

# Biostimulants: Opportunities and challenges to increase soil fertility

## *Antonis Angeletakis*

Global Symposium on Soils for Nutrition | 26-29 July 2022

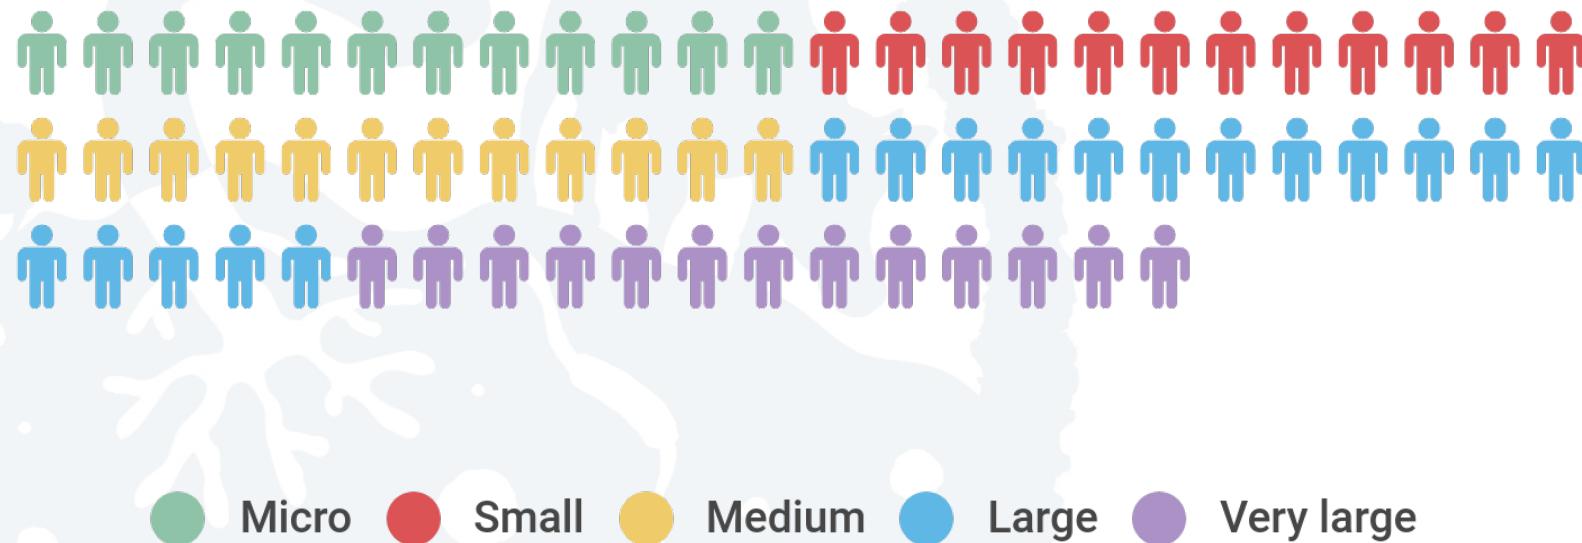

EBIC's mission is to ensure biostimulant technologies are valued as integral to sustainable agriculture, while securing an enabling regulatory framework for all of them

Breakdown by size (based on global turnover and headcount)

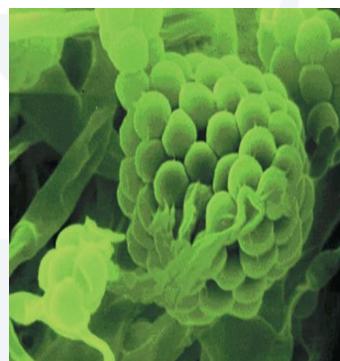

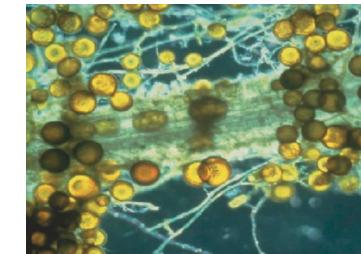

As of June 1st, 2022

Global Symposium on Soils for Nutrition | 26-29 July 2022

**Biostimulants** act on natural processes in plants and the area around the roots to **enhance**:

1. nutrient uptake, nutrient efficiency
2. tolerance to abiotic stress
3. crop quality

With benefits for yield and vigor

**Component materials include seaweed and plant extracts, humic and fulvic acids, hydrolysed proteins and micro-organisms, among others**

We are all aware  
of the need to  
optimise nutrient  
use while  
maintaining or  
improving soil  
quality

# SOIL FERTILITY

Soil fertility is made up of **three core aspects**: physical structure, chemical composition and biological diversity. All of these aspects are essential for healthy and fertile agricultural soils.

