified as a major component in the barley leaves, amounting to 58% TRR at 15 days after the treatment and 43% TRR at 30 days after the treatment. W 1084 was also observed in the 0.1M HCl extract (8.4–13% TRR).

In the second indoor barley metabolism study, the leaves of barley plants root-treated with [piperazine- ^3H]-triforine were collected 30 days after treatment. The major component was identified as triforine, accounted for 45% TRR, and W 1084 and piperazine were also observed.

In the third outdoor barley metabolism study, the plants (during the stem extension stage when the second node of the stem was formed and the next-to-last leaf was just visible) were sprayed with an aqueous emulsion of a mixture of the commercial formulation of triforine and [piperazine- ^3H]-triforine at a rate of 0.25 kg ai/ha. Barley was harvested when ripe, and straw and grain were analysed separately.

The methanol soluble radioactive residue contained triforine and its metabolites which were free in barley straw and grain. Triforine accounted for 0.034 mg/kg (18% TRR) in straw and 0.0018 mg/kg in grain (13% TRR). W 1084 was identified as a minor component. Two other radiolabelled components were identified in straw: glycine at 0.043 mg/kg (33% TRR) and iminodiacetic acid at 0.021 mg/kg (17% TRR), respectively.

In the plant metabolism studies, triforine was the major component of the residues found in all plants studied.

Environmental fate

The Meeting received information on aerobic degradation in soil, photolysis on soil surface and hydrolytic degradation study.

In soil under the aerobic conditions, the DT_{50} ranged from 1–70 days at 20 °C. Many minor degradation products were detected in the extracts during the study. Most of the radioactivity was

recovered from natural components. Mineralization was up to 45%. Minor degradates were identified as W 625, WOS 2379, piperazine and W 1069, but all of them were less than 3% TAR.

In soil photolysis study, the degradation was biphasic. The photodegradation half-life of triforine was 11 hours of artificial sunlight or 0.5 natural sunlight days for phase 1 (hours 0 to 8). For phase 2 (hours 8 to 48), the half-life was 71 hours of artificial sunlight equivalent to 3.2 natural sunlight days.

In summary, triforine was rapidly and completely degraded in soil and is unlikely to be taken up by crops from the soil after soil treatment.

Methods of analysis

The Meeting received description of validation data on analytical methods for residues of triforine in plant and animal commodities.

In most of the methods for the determination of triforine in plant, homogenized samples were extracted with acetone, and the extract was partitioned into organic solvent and the active substance was degraded by heating with dilute sulphuric acid. Chloral hydrate thus formed was determined by GC-ECD. The methods of analysis with GC-ECD for a range of matrices were validated with acceptable recoveries with the LOQs of 0.01 mg/kg for triforine.

New methods using LC-MS or LC-MS/MS were developed for analysing triforine directly. In the methods, homogenized samples were extracted with acetone, and the extract was purified with SPE cartridge clean-ups. The methods of analysis with LC-MS or LC-MS/MS for a range of matrices were validated with acceptable recoveries with the LOQs of 0.01 mg/kg except for tomato paste for which the LOQ was 0.05 mg/kg.

In the methods for animal commodities, homogenized samples were extracted with acetone, or were diluted with water. Triforine and possible metabolites containing the $\text{Cl}_3\text{C-CH}$ group in the acetone extract or diluted homogenate were degraded by heating with dilute sulphuric acid. Chloral hydrate thus formed was determined by GC-ECD. These methods were validated with acceptable recoveries with the LOQ of 0.001–0.003 mg/kg for milk and animal tissues, and 0.01 mg/kg for egg.

The Meeting was aware that the QuEChRS-multi residue method was validated for most plant matrices with LOQs of 0.01–0.02 mg/kg for triforine.

Stability of residues in stored analytical samples

The Meeting received information on the freezer storage stability of triforine in plant (apples, cherries, plums, peaches, blueberries and hops) and their processed (beer) commodities. Analysis was done by the common moiety method.

Using the common moiety method, storage stability results indicated that residues with common moiety including triforine were stable for at least 1 month in processed hops (beer), at least 6 months in plums and hops (dried cones), at least 12 months in apples, cherries, peaches and blueberries. However, according to the result of plant metabolism study on tomato, triforine seems stable for at least 5 months.

Definition of the residue

In the lactating goat metabolism studies, TRRs in liver and kidney were higher than those in milk, muscle and fat. Triforine, WOS 2379 and W 1084 accounted for 15%, 15% and 13% TRR in liver, and 19%, 8.4% and 19% TRR in kidney. The polar unknown fraction M1 represented 18% TRR in liver and 31% TRR in kidney. In the laying hen metabolism studies, TRR in liver was also higher than those in other tissues. In the study using [side chain- ^{14}C]-triforine, the trichloroethanol sulphate conjugate and W 1069 were the main components in muscle (22% TRR) and egg yolk (10–25% TRR).

The analytical methods for animal commodities provided determine only the residues of triforine and metabolites containing the $\text{Cl}_3\text{C-CH}$ group converted to chloral hydrate which is formed

by heating in acidic condition. No method of analysis was available for quantification of triforine alone.

The Meeting decided that triforine and its metabolites containing the $\text{Cl}_3\text{C-CH}$ group were suitable analytes for enforcement purposes and dietary risk assessment for animal commodities.

The octanol/water coefficient ($\log P_{ow}$) of triforine was 2.2 at 20 °C. In the lactating goat and the laying hen metabolism studies, triforine and its metabolites found in muscle were 2–100 times higher than those in fat. Fractionation of whole milk showed that 32% of the radioactivity was found in cream and 76% was found in skim milk. In the lactating goat feeding study, triforine and its metabolites were detected at 0.003–0.007 mg/kg in liver, kidney and muscle but less than LOQ (< 0.003 mg/kg) in fat. The Meeting considered the residue of triforine is not fat soluble.

In plant metabolism studies, parent triforine was the major component (43–93% TRR) in apple, tomato, cucumber and barley. Several metabolites identified accounted for $< 10\%$ TRR.

In most of the analytical methods for triforine in plant, since chloral hydrate formed by heating with dilute sulphuric acid was quantified with GC-ECD, triforine and its metabolites containing piperazine ring were simultaneously measured. As the predominant residue was the parent compound in the plant metabolism study, using the common moiety method would result in only slight over-estimation of residues if PHI was short. Recently LC-MS and LC-MS/MS methods were available for determining triforine only.

The Meeting decided that parent triforine was a suitable analyte for enforcement purposes and dietary risk assessment in plant commodities.

The Meeting recommended the following residue definition:

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for plant commodities: *Triforine*

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for animal commodities: *Triforine and its metabolites determined as chloral hydrate expressed as triforine*

The residue is not fat soluble

Residue of supervised residue trials on crops

The Meeting received supervised trial data for the foliar application of triforine on apple, pear, cherry, plum, apricot, nectarine, peach, raspberry, blueberry, black currant, grape, cranberry, strawberry, cucumber, squash, melon, peppers, eggplant, tomato, common bean, barley and wheat. Residue trials were conducted in Australia, Brazil, Canada, Denmark, France, Germany, Greece, Hungary, Italy, Japan, Mexico, New Zealand, South Africa, South Korea, the United Kingdom (UK) and the USA. Most of the supervised residue trials employed the common moiety method, while the results of plant metabolism studies showed that triforine was the main component of residues in crops.

Labels were available from a number of countries in North and South America, Africa, Asia and Oceania describing the registered uses of triforine.

Pome fruits

Apple

Data were available from supervised trials conducted on apples in the USA, Canada, Australia, Germany, France and Brazil.

The GAP on apples in Canada was five foliar applications at a maximum rate of 0.475 kg ai/ha between tight cluster and petal fall stage. Trials in the USA and Canada on apples were conducted with foliar applications of EC formulation. Triforine residues in apple from the trials in Canada matching GAP of Canada were (n=1): 0.041 mg/kg.

Trials in Australia on apples were conducted with one to ten foliar applications of EC formulation (GAP: four foliar applications at a maximum spray concentration of 0.023 kg ai/hL with a PHI of 1 day). Triforine residue trials on apples in the Australia did not match the GAP of Australia.

Trials in Germany and France on apples were conducted with foliar applications of EC formulation. No GAP from European countries was available for apple.

The GAP on apples from Brazil was three foliar applications at a maximum concentration of 0.024 kg ai/hL with a PHI of 5 days. Triforine residues in apple from the trials in Brazil matching Brazilian GAP were (n=2): < 0.02 mg/kg (2).