## BIOLOGICAL DIVERSITY

The biological diversity of the soil can enhance soil structure and improve the availability of nutrients for plants. A fertile soil is one that has good structure, plenty of organic matter to foster biodiversity, and a balanced pH level.

pH

## CHEMICAL COMPOSITION

The acidity of the soil (pH) directly affects whether nutrients can be extracted and absorbed by plants, and can adversely affect the soil's biological diversity – which, in turn, can impact nutrient availability and soil structure.

## PHYSICAL STRUCTURE

This is strongly influenced by the presence of organic matter in soil, as well as its biodiversity. Roots, insects, worms and other creatures loosen and mix the soil, improving its structure and fertility.

# Soil biodiversity

Microbial plant biostimulants help reinforce and replenish communities of beneficial microorganisms that fix nitrogen, solubilize minerals, and/or encourage plant exudates involved in nutrient exchanges, among other benefits.

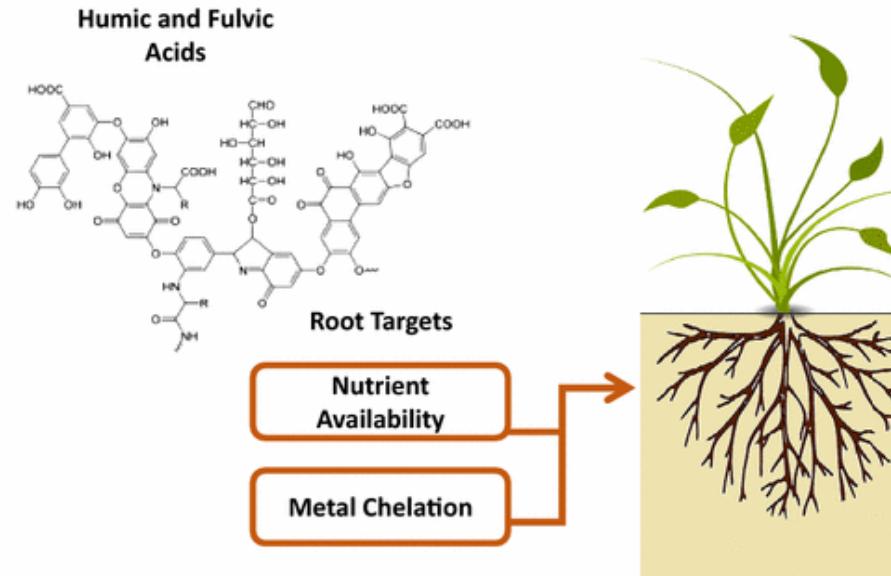

Source: ICL

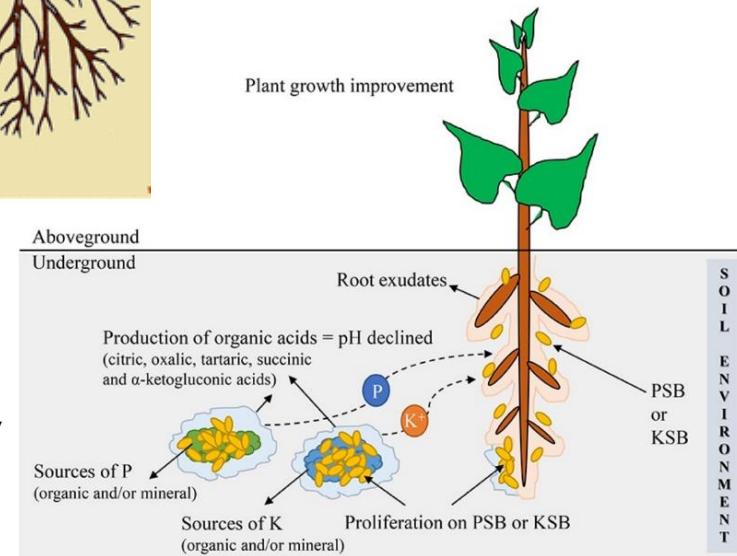

**Microorganisms cooperate or compete with the crop for nutrients. Increasing soil quality as a habitat for cooperative microorganisms increases productivity.**

# Chemical composition

Some plant biostimulants (e.g. those containing humic and fulvic acids and some microorganisms) can positively influence the chemical composition of soils around plants' roots, including soil pH.