As the data were insufficient for estimating a maximum residue level, the Meeting agreed to withdraw its previous recommendation for apple.

Pear

Data were available from a supervised trial on pears in Australia. No GAP from Australia was available for pear.

The Meeting agreed that estimation of maximum residue level was not possible for pear.

Stone fruits

Cherry

Data were available from supervised trials on cherries conducted in the USA, Canada and Germany.

The GAP on cherries in Canada was for three foliar applications at a maximum spray concentration of 0.014 kg/hL or a rate of 0.475 kg ai/ha between early and full bloom stages. Triforine residue in cherries from the trials in Canada and the USA matching GAP of Canada was (n=1): 0.007 mg/kg.

Trials in Germany on cherries were conducted with foliar applications of an EC formulation. No GAP from European countries was available for cherries.

The Meeting agreed to withdraw its previous recommendation for cherries.

Plum

Data were available from supervised trials on plums conducted in the USA, Canada, Germany, France and South Africa.

The GAP on plums in Canada is for three foliar applications at a maximum spray concentration of 0.014 kg/hL or a rate of 0.475 kg ai/ha between early and full bloom stages. No trials on plums in Canada and the USA matched the GAP of Canada.

Trials in Germany and France were conducted with foliar applications of an EC formulation. No GAP from European countries was available for plums.

The GAP on plums in South Africa was two foliar applications at a rate of 0.87 kg ai/ha with a PHI of 3 days. No trials for plums in South Africa matched the GAP of South Africa.

The Meeting agreed to withdraw its previous recommendation for plums.

Apricot

Data were available from supervised trials on apricots from the USA, France, Greece and Italy.

Trials in the USA on apricots were conducted with one to three foliar applications of an EC formulation at a spray concentration of 0.018 kg ai/hL. No GAP of the USA was available.

Trials in France, Greece and Italy on apricots were conducted with three foliar applications of DC formulation at a spray concentration of 0.038 kg ai/hL. No GAP from European countries was available for apricots.

The Meeting agreed that estimation of maximum residue level was not possible for apricots.

Nectarine

Data were available from supervised trials on nectarines from the USA.

Trials in the USA on nectarines were conducted with one to four foliar applications of an EC formulation at a spray concentration of 0.015–0.018 kg ai/hL. No GAP from the USA was available.

The Meeting agreed that the estimation of maximum residue level was not possible for nectarines.

Peach

Data were available from supervised trials on peaches from the USA, Canada, France, Greece, Japan, Brazil and South Africa.

The GAP on peaches in Canada is three foliar applications at a maximum spray concentration of 0.014 kg/hL or a rate of 0.475 kg ai/ha between early and full bloom stages. Triforine residue in peaches from trials in Canada and the USA matching GAP of Canada was (n=1): 0.02 mg/kg.

The GAP on peaches in Brazil is for three foliar applications at a maximum spray concentration of 0.024 kg ai/hL with a PHI of 3 days. Triforine residues in peaches from trials in Brazil matching GAP were (n=2): < 0.01 and 9.4 mg/kg.

Trials in France and Greece on peaches were conducted with one to eight foliar applications of a DC formulation at a rate of 0.36–0.38 kg ai/ha. No GAP from European countries was available for peaches.

The GAP on peaches in South Africa is two foliar applications at a maximum rate of 0.67 kg ai/ha with a PHI of 3 days. No trials from South Africa on peaches matched the GAP of South Africa.

The GAP on peaches in Japan is five foliar applications at a maximum spray concentration of 0.018 kg ai/hL with a PHI of 1 day. Triforine residues in peaches from the trials in Japan matching GAP of Japan were (n=2): 0.77 and 1.4 mg/kg.

The Meeting considered the data insufficient for the estimation of a maximum residue level, and agreed to withdraw its previous recommendation for peaches.

Berries and other small fruits

Raspberries, Red, black

Data were available from supervised trials on raspberries in France. No GAP from European countries was available for raspberry.

The Meeting agreed that estimation of maximum residue level was not possible for raspberry.

Blueberries

Data were available from supervised trials on blueberries in Canada.

The GAP on blueberries in Canada (except for Eastern Canada) is four foliar applications at a maximum rate of 0.570 kg ai/ha from bud break to 10–14 days after early bloom with a PHI of 60 days. Triforine residues in blueberries from the trials conducted in Canada (except for Eastern Canada) matching this GAP were (n=2): < 0.01 and 0.015 mg/kg.

The GAP for Eastern Canada (only) is three foliar applications at a maximum rate of 0.570 kg ai/ha from leaf-bud break to pink-bud stage with a PHI of 60 days. Triforine residues in blueberries from the trials conducted in Eastern Canada matching this GAP were (n=3): < 0.01(3) mg/kg.

Based on the trials on blueberries in Canada, the Meeting estimated a maximum residue level of 0.03 mg/kg to replace its previous recommendation (1 mg/kg) for blueberry. The Meeting also estimated an STMR and an HR for triforine in blueberry of 0.01 and 0.018 mg/kg, respectively. The highest residue concentration in an individual sample was selected for HR.

Currant, Black

Data were available from supervised trials on black currants in Germany and UK. No GAP from European countries was available for black currants.

The Meeting agreed to withdraw its previous recommendation for black currants.

Grapes

Data were available from supervised trials on grapes from Germany, Mexico and New Zealand.

Trials in Germany on grapes were conducted with one to three foliar applications of an EC formulation at a rate equivalent to 0.28–0.57 kg ai/ha. No GAP from European countries was available for grapes.

Trials in Mexico on grapes were conducted with one foliar application of EC formulation at a rate equivalent to 0.28 kg ai/ha. No GAP from Mexico was available for grapes.

The GAP on grapes in New Zealand is four foliar applications at a rate of at least 0.38 kg ai/ha with a PHI 14 days. No trials in New Zealand on grapes matched the GAP of New Zealand.

The Meeting agreed that estimation of maximum residue level was not possible for grapes.

Cranberry

Data were available from supervised trials on cranberries from the USA.

The GAP on cranberries in Canada was three foliar applications at a maximum rate of 0.570 kg ai/ha with a PHI of 60 days. No trials for cranberries from the USA matching the GAP of Canada were available.

The Meeting agreed that estimation of maximum residue level was not possible for cranberry.

Strawberry

Data were available from supervised trials on strawberries from Mexico, Brazil and Japan.

The GAP on strawberries in Mexico was four foliar applications at a maximum rate of 0.19 kg ai/ha with a PHI of 14 days. Triforine residue in strawberries from the trials in Mexico matching GAP of Mexico was (n=1): 0.57 mg/kg.

The GAP on strawberries in Brazil was four foliar applications at a maximum rate of 0.23 kg ai/ha with a PHI of 2 days. No trials in Brazil on strawberries matched the GAP of Brazil.

The GAP on strawberries in Japan is five foliar applications at a spray concentration equivalent to 0.009 kg ai/hL with a PHI of 1 day. Triforine residues in strawberries from the trials in Japan matching GAP of Japan were (n=4): 0.20, 0.39, 0.48 and 0.78 mg/kg.

The Meeting considered that the data was insufficient for estimating a maximum residue level, the Meeting agreed to withdraw its previous recommendation for strawberry.

Gooseberry

No supervised trials on gooseberry were available.

The Meeting agreed to withdraw its previous recommendation for gooseberry.

*Brassica vegetables**Brussels sprouts*

No supervised trials on Brussels sprouts were available.

The Meeting agreed to withdraw its previous recommendation for Brussels sprouts.

*Fruiting vegetables, Cucurbits**Cucumber*

Data were available from supervised trials on cucumbers from the USA, Canada, Mexico, Hungary, France and Germany.

Trials from the USA on cucumbers were conducted with four or five foliar applications of an EC formulation at a rate equivalent to 0.29–0.57 kg ai/ha. No GAP from the USA was available for cucumber.

One trial in Canada on cucumbers was conducted with one foliar application of an EC formulation at a rate of 0.29 kg ai/ha. No GAP from Canada was available for cucumber.

The GAP on cucumbers in Mexico is three foliar applications at a maximum rate of 0.29 kg ai/ha with a PHI of 7 days. Triforine residue in cucumber from a trial in Mexico matching the GAP of Mexico was (n=1): 0.066 mg/kg.

Trials in Hungary, France and Germany on cucumbers were conducted but no GAP from European countries were available.