DOI: 10.1016/j.ecoleng.2017.03.008 and adapted from Van Oosten, M.J., Pepe, O., De Pascale, S. et al. Chem. Biol. Technol. Agric. (2017) 4: 5. DOI:10.1186/s40538-017-0089-5

# Physical structure

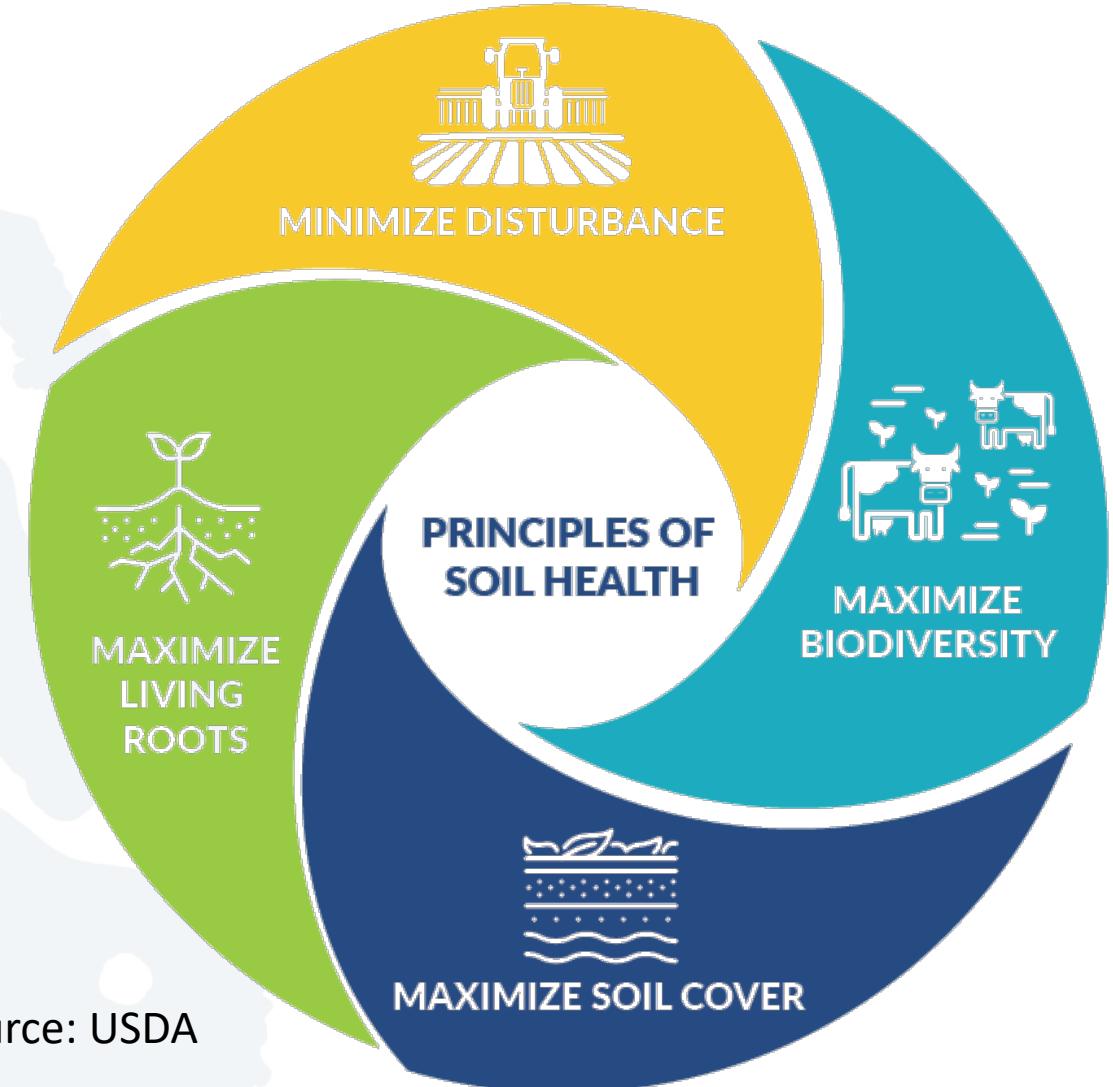

Plant biostimulants that foster root development improve soil structure and carbon content if the roots are left in the soil at harvest.