The Meeting considered that the data was insufficient for estimating a maximum residue level for cucumbers.

Squash

Data were available from supervised trials on summer squash and winter squash from the USA, France and Germany. No GAP from the USA or European countries was available for squash.

The Meeting agreed that estimation of maximum residue level was not possible for squash.

Melon

Data were available from supervised trials on melon from the USA, Mexico, France, Italy and Japan.

Trials in the USA on melons were conducted with one or five foliar applications of an EC formulation at a rate of 0.23–0.46 kg ai/ha. No GAP from the USA was available for melons.

The GAP on melons in Mexico is three foliar applications at a maximum rate of 0.29 kg ai/ha with a PHI of 7 days. Triforine residue in melon from one trial in Mexico matching GAP of Mexico was (n=1): 0.039 mg/kg.

Trials from Italy and France on melon were conducted with one or four foliar applications of an EC formulation at a rate of 0.20–0.29 kg ai/ha. No GAP from European countries was available for melons.

The GAP on melon in Japan is six foliar applications at a spray concentration of 0.009 mg/hL with a PHI of 1 day. Triforine residues in melon from the trials in Japan were (n=2): < 0.005 and 0.006 mg/kg.

The Meeting considered the data was insufficient for estimating a maximum residue level for melons.

The Meeting agreed to withdraw its previous recommendation for fruiting vegetables, cucurbits.

*Fruiting vegetables, other than Cucurbits**Peppers*

Data were available from supervised trials on peppers from Mexico, Japan and South Korea.

The GAP on peppers in Mexico is three foliar applications at a maximum rate of 0.29 kg ai/ha with a PHI of 14 days. Triforine residue in peppers from the trials in Mexico matching GAP of Mexico was (n=1): 0.12 mg/kg.

The GAP on peppers in Japan is three foliar applications at a spray concentration of 0.018 kg ai/hL with a PHI of 14 days. Triforine residues in peppers from trials in Japan matching GAP of Japan were (n=2): 0.06 and 0.22 mg/kg.

The GAP on chili peppers in South Korea is two foliar applications at a spray concentration equivalent to 0.019 kg ai/ha with a PHI of 7 days. Triforine residue in peppers from the trial in South Korea matching GAP of South Korea was (n=1): 0.35 mg/kg.

The Meeting considered that the data was insufficient for estimating a maximum residue level for peppers.

Egg plant

Data were available from supervised trials on egg plants in Mexico and Japan.

The GAP on egg plants in Mexico is three foliar applications at a maximum rate of 0.29 kg ai/ha with a PHI of 15 days. Triforine residue in egg plants from a trial in Mexico matching GAP of Mexico was (n=1): 0.066 mg/kg.

The GAP on eggplants in Japan is five foliar applications at a spray concentration of 0.018 kg ai/hL with a PHI of 1 day. Triforine residues in egg plants from the trials in Japan matching GAP of Japan were (n=5): 0.25, 0.28, 0.29, 0.38 and 0.39 mg/kg.

Based on the trials on egg plants in Japan, the Meeting estimated a maximum residue level, an STMR and an HR for triforine in egg plants of 1, 0.29 and 0.39 mg/kg, respectively.

Tomato

Data were available from supervised trials on tomatoes in the USA, Mexico, Denmark and Japan.

One trial from Denmark on tomatoes was conducted with one foliar application of EC formulation at a rate equivalent to 0.95 kg ai/ha. No GAP of European countries were available for tomatoes.

The GAP on tomatoes in Japan was three foliar applications at a spray concentration of 0.018 kg ai/hL with a PHI of 1 day. Triforine residues in tomatoes from trials in Japan matching GAP of Japan were (n=5): 0.14, 0.17, 0.26, 0.28 and 0.56 mg/kg.

The GAP on tomatoes in Mexico is four foliar applications at a maximum rate of 0.38 kg ai/ha with a PHI of 3 days. Triforine residues in tomatoes from the trials in Mexico matching GAP of Mexico were (n=5): 0.083, 0.096, 0.13, 0.27 and 0.40 mg/kg.

Trials from the USA on tomatoes were conducted with four or five foliar applications of an EC formulation at a rate of 0.18–0.41 kg ai/ha. Triforine residues in tomatoes from the trials in the USA matching GAP of Mexico were (n=3): 0.072, 0.17 and 0.28 mg/kg.

The Meeting decided to use the triforine residue data from the trials in Mexico and the USA. Triforine residues in tomatoes from the trials in Mexico and the USA matching GAP of Mexico were (n=8): 0.072, 0.083, 0.096, 0.13, 0.17, 0.27, 0.28, 0.40 mg/kg.

Based on the data, the Meeting estimated a maximum residue level of 0.7 mg/kg to replace its previous recommendation (0.5 mg/kg). The Meeting also estimated an STMR and an HR for triforine in tomato of 0.15 and 0.40 mg/kg, respectively.

*Legume vegetables**Common bean*

Data were available from supervised trials on common beans from Brazil and South Africa.

The GAP on beans in Brazil is three foliar applications at a maximum rate of 0.29 kg ai/ha with a PHI of 10 days. Triforine residue in bean seeds from the trials in Brazil matching GAP of Brazil was (n=1): < 0.01 mg/kg.

The GAP on beans in South Africa is for foliar application(s) with spray at a rate of 0.29 kg ai/ha with a PHI of 3 days (the maximum numbers of applications not specified). Triforine residue in beans from one trial in South Africa matching GAP of South Africa was (n=1): 0.44 mg/kg.

As the available data was insufficient for estimating a maximum residue level, the Meeting agreed to withdraw its previous recommendation for common bean (pods and immature seeds).

Cereal grains

Data were available from supervised trials on barley in France. No GAP from European countries was available for barley.

Data were available from supervised trials on wheat in Austria, France, UK and Brazil. No GAP from European countries and Brazil was available for wheat.

No other information was available for any other cereal grains.

The Meeting agreed that the estimation of maximum residue level was not possible for cereal grains.

The Meeting agreed to withdraw its previous recommendation for cereal grains.

*Animal feedstuffs**Barley straw and forage*

Data were available from supervised trials on barley straw and forage in France. No GAP from European countries was available for barley straw and forage.

The Meeting agreed that the estimation of a maximum residue level was not possible for barley straw and forage.

Wheat straw and forage

Data were available from supervised trials on wheat straw and forage in France and UK. No GAP from European countries was available for wheat straw and forage.

The Meeting agreed that the estimation of a maximum residue level was not possible for wheat straw and forage.

Fate of residues during processing*Residues in processed commodities*

The fate of triforine residues following the processing of plums, grapes and tomatoes was made available to the Meeting. Estimated processing factors and the derived STMR-Ps are summarized in the Table below.

Processing factors, STMR-P for food

Raw agricultural commodity (RAC)	Processed commodity	Calculated processing factors ^a	PF (Mean or best estimate)	RAC STMR (mg/kg)	STMR-P (mg/kg)
Tomato	Juice	0.74 ^b , 0.76 ^b	0.75	0.15	0.11
	Paste	< 0.008	< 0.008		< 0.001

Raw agricultural commodity (RAC)	Processed commodity	Calculated processing factors ^a	PF (Mean or best estimate)	RAC STMR (mg/kg)	STMR-P (mg/kg)
	Puree	0.14, 2.3 ^b , 2.6 ^b	2.3		0.35
	Wet pomace	< 0.12	< 0.12		< 0.018
	Dry pomace	1.6	1.6		0.24

^a Each value represents a separate study.

^b RAC was dipped in EC formulation solution.

Residues in animal commodities

Estimated maximum and mean dietary burdens of farm animals

The maximum and mean dietary burdens were calculated using the median residue of triforine in dry tomato pomace estimated at the current Meeting on a basis of the OECD Animal Feeding Table.

Summary of livestock dietary burdens (ppm of dry matter diet)

Livestock dietary burden, triforine, ppm of dry matter diet								
	US-Canada		EU		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0	0	0	0	0.027 ^a	0.027 ^b	0	0
Dairy cattle	0	0	0	0	0.027	0.027 ^c	0	0
Broilers	0	0	0	0	0	0	0	0
Layers	0	0	0	0	0	0	0	0

^a Highest maximum beef cattle dietary burden suitable for MRL estimates for mammalian meat, fat, edible offal and milk

^b Highest mean beef cattle dietary burden suitable for STMR estimates for mammalian meat, fat and edible offal

^c Highest mean dairy cattle dietary burden suitable for STMR estimates for milk

Farm animal feeding studies

The Meeting received a lactating dairy goat feeding studies using triforine, which provided information on likely residues resulting in animal commodities and milk from triforine residues in the animal diet.