Image: ICL

# Soil Health

This means that plant biostimulants contribute to all of the principles of soil health as defined by USDA, except for minimizing disturbances.

# Plant nutrition & soil fertility

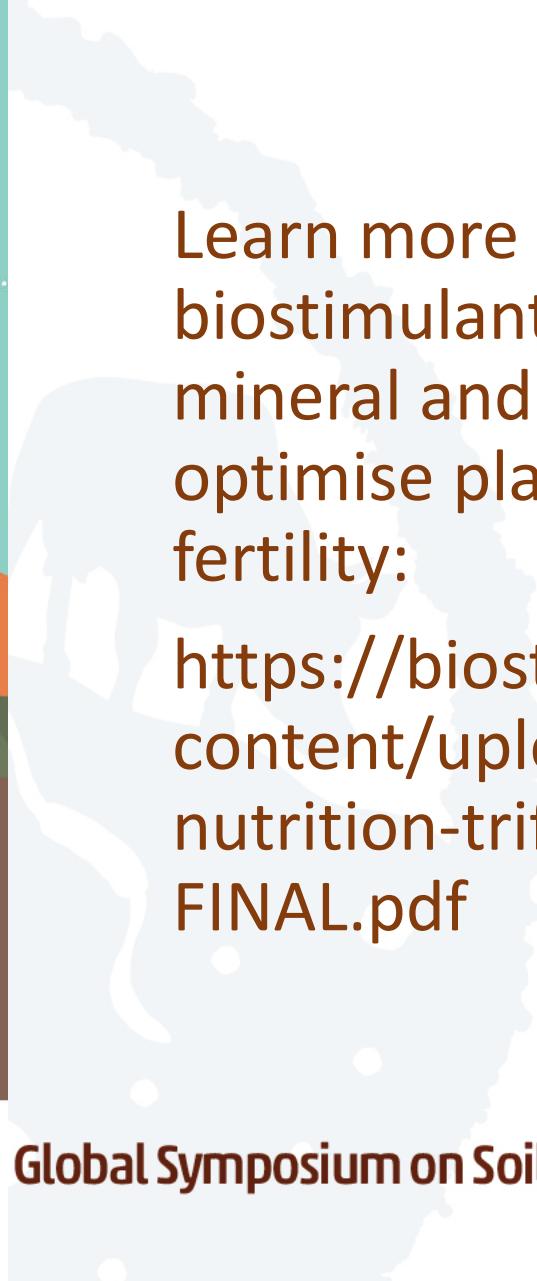

Key to deliver Europe's Green Deal objectives

The different plant nutrition and soil fertility solutions grouped under the heading "fertilizing product" in Regulation (EU) 2019/1009 play different and complementary roles in helping farmers produce plentiful, high-quality crops while helping the EU move towards more sustainable agriculture.

This factsheet explains the importance of combining a full range of fertilizing products to ensure an optimum impact on plant yield and quality and minimal environmental impact.

# Failed harvests = wasted nutrients

A photograph of a dry, cracked field. In the foreground, the ground is parched and shows deep, irregular cracks. Sparse, yellowish-brown crop stubble or weeds are scattered across the surface. In the middle ground, a vast expanse of similar dry land stretches to a distant horizon. The sky above is a pale blue with scattered, wispy white clouds.

By helping crops cope with heat, drought, and other harsh conditions, plant biostimulants not only prevent the nutrient waste that would result if a crop is lost to bad weather, but they <sup>12</sup> also help maintain crop cover which helps prevent erosion and foster water retention.

# Scientific evidence about the benefits of biostimulants grows as product development and management improves

## In conclusion

In just 10 years, plant biostimulants have moved from being viewed as “snake oil” to an essential element of efficient, regenerative farming that sees soil health and food production as intertwined goals.

# Thank you !