Lactating dairy goats

Lactating dairy goats were dosed with triforine for 30 days at doses equivalent to 5, 15 and 50 ppm in the diet. Residues of triforine were at or less than the LOQ (0.001 mg/L) in whole milk at the 5 ppm of feeding level except on sampling day 29 (< 0.001–0.003 mg/L). In the highest dose group (50 ppm feed), triforine residues in milk reached a plateau at the level of 0.002–0.010 mg/L after 3 days. In tissues, no measurable residues were found in fat, liver, kidney and muscle of the 5 ppm feed group. In the 15 ppm feed group, triforine concentration slightly exceeded the LOQ in several samples. In the 50 ppm feed group, residues were detected in all of the analysed tissues with exception of muscle in one animal and fat of all animals. The maximum values in kidney and liver were 0.009 and 0.012 ppm, respectively.

Animal commodities maximum residue levels

For MRL estimation, the residue in the animal commodities is triforine.

The maximum dietary burden for beef and dairy cattle was 0.027 ppm. The maximum dietary burden for beef and dairy cattle was 0.54% of the lowest dose of 5 ppm in feed of the lactating goat feeding study. In the lactating goat feeding study at 5 ppm, triforine was at < 0.01 mg/kg in milk and < 0.01 mg/kg in liver.

The Meeting estimated a maximum residue level of 0.01* mg/kg and an STMR of 0 mg/kg in milk.

The Meeting estimated a maximum residue level of 0.01* mg/kg, an STMR of 0 mg/kg and an HR of 0 mg/kg in mammalian meat and fat.

The Meeting estimated a maximum residue level of 0.01* mg/kg, an STMR of 0 mg/kg and an HR of 0 mg/kg in mammalian edible offal.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for estimating maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for plant commodities: *Triforine*.

Definition of the residue (for compliance with the MRL and for estimation of dietary intake) for animal commodities: *Triforine and its metabolites determined as chloral hydrate expressed as triforine*.

The residue is not fat soluble.

DIETARY RISK ASSESSMENT

Long-term intake

The International Estimated Daily Intakes (IEDIs) of triforine were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the current Meeting (Annex 3). The ADI is 0–0.03 mg/kg bw and the calculated IEDIs were 0–2% of the maximum ADI. The Meeting concluded

that the long-term intakes of residues of triforine, resulting from the uses considered by current JMPR, are unlikely to present a public health concern.

Short-term intake

The ARfD for triforine is 0.3 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for triforine were calculated for the food commodities for which STMRS or HRs were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2014 JMPR Report. The IESTIs were 0–5% of the ARfD for children and the general population. The Meeting concluded that the short-term intake of residues of triforine from other uses that have been considered by the present Meeting is unlikely to present a public health concern.

The annual Joint Meeting of the FAO Panel of Experts on Pesticide Residues in Food and the Environment and the WHO Core Assessment Group on Pesticide Residues was held in Rome, Italy, from 16 to 25 September 2014. The FAO Panel of Experts had met in preparatory sessions from 11 to 15 September 2014. The Meeting was held in pursuance of recommendations made by previous Meetings and accepted by the governing bodies of FAO and WHO that studies should be undertaken jointly by experts to evaluate possible hazards to humans arising from the occurrence of pesticide residues in foods. During the meeting the FAO Panel of Experts was responsible for reviewing pesticide use patterns (use of good agricultural practices), data on the chemistry and composition of the pesticides and methods of analysis for pesticide residues and for estimating the maximum residue levels that might occur as a result of the use of the pesticides according to good agricultural use practices. The WHO Core Assessment Group was responsible for reviewing toxicological and related data and for estimating, where possible and appropriate, acceptable daily intakes (ADIs) and acute reference doses (ARfDs) of the pesticides for humans. This report contains information on ADIs, ARfDs, maximum residue levels, and general principles for the evaluation of pesticides. The recommendations of the Joint Meeting, including further research and information, are proposed for use by Member governments of the respective agencies and other interested parties.
